About VMware Cloud on AWS Networking and Security

The *VMware Cloud on AWS Networking and Security* guide provides information about configuring NSX-T networking and security for VMware Cloud on AWS.

**Intended Audience**

This information is intended for anyone who wants to use VMware Cloud on AWS to create an SDDC that has the networking and security infrastructure necessary to migrate workloads off premises and run them securely in the cloud. It was written for readers who have used vSphere in an on-premises environment and are familiar with the fundamentals of IP networking using NSX-T or another networking solution. In-depth knowledge of vSphere or Amazon Web Services is not required.

For a detailed discussion of how VMware Cloud on AWS uses NSX-T networking, see the VMware Press eBook *VMware Cloud on AWS: NSX Networking and Security*. 
NSX-T Networking Concepts

VMware Cloud on AWS uses NSX-T to create and manage internal SDDC networks and provide endpoints for VPN connections from your on-premises network infrastructure.

Connecting to your SDDC

To connect your on-premises data center to your VMware Cloud on AWS SDDC, you can create a VPN that uses the public Internet, a VPN that uses AWS Direct Connect, or just use AWS Direct Connect alone.

Figure 1-1. SDDC Connections to your On-Premises Data Center

Layer 3 (L3) VPN
A layer 3 VPN provides a management network that connects your on-premises data center to your SDDC. These IPsec VPNs can be either route-based or policy-based. You can create up to sixteen VPNs of each type, using any on-premises router that supports the settings listed in the IPsec VPN Settings Reference. An L3 VPN can connect your on-premises data center to the SDDC over the public Internet or over AWS Direct Connect.

Layer 2 (L2) VPN
A layer 2 VPN provides an extended, or stretched, network with a single IP address space that spans your on-premises data center and your SDDC and enables hot or cold migration of on-premises workloads to the SDDC.
You can create only a single L2VPN tunnel in any SDDC. The on-premises end of the tunnel requires NSX. If you are not already using NSX in your on-premises data center, you can download a standalone NSX Edge appliance to provide the required functionality. An L2 VPN can connect your on-premises data center to the SDDC over the public Internet or over AWS Direct Connect.

**AWS Direct Connect (DX)**

AWS Direct Connect is a service provided by AWS that allows you to create a high-speed, low latency connection between your on-premises data center and AWS services. When you configure AWS Direct Connect, VPNs can use it instead of routing traffic over the public Internet. Because Direct Connect implements Border Gateway Protocol (BGP) routing, use of an L3VPN for the management network is optional when you configure Direct Connect. Traffic over Direct Connect is not encrypted. If you want to encrypt that traffic, configure your L3 VPN to use Direct Connect.

**VMware HCX**

VMware HCX, a multi-cloud app mobility solution, is provided free to all SDDCs and facilitates migration of workload VMs to and from your on-premises data center to your SDDC. For more information about installing, configuring, and using HCX, see the Hybrid Migration with HCX Checklist.

**SDDC Network Topology**

When you create an SDDC, it includes a Management Network and a Compute Network. The Management Network CIDR block must be specified when you created the SDDC and cannot be changed. The Management Network has two subnets:

**Appliance Subnet**

A subnet of the CIDR range you specified for the Management Subnet when you created the SDDC. This subnet is used by the vCenter, NSX, and HCX appliances in the SDDC. When you add appliance-based services such as SRM to the SDDC, they also connect to this subnet.

**Infrastructure Subnet**

A subnet of the CIDR range you specified for the Management Subnet when you created the SDDC. This subnet is used by the ESXi hosts in the SDDC.

The compute network can have up to 16 segments for your workload VMs. In a Single Host SDDC starter configuration, we create a compute network with a single routed segment. In SDDC configurations that have more hosts, you’ll have to create compute network segments to meet your needs.

A Tier 0 NSX Edge appliance sits between your on-premises networks and your SDDC networks, and routes traffic to either the management network or the compute network as appropriate.
Figure 1-2. SDDC Network Topology

**Tier 0 Edge Appliance**
All traffic between your on-premises networks and the SDDC passes through this appliance. Compute Gateway firewall rules, which control access to workload VMs, are applied on its uplink interfaces.

**Management Gateway (MGW)**
The MGW is an NSX Edge Security gateway that provides north-south network connectivity for the vCenter Server and other management appliances running in the SDDC. The Internet-facing IP address (Public IP #1) is automatically assigned from the pool of AWS public IP addresses when the SDDC is created. Pick an address range (CIDR block) for the management subnet that can support the number of ESXi hosts in your
SDDC. If you don't specify a range when you create the SDDC, the system uses a default of 10.2.0.0/16.

**Compute Gateway (CGW)**

The CGW provides north-south network connectivity for virtual machines running in the SDDC. In a single-node SDDC, VMware Cloud on AWS creates a default logical network segment (CIDR block 192.168.1.0/24) to provide networking for these VMs. You can create additional logical networks on the **Networking & Security** tab.

### Routing Between Your SDDC and the Connected VPC

**Important** All SDDC subnets and any VPC subnets on which AWS services or instances communicate with the SDDC must be associated with the main route table of the connected VPC. Use of a custom route table or replacement of the main route table is not supported.

When you create an SDDC, we connect the ENI of the VPC owned by the AWS account you specify to the NSX Edge Appliance in the SDDC. That VPC becomes the Connected VPC, and the connection supports network traffic between SDDC VMs and AWS instances and native services in the Connected VPC. The main route table of the connected VPC includes all the subnets in the VPC as well as all SDDC (NSX-T network segment) subnets. When you create or delete routed network segments on the workload network, the main route table is automatically updated. When the NSX Edge Appliance in your SDDC is moved to another host, either to recover from a failure or during SDDC maintenance, the main route table is updated to reflect the ENI used by the new NSX Edge host. If you have replaced the main route table or are using a custom route table, that update fails and network traffic can no longer be routed between SDDC networks and the Connected VPC.

For more information, see [View Connected VPC Information](#).

### Multicast Support in SDDC Networks

In SDDC networks, layer 2 multicast traffic is treated as broadcast traffic on the network segment where the traffic originates. It is not routed beyond that segment. Layer 2 multicast traffic optimization features such as IGMP snooping are not supported. Layer 3 multicast (such as Protocol Independent Multicast) is not supported in VMware Cloud on AWS.

This chapter includes the following topics:

- **Features Supported with NSX-T**

### Features Supported with NSX-T

SDDCs backed by NSX-T support a wide range of networking and security solutions.

### NSX-T Configuration Maximums

NSX-T Configuration Maximums are now included in Configuration Maximums for VMware Cloud on AWS.
Configuring VMware Cloud on AWS Networking Using NSX-T

Follow this workflow to configure networking in your SDDC using NSX-T.

Procedure

1 Assign NSX Service Roles to Organization Members
   Grant users in your organization the NSX Admin service role to allow them to view and configure features on the Networking & Security tab.

2 Configure AWS Direct Connect for VMware Cloud on AWS
   If traffic between your on-premises network and your SDDC requires higher speeds and lower latency than you can achieve with a connection over the public Internet, you can configure VMware Cloud on AWS to use AWS Direct Connect.

3 Configure a VPN Connection Between Your SDDC and On-Premises Data Center
   Configure a VPN to provide a secure connection to your SDDC over the public Internet or AWS Direct Connect. Route-based and policy-based VPNs are supported. Either type of VPN can connect to the SDDC over the Internet. A route-based VPN can also connect to the SDDC over AWS Direct Connect.

4 Configure Compute Gateway and Workload Networking
   Compute gateway networking includes a compute network with one or more segments and the DNS, DHCP, and firewall configurations that manage network traffic for workload VMs. It can also include a layer 2 VPN and extended network that provides a single broadcast domain that spans your on-premises network and you SDDC workload network.

5 Managing Workload Connections
   Workload VMs connect to the Internet by default. NAT rules and distributed firewall rules give you fine-grained control over these connections.

Assign NSX Service Roles to Organization Members

Grant users in your organization the NSX Admin service role to allow them to view and configure features on the Networking & Security tab.
Organization roles specify the privileges that an organization member has over organization assets. Service roles specify the privileges that an organization member has when accessing VMware Cloud Services that the organization uses. All service roles can be assigned and changed by a user with organization owner privileges, so restrictive roles such as Administrator (Delete Restricted) or NSX Cloud Auditor should be assigned along with the role of organization member to prevent modification.

A user must log out and then log back in for a new service role to take effect.

**Prerequisites**

You must be an Organization Owner to assign a role to an organization member.

**Procedure**

2. Click the services icon and select **Identity & Access Management**.
3. Select a user and click **Edit Roles**.
4. Select a role name from the **Assign Organization Roles** drop-down control.
   
   The following roles are available:
   
   - **Organization Owner**: This role has full rights to manage organization members and assets.
   - **Organization Member**: This role has rights to access organization assets.

5. Select the **VMware Cloud on AWS** service name under **Assign Service Roles**.
6. Select an NSX service role to assign.
   
   The following NSX service roles are available:
   
   - **NSX Cloud Auditor**: This role can view NSX service settings and events but cannot make any changes to the service.
   - **NSX Cloud Admin**: This role can perform all tasks related to deployment and administration of the NSX service.

   **Note**  
   When multiple service roles are assigned to an organization user, permissions are granted for the most permissive role. For example, an organization member who has both the NSX Cloud Admin and NSX Cloud Auditor roles is granted all the NSX Cloud Admin permissions, which include those granted to the NSX Cloud Auditor role.

7. Click **SAVE** to save your changes.

**What to do next**

Ensure that any users whose roles were changed log out and log back in for the changes to take effect.
Configure AWS Direct Connect for VMware Cloud on AWS

If traffic between your on-premises network and your SDDC requires higher speeds and lower latency than you can achieve with a connection over the public Internet, you can configure VMware Cloud on AWS to use AWS Direct Connect.

