- Check the installed PostGIS package version with the `gppkg` utility. This command lists all installed Greenplum packages.

```
gppkg -q --all
```

- Check the enabled PostGIS version in a database with the `postgis_version()` function. This `psql` command displays the version PostGIS that is enabled for the database `testdb`.

```
psql -d testdb -c 'select postgis_version();'
```

If PostGIS is not enabled for the database, Greenplum returns a `function does not exist` error.

- For the Greenplum PostGIS package `postgis-2.5.4+pivotal.2` and later, you can display the PostGIS extension version and state in a database with this query.

```
# SELECT * FROM pg_available_extensions WHERE name = 'postgis' ;
```

The query displays the version whether the extension is installed and enabled in a database. If the PostGIS package is not installed, no rows are returned.

## Notes

Starting with the Greenplum `postgis-2.5.4+pivotal.2` package, you enable support for PostGIS in a database with the `CREATE EXTENSION` command. For previous PostGIS 2.5.4 packages and all PostGIS 2.1.5 packages, you use an SQL script.

## Text Analytics and Search

Greenplum Database offers two different methods for text search and analytics, **Greenplum Database full text search** and **Tanzu Greenplum Text**.

### Greenplum Database Full Text Search

Greenplum Database text search is PostgreSQL text search ported to the Greenplum Database MPP platform. Greenplum Database text search is immediately available to you, with no need to install and maintain additional software. For full details on this topic, see [Greenplum Database text search](#).

### Tanzu Greenplum Text

For advanced text analysis applications, VMware also offers [Tanzu Greenplum Text](#), which integrates Greenplum Database with the Apache Solr text search platform. Tanzu Greenplum Text installs an Apache Solr cluster alongside your Greenplum Database cluster and provides Greenplum Database functions you can use to create Solr indexes, query them, and receive results in the database session.

Both of these systems provide powerful, enterprise-quality document indexing and searching services. Tanzu Greenplum Text, with Solr, has many capabilities that are not available with Greenplum Database text search. In particular, Tanzu Greenplum Text is better for advanced text analysis applications. For a comparative between these methods, see [Comparing Greenplum Database Text Search with Tanzu Greenplum Text](#).

## Procedural Languages

Greenplum supports a pluggable procedural language architecture by virtue of its PostgreSQL heritage. This allows user-defined functions to be written in languages other than SQL and C. It may be more convenient to develop analytics functions in a familiar procedural language compared to using only SQL constructs. For example, suppose you have existing Python code that you want to use on data in Greenplum, you can wrap this code in a PL/Python function and call it from SQL.

The available Greenplum procedural languages are typically packaged as extensions. You register a language in a database using the `CREATE EXTENSION` command. You remove a language from a database with `DROP EXTENSION`.

The Greenplum Database distribution supports the following procedural languages; refer to the linked language documentation for installation and usage instructions:

- [PL/Container](#)
- [PL/Java](#)
- [PL/Perl](#)
- [PL/pgSQL](#)
- [PL/Python](#)
- [PL/R](#)

## PL/Container Language

PL/Container enables users to run Greenplum procedural language functions inside a Docker container, to avoid security risks associated with running Python or R code on Greenplum segment hosts. This topic covers information about the architecture, installation, and setup of PL/Container:

- [About the PL/Container Language Extension](#)
- [Install PL/Container](#)
- [Upgrade PL/Container](#)
- [Uninstall PL/Container](#)
- [Docker References](#)

For detailed information about using PL/Container, refer to:

- [PL/Container Resource Management](#)
- [PL/Container Functions](#)

The PL/Container language extension is available as an open source module. For information about the module, see the README file in the GitHub repository at <https://github.com/greenplum-db/plcontainer>.