AWS Direct Connect (DX) provides a dedicated network connection between your on-premises network infrastructure and a virtual interface (VIF) to your AWS VPC. DX supports two kinds of virtual interfaces:

- A private VIF enables access to your AWS Virtual Private Cloud (VPC).
- A public VIF enables access to services such as Amazon EC2 and S3.

Configure DX over a private VIF to carry workload and management traffic, including VPN and vMotion, between your on-premises data center and your connected VPC. Configure DX over a public VIF if you need to connect to AWS public endpoints such as EC2 and S3. You can route VPN traffic over either kind of VIF to provide additional data security.

Private and Public VIFs

A DX connection over a private VIF can be used for all traffic between your on-premises data center and your SDDC. It terminates in your connected Amazon VPC, provides a private IP address space, and uses BGP to advertise routes in your SDDC and learn routes in your on-premise data center.

A DX connection over a public VIF is typically used only for traffic between your on-premises data center and public AWS services, which you cannot access over a private VIF. It terminates at the AWS region level in the region occupied by your connected Amazon VPC, and uses BGP to advertise AWS global routes.

Set Up an AWS Direct Connect Connection

To set up an AWS Direct Connect connection, you must place an order through the AWS console. Refer to Getting Started with AWS Direct Connect for information about how to request an AWS Direct Connect connection.

Prerequisites

Request your Direct Connect access in a region where VMware Cloud on AWS is available.

What to do next

After your AWS Direct Connect connection is established, create a private virtual interface to connect to your VMware Cloud on AWS SDDC.

Create a Private Virtual Interface for vMotion, ESXi Management, Management Appliance, and Workload Traffic

The private virtual interface allows vMotion, ESXi management, management appliance, and workload traffic to flow over the Direct Connect connection between your on-premises environment and your SDDC.
Create one virtual interface for each Direct Connect link you want to make to your SDDC. For example, if you want to create two Direct Connect links for redundancy, create two virtual interfaces.

Each private virtual interface allows you to expose up to 16 logical segments to your on-premises infrastructure.

**Prerequisites**

- Ensure that you meet the prerequisites for virtual interfaces as described in [Prerequisites for Virtual Interfaces](#).

**Procedure**

1. Log in to the AWS Console and complete the *Creating a Hosted Private Virtual Interface* procedure under Create a Hosted Virtual Interface.
   - For the Interface Owner field, use the account shown in the AWS Account ID field of the Direct Connect page of the Networking & Security tab.
   - Select Auto-generate peer IPs and Auto-generate BGP key.

   When the interface has been created, the AWS console reports that it is ready for acceptance.

2. In the VMC Console, select Networking & Security > Direct Connect and accept the virtual interface by clicking ATTACH.
   
   Before it has been accepted, a new VIF is visible in all SDDCs in your organization. After you accept the VIF, it is no longer visible in any other SDDC.

   It can take up to 10 minutes for the BGP session to become active. When the connection is ready, the State shows as Attached and the BGP Status as Up.

3. (Optional) Configure a route-based VPN as backup to Direct Connect

   In the default configuration, traffic on any route advertised over BGP by both DX and a route-based VPN uses the VPN by default. To have a route advertised by both DX and VPN use DX by default and failover to the VPN when DX is unavailable, select Networking & Security > Direct Connect and set the Use VPN as backup to Direct Connect switch to Enabled.

   **Note** This configuration requires a route-based VPN. You cannot use a policy-based VPN as a backup to Direct Connect.

   The system requires a minute or so to update your routing preference. When the operation completes, routes advertised by both DX and VPN default to the DX connection, using the VPN only when DX is unavailable.

   A list of Advertised BGP Routes and Learned BGP Routes is displayed as the routes are learned and advertised. Click the refresh icon to refresh these lists. Only the following management network subnets are advertised as BGP routes.

   - Subnet 1 includes routes used by ESXi host vmks and router interfaces.
Subnet 2 includes routes used for Multi-AZ support and AWS integration

Subnet 3 includes management VMs

The actual CIDR blocks advertised depend on your management subnet CIDR block. The following table shows the CIDR blocks for these routes in an SDDC that uses the default management network CIDR of 10.2.0.0 in block sizes /16, /20, and /22.

Table 2-1. Advertised Routes for 10.2.0.0 Default MGW CIDR

<table>
<thead>
<tr>
<th>MGW CIDR</th>
<th>Subnet 1</th>
<th>Subnet 2</th>
<th>Subnet 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.2.0.0/23</td>
<td>10.2.0.0/24</td>
<td>10.2.1.0/26</td>
<td>10.2.1.128/25</td>
</tr>
<tr>
<td>10.2.0.0/20</td>
<td>10.2.0.0/21</td>
<td>10.2.8.0/23</td>
<td>10.2.12.0/22</td>
</tr>
<tr>
<td>10.2.0.0/16</td>
<td>10.2.0.0/17</td>
<td>10.2.128.0/19</td>
<td>10.2.192.0/18</td>
</tr>
</tbody>
</table>

What to do next

Ensure the vMotion interfaces are configured to use Direct Connect. See Configure vMotion Interfaces for Use with Direct Connect.

Create a Public Virtual Interface for Access to AWS Services

You can configure a public virtual interface to provide your workload VMs with access to AWS EC2 instances and services such as S3 without having to route that traffic over the Internet.

In typical configurations, traffic between your on-premises data center and your SDDC flows over a private VIF. When you need to access AWS services from your SDDC, use direct connect with a public VIF. You can configure AWS security groups to manage traffic between AWS services and VMs in your SDDC.

Prerequisites

- Ensure that you meet the prerequisites for virtual interfaces as described in Prerequisites for Virtual Interfaces.

Procedure

1. Log in to the AWS Console and complete the steps for creating a hosted public virtual interface under Create a Hosted Virtual Interface.
   - In the Interface Owner field, select My AWS Account.
   - Specify Your router peer IP and Amazon router peer IP.
   - Select Auto-generate BGP key and list any on-premises routes that you want advertised on the AWS backbone in Prefixes you want to advertise.

   When the interface has been created, the AWS console reports that it is ready for acceptance.

2. In the VMC Console, select Networking & Security > Direct Connect and accept the virtual interface by clicking ATTACH.
Configure vMotion Interfaces for Use with Direct Connect

If you are using a Direct Connect connection between your on-premises data center and your cloud SDDC, you must configure the vMotion interfaces for your on-premises hosts to route vMotion traffic over the Direct Connect connection.

**Prerequisites**

Configure Direct Connect and create a private virtual interface.

**Procedure**

1. Select one of the following methods to configure the vMotion interface on each host in your on-premises environment.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Override the default gateway</td>
<td>For each host, edit the VMkernel adapter used for vMotion traffic, and select the option to override the default gateway. Enter an IP address in your on-premises vMotion subnet that is capable of routing traffic to the on-premises side of the Direct Connect connection. See Edit a VMkernel Adapter Configuration.</td>
</tr>
<tr>
<td>Configure the vMotion TCP/IP stack</td>
<td>For each host:</td>
</tr>
<tr>
<td></td>
<td>a. Remove any existing vMotion VMkernel adapters.</td>
</tr>
<tr>
<td></td>
<td>b. Create a new VMkernel adapter and select the vMotion TCP/IP stack. See Place vMotion Traffic on the vMotion TCP/IP Stack of an ESXi Host.</td>
</tr>
<tr>
<td></td>
<td>c. Edit the host vMotion TCP/IP stack to change the routing to use an IP address in your on-premises vMotion subnet that is capable of routing traffic to the on-premises side of the Direct Connect connection. See Change the Configuration of a TCP/IP Stack on a Host.</td>
</tr>
</tbody>
</table>

2. (Optional) Test connectivity between an on-premises host and a cloud SDDC host using `vmkping`. See [https://kb.vmware.com/s/article/1003728](https://kb.vmware.com/s/article/1003728) for more information.

Configure a VPN Connection Between Your SDDC and On-Premises Data Center

Configure a VPN to provide a secure connection to your SDDC over the public Internet or AWS Direct Connect. Route-based and policy-based VPNs are supported. Either type of VPN can connect to the SDDC over the Internet. A route-based VPN can also connect to the SDDC over AWS Direct Connect.

- **Create a Route-Based VPN**
  A route-based VPN creates an IPsec tunnel interface and routes traffic through it as dictated by the SDDC routing table. A route-based VPN provides resilient, secure access to multiple subnets. When you use a route-based VPN, new routes are added automatically when new networks are created.

- **Create a Policy-Based VPN**
  A policy-based VPN creates an IPsec tunnel and a policy that specifies how traffic uses it. When you use a policy-based VPN, you must update the routing tables on both ends of the network when new routes are added.
**View Connected VPC Information**
The Connected Amazon VPC contains your SDDC and all its networks. Information about this VPC, including the active ENI, VPC subnet, and VPC ID, is available on the Networking & Security tab.

**View VPN Tunnel Status and Statistics**
The VMC Console provides status and statistics for IPSec VPNs and L2VPN segments.

**IPsec VPN Settings Reference**
The on-premises end of any IPsec VPN must be configured to match the settings you specified for the SDDC end of that VPN.

**Mapping NSX Parameters to VMC Console VPN Parameters**
The table below matches terms for VPN parameters used in NSX Edge configuration to the terms used in the VMC Console.

**Configure Management Gateway Networking**
To complete configuration of management gateway networking, set up a DNS server for the management network, specify whether you want to access the SDDC vCenter at a public or private IP address, and create management gateway firewall rules.

### Create a Route-Based VPN
A route-based VPN creates an IPsec tunnel interface and routes traffic through it as dictated by the SDDC routing table. A route-based VPN provides resilient, secure access to multiple subnets. When you use a route-based VPN, new routes are added automatically when new networks are created.

Route based VPNs in your VMware Cloud on AWS SDDC use an IPsec protocol to secure traffic and the Border Gateway Protocol (BGP) to discover and propagate routes as new networks are created. To create a route-based VPN, you configure BGP information for the local (SDDC) and remote (on-premises) endpoints, then specify tunnel security parameters for the SDDC end of the tunnel.

**Procedure**

2. Click Networking & Security > VPN > Route Based.
3. (Optional) Change the default local Autonomous System Number (ASN).

   All route-based VPNs in the SDDC use the same local ASN value in their implementation of BGP. It cannot be the same as the remote ASN for any configured VPN connections. The default value is 65000. To change this, click EDIT LOCAL ASN, enter a new value in the range 64521 to 65535, and click APPLY.

4. Click ADD VPN and give the new VPN a Name.
5. Select a Local IP Address from the drop-down menu.

   - If you have configured AWS Direct Connect for this SDDC and want the VPN to use it, select the private IP address. See Create a Private Virtual Interface for vMotion, ESXi Management, Management Appliance, and Workload Traffic.
Select the public IP address if you want the VPN to connect over Internet.

6 (Optional) If your on-premises gateway has a NAT address, enter that address as the **Remote Public IP**.

This IP address must match the local identity (IKE ID) sent by the on-premises VPN gateway. If this field is empty, the **Remote Public IP** field is used to match the local identity of the on-premises VPN gateway.

7 For **BGP Local IP/Prefix Length**, enter the IP address, in CIDR format, of the local VPN tunnel.

Choose a network of size of /30 from the 169.254.0.0/16 subnet. The second and third IP addresses in this range are configured as the remote and local VTI (VPN Tunnel interfaces). For example, in the CIDR block 169.254.111.0/30 (address range 169.254.111.0-169.254.111.3), the local (SDDC) interface is 169.254.111.2/30 and the remote (on-premises) interface 169.254.111.1/30.

**Note**  The following networks are reserved for internal use. The network you specify for **BGP Local IP/Prefix Length** must not overlap any of them.

- 169.254.0.2/28
- 169.254.10.1/24
- 169.254.11.1/24
- 169.254.12.1/24
- 169.254.13.1/24
- 169.254.101.253/30

8 For **BGP Remote IP**, enter the IP address of your on-premises VPN gateway.

9 For **BGP Remote ASN**, enter the ASN of your on-premises VPN gateway.

10 Configure **Advanced Tunnel Parameters**.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tunnel Encryption</td>
<td>Select a Phase 2 security association (SA) cipher that is supported by your on-premises VPN gateway.</td>
</tr>
<tr>
<td>Tunnel Digest Algorithm</td>
<td>Select a Phase 2 digest algorithm that is supported by your on-premises VPN gateway.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>  If you specify a GCM-based cipher for <strong>Tunnel Encryption</strong>, set <strong>Tunnel Digest Algorithm</strong> to <strong>None</strong>. The digest function is integral to the GCM cipher.</td>
</tr>
<tr>
<td>Perfect Forward Secrecy</td>
<td>Enable or Disable to match the setting of your on-premises VPN gateway. Enabling Perfect Forward Secrecy prevents recorded (past) sessions from being decrypted if the private key is ever compromised.</td>
</tr>
<tr>
<td>Preshared Key</td>
<td>Enter the preshared key string. The maximum key length is 128 characters. This key must be identical for both ends of the VPN tunnel.</td>
</tr>
<tr>
<td>IKE Encryption</td>
<td>Select a Phase 1 (IKE) cipher that is supported by your on-premises VPN gateway.</td>
</tr>
</tbody>
</table>
IKE Digest Algorithm

Select a Phase 1 digest algorithm that is supported by your on-premises VPN gateway. The best practice is to use the same algorithm for both the IKE Digest Algorithm and the Tunnel Digest Algorithm.

**Note** If you specify a GCM-based cipher for IKE Encryption, set IKE Digest Algorithm to None. The digest function is integral to the GCM cipher. You must use IKE V2 if you use a GCM-based cipher.

IKE Type

- Specify IKE V1 to initiate and accept the IKEV1 protocol.
- Specify IKE V2 to initiate and accept the IKEV2 protocol. You must use IKEV2 if you have specified a GCM-based IKE Digest Algorithm.
- Specify IKE FLEX to accept either IKEV1 or IKEV2 and then initiate using IKEV2. If IKEV2 initiation fails, IKE FLEX will not fall back to IKEV1.

Diffie Hellman

Select a Diffie Hellman group that is supported by your on-premises VPN gateway. This value must be identical for both ends of the VPN tunnel. Higher group numbers offer better protection. The best practice is to select group 14 or higher.

11 (Optional) Under **Advanced BGP Parameters**, enter a BGP Secret that matches the one used by the on-premises gateway.

12 Click **Save**.

The VPN creation process might take a few minutes. When the route-based VPN becomes available, the tunnel status and BGP session state are displayed. The following actions are available to help you with troubleshooting and configuring the on-premises end of the VPN:

- Click **DOWNLOAD CONFIG** to download a file that contains VPN configuration details. You can use these details to configure the on-premises end of this VPN.
- Click **VIEW STATISTICS** to view packet traffic statistics for this VPN. See **View VPN Tunnel Status and Statistics**.
- Click **VIEW ROUTES** to open a display of routes advertised and learned by this VPN.
- Click **DOWNLOAD ROUTES** to download a list of **Advertised Routes** or **Learned Routes** in CSV format.

**What to do next**

Create or update firewall rules as needed. To allow traffic through the route-based VPN, specify VPN Tunnel Interface in the **Applied to** field. The **All Uplinks** option does not include the routed VPN tunnel.

**Create a Policy-Based VPN**

A policy-based VPN creates an IPsec tunnel and a policy that specifies how traffic uses it. When you use a policy-based VPN, you must update the routing tables on both ends of the network when new routes are added.
Policy-based VPNs in your VMware Cloud on AWS SDDC use an IPsec protocol to secure traffic. To create a policy-based VPN, you configure the local (SDDC) endpoint, then configure a matching remote (on-premises) endpoint. Because each policy-based VPN must create a new IPsec security association for each network, an administrator must update routing information on premises and in the SDDC whenever a new policy-based VPN is created. A policy-based VPN can be an appropriate choice when you have only a few networks on either end of the VPN, or if your on-premises network hardware does not support BGP (which is required for route-based VPNs).

Procedure

2. Select **Networking & Security > VPN > Policy Based**.
3. Click **ADD VPN** and give the new VPN a **Name**.
4. Select a **Local IP Address** for the VPN.
   Specify a public IP address to have the VPN connect over the Internet. If you have configured AWS Direct Connect for this SDDC, you can select an available private IP address to create a VPN that uses Direct Connect and a private VIF. See Using AWS Direct Connect with VMware Cloud on AWS for more information about Direct Connect.

   **Note** Because of the way Direct Connect handles the security association (SA) required by the IPSec protocol (only a single SA is supported), a route-based VPN is usually a better choice for use with Direct Connect. And while you can configure a policy-based VPN to use Direct Connect, you cannot configure Direct Connect failover to a policy-based VPN.

5. Enter the **Remote Public IP** address of your on-premises gateway.
   This IP address must be reachable over the Internet if you specified a public IP in Step 4. If you specified a private IP, it must be reachable over Direct Connect to a private VIF. Default gateway firewall rules allow inbound and outbound traffic over the VPN connection, but you must create firewall rules to manage traffic over the VPN tunnel.

6. (Optional) If your on-premises gateway is behind a NAT device, enter the gateway address as the **Remote Private IP**.
   This IP address must match the local identity (IKE ID) sent by the on-premises VPN gateway. If this field is empty, the **Remote Public IP** field is used to match the local identity of the on-premises VPN gateway.

7. Specify the **Remote Networks** that this VPN can connect to.
   This list must include all networks defined as local by the on-premises VPN gateway. Enter each network in CIDR format, separating multiple CIDR blocks with commas.
8 Specify the **Local Networks** that this VPN can connect to.

This list includes all routed compute networks in the SDDC, as well as the entire Management network and the appliance subnet (a subset of the Management network that includes vCenter and other management appliances, but not the ESXi hosts). It also includes the CGW DNS Network, a single IP address used to source requests forwarded by the CGW DNS service.

9 Configure **Advanced Tunnel Parameters**.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tunnel Encryption</td>
<td>Select a Phase 2 security association (SA) cipher that is supported by your on-premises VPN gateway.</td>
</tr>
<tr>
<td>Tunnel Digest Algorithm</td>
<td>Select a Phase 2 digest algorithm that is supported by your on-premises VPN gateway.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>If you specify a GCM-based cipher for <strong>Tunnel Encryption</strong>, set <strong>Tunnel Digest Algorithm</strong> to <strong>None</strong>. The digest function is integral to the GCM cipher.</td>
</tr>
<tr>
<td>Perfect Forward Secrecy</td>
<td>Enable or Disable to match the setting of your on-premises VPN gateway. Enabling Perfect Forward Secrecy prevents recorded (past) sessions from being decrypted if the private key is ever compromised.</td>
</tr>
<tr>
<td>IKE Encryption</td>
<td>Select a Phase 1 (IKE) cipher that is supported by your on-premises VPN gateway.</td>
</tr>
<tr>
<td>IKE Digest Algorithm</td>
<td>Select a Phase 1 digest algorithm that is supported by your on-premises VPN gateway. The best practice is to use the same algorithm for both the IKE Digest Algorithm and the Tunnel Digest Algorithm.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>If you specify a GCM-based cipher for <strong>IKE Encryption</strong>, set <strong>IKE Digest Algorithm</strong> to <strong>None</strong>. The digest function is integral to the GCM cipher. You must use IKE V2 if you use a GCM-based cipher.</td>
</tr>
</tbody>
</table>
| IKE Type              | - Specify **IKE V1** to initiate and accept the IKEv1 protocol.  
                          - Specify **IKE V2** to initiate and accept the IKEv2 protocol. You must use IKEv2 if you have specified a GCM-based IKE Digest Algorithm.  
                          - Specify **IKE FLEX** to accept either IKEv1 or IKEv2 and then initiate using IKEv2. If IKEv2 initiation fails, IKE FLEX will not fall back to IKEv1. |
| Diffie Hellman        | Select a Diffie Hellman group that is supported by your on-premises VPN gateway. This value must be identical for both ends of the VPN tunnel. Higher group numbers offer better protection. The best practice is to select group 14 or higher. |
| Preshared Key         | Enter a preshared key used by both ends of the tunnel to authenticate with each other.  
                          - The string has a maximum length of 128 characters. |

10 Click **Save**.

The VPN creation process might take a few minutes. When the policy-based VPN becomes available, the following actions are available to help you with troubleshooting and configuring the on-premises end of the VPN:

- Click **DOWNLOAD CONFIG** to download a file that contains VPN configuration details. You can use these details to configure the on-premises end of this VPN.
Click **VIEW STATISTICS** to view packet traffic statistics for this VPN. See **View VPN Tunnel Status and Statistics**.