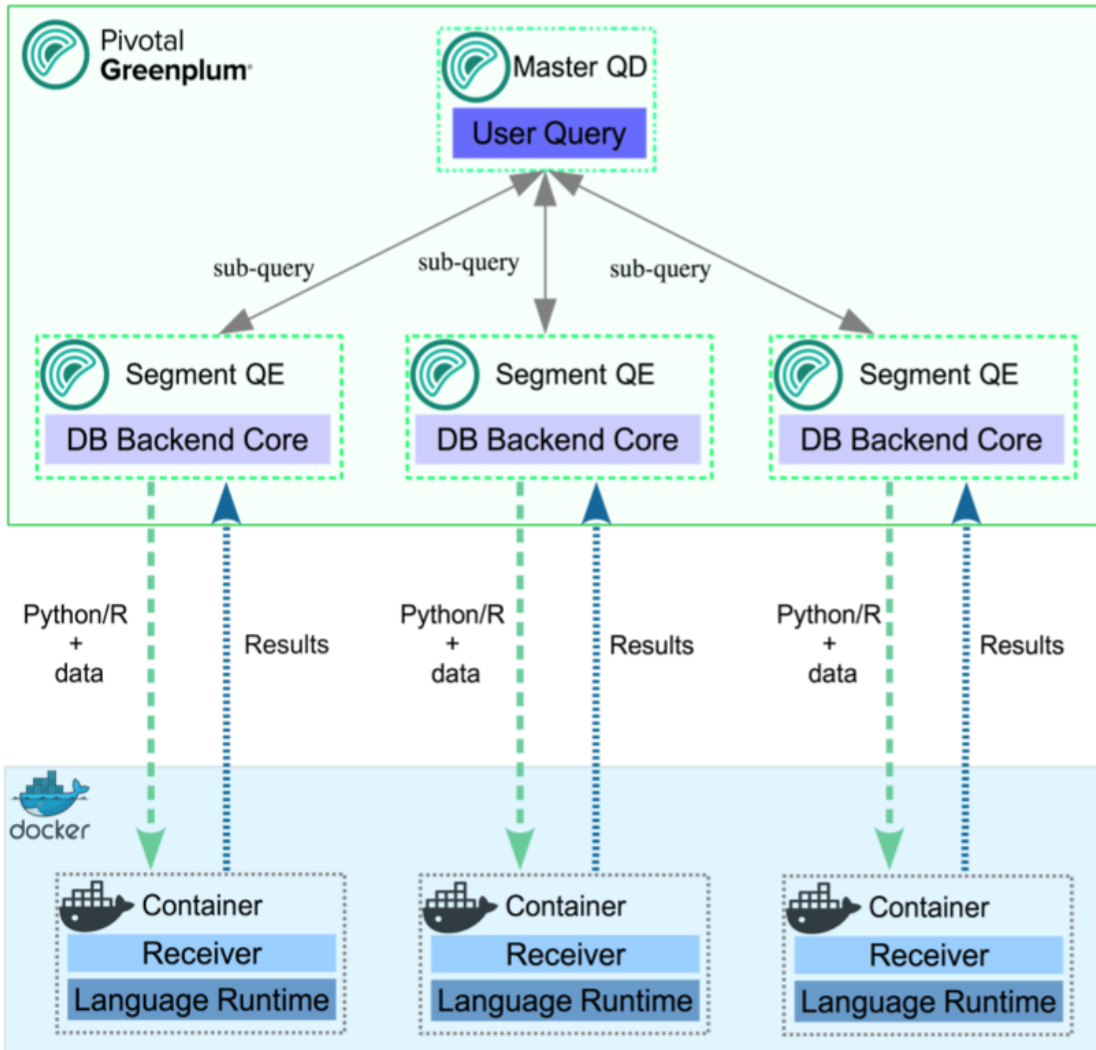

## About the PL/Container Language Extension

The Greenplum Database PL/Container language extension allows users to create and run PL/Python or PL/R user-defined functions (UDFs) securely, inside a Docker container. Docker provides the ability to package and run an application in a loosely isolated environment called a container. For information about Docker, see the [Docker web site](#).

Running UDFs inside the Docker container ensures that:

- The function execution process takes place in a separate environment and allows decoupling of the data processing. SQL operators such as "scan," "filter," and "project" are run at the query executor (QE) side, and advanced data analysis is run at the container side.
- User code cannot access the OS or the file system of the local host.
- User code cannot introduce any security risks.
- Functions cannot connect back to the Greenplum Database if the container is started with limited or no network access.

## PL/Container Architecture

**Example of the process flow:**

Consider a query that selects table data using all available segments, and transforms the data using a PL/Container function. On the first call to a function in a segment container, the query executor on the master host starts the container on that segment host. It then contacts the running container to obtain the results. The container might respond with a Service Provider Interface (SPI) - a SQL query run by the container to get some data back from the database - returning the result to the query executor.

A container running in standby mode waits on the socket and does not consume any CPU resources. PL/Container memory consumption depends on the amount of data cached in global dictionaries.

The container connection is closed by closing the Greenplum Database session that started the container, and the container shuts down.

**About PL/Container 3 Beta**

Greenplum Database 6.5 introduces PL/Container version 3 Beta, which:

- Provides support for the new GreenplumR interface.

- Reduces the number of processes created by PL/Container, in order to save system resources.
- Supports more containers running concurrently.
- Includes improved log messages to help diagnose problems.
- Supports the `DO` command (anonymous code block).

PL/Container 3 is currently a Beta feature, and provides only a Beta R Docker image for running functions; Python images are not yet available. Save and uninstall any existing PL/Container software before you install PL/Container 3 Beta.

## Install PL/Container

This topic includes how to:

- [Install Docker](#)
- [Install PL/Container](#)
- [Install the PL/Container Docker images](#)
- [Test the PL/Container installation](#)

The following sections describe these tasks in detail.

### Prerequisites

- For PL/Container 2.1.x use Greenplum Database 6 on CentOS 7.x (or later), RHEL 7.x (or later), or Ubuntu 18.04.  
**Note:** PL/Container 2.1.x supports Docker images with Python 3 installed.
- For PL/Container 3 Beta use Greenplum Database 6.1 or later on CentOS 7.x (or later), RHEL 7.x (or later), or Ubuntu 18.04.
- The minimum Linux OS kernel version supported is 3.10. To verify your kernel release use:

```
$ uname -r
```

- The minimum Docker versions on all hosts needs to be Docker 19.03.

### Install Docker

To use PL/Container you need to install Docker on all Greenplum Database host systems. These instructions show how to set up the Docker service on CentOS 7 but RHEL 7 is a similar process.

These steps install the docker package and start the Docker service as a user with sudo privileges.

1. Ensure the user has sudo privileges or is root.
2. Install the dependencies required for Docker:

```
sudo yum install -y yum-utils device-mapper-persistent-data lvm2
```

3. Add the Docker repo:

```
sudo yum-config-manager --add-repo https://download.docker.com/linux/centos/docker-ce.repo
```

4. Update yum cache:

```
sudo yum makecache fast
```

5. Install Docker:

```
sudo yum -y install docker-ce
```

6. Start Docker daemon:

```
sudo systemctl start docker
```

7. On each Greenplum Database host, the `gpadmin` user should be part of the `docker` group for the user to be able to manage Docker images and containers. Assign the Greenplum Database administrator `gpadmin` to the group `docker`:

```
sudo usermod -aG docker gpadmin
```

8. Exit the session and login again to update the privileges.

9. Configure Docker to start when the host system starts:

```
sudo systemctl enable docker.service
```

```
sudo systemctl start docker.service
```

10. Run a Docker command to test the Docker installation. This command lists the currently running Docker containers.

```
docker ps
```

11. After you install Docker on all Greenplum Database hosts, restart the Greenplum Database system to give Greenplum Database access to Docker.

```
gpstop -ra
```

For a list of observations while using Docker and PL/Container, see the [Notes](#) section. For a list of Docker reference documentation, see [Docker References](#).

## Install PL/Container

Install the PL/Container language extension using the `gppkg` utility.

1. Download the "PL/Container for RHEL 7" package that applies to your Greenplum Database version, from the [VMware Tanzu Network](#). PL/Container is listed under Greenplum Procedural Languages.
2. As `gpadmin`, copy the PL/Container language extension package to the master host.