**What to do next**

Create or update firewall rules as needed. To allow traffic through the policy-based VPN, specify **Internet Interface** in the **Applied to** field.

**View Connected VPC Information**

The Connected Amazon VPC contains your SDDC and all its networks. Information about this VPC, including the active ENI, VPC subnet, and VPC ID, is available on the **Networking & Security** tab.

Click **Connected VPC** in the **System** category on the **Networking & Security** tab to open the **Connected Amazon VPC** page, which provides the following information:

- **AWS Account ID**: The AWS account ID you specified when you created your SDDC.
- **VPC ID**: The AWS ID of this VPC.
- **VPC Subnet**: The AWS ID of the VPC subnet you specified when you created your SDDC.
- **Active Network Interface**: The identifier for the ENI used by VMC in this VPC.
- **IAM Role Names**: AWS Identity and Access Management role names defined in this VPC.
- **Cloud Formation Stack Names**: The name of the AWS Cloud Formation stack used to create your SDDC.
- **Service Access**: A list of AWS services enabled in this VPC.

**View VPN Tunnel Status and Statistics**

The VMC Console provides status and statistics for IPSec VPNs and L2VPN segments.

**Procedure**

1. Log in to the VMC Console at [https://vmc.vmware.com](https://vmc.vmware.com).
2. Select **Networking & Security > VPN**.
3. Click either **Route Based**, **Policy Based**, or **Layer 2**.
   
   You can retrieve status and statistics for any tunnel that is up.
Click the Information icon to display a Status Detail message that provides more information about channel (IKE Phase 1 negotiation) and tunnel status. For a VPN with a Status of Disconnected, the Status Detail tab displays any relevant log messages. You can use these messages in conjunction with the Tunnel Statistics and Error Counts to help understand channel or tunnel failures.

Click the Refresh icon to refresh tunnel statistics. All VPN statistics are reset to 0 when the tunnel is disabled or re-enabled.

**What to do next**

For more information about troubleshooting VPN connection issues, see Troubleshooting Virtual Private Networks (VPN) in the NSX Data Center for vSphere documentation and also the NSX-T Data Center Troubleshooting Guide.

**IPsec VPN Settings Reference**

The on-premises end of any IPsec VPN must be configured to match the settings you specified for the SDDC end of that VPN.

Information in the following tables summarizes the available SDDC IPsec VPN settings. Some of the settings can be configured. Some are static. Use this information to verify that your on-premises VPN solution can be configured to match the one in your SDDC. Choose an on-premises VPN solution that supports all the static settings and any of the configurable settings listed in these tables.

On-Premises IPsec VPN Configuration

Click **DOWNLOAD CONFIG** on the status page of any VPN to download a file that contains VPN configuration details. You can use these details to configure the on-premises end of the VPN.

**Note** Do not configure the on-premises side of a VPN to have an idle timeout (for example, the NSX Session idle timeout setting). On-premises idle timeouts can cause the VPN to become periodically disconnected.

Mapping NSX Parameters to VMC Console VPN Parameters

The table below matches terms for VPN parameters used in NSX Edge configuration to the terms used in the VMC Console.

**Configure Management Gateway Networking**

To complete configuration of management gateway networking, set up a DNS server for the management network, specify whether you want to access the SDDC vCenter at a public or private IP address, and create management gateway firewall rules.

**Procedure**

1. **Specify Management Gateway DNS Servers**
   Specifying a DNS server allows the management gateway to resolve fully-qualified domain names (FQDNs) to IP addresses on the management network.

2. **Set vCenter Server FQDN Resolution Address**
   You can connect to the SDDC vCenter Server at either a public or private IP address. A private IP address can be resolved from an SDDC VPN. A public IP address can be resolved from the Internet.

3. **Set HCX FQDN Resolution Address**
   You can connect to HCX at either a public or private IP address. A private IP address can be resolved from an SDDC VPN. A public IP address can be resolved from the internet.

4. **Add or Modify Management Gateway Firewall Rules**
   By default, the management gateway blocks traffic to all destinations from all sources. Add Management Gateway firewall rules to allow traffic as needed.

**Specify Management Gateway DNS Servers**

Specifying a DNS server allows the management gateway to resolve fully-qualified domain names (FQDNs) to IP addresses on the management network.

Unless you intend to use only static routing, you must specify a DNS server that can resolve IP addresses on both sides of the management gateway to VM FQDNs. Specify the IP address of at least one DNS server when you configure the management gateway. If you specify an optional backup DNS server, be sure that both servers are configured identically.

**Procedure**

1. Log in to the VMC Console at [https://vmc.vmware.com](https://vmc.vmware.com).
2. Select **Networking & Security > DNS**.
3. Under **Management Gateway**, click the ellipses button.
4. Click **Edit** and enter the IP address for **DNS Server 1**.
5. (Optional) Enter the IP address for **DNS Server 2**.
   - If you specify an address for **DNS Server 2**, be sure that both DNS servers are configured identically.
Click Save.

Set vCenter Server FQDN Resolution Address
You can connect to the SDDC vCenter Server at either a public or private IP address. A private IP address can be resolved from an SDDC VPN. A public IP address can be resolved from the Internet.

**Prerequisites**
Before you can access the SDDC vCenter Server at a private IP address, you'll need to set up a VPN connecting your SDDC to your on-premises datacenter. See Create a Route-Based VPN or Create a Policy-Based VPN.

**Procedure**
2. Navigate to the *Settings* tab of your SDDC.
3. Expand *vCenter FQDN*, and click *Edit*.
4. Under *Resolution Address* Select either the *Public IP* address or the *Private IP* address and click *SAVE*.

Set HCX FQDN Resolution Address
You can connect to HCX at either a public or private IP address. A private IP address can be resolved from an SDDC VPN. A public IP address can be resolved from the internet.

**Prerequisites**
Before you can access HCX at a private IP address, you'll need to set up a VPN connecting your SDDC to your on-premises datacenter. See Create a Route-Based VPN or Create a Policy-Based VPN.

**Procedure**
2. Navigate to the *Settings* tab of your SDDC.
3. Expand *HCX FQDN*, and click *Edit*.
4. Under *Resolution Address* select either the *Public IP* address or the *Private IP* address and click *SAVE*.

Add or Modify Management Gateway Firewall Rules
By default, the management gateway blocks traffic to all destinations from all sources. Add Management Gateway firewall rules to allow traffic as needed.

**Prerequisites**
Verify that management groups and services are configured. See Add a Management Group.
Procedure

3. On the Gateway Firewall card, click Management Gateway, then click ADD NEW RULE.
4. Enter the firewall rule parameters.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rule Name</td>
<td>Enter a descriptive name for the rule.</td>
</tr>
<tr>
<td>Source</td>
<td>Click Set Source and enter or select one of the following options: Select Any to allow traffic from any source address or address range. Select System Defined Groups and select one of the following source options: - ESXi to allow traffic from your SDDC’s ESXi hosts. - NSX Manager to allow traffic from your SDDC’s NSX-T manager appliance. - vCenter to allow traffic from your SDDC’s vCenter Server. Select User Defined Groups to use a management group that you have defined. See Add a Management Group.</td>
</tr>
<tr>
<td>Destination</td>
<td>Click Set Destination and enter or select one of the following options: Select Any to allow traffic to any destination address or address range. Select System Defined Groups and select one of the following destination options: - ESXi to allow traffic to your SDDC’s ESXi management. - NSX Manager to allow traffic to your SDDC’s NSX-T. - vCenter to allow traffic to your SDDC’s vCenter Server.</td>
</tr>
<tr>
<td>Services</td>
<td>Select one of the following service types to apply the rule to: - Provisioning and Remote Console (TCP 902) applies only to the ESXi system-defined group as a Destination. - vMotion (TCP 8000). See Required Firewall Rules for vMotion. - HTTPS (TCP 443) applies only to vCenter Server system-defined group as a Destination. - ICMP (All ICMP) - SSO (TCP 7444) applies only to vCenter Serversystem-defined group as a Destination.</td>
</tr>
<tr>
<td>Action</td>
<td>The only action available for a management gateway firewall rule is Allow.</td>
</tr>
<tr>
<td>Logging</td>
<td>Enable or disable packet logging for this firewall rule. If enabled, the packet logs are forwarded to the Log Intelligence service. To access the logs, visit the Log Intelligence service console.</td>
</tr>
</tbody>
</table>

5. Click PUBLISH to create the rule.

Firewall rules are applied in order from top to bottom. Because there is always a default drop rule at the bottom, and the rules above are always Allow rules, rule order has no impact on traffic flow.
Example: Create a Firewall Rule
To create a firewall rule that enables vMotion traffic from the on-premises ESXi hosts to the ESXi hosts in the SDDC:

1. Create a management inventory group that contains the on-premises ESXi hosts that you want to enable for vMotion to the SDDC.
2. Create a management gateway rule with source ESXi and destination on-premises ESXi hosts.
3. Create another management gateway rule with source on-premises ESXi hosts group and destination ESXi with a vMotion service.

Add a Management Group
Management inventory groups contain managed SDDC infrastructure components and on-premises infrastructure components. You can use these groups in management gateway firewall policies.

Management inventory groups are created automatically for SDDC infrastructure components such as vCenter and NSX Manager. You can create additional management inventory groups by specifying the CIDR blocks to which group members are connected. For example, you could create an inventory group for ESXi hosts in the on-premises data center.

Procedure
3. Click Add Group and give the new group a Name.
4. In the Members column, enter one or more IP addresses in CIDR format specifying the subnets to which group members are connected.
   - Member Type must be an IP Address. Separate multiple addresses with commas.
5. Click Save to create the group.

Example Management Gateway Firewall Rules
Some common firewall rule configurations include opening access to the vSphere Client from the internet, allowing access to vCenter Server through the management VPN tunnel, and allowing remote console access.

Commonly Used Firewall Rules
The following table shows the Service, Source, and Destination settings for commonly-used firewall rules.
Table 2-6. Commonly-Used Firewall Rules

<table>
<thead>
<tr>
<th>Use Cases</th>
<th>Service</th>
<th>Source</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provide access to vCenter Server from the internet.</td>

<td>IP address or CIDR block from on-premises data center.</td>
</tr>
</tbody>
</table>

Configure Compute Gateway and Workload Networking

Compute gateway networking includes a compute network with one or more segments and the DNS, DHCP, and firewall configurations that manage network traffic for workload VMs. It can also include a layer 2 VPN and extended network that provides a single broadcast domain that spans your on-premises network and you SDDC workload network.

Procedure

1. Create a Network Segment

   Network segments are logical networks for use by workload VMs in the SDDC.
2 Configure a Layer 2 VPN and Extended Network
A VMware Cloud on AWS extended network uses a layer 2 Virtual Private Network (L2VPN) to extend an on-premises network to multiple VLAN based networks that can be extended with different tunnel IDs on the same L2VPN tunnel. This extended network is a single subnet with a single broadcast domain, so you can migrate VMs to and from your cloud SDDC without having to change their IP addresses.

3 Add or Modify Compute Gateway Firewall Rules
By default, the compute gateway blocks traffic to all uplinks. Add Compute Gateway firewall rules to allow traffic as needed.

4 Add or Modify Distributed Firewall Rules
Distributed firewall rules apply at the VM level and control East-West traffic within the SDDC.

5 Add a Compute Gateway DNS Zone
The Compute Gateway is configured with a single default DNS zone. You can add up to four more zones if you want to provide the flexibility of having multiple DNS servers.

6 Configure Compute Gateway DHCP Relay
In the default configuration a local server handles DHCP requests for workload VMs on all routed segments. If you have an external DHCP server that manages IP addresses on your workload networks, you can configure the Compute Gateway to forward DHCP requests to that server.

Create a Network Segment
Network segments are logical networks for use by workload VMs in the SDDC.

VMware Cloud on AWS supports three types of logical network segments: routed, extended and disconnected.

- A routed network segment (the default type) has connectivity to other logical networks in the SDDC and, through the SDDC firewall, to external networks.
- An extended network segment extends an existing L2VPN tunnel, providing a single IP address space that spans the SDDC and an on-premises network.
- A disconnected network segment has no uplink, and provides an isolated network accessible only to VMs connected to it. Disconnected segments are created when needed by HCX (see Getting started with VMware HCX). You can also create them yourself, and can convert them to other segment types.

See Configuration Maximums for VMware Cloud on AWS for limits on segments per SDDC and network connections per segment.

A Single Host Starter SDDC is created with a single routed network segment named sddc-cgw-network-1. This network uses CIDR block 192.168.1.0/24, unless that conflicts with the CIDR block you chose for the SDDC management network. In that case, the default network uses CIDR block 172.10.1.0/24.

Multi-host SDDCs are not created with a default network segment, so you must create at least one for your workload VMs. You can use the VMC Console to create additional network segments or delete ones that are no longer in use.
When you create a network segment, ensure that it does not overlap your management network or any of the subnets in your connected Amazon VPC.

**Procedure**

1. Select **Networking & Security > Segments > Add Segments**.
2. Enter a **Name** for the segment.
3. Select a segment **Type** from the drop-down menu and configure the segment.

<table>
<thead>
<tr>
<th>Type</th>
<th>Configuration</th>
</tr>
</thead>
</table>
| Routed     | a. Specify the CIDR block of the segment in the **Gateway/Prefix Length** field.  
             | b. (Optional) Select **Enabled** to enable native NSX-T DHCP services for VMs on  
                 |     this segment. Specify a DHCP IP address range and a DNS suffix for the      
                 |     segment. VMs connecting to the segment get their IP addresses from the      
                 |     specified DHCP server and their FQDN has the specified DNS suffix.         |
|            | **Note** If you enable native NSX-T DHCP on any Compute Network segment you     |
|            |     cannot enable DHCP relay for the Compute Gateway. See **Configure Compute  |
|            |     Gateway DHCP Relay**.                                                    |
| Extended   | Specify the ID of an existing L2VPN tunnel block of the segment in the **Tunnel ID** field. |
| Disconnected | Specify the CIDR block of the segment in the **Gateway/Prefix Length** field. |

4. Click **Save**.

The system creates the requested segment. This operation can take up to 15 seconds to complete.

**Configure a Layer 2 VPN and Extended Network**

A VMware Cloud on AWS extended network uses a layer 2 Virtual Private Network (L2VPN) to extend an on-premises network to multiple VLAN based networks that can be extended with different tunnel IDs on the same L2VPN tunnel. This extended network is a single subnet with a single broadcast domain, so you can migrate VMs to and from your cloud SDDC without having to change their IP addresses.

In addition to data center migration, you can use an extended L2VPN network for disaster recovery, or for dynamic access to cloud computing resources as needed (often referred to as "cloud bursting").

An L2VPN on the Compute Gateway can extend up to 100 of your on-premises networks. VMware Cloud on AWS uses NSX-T to provide the L2VPN server in your cloud SDDC. L2VPN client functions can be provided by a standalone NSX Edge that you download and deploy into your on-premises data center.
The VMware Cloud on AWS L2VPN feature supports extending VLAN networks. The L2VPN connection to the NSX-T server uses an IPsec tunnel. The L2VPN extended network is used to extend Virtual Machine networks and carries only workload traffic. It is independent of the VMkernel networks used for migration traffic (ESXi management or vMotion), which use either a separate IPsec VPN or a Direct Connect connection.

**Important** You cannot bring up an L2VPN tunnel until you have configured the L2VPN client and server and created an extended network that specifies the tunnel ID you assigned to the client.

**Procedure**

1. **Configure a Layer 2 VPN Tunnel in the SDDC**
   - Specify a local (AWS) IP address, a remote (on-premises) public IP address, and a remote private IP address to create the SDDC end of the Layer 2 VPN tunnel.

2. **Configure Layer 2 VPN Extended Segment**
   - Extended networks require a layer 2 Virtual Private Network (L2VPN), which provides a secure communications tunnel between an on-premises network and one in your cloud SDDC.

3. **Download and Configure the Standalone NSX Edge**
   - The on-premises end of your L2VPN requires a specially configured standalone NSX Edge appliance. You must download, install, and configure this appliance and related on-premises vSphere networking before you can create an L2VPN.

**Configure a Layer 2 VPN Tunnel in the SDDC**

Specify a local (AWS) IP address, a remote (on-premises) public IP address, and a remote private IP address to create the SDDC end of the Layer 2 VPN tunnel.

VMware Cloud on AWS supports a single Layer 2 VPN tunnel between your on-premises installation and your SDDC.

**Procedure**

1. Log in to the VMC Console at [https://vmc.vmware.com](https://vmc.vmware.com).
2. Select **Networking & Security > VPN > Layer 2**.
3. Click **Add VPN Tunnel**.
Configure the VPN parameters.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| Local IP Address  | - If you have configured AWS Direct Connect for this SDDC and want the VPN to use it, select the private IP address. See Create a Private Virtual Interface for vMotion, ESXi Management, Management Appliance, and Workload Traffic.  
  - Select the public IP address if you want the VPN to connect over Internet. |
| Remote Public IP  | Enter the remote public IP address of your on-premise L2VPN gateway. For an L2VPN, this is always the standalone NSX Edge appliance (see Download and Configure the Standalone NSX Edge). |
| Remote Private IP | Enter the remote private IP address if the on-premise gateway is configured behind NAT.                                                   |

5 Click Save.

Depending on your SDDC environment, the Layer 2 VPN creation process might take a few minutes. When the Layer 2 VPN tunnel becomes available, the status changes to Up.

Configure Layer 2 VPN Extended Segment

Extended networks require a layer 2 Virtual Private Network (L2VPN), which provides a secure communications tunnel between an on-premises network and one in your cloud SDDC.

Each end of this tunnel has an ID. When the tunnel ID matches on the cloud SDDC and the on-premises side of the tunnel, the two networks become part of the same broadcast domain. Extended networks use an on-premises gateway as the default gateway. Other network services such as DHCP and DNS are also provided on-premises.

You can change a logical network from routed to extended or from extended to routed. For example, you might configure a logical network as extended to allow migration of VMs from your on-premises data center to your cloud SDDC. When the migration is complete, you might then change the network to routed to allow the VMs to use VMware Cloud on AWS networking services.