- Follow the instructions in [Verifying the Greenplum Database Software Download](#) to verify the integrity of the **Greenplum Procedural Languages PL/Container** software.
- Run the package installation command:

```
gppkg -i plcontainer-2.1.1-rhel7-x86_64.gppkg
```

- Source the file `$GPHOME/greenplum_path.sh`:

```
source $GPHOME/greenplum_path.sh
```

- Make sure Greenplum Database is up and running:

```
gpstate -s
```

If it's not, start it:

```
gpstart -a
```

- For PL/Container version 3 Beta only, add the `plc_coordinator` shared library to the Greenplum Database `shared_preload_libraries` server configuration parameter. Be sure to retain any previous setting of the parameter. For example:

```
gpconfig -s shared_preload_libraries
Values on all segments are consistent
GUC           : shared_preload_libraries
Coordinator value: diskquota
Segment      value: diskquota
gpconfig -c shared_preload_libraries -v 'diskquota,plc_coordinator'
```

- Restart Greenplum Database:

```
gpstop -ra
```

- Login into one of the available databases, for example:

```
psql postgres
```

- Register the PL/Container extension, which installs the `plcontainer` utility:

```
CREATE EXTENSION plcontainer;
```

You'll need to register the utility separately on each database that might need the PL/Container functionality.

## Install PL/Container Docker Images

Install the Docker images that PL/Container will use to create language-specific containers to run the UDFs.

**Note:** The PL/Container open source module contains dockerfiles to build Docker images that can be used with PL/Container. You can build a Docker image to run PL/Python UDFs and a Docker

image to run PL/R UDFs. See the dockerfiles in the GitHub repository at <https://github.com/greenplum-db/plcontainer>.

- Download the files that contain the Docker images from the [VMware Tanzu Network](#). For example, for Greenplum 6.5, click on "PL/Container Docker Image for Python 2.1.1" which downloads **plcontainer-python-image-2.1.1-gp6.tar.gz** with Python 2.7.12 and the *Python Data Science Module Package*.

If you require different images from the ones provided by Tanzu Greenplum, you can create custom Docker images, install the image and add the image to the PL/ Container configuration.

- If you are using PL/Container 3 Beta, note that this Beta version is compatible only with the associated `plcontainer-r-image-3.0.0-beta-gp6.tar.gz` image.
- Follow the instructions in [Verifying the Greenplum Database Software Download](#) to verify the integrity of the **Greenplum Procedural Languages PL/Container Image** software.
- Use the `plcontainer image-add` command to install an image on all Greenplum Database hosts. Provide the `-f` option to specify the file system location of a downloaded image file. For example:

```
# Install a Python 2 based Docker image
plcontainer image-add -f /home/gpadmin/plcontainer-python-image-2.1.1-gp6.tar.gz

# Install a Python 3 based Docker image
plcontainer image-add -f /home/gpadmin/plcontainer-python3-image-2.1.1-gp6.tar.gz

# Install an R based Docker image
plcontainer image-add -f /home/gpadmin/plcontainer-r-image-2.1.1-gp6.tar.gz

# Install the Beta R image for use with PL/Container 3.0.0 Beta
plcontainer image-add -f /home/gpadmin/plcontainer-r-image-3.0.0-beta-gp6.tar.gz
```

The utility displays progress information, similar to:

```
20200127:21:54:43:004607 plcontainer:mdw:gpadmin-[INFO]:-Checking whether docker is installed on all hosts...
20200127:21:54:43:004607 plcontainer:mdw:gpadmin-[INFO]:-Distributing image file /home/gpadmin/plcontainer-python-images-1.5.0.tar to all hosts...
20200127:21:54:55:004607 plcontainer:mdw:gpadmin-[INFO]:-Loading image on all hosts...
20200127:21:55:37:004607 plcontainer:mdw:gpadmin-[INFO]:-Removing temporary image files on all hosts...
```

By default, the `image-add` command copies the image to each Greenplum Database segment and standby master host, and installs the image. When you specify the `[-ulc | --use_local_copy]` option, `plcontainer` installs the image only on the host on which you run the command. Use this option when the PL/Container image already resides on disk on a host.

For more information on `image-add` options, visit the [plcontainer](#) reference page.

- To display the installed Docker images on the local host use:

```
$ plcontainer image-list
```

| REPOSITORY                             | TAG   | IMAGE ID     | CREATED       |
|--|-------|--------------|---------------|
| pivotaldata/plcontainer_r_shared       | devel | 7427f920669d | 10 months ago |
| pivotaldata/plcontainer_python_shared  | devel | e36827eba53e | 10 months ago |
| pivotaldata/plcontainer_python3_shared | devel | y32827ebe55b | 5 months ago  |

- Add the image information to the PL/Container configuration file using `plcontainer runtime-add`, to allow PL/Container to associate containers with specified Docker images.

Use the `-r` option to specify your own user defined runtime ID name, use the `-i` option to specify the Docker image, and the `-l` option to specify the Docker image language. When there are multiple versions of the same docker image, for example 1.0.0 or 1.2.0, specify the TAG version using ":" after the image name.

```
# Add a Python 2 based runtime
plcontainer runtime-add -r plc_python_shared -i pivotaldata/plcontainer_python_
shared:devel -l python

# Add a Python 3 based runtime that is supported with PL/Container 2.1.x
plcontainer runtime-add -r plc_python3_shared -i pivotaldata/plcontainer_python
3_shared:devel -l python3

# Add an R based runtime
plcontainer runtime-add -r plc_r_shared -i pivotaldata/plcontainer_r_shared:dev
el -l r
```

The utility displays progress information as it updates the PL/Container configuration file on the Greenplum Database instances.

For details on other `runtime-add` options, see the [plcontainer](#) reference page.

- Optional: Use Greenplum Database resource groups to manage and limit the total CPU and memory resources of containers in PL/Container runtimes. In this example, the Python runtime will be used with a preconfigured resource group 16391:

```
plcontainer runtime-add -r plc_python_shared -i pivotaldata/plcontainer_python_
shared:devel -l
python -s resource_group_id=16391
```

For more information about enabling, configuring, and using Greenplum Database resource groups with PL/Container, see [PL/Container Resource Management](#).

You can now create a simple function to test your PL/Container installation.

## Test the PL/Container Installation

List the names of the runtimes your created and added to the PL/Container XML file:

```
plcontainer runtime-show
```

which will show a list of all installed runtimes:

```
PL/Container Runtime Configuration:
-----
Runtime ID: plc_python_shared
Linked Docker Image: pivotaldata/plcontainer_python_shared:devel
Runtime Setting(s):
Shared Directory:
---- Shared Directory From HOST '/usr/local/greenplum-db/./bin/plcontainer_clients'
to Container '/clientdir', access mode is 'ro'
-----
```

You can also view the PL/Container configuration information with the `plcontainer runtime-show -r <runtime_id>` command. You can view the PL/Container configuration XML file with the `plcontainer runtime-edit` command.