Prerequisites

Verify that Layer 2 VPN tunnel is available. See Configure a Layer 2 VPN Tunnel in the SDDC.

Procedure

1 Log in to the VMC Console at https://vmc.vmware.com.
2 Select Networking & Security > VPN > Layer 2.
3 Click ADD EXTENDED SEGMENT.
4 Enter the extended segment name.
5 Enter the L2VPN tunnel ID.
6 Click SAVE.
7 Click DOWNLOAD CONFIG to download a file containing the peer code and other information you’ll need when configuring the on-premises of the remote side VPN configuration.
Click **REMOTE STANDALONE EDGE DOWNLOAD** to download an NSX Standalone Edge image in OVF format that you must install and configure as the client side of the L2VPN. See Download and Configure the Standalone NSX Edge.

**Download and Configure the Standalone NSX Edge**

The on-premises end of your L2VPN requires a specially configured standalone NSX Edge appliance. You must download, install, and configure this appliance and related on-premises vSphere networking before you can create an L2VPN.

Before you can create an L2VPN, you must download and configure a standalone NSX Edge appliance. See Configure Layer 2 VPN Extended Segment. You cannot use your on-premises NSX-T Edge to create the L2VPN client side.

**Procedure**

1. Create a vSphere distributed switch.
2. Add multiple hosts to the newly created vSphere distributed switch.
3. Add a distributed uplink port group to the vSphere Distributed Switch you created in Step 1.
   - Follow the procedure in Add a distributed uplink port group and use these customization values on the **Configure Settings** and **Security** pages.
   - **Configure Settings**
     - Select VLAN trunking from the drop-down menu.
     - Set the VLAN trunk range value to the VLAN IDs of the VLANs that you plan to extend to the SDDC.
     - Select the Customize default policies configuration option.
   - **Security**
     - Set Promiscuous mode to Reject.
     - Set MAC address changes to Reject.
     - Set Forged transmits to Accept.
4. Add a distributed trunk port group to the vSphere Distributed Switch you created in Step 1.
   - Follow the procedure in Add a distributed trunk port group and use these customization values on the **Configure Settings** and **Security** pages.
   - **Configure Settings**
     - Select VLAN from the drop-down menu.
     - Select the Customize default policies configuration option.
   - **Security**
     - Set Promiscuous mode to Reject.
     - Set MAC address changes to Reject.
     - Set Forged transmits to Reject.
5. Configure a sink port in the distributed trunk port group you created in Step 4.
   - See Configure a Sink Port in the VMware NSX Data Center for vSphere documentation.
6 Download and configure the standalone NSX Edge.

On the L2VPN page, click **REMOTE STANDALONE EDGE DOWNLOAD**. From the download, select the files `NSX-l2t-client-large.ovf`, `NSX-l2t-client-large.mf`, and `nsx-edge-disk*.vmdk` (8 files altogether). Follow the procedure in Deploy the OVF template to deploy these files and create the standalone Edge appliance VM. Specify the following configuration details on the Select networks and Customize template pages of the Deploy OVF Template page.

<table>
<thead>
<tr>
<th>Page</th>
<th>Configuration Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select networks</td>
<td>- Connect the <strong>Trunk</strong> network to the trunk port group you created in Step 4.</td>
</tr>
<tr>
<td></td>
<td>- Connect the <strong>Public</strong> network to the uplink port group you created in Step 3.</td>
</tr>
<tr>
<td>Customize template</td>
<td>- Add the peer address and peer code values from the download config file. See Configure Layer 2 VPN Extended Segment.</td>
</tr>
<tr>
<td></td>
<td>- Enter the ID of the VLAN extended by the segment and the L2VPN tunnel ID in the form <code>VLAN-ID(tunnel-number)</code> where VLAN-ID is the ID of the VLAN you are extending and tunnel-number is the L2VPN tunnel number. In the default configuration the VLAN ID is 100 and the tunnel number is 10, which you enter as <code>100(10)</code>.</td>
</tr>
<tr>
<td></td>
<td>- Select <strong>Enable TCP Loose Setting</strong> to enabling loose TCP window checking by the Edge appliance.</td>
</tr>
<tr>
<td></td>
<td>- Assign the Edge appliance a static IP address.</td>
</tr>
<tr>
<td></td>
<td>- Assign the unused IP address as the NSX Edge IP address, subnet, and gateway for internet access.</td>
</tr>
<tr>
<td></td>
<td>- Configure High Availability options. Don't select <strong>Enable HA for this appliance</strong> unless you have downloaded and configured an additional standalone edge. For more information about deploying the Edge appliance in HA mode, see Configure HA on Standalone L2 VPN Clients.</td>
</tr>
<tr>
<td></td>
<td>- Enter the admin and root passwords for the Edge appliance.</td>
</tr>
<tr>
<td></td>
<td>- Select <strong>Power on after deployment</strong>.</td>
</tr>
</tbody>
</table>

**Add or Modify Compute Gateway Firewall Rules**

By default, the compute gateway blocks traffic to all uplinks. Add Compute Gateway firewall rules to allow traffic as needed.

Compute gateway firewall rules specify actions to take on network traffic from a specified source to a specified destination. Actions can be either allow (allow the traffic) or drop (drop all packets matching the specified source and destination). Sources and destinations can be chosen from a list of a physical network interfaces, or a generic specification of All Uplinks that refers to all traffic leaving the Compute gateway and going to the VPC interface, Internet Interface, or Direct Connect interface. A firewall rule applied to All Uplinks does not apply to the VPN Tunnel Interface (VTI), which is a virtual interface and not a physical uplink. The VPN Tunnel Interface must be specified explicitly in the Applied To parameter of any firewall rule that manages workload VM communications over a route-based or policy-based VPN. The compute gateway includes a Default VTI Rule that drops all traffic to the VTI. To enable workload VMs to communicate over the VTI, modify this rule or move it to a lower place in the rule hierarchy, after more permissive rules.
Prerequisites

Compute Gateway firewall rules require named inventory groups for Source and Destination values. See Add or Modify an Inventory Group.

Procedure

3. On the Gateway Firewall card, click Compute Gateway, then click ADD NEW RULE.
   You can also select an existing rule, then click the ellipsis button and select Add Rule Above or Add Rule Below.
4. Enter the firewall rule parameters.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Give the rule a descriptive name.</td>
</tr>
<tr>
<td>Source</td>
<td>Click Set Source and select an inventory group for source network traffic and click SAVE.</td>
</tr>
<tr>
<td>Destination</td>
<td>Click Set Destination and select an inventory group for destination network traffic and click SAVE.</td>
</tr>
<tr>
<td>Services</td>
<td>Select a service from the drop-down list, or type Any if you want the rule to apply to any protocol or port.</td>
</tr>
<tr>
<td>Action</td>
<td>Select Allow to allow the specified traffic or Drop to deny it.</td>
</tr>
<tr>
<td>Applied To</td>
<td>Define the type of traffic that the rule applies to:</td>
</tr>
<tr>
<td></td>
<td>- Select VPN Tunnel Interface if you want the rule to apply to traffic over the route-based VPN.</td>
</tr>
<tr>
<td></td>
<td>- Select VPC Interface if you want the rule to apply to traffic over the linked AWS VPC connection.</td>
</tr>
<tr>
<td></td>
<td>- Select Internet Interface if you want the rule to apply to traffic over the Internet, including over policy-based VPNs using Public IP.</td>
</tr>
<tr>
<td></td>
<td>- Select Direct Connect Interface if you want the rule to allow traffic over AWS Direct Connect (private VIF), including over policy-based VPNs using Private IP.</td>
</tr>
<tr>
<td></td>
<td>- All Uplinks if you want the rule to apply to the VPC Interface, the Internet Interface, and the Direct Connect Interface, but not to the VPN Tunnel Interface.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> The VPN Tunnel Interface is not classified as an uplink.</td>
</tr>
<tr>
<td>Logging</td>
<td>Enable or disable packet logging for this firewall rule. If enabled, the packet logs are forwarded to the Log Intelligence service. To access the logs, visit the Log Intelligence service console.</td>
</tr>
</tbody>
</table>

5. (Optional) Reorder firewall rules.

A rule created from the ADD NEW RULE button is placed at the top of the list. Firewall rules are applied in order from top to bottom. To change the position of a rule in the list, select it, then click the ellipsis button and select Move Rule Up or Move Rule Down.
6   Click **PUBLISH** to create the rule.

**Add or Modify an Inventory Group**

Inventory groups categorize VMs based on VM names, IP addresses, and matching criteria of VM name and tag. You use inventory groups to specify sources and destinations when you create firewall rules, and to simplify managing workload VMs that require similar configurations.

Firewall rules often apply to a group of VMs that have certain common characteristics including:

- names that follow a naming convention (like Win* for Windows VMs or Photon* for Photon VMs)
- IP addresses within a specific range or CIDR block
- security tags

VMC Networking & Security inventory groups, like AWS Security Groups, give you a way to create named groups of management or workload VMs that you can reference in firewall rules.

**Procedure**

1  Log in to the VMC Console at https://vmc.vmware.com.

2  On the **Networking & Security** tab, click **Inventory > Groups**.

3  On the **Groups** card, click **Management Groups** or **Workload Groups**, then click **ADD GROUP**.

   Management groups contain VMs on the Management Network. Workload groups contain VMs on the Compute network. To modify an existing group, select it and click the ellipsis button.

4  Enter a descriptive **Name** for the group.

5  Select a Member Type.

   The choices are **Virtual Machine**, **IP address**, or **Membership Criteria**.
6 Enter a definition for your group.