Use the `psql` utility and select an existing database:

```
psql postgres;
```

If the PL/Container extension is not registered with the selected database, first enable it using:

```
postgres=# CREATE EXTENSION plcontainer;
```

Create a simple function to test your installation; in the example, the function will use the runtime `plc_python_shared`:

```
postgres=# CREATE FUNCTION dummyPython() RETURNS text AS $$
# container: plc_python_shared
return 'hello from Python'
$$ LANGUAGE plcontainer;
```

And test the function using:

```
postgres=# SELECT dummyPython();
 dummypython
-----
hello from Python
(1 row)
```

Similarly, to test the R runtime:

```
postgres=# CREATE FUNCTION dummyR() RETURNS text AS $$
# container: plc_r_shared
return ('hello from R')
$$ LANGUAGE plcontainer;
CREATE FUNCTION
postgres=# select dummyR();
 dummyr
-----
```

```
hello from R
(1 row)
```

For further details and examples about using PL/Container functions, see [PL/Container Functions](#).

## Upgrade PL/Container

To upgrade PL/Container, you save the current configuration, upgrade PL/Container, and then restore the configuration after upgrade. There is no need to update the Docker images when you upgrade PL/Container.

**Note:** Before you perform this upgrade procedure, ensure that you have migrated your PL/Container package from your previous Greenplum Database installation to your new Greenplum Database installation. Refer to the [gppkg](#) command for package installation and migration information.

**Note:** You cannot upgrade to PL/Container 3 Beta. To install PL/Container 3 Beta, first save and then uninstall your existing PL/Container software. Then follow the instructions in [Install PL/Container](#).

To upgrade, perform the following procedure:

1. Save the PL/Container configuration. For example, to save the configuration to a file named `plcontainer202-backup.xml` in the local directory:

```
$ plcontainer runtime-backup -f plcontainer202-backup.xml
```

2. Use the Greenplum Database `gppkg` utility with the `-u` option to update the PL/Container language extension. For example, the following command updates the PL/Container language extension to version 2.1.1 on a Linux system:

```
$ gppkg -u plcontainer-2.1.1-gp6-rhel7_x86_64.gppkg
```

3. Source the Greenplum Database environment file `$GPHOME/greenplum_path.sh`.

```
$ source $GPHOME/greenplum_path.sh
```

4. Restore the PL/Container configuration that you saved in a previous step:

```
$ plcontainer runtime-restore -f plcontainer202-backup.xml
```

5. Restart Greenplum Database.

```
$ gpstop -ra
```

6. You do not need to re-register the PL/Container extension in the databases in which you previously created the extension but ensure that you register the PL/Container extension in each new database that will run PL/Container UDFs. For example, the following command registers PL/Container in a database named `mytest`:

```
$ psql -d mytest -c 'CREATE EXTENSION plcontainer;'
```

The command also creates PL/Container-specific functions and views.

## Uninstall PL/Container

To uninstall PL/Container, remove Docker containers and images, and then remove the PL/Container support from Greenplum Database.

When you remove support for PL/Container, the `plcontainer` user-defined functions that you created in the database will no longer work.

## Uninstall Docker Containers and Images

On the Greenplum Database hosts, uninstall the Docker containers and images that are no longer required.

The `plcontainer image-list` command lists the Docker images that are installed on the local Greenplum Database host.

The `plcontainer image-delete` command deletes a specified Docker image from all Greenplum Database hosts.

Some Docker containers might exist on a host if the containers were not managed by PL/Container. You might need to remove the containers with Docker commands. These `docker` commands manage Docker containers and images on a local host.

- The command `docker ps -a` lists all containers on a host. The command `docker stop` stops a container.
- The command `docker images` lists the images on a host.
- The command `docker rmi` removes images.
- The command `docker rm` removes containers.

## Remove PL/Container Support for a Database

To remove support for PL/Container, drop the extension from the database. Use the `psql` utility with `DROP EXTENSION` command (using `-c`) to remove PL/Container from `mytest` database.

```
psql -d mytest -c 'DROP EXTENSION plcontainer CASCADE;'
```

The `CASCADE` keyword drops PL/Container-specific functions and views.

## Remove PL/Container 3 Beta Shared Library

This step is required only if you have installed PL/Container 3 Beta. Before you remove the extension from your system with `gppkg`, remove the shared library configuration for the `plc_coordinator` process:

1. Examine the `shared_preload_libraries` server configuration parameter setting.

```
$ gpconfig -s shared_preload_libraries
```

- If `plc_coordinator` is the only library listed, remove the configuration parameter setting:

```
$ gpconfig -r shared_preload_libraries
```

Removing a server configuration parameter comments out the setting in the `postgresql.conf` file.

- o If there are multiple libraries listed, remove `plc_coordinator` from the list and re-set the configuration parameter. For example, if `shared_preload_libraries` is set to `'diskquota,plc_coordinator'`:

```
$ gpconfig -c shared_preload_libraries -v 'diskquota'
```

2. Restart the Greenplum Database cluster:

```
$ gpstop -ra
```

## Uninstall the PL/Container Language Extension

If no databases have `plcontainer` as a registered language, uninstall the Greenplum Database PL/Container language extension with the `gppkg` utility.

1. Use the Greenplum Database `gppkg` utility with the `-r` option to uninstall the PL/Container language extension. This example uninstalls the PL/Container language extension on a Linux system:

```
$ gppkg -r plcontainer-2.1.1
```

You can run the `gppkg` utility with the options `-q --all` to list the installed extensions and their versions.

2. Reload `greenplum_path.sh`.

```
$ source $GPHOME/greenplum_path.sh
```

3. Restart the database.

```
$ gpstop -ra
```

## Notes

### Docker Notes

- If a PL/Container Docker container exceeds the maximum allowed memory, it is terminated and an out of memory warning is displayed.
- PL/Container does not limit the Docker base device size, the size of the Docker container. In some cases, the Docker daemon controls the base device size. For example, if the Docker storage driver is `devicemapper`, the Docker daemon `--storage-opt` option flag `dm.basesize` controls the base device size. The default base device size for `devicemapper` is 10GB. The Docker command `docker info` displays Docker system information including the storage driver. The base device size is displayed in Docker 1.12 and later. For information about Docker storage drivers, see the Docker information [Daemon storage-driver](#).

When setting the Docker base device size, the size must be set on all Greenplum Database hosts.

- *Known issue:*

Occasionally, when PL/Container is running in a high concurrency environment, the Docker daemon hangs with log entries that indicate a memory shortage. This can happen even when the system seems to have adequate free memory.

The issue seems to be triggered by the aggressive virtual memory requirement of the Go language (golang) runtime that is used by PL/Container, and the Greenplum Database Linux server kernel parameter setting for *overcommit\_memory*. The parameter is set to 2 which does not allow memory overcommit.

A workaround that might help is to increase the amount of swap space and increase the Linux server kernel parameter *overcommit\_ratio*. If the issue still occurs after the changes, there might be memory shortage. You should check free memory on the system and add more RAM if needed. You can also decrease the cluster load.

## Using PL/Container

This topic covers further details on:

- [PL/Container Resource Management](#)
- [PL/Container Functions](#)

## PL/Container Resource Management

The Docker containers and the Greenplum Database servers share CPU and memory resources on the same hosts. In the default case, Greenplum Database is unaware of the resources consumed by running PL/Container instances. You can use Greenplum Database resource groups to control overall CPU and memory resource usage for running PL/Container instances.

PL/Container manages resource usage at two levels - the container level and the runtime level. You can control container-level CPU and memory resources with the `memory_mb` and `cpu_share` settings that you configure for the PL/Container runtime. `memory_mb` governs the memory resources available to each container instance. The `cpu_share` setting identifies the relative

weighting of a container's CPU usage compared to other containers. See [plcontainer Configuration File](#) for further details.

You cannot, by default, restrict the number of running PL/Container container instances, nor can you restrict the total amount of memory or CPU resources that they consume.

## Using Resource Groups to Manage PL/Container Resources

With PL/Container 1.2.0 and later, you can use Greenplum Database resource groups to manage and limit the total CPU and memory resources of containers in PL/Container runtimes. For more information about enabling, configuring, and using Greenplum Database resource groups, refer to [Using Resource Groups](#) in the *Greenplum Database Administrator Guide*.

**Note:** If you do not explicitly configure resource groups for a PL/Container runtime, its container instances are limited only by system resources. The containers may consume resources at the expense of the Greenplum Database server.

Resource groups for external components such as PL/Container use Linux control groups (cgroups) to manage component-level use of memory and CPU resources. When you manage PL/Container resources with resource groups, you configure both a memory limit and a CPU limit that Greenplum Database applies to all container instances that share the same PL/Container runtime configuration.

When you create a resource group to manage the resources of a PL/Container runtime, you must specify `MEMORY_AUDITOR=cgroup` and `CONCURRENCY=0` in addition to the required CPU and memory limits. For example, the following command creates a resource group named `plpy_run1_rg` for a PL/Container runtime:

```
CREATE RESOURCE GROUP plpy_run1_rg WITH (MEMORY_AUDITOR=cgroup, CONCURRENCY=0,
                                         CPU_RATE_LIMIT=10, MEMORY_LIMIT=10);
```

PL/Container does not use the `MEMORY_SHARED_QUOTA` and `MEMORY_SPILL_RATIO` resource group memory limits. Refer to the [CREATE RESOURCE GROUP](#) reference page for detailed information about this SQL command.

You can create one or more resource groups to manage your running PL/Container instances. After you create a resource group for PL/Container, you assign the resource group to one or more PL/Container runtimes. You make this assignment using the `groupid` of the resource group. You can determine the `groupid` for a given resource group name from the `gp_resgroup_config` `gp_toolkit` view. For example, the following query displays the `groupid` of a resource group named `plpy_run1_rg`:

```
SELECT groupname, groupid FROM gp_toolkit.gp_resgroup_config
WHERE groupname='plpy_run1_rg';

groupname | groupid
-----+-----
plpy_run1_rg | 16391
(1 row)
```

You assign a resource group to a PL/Container runtime configuration by specifying the `-s resource_group_id=rg\groupid` option to the `plcontainer runtime-add` (new runtime) or `plcontainer runtime-replace` (existing runtime) commands. For example, to assign the `plpy_run1_rg` resource group to a new PL/Container runtime named `python_run1`:

```
plcontainer runtime-add -r python_run1 -i pivotaldata/plcontainer_python_shared:devel
-l python -s resource_group_id=16391
```

You can also assign a resource group to a PL/Container runtime using the `plcontainer runtime-edit` command. For information about the `plcontainer` command, see [plcontainer](#) reference page.

After you assign a resource group to a PL/Container runtime, all container instances that share the same runtime configuration are subject to the memory limit and the CPU limit that you configured for the group. If you decrease the memory limit of a PL/Container resource group, queries running in containers in the group may fail with an out of memory error. If you drop a PL/Container resource group while there are running container instances, Greenplum Database terminates the running containers.

## Configuring Resource Groups for PL/Container

To use Greenplum Database resource groups to manage PL/Container resources, you must explicitly configure both resource groups and PL/Container.

Perform the following procedure to configure PL/Container to use Greenplum Database resource groups for CPU and memory resource management:

1. If you have not already configured and enabled resource groups in your Greenplum Database deployment, configure cgroups and enable Greenplum Database resource groups as described in [Using Resource Groups](#) in the *Greenplum Database Administrator Guide*.

**Note:** If you have previously configured and enabled resource groups in your deployment, ensure that the Greenplum Database resource group `gpdb.conf` cgroups configuration file includes a `memory { }` block as described in the previous link.