The group definition comprises one or more membership criteria. VMs that match all of the selected criteria are included in the group.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual Machine</td>
<td>Select one or more VMs from the list.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>This member type is available only for Workload Groups.</td>
</tr>
<tr>
<td>IP address</td>
<td>Enter an IP address, CIDR block, or a range of IP addresses in the form ip-ip (for example 192.168.1.1-192.168.1.100).</td>
</tr>
</tbody>
</table>
| Membership Criteria  | Click **Set Membership Criteria** to open the Membership Criteria page. Click **ADD CRITERIA** and specify one or more criteria as **Property**, **Condition**, **Value** tuples. For example:  
  - `VM Name Contains db_ ` to include VMs whose names contain the string `db_` in the group, or  
  - `Tag Equals Secure` to include VMs tagged with the tag `Secure`.  
  **Note** This member type is available only for Workload Groups. |

7 Click **SAVE** to create the group.

8 (Optional) Review group members. Select the newly created group and click the ellipsis button.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>View Members</td>
<td>View the members of the group.</td>
</tr>
<tr>
<td>View References</td>
<td>View any firewall rules that reference the group.</td>
</tr>
</tbody>
</table>

**Add a Custom Service**

Predefined and custom services can be used in firewall rules.

When you create a firewall rule, you can specify that the rule applies to one or more of the network services defined in your SDDC. The default list includes VMware services such as remote console and provisioning, standard services such as IKE, ICMP, and TCP, and many well-known third party services. You can add services to this list by selecting values, typically ports and protocols, from a list of service types and additional service properties.

**Procedure**

1 Log in to the VMC Console at [https://vmc.vmware.com](https://vmc.vmware.com).

2 Select **Networking & Security > Services**.

3 Click **ADD NEW SERVICE** and type the service name.
4 Select **Set Service Entries > ADD NEW SERVICE ENTRY**.

5 Select the **Service Type** from the drop-down menu and specify any **Additional Properties** of the service.

6 Click **SAVE** to create the service definition.

**Add or Modify Distributed Firewall Rules**

Distributed firewall rules apply at the VM level and control East-West traffic within the SDDC.

All traffic attempting to pass through the firewall is subjected to the rules in the order shown in the rules table, beginning at the top and proceeding to the rules at the bottom. In some cases, the order of precedence of two or more rules might be important in determining the disposition of a packet. The default firewall rules apply to traffic that does not match any of the user-defined firewall rules, and allows all L3 and L2 traffic.

**Note**  The default L3 firewall rule applies to all traffic, including DHCP. If you change the **Action** in this rule to **Drop** or **Reject**, DHCP traffic is blocked.

**Prerequisites**

Verify that multiple security groups and services are configured. See **Add or Modify an Inventory Group** and **Add a Custom Service**.

**Procedure**

1 Log in to the VMC Console at [https://vmc.vmware.com](https://vmc.vmware.com).

2 Select **Networking & Security > Distributed Firewall**.

3 If you are an NSX Administrator, you can edit an existing section to add, remove, or reorder rules.

   To create a new section, click **ADD NEW SECTION** and give the section a **Name**.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Emergency Rules</td>
<td>Applies to temporary rules needed in emergency situations.</td>
</tr>
<tr>
<td></td>
<td>For example, block traffic to a Web server due to malicious content.</td>
</tr>
<tr>
<td>Infrastructure Rules</td>
<td>Applies to infrastructure rules only.</td>
</tr>
<tr>
<td></td>
<td>Such as, ESXi, vCenter Server or connectivity to on-premise data center.</td>
</tr>
<tr>
<td>Environment Rules</td>
<td>Applies to broad groups.</td>
</tr>
<tr>
<td></td>
<td>Such as, setting rules so that the production environment cannot reach the test environment.</td>
</tr>
<tr>
<td>Application Rules</td>
<td>Applies to specific application rules.</td>
</tr>
<tr>
<td>Default Rules</td>
<td>The default rules allows all traffic.</td>
</tr>
</tbody>
</table>

4 To add a rule to a new or existing section, select the section and click **ADD NEW RULE**.
Enter the parameters for the new rule.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>Give the rule a descriptive name.</td>
</tr>
<tr>
<td><strong>Sources</strong></td>
<td>Click Set Source and select an inventory group for source network traffic, or click CREATE NEW GROUP to create a new user-defined inventory group to use for this rule. Click SAVE.</td>
</tr>
<tr>
<td><strong>Destinations</strong></td>
<td>Click Set Destination and select an inventory group for destination network traffic, or click CREATE NEW GROUP to create a new user-defined inventory group to use for this rule. Click SAVE.</td>
</tr>
<tr>
<td><strong>Services</strong></td>
<td>Select a service from the drop-down list, or select Any if you want the rule to apply to any protocol or port. Click SAVE.</td>
</tr>
<tr>
<td><strong>Action</strong></td>
<td>Select Allow to allow all L2 and L3 traffic to pass through the firewall.</td>
</tr>
<tr>
<td></td>
<td>Select Drop to drop packets with the specified source, destination, and service protocol. Drop is a silent action with no notification to the source or destination systems. Dropping the packet causes the connection to be retried until the retry threshold is reached.</td>
</tr>
<tr>
<td></td>
<td>Select Reject to reject packets with the specified source, destination, and service protocol. Reject action returns a &quot;destination unreachable message&quot; to the sender. If the protocol is TCP, a TCP RST message is sent. ICMP messages with administratively prohibited code are sent for UDP, ICMP, and other IP connections. One benefit of using Reject is that the sending application is notified after only one attempt that the connection cannot be established.</td>
</tr>
<tr>
<td><strong>Logging</strong></td>
<td>Enable or disable packet logging for this firewall rule. If enabled, the packet logs are forwarded to the Log Intelligence service. To access the logs, visit the Log Intelligence service console.</td>
</tr>
</tbody>
</table>

Click PUBLISH.

**Manage Distributed Firewall Rules**

Traffic packet attempting to pass through the firewall is subjected to the rules in the order shown in the rules table, beginning at the top and proceeding to the rules at the bottom of the list.

You can reorder the distributed firewall sections and rules within a section. You can also edit existing distributed firewall configuration, delete, or clone a firewall rule or section.

When you delete a firewall rule section, all rules in that section are deleted. You cannot delete a section and add it again at a different place in the firewall table. To do so, you must delete the section and publish the configuration. Then add the deleted section to the firewall table and re-publish the configuration.

**Prerequisites**

Verify that you have multiple distributed firewall sections and rules configured. See Add or Modify Distributed Firewall Rules.

**Procedure**

2. Select **Networking & Security > Distributed Firewall**.

3. Manage rules in a new or existing section, select the section and click the vertical ellipses button.
   - Reorder the firewall rules within a section or reorder the sections.
   - Edit a firewall section or rule configuration.
   - Clone a distributed firewall rule.
     - You cannot clone a firewall rule section.
   - Delete a firewall section or a rule within the section.

4. Click **PUBLISH**.

### Add a Compute Gateway DNS Zone

The Compute Gateway is configured with a single default DNS zone. You can add up to four more zones if you want to provide the flexibility of having multiple DNS servers.

Compute gateway Domain Name Servers (DNS) enable workload VMs to resolve fully-qualified domain names (FQDNs) to IP addresses.

**Procedure**

1. Log in to the VMC Console at [https://vmc.vmware.com](https://vmc.vmware.com).

2. Select **Networking & Security > DNS**.

3. Click **ADD DNS ZONE** and give the new zone a **Name**.
   - You use this **Name** if you create DNS firewall rules that apply to traffic in this zone.

4. Enter a **Domain Name** for the zone.
   - This must be a fully qualified domain name, such as example.com.

5. Enter the IP address for **DNS Server 1**.

6. (Optional) Enter the IP address for **DNS Server 2**.
   - If you specify an address for **DNS Server 2**, be sure that both DNS servers are configured identically.

7. Click **Save**.

### Configure Compute Gateway DHCP Relay

In the default configuration a local server handles DHCP requests for workload VMs on all routed segments. If you have an external DHCP server that manages IP addresses on your workload networks, you can configure the Compute Gateway to forward DHCP requests to that server.
Organizations that want to use an existing IP Address Management (IPAM) solution for workload VMs in their SDDC can use the NSX-T DHCP relay feature to specify the server and attach it to the Compute Gateway. For more information about how NSX-T implements DHCP relay, see Configuring DHCP Relay in the NSX for vSphere documentation.

**Note** You cannot configure DHCP Relay if the Compute Gateway includes any segments that provide their own DHCP services.

### Procedure

1. Log in to the VMC Console at [https://vmc.vmware.com](https://vmc.vmware.com).
2. Select **Networking & Security > DHCP**.
3. Click **CONFIGURE DHCP RELAY**.
   
   Fill in the name and IP address of your DHCP server, then click **Attach** to attach the server to the Compute Gateway.

### Managing Workload Connections

Workload VMs connect to the Internet by default. NAT rules and distributed firewall rules give you fine-grained control over these connections.

#### Attach a VM to or Detach a Workload VM from a Compute Network Segment

Use the vSphere Web Client to manage attachment of workload VMs to compute network segments.

### Prerequisites

### Procedure

1. Log in to the vSphere Client for your SDDC.
2. Select **Menu > Global Inventory Lists**.
3. Select **Logical Networks**.
4. In the **vCenter Server** drop down menu, select the vCenter Server that manages the logical network you want to use.
5 Click next to the logical network name to select it.

6 Select whether to attach or detach VMs.
   - Click Attach VM to attach VMs to the selected network.
   - Click Detach VM to detach VMs from the selected network.

7 Select the virtual machine(s) you want to attach or detach, click >> to move them to the Selected Objects column, and click Next.

8 For each VM, select the virtual NIC you want to attach and click Next.

9 Click Finish.

Request a Public IP Address

You can request public IP addresses to assign to workload VMs to allow access to these VMs from the internet. VMware Cloud on AWS provisions the IP address from AWS.