2. Analyze the resource usage of your Greenplum Database deployment. Determine the percentage of resource group CPU and memory resources that you want to allocate to PL/Container Docker containers.
3. Determine how you want to distribute the total PL/Container CPU and memory resources that you identified in the step above among the PL/Container runtimes. Identify:
  - The number of PL/Container resource group(s) that you require.
  - The percentage of memory and CPU resources to allocate to each resource group.
  - The resource-group-to-PL/Container-runtime assignment(s).
4. Create the PL/Container resource groups that you identified in the step above. For example, suppose that you choose to allocate 25% of both memory and CPU Greenplum Database resources to PL/Container. If you further split these resources among 2 resource groups 60/40, the following SQL commands create the resource groups:

```
CREATE RESOURCE GROUP plr_run1_rg WITH (MEMORY_AUDITOR=cgroup, CONCURRENCY=0,
                                         CPU_RATE_LIMIT=15, MEMORY_LIMIT=15);
CREATE RESOURCE GROUP plpy_run1_rg WITH (MEMORY_AUDITOR=cgroup, CONCURRENCY=0,
                                         CPU_RATE_LIMIT=10, MEMORY_LIMIT=10);
```

5. Find and note the `groupid` associated with each resource group that you created. For example:

```
SELECT groupname, groupid FROM gp_toolkit.gp_resgroup_config
WHERE groupname IN ('plpy_run1_rg', 'plr_run1_rg');
```

```
groupname | groupid
-----+-----
plpy_run1_rg | 16391
plr_run1_rg | 16393
(1 row)
```

- Assign each resource group that you created to the desired PL/Container runtime configuration. If you have not yet created the runtime configuration, use the `plcontainer runtime-add` command. If the runtime already exists, use the `plcontainer runtime-replace` or `plcontainer runtime-edit` command to add the resource group assignment to the runtime configuration. For example:

```
plcontainer runtime-add -r python_run1 -i pivotaldata/plcontainer_python_share
d:devel -l python -s resource_group_id=16391
plcontainer runtime-replace -r r_run1 -i pivotaldata/plcontainer_r_shared:devel
-l r -s resource_group_id=16393
```

For information about the `plcontainer` command, see [plcontainer](#) reference page.

## Notes

### PL/Container logging

When PL/Container logging is enabled, you can set the log level with the Greenplum Database server configuration parameter `log_min_messages`. The default log level is `warning`. The parameter controls the PL/Container log level and also controls the Greenplum Database log level.

- PL/Container logging is enabled or deactivated for each runtime ID with the `setting` attribute `use_container_logging`. The default is no logging.
- The PL/Container log information is the information from the UDF that is run in the Docker container. By default, the PL/Container log information is sent to a system service. On Red Hat 7 or CentOS 7 systems, the log information is sent to the `journald` service.
- The Greenplum Database log information is sent to log file on the Greenplum Database master.
- When testing or troubleshooting a PL/Container UDF, you can change the Greenplum Database log level with the `SET` command. You can set the parameter in the session before you run your PL/Container UDF. This example sets the log level to `debug1`.

```
SET log_min_messages='debug1' ;
```

**Note:** The parameter `log_min_messages` controls both the Greenplum Database and PL/Container logging, increasing the log level might affect Greenplum Database performance even if a PL/Container UDF is not running.

## PL/Container Functions

When you enable PL/Container in a database of a Greenplum Database system, the language `plcontainer` is registered in that database. Specify `plcontainer` as a language in a UDF definition to create and run user-defined functions in the procedural languages supported by the PL/Container Docker images.

## Limitations

Review the following limitations when creating and using PL/Container PL/Python and PL/R functions:

- Greenplum Database domains are not supported.
- Multi-dimensional arrays are not supported.
- Python and R call stack information is not displayed when debugging a UDF.
- The `plpy.execute()` methods `nrows()` and `status()` are not supported.
- The PL/Python function `plpy.SPIError()` is not supported.
- Running the `SAVEPOINT` command with `plpy.execute()` is not supported.
- The `DO` command (anonymous code block) is supported only with PL/Container 3 (currently a Beta feature).
- Container flow control is not supported.
- Triggers are not supported.
- `OUT` parameters are not supported.
- The Python `dict` type cannot be returned from a PL/Python UDF. When returning the Python `dict` type from a UDF, you can convert the `dict` type to a Greenplum Database user-defined data type (UDT).

## Using PL/Container functions

A UDF definition that uses PL/Container must have the these items.

- The first line of the UDF must be `# container: ID`
- The `LANGUAGE` attribute must be `plcontainer`

The ID is the name that PL/Container uses to identify a Docker image. When Greenplum Database runs a UDF on a host, the Docker image on the host is used to start a Docker container that runs the UDF. In the XML configuration file `plcontainer_configuration.xml`, there is a `runtime` XML element that contains a corresponding `id` XML element that specifies the Docker container startup information. See [../utility\\_guide/ref/plcontainer-configuration.md#](#) for information about how PL/Container maps the ID to a Docker image.

The PL/Container configuration file is read only on the first invocation of a PL/Container function in each Greenplum Database session that runs PL/Container functions. You can force the configuration file to be re-read by performing a `SELECT` command on the view `plcontainer_refresh_config` during the session. For example, this `SELECT` command forces the configuration file to be read.

```
SELECT * FROM plcontainer_refresh_config;
```

The command runs a PL/Container function that updates the configuration on the master and segment instances and returns the status of the refresh.

```
gp_segment_id | plcontainer_refresh_local_config
-----+-----
1 | ok
0 | ok
-1 | ok
(3 rows)
```

Also, you can show all the configurations in the session by performing a `SELECT` command on the view `plcontainer_show_config`. For example, this `SELECT` command returns the PL/Container configurations.

```
SELECT * FROM plcontainer_show_config;
```

Running the command executes a PL/Container function that displays configuration information from the master and segment instances. This is an example of the start and end of the view output.

```
INFO: plcontainer: Container 'plc_py_test' configuration

-1 | ok
1 | ok
```

The PL/Container function `plcontainer_containers_summary()` displays information about the currently running Docker containers.

```
SELECT * FROM plcontainer_containers_summary();
```

## About PL/Container Running PL/Python

In the Python language container, the module `plpy` is implemented. The module contains these methods:

- `plpy.execute(stmt)` - Runs the query string `stmt` and returns query result in a list of dictionary objects. To be able to access the result fields ensure your query returns named fields.
- `plpy.prepare(stmt[, argtypes])` - Prepares the execution plan for a query. It is called with a query string and a list of parameter types, if you have parameter references in the query.
- `plpy.execute(plan[, argtypes])` - Runs a prepared plan.
- `plpy.debug(msg)` - Sends a DEBUG2 message to the Greenplum Database log.
- `plpy.log(msg)` - Sends a LOG message to the Greenplum Database log.
- `plpy.info(msg)` - Sends an INFO message to the Greenplum Database log.
- `plpy.notice(msg)` - Sends a NOTICE message to the Greenplum Database log.
- `plpy.warning(msg)` - Sends a WARNING message to the Greenplum Database log.
- `plpy.error(msg)` - Sends an ERROR message to the Greenplum Database log. An ERROR message raised in Greenplum Database causes the query execution process to stop and the transaction to rollback.
- `plpy.fatal(msg)` - Sends a FATAL message to the Greenplum Database log. A FATAL message causes Greenplum Database session to be closed and transaction to be rolled back.
- `plpy.subtransaction()` - Manages `plpy.execute` calls in an explicit subtransaction. See [Explicit Subtransactions](#) in the PostgreSQL documentation for additional information about `plpy.subtransaction()`.

If an error of level `ERROR` or `FATAL` is raised in a nested Python function call, the message includes the list of enclosing functions.

The Python language container supports these string quoting functions that are useful when constructing ad-hoc queries.

- `plpy.quote_literal(string)` - Returns the string quoted to be used as a string literal in an SQL statement string. Embedded single-quotes and backslashes are properly doubled. `quote_literal()` returns null on null input (empty input). If the argument might be null, `quote_nullable()` might be more appropriate.
- `plpy.quote_nullable(string)` - Returns the string quoted to be used as a string literal in an SQL statement string. If the argument is null, returns `NULL`. Embedded single-quotes and backslashes are properly doubled.
- `plpy.quote_ident(string)` - Returns the string quoted to be used as an identifier in an SQL statement string. Quotes are added only if necessary (for example, if the string contains non-identifier characters or would be case-folded). Embedded quotes are properly doubled.

When returning text from a PL/Python function, PL/Container converts a Python unicode object to text in the database encoding. If the conversion cannot be performed, an error is returned.

PL/Container does not support this Greenplum Database PL/Python feature:

- Multi-dimensional arrays.

Also, the Python module has two global dictionary objects that retain the data between function calls. They are named GD and SD. GD is used to share the data between all the function running within the same container, while SD is used for sharing the data between multiple calls of each separate function. Be aware that accessing the data is possible only within the same session, when the container process lives on a segment or master. Be aware that for idle sessions Greenplum Database terminates segment processes, which means the related containers would be shut down and the data from GD and SD lost.

For information about PL/Python, see [PL/Python Language](#).

For information about the `p_lpy` methods, see <https://www.postgresql.org/docs/9.4/plpython-database.htm>.

## About PL/Container Running PL/Python with Python 3

PL/Container for Greenplum Database 5 supports Python version 3.6+. PL/Container for Greenplum Database 6 supports Python 3.7+.

If you want to use PL/Container to run the same function body in both Python2 and Python3, you must create 2 different user-defined functions.

Keep in mind that UDFs that you created for Python 2 may not run in PL/Container with Python 3. The following Python references may be useful:

- Changes to Python - [What's New in Python 3](#)
- Porting from Python 2 to 3 - [Porting Python 2 Code to Python 3](#)

## About PL/Container Running PL/R

In the R language container, the module `pg.spi` is implemented. The module contains these methods:

- `pg.spi.exec(stmt)` - Runs the query string `stmt` and returns query result in R `data.frame`. To be able to access the result fields make sure your query returns named fields.
- `pg.spi.prepare(stmt[, argtypes])` - Prepares the execution plan for a query. It is called with a query string and a list of parameter types if you have parameter references in the query.
- `pg.spi.execp(plan[, argtypes])` - Runs a prepared plan.
- `pg.spi.debug(msg)` - Sends a DEBUG2 message to the Greenplum Database log.
- `pg.spi.log(msg)` - Sends a LOG message to the Greenplum Database log.
- `pg.spi.info(msg)` - Sends an INFO message to the Greenplum Database log.
- `pg.spi.notice(msg)` - Sends a NOTICE message to the Greenplum Database log.
- `pg.spi.warning(msg)` - Sends a WARNING message to the Greenplum Database log.
- `pg.spi.error(msg)` - Sends an ERROR message to the Greenplum Database log. An ERROR message raised in Greenplum Database causes the query execution process to stop

and the transaction to rollback.

- `pg.spi.fatal(msg)` - Sends a FATAL message to the Greenplum Database log. A FATAL message causes Greenplum Database session to be closed and transaction to be rolled back.

PL/Container does not support this PL/R feature:

- Multi-dimensional arrays.

For information about PL/R, see [PL/R Language](#).

For information about the `pg.spi` methods, see <http://www.joeconway.com/plr/doc/plr-spi-support-funcs-normal.html>

## PL/Java Language

This section contains an overview of the Greenplum Database PL/Java language.

## About PL/Java

With the Greenplum Database PL/Java extension, you can write Java methods using your favorite Java IDE and install the JAR files that contain those methods into Greenplum Database.

Greenplum Database PL/Java package is based on the open source PL/Java 1.5.0. Greenplum Database PL/Java provides the following features.

- Ability to run PL/Java functions with Java 8 or Java 11.
- Ability to specify Java runtime.

- Standardized utilities (modeled after the SQL 2003 proposal) to install and maintain Java code in the database.
- Standardized mappings of parameters and result. Complex types as well as sets are supported.
- An embedded, high performance, JDBC driver utilizing the internal Greenplum Database SPI routines.
- Metadata support for the JDBC driver. Both `DatabaseMetaData` and `ResultSetMetaData` are included.
- The ability to return a `ResultSet` from a query as an alternative to building a `ResultSet` row by row.
- Full support for savepoints and exception handling.
- The ability to use IN, INOUT, and OUT parameters.
- Two separate Greenplum Database languages:
  - `pljava`, TRUSTED PL/Java language
  - `pljavau`, UNTRUSTED PL/Java language
- Transaction and Savepoint listeners enabling code execution when a transaction or savepoint is committed or rolled back.
- Integration with GNU GCJ on selected platforms.