As a best practice, release the public IP addresses that are not in use.

Prerequisites

Verify that your VM has a static IP address assigned from its logical network.

Procedure

1 Log in to the VMC Console at https://vmc.vmware.com.

2 Select Networking & Security > Public IPs.

3 Click Request Public IP.

4 Enter applicable notes about the IP address.

5 Click Save.

   After a few moments, the Public IP address is provisioned.

What to do next

After the public IP address is provisioned, configure NAT to direct traffic from the public IP address to the internal IP address of a VM in your SDDC. See Configure NAT Settings.
Configure NAT Settings

Inbound Network Address Translation (NAT) allows you to map internet traffic to a public-facing IP address and port to a private IP address and port inside your SDDC’s compute network.

When configuring NAT rules, you can configure either one-to-one NAT or one-to-many NAT. Use one-to-one NAT when you want to map a single public IP address and port to a single internal IP address and port.

For example, a public IP of 198.51.100.5 and port 443 is mapped to 172.100.100.20 and port 443. In some cases, you might choose to map a source port to a different destination port. For example, 198.51.100.5 and port 80 might be mapped to 172.100.100.20 and port 8080.

Use one-to-many NAT when a single public IP address and port is mapped to one internal IP address and multiple ports, or to multiple internal IP addresses and ports.

Prerequisites

Before you can assign a public IP address to a virtual machine, you must assign the virtual machine to a logical network and give it a static IP address. See Request a Public IP Address.

Procedure

2. Select Networking & Security > NAT.
3. Enter the NAT parameter details.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a NAT rule name.</td>
</tr>
<tr>
<td>Public IP</td>
<td>Provisioned public IP address for the VM is populated.</td>
</tr>
<tr>
<td>Service</td>
<td>Select one of the following.</td>
</tr>
<tr>
<td>Public Ports</td>
<td>If you selected Any Traffic, the default public port is Any.</td>
</tr>
<tr>
<td></td>
<td>If you selected a particular service, then the designated public port for</td>
</tr>
<tr>
<td></td>
<td>that service appears.</td>
</tr>
<tr>
<td>Internal IP</td>
<td>Enter the internal (private) IP address to direct the traffic from the public</td>
</tr>
<tr>
<td></td>
<td>address to.</td>
</tr>
<tr>
<td>Internal Ports</td>
<td>If you selected Any Traffic, the default internal port is Any. If you selected</td>
</tr>
<tr>
<td></td>
<td>a particular service, then the designated internal port for that service</td>
</tr>
<tr>
<td></td>
<td>appears.</td>
</tr>
</tbody>
</table>

4. Click Save.
Creating Firewall Rules to Manage Traffic Between the Compute and Management Networks

In the default configuration, firewall rules prevent VMs on the compute network from accessing VMs on the management network. To allow individual workload VMs to access management VMs, create Workload and Management inventory groups, then create management gateway firewall rules that reference them.

Procedure

1. Create Workload inventory groups: one for the management network and one for the workload VM that you want to have access to it.

   On the **Networking & Security tab**, click **Groups** in the **Inventory** category, then click **Workload Groups**. Create two workload groups:
   - Click **ADD GROUP** and create a group with a **Member Type** of IP address and the CIDR block of the management network. Click **SAVE** to create the group.
   - Click **ADD GROUP** and create a group with a **Member Type** of Virtual Machine and a Member VM from your vSphere inventory. Click **SAVE** to create the group.

2. Create a Management inventory group to represent the management network that you want to access from the Workload group.

   On the **Networking & Security tab** tab, click **Groups** in the **Inventory** category, then click **Management Groups**. Click **ADD GROUP** and create a group with a **Member Type** of IP address and the management network CIDR block. Click **SAVE** to create the group.

3. Create a compute gateway firewall rule allowing outbound traffic to the management network.

   See *Add or Modify Compute Gateway Firewall Rules* for information about creating compute gateway firewall rules. Assuming your workload VMs only need to access vSphere and PowerCLI/OVFtool on management VMs, then the rule need only allow access on port 443.

   **Table 2-7. Compute Gateway Rule to Allow Outbound Traffic to ESXi and vCenter**

<table>
<thead>
<tr>
<th>Name</th>
<th>Source</th>
<th>Destination</th>
<th>Services</th>
<th>Action</th>
<th>Applied To</th>
</tr>
</thead>
<tbody>
<tr>
<td>Outbound to management network on port 443</td>
<td>Workload VM private IP</td>
<td>VMC Management Network</td>
<td>HTTPS</td>
<td>Allow</td>
<td>All Uplinks</td>
</tr>
</tbody>
</table>

4. Create a management gateway firewall rule allowing inbound traffic to the vCenter server and ESXi.

   See *Add or Modify Management Gateway Firewall Rules* for information about creating management gateway firewall rules. Assuming your workload VMs only need to access vSphere, PowerCLI, or OVFtool on vCenter and ESXi, then the rule need only allow access on port 443.
### Table 2-8. Management Gateway Rule to Allow Inbound Traffic to ESXi and vCenter

<table>
<thead>
<tr>
<th>Name</th>
<th>Source</th>
<th>Destination</th>
<th>Services</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inbound to ESXi port 443</td>
<td>Workload VM private IP</td>
<td>ESXi</td>
<td>HTTPS (TCP 443)</td>
<td>Allow</td>
</tr>
<tr>
<td>Inbound to vCenter port 443</td>
<td>Workload VM private IP</td>
<td>vCenter</td>
<td>HTTPS (TCP 443)</td>
<td>Allow</td>
</tr>
</tbody>
</table>
Configure Monitoring and Troubleshooting Features

Use IPFIX and Port Mirroring functionality provided by NSX-T to monitor and troubleshoot SDDC networking and security.

By default, SDDC ESXi hosts have access to the overlay network, allowing them to communicate with monitoring and troubleshooting applications deployed as VM workloads in your SDDC. However, you must configure the firewall to allow traffic between the ESXi hosts and the logical segment the VMs are attached to.

- **Configure IPFIX**
  IPFIX (Internet Protocol Flow Information Export) is a standard for the format and export of network flow information for troubleshooting, auditing, or collecting analytics information.

- **Configure Port Mirroring**
  Port mirroring lets you replicate and redirect all of the traffic coming from a source. The mirrored traffic is sent encapsulated within a Generic Routing Encapsulation (GRE) tunnel to a collector so that all of the original packet information is preserved while traversing the network to a remote destination.

**Configure IPFIX**

IPFIX (Internet Protocol Flow Information Export) is a standard for the format and export of network flow information for troubleshooting, auditing, or collecting analytics information.

You can configure flow monitoring on a logical segment. All the flows from the VMs connected to that logical segment are captured and sent to the IPFIX collector. The IPFIX collector can be in the on-premise data center on one of the logical segment.

You can control sampling rate and timeout parameters and capture specific granularity of data. If you have large number of flows, you can lower the sampling rate.

After you enable IPFIX, all configured segments send IPFIX messages to the IPFIX collectors using the default port UDP 4739. You can also assign another port number.

**Prerequisites**

Verify that a logical segment is configured. See Create a Network Segment.
Procedure

3. Enter the collector IP address and port.
   The default UDP port is 4739. You can add up to 4 IPFIX collectors.
4. Click Save.
5. Click Add IPFIX Session.
6. Enter IPFIX session name.
7. Set the IPFIX session active and idle timeout in seconds.
   The active timeout indicates the time the session must remain active for collecting the data. Idle timeout indicates the time the session can be idle without triggering a session failure.
   The minimum timeout duration should be 60 seconds.
8. Enter the sampling probability of the IPFIX session.

<table>
<thead>
<tr>
<th>Probability</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>100%</td>
<td>All the exported data packets are captured.</td>
</tr>
<tr>
<td>2%</td>
<td>Two percent of the exported data is captured and the rest of the data packets are dropped.</td>
</tr>
</tbody>
</table>
9. Assign a logical segment tag to this IPFIX session.
10. (Optional) Click the ellipses button next to a IPFIX session and click Edit to make configuration changes.
11. Click Save.

Configure Port Mirroring

Port mirroring lets you replicate and redirect all of the traffic coming from a source. The mirrored traffic is sent encapsulated within a Generic Routing Encapsulation (GRE) tunnel to a collector so that all of the original packet information is preserved while traversing the network to a remote destination.

Port mirroring is used in the following scenarios:

- Troubleshooting - Analyze the traffic to detect intrusion and debug and diagnose errors on a network.
- Compliance and monitoring - Forward all of the monitored traffic to a network appliance for analysis and remediation.

Port mirroring includes a source group where the data is monitored and a destination group where the collected data is copied to. The source group membership criteria require VMs to be grouped based on the workload such as web group or application group. The destination group membership criteria require VMs to be grouped based on IP addresses.
Port mirroring has one enforcement point, where you can apply policy rules to your SDDC environment. The traffic direction for port mirroring is Ingress, Egress, or Bi Directional traffic.

- Ingress is the outbound network traffic from the VM to the logical network.
- Egress is the inbound network traffic from the logical network to the VM.
- Bi Directional is the two-way of traffic from the VM to the logical network and from the logical network to the VM. This is the default option.

**Prerequisites**

Verify that workload groups with IP address and VM membership criteria are available. See [Add or Modify an Inventory Group](#).

**Procedure**

1. Log in to the VMC Console at [https://vmc.vmware.com](https://vmc.vmware.com).
2. Select **Networking & Security > Port Mirroring**.
3. Click **ADD SESSION** and give the session a **Name**.
4. Select a **Source** workload group name and click **SAVE**.
5. Select a **Destination** IP address for the group and click **SAVE**.
6. Select a traffic **Direction** from the drop-down menu.
7. Click **SAVE** to save the session.
8. Click the ellipses button next to a port mirroring session and select **Edit** to make configuration changes.