A function in SQL will appoint a static method in a Java class. In order for the function to run, the appointed class must be available on the class path specified by the Greenplum Database server configuration parameter `pljava_classpath`. The PL/Java extension adds a set of functions that help with installing and maintaining the Java classes. Classes are stored in normal Java archives, JAR files. A JAR file can optionally contain a deployment descriptor that in turn contains SQL commands to be run when the JAR is deployed or undeployed. The functions are modeled after the standards proposed for SQL 2003.

PL/Java implements a standardized way of passing parameters and return values. Complex types and sets are passed using the standard JDBC `ResultSet` class.

A JDBC driver is included in PL/Java. This driver calls Greenplum Database internal SPI routines. The driver is essential since it is common for functions to make calls back to the database to fetch data. When PL/Java functions fetch data, they must use the same transactional boundaries that are used by the main function that entered PL/Java execution context.

PL/Java is optimized for performance. The Java virtual machine runs within the same process as the backend to minimize call overhead. PL/Java is designed with the objective to enable the power of Java to the database itself so that database intensive business logic can run as close to the actual data as possible.

The standard Java Native Interface (JNI) is used when bridging calls between the backend and the Java VM.

## About Greenplum Database PL/Java

There are a few key differences between the implementation of PL/Java in standard PostgreSQL and Greenplum Database.

## Functions

The following functions are not supported in Greenplum Database. The classpath is handled differently in a distributed Greenplum Database environment than in the PostgreSQL environment.

- `sqlj.install_jar`
- `sqlj.replace_jar`
- `sqlj.remove_jar`
- `sqlj.get_classpath`
- `sqlj.set_classpath`

Greenplum Database uses the `pljava_classpath` server configuration parameter in place of the `sqlj.set_classpath` function.

## Server Configuration Parameters

The following server configuration parameters are used by PL/Java in Greenplum Database. These parameters replace the `pljava.*` parameters that are used in the standard PostgreSQL PL/Java implementation:

- `pljava_classpath`

A colon (:) separated list of the jar files containing the Java classes used in any PL/Java functions. The jar files must be installed in the same locations on all Greenplum Database hosts. With the trusted PL/Java language handler, jar file paths must be relative to the `$GPHOME/lib/postgresql/java/` directory. With the untrusted language handler (javaU language tag), paths may be relative to `$GPHOME/lib/postgresql/java/` or absolute.

The server configuration parameter `pljava_classpath_insecure` controls whether the server configuration parameter `pljava_classpath` can be set by a user without Greenplum Database superuser privileges. When `pljava_classpath_insecure` is enabled, Greenplum Database developers who are working on PL/Java functions do not have to be database superusers to change `pljava_classpath`.

**Warning:** Enabling `pljava_classpath_insecure` exposes a security risk by giving non-administrator database users the ability to run unauthorized Java methods.

- `pljava_statement_cache_size`

Sets the size in KB of the Most Recently Used (MRU) cache for prepared statements.

- `pljava_release_lingering_savepoints`

If `TRUE`, lingering savepoints will be released on function exit. If `FALSE`, they will be rolled back.

- `pljava_vmoptions`

Defines the start up options for the Greenplum Database Java VM.

See the *Greenplum Database Reference Guide* for information about the Greenplum Database server configuration parameters.

## Installing Java

PL/Java requires a Java runtime environment on each Greenplum Database host. Ensure that the same Java environment is at the same location on all hosts: masters and segments. The command `java -version` displays the Java version.

The commands that you use to install Java depend on the host system operating system and Java version. This list describes how to install OpenJDK 8 or 11 (Java 8 JDK or Java 11 JDK) on RHEL/CentOS or Ubuntu.

- RHEL 7/CentOS 7 - This `yum` command installs OpenJDK 8 or 11.

```
$ sudo yum install java-<version>-openjdk-devel
```

For OpenJDK 8 the version is `1.8.0`, for OpenJDK 11 the version is `11`.

- RHEL 6/CentOS 6
  - Java 8 - This `yum` command installs OpenJDK 8.

```
$ sudo yum install java-1.8.0-openjdk-devel
```

- Java 11 - Download the OpenJDK 11 tar file from <http://jdk.java.net/archive/> and install and configure the operating system to use Java 11.

1. This example `tar` command installs the OpenJDK 11 in `/usr/lib/jvm`.

```
$ sudo tar xzf openjdk-11.0.2_linux-x64_bin.tar.gz --directory /usr/lib/jvm
```

2. Run these two commands to add OpenJDK 11 to the `update-alternatives` command. The `update-alternatives` command maintains symbolic links that determine the default version of operating system commands.

```
$ sudo sh -c 'for bin in /usr/lib/jvm/jdk-11.0.2/bin/*; do update-alternatives --install /usr/bin/$(basename $bin) $(basename $bin) $bin 100; done'
$ sudo sh -c 'for bin in /usr/lib/jvm/jdk-11.0.2/bin/*; do update-alternatives --set $(basename $bin) $bin; done'
```

The second command returns some `failed to read link` errors that can be ignored.

- Ubuntu - These `apt` commands install OpenJDK 8 or 11.

```
$ sudo apt update
$ sudo apt install openjdk-<version>-jdk
```

For OpenJDK 8 the version is `8`, for OpenJDK 11 the version is `11`.

After installing OpenJDK on a RHEL or CentOS system, run this `update-alternatives` command to change the default Java. Enter the number that represents the OpenJDK version to use as the default.

```
$ sudo update-alternatives --config java
```

The `update-alternatives` command is not required on Ubuntu systems.

**Note:** When configuring host systems, you can use the `gpssh` utility to run bash shell commands on multiple remote hosts.

## Installing PL/Java

For Greenplum Database, the PL/Java extension is available as a package. Download the package from the Greenplum Database page on [VMware Tanzu Network](#) and then install the software with the Greenplum Package Manager (`gppkg`).

The `gppkg` utility installs Greenplum Database extensions, along with any dependencies, on all hosts across a cluster. It also automatically installs extensions on new hosts in the case of system expansion and segment recovery.

To install and use PL/Java:

1. Specify the Java version used by PL/Java. Set the environment variables `JAVA_HOME` and `LD_LIBRARY_PATH` in the `greenplum_path.sh`.
2. Install the Greenplum Database PL/Java extension.
3. Enable the language for each database where you intend to use PL/Java.
4. Install user-created JAR files containing Java methods into the same directory on all Greenplum Database hosts.
5. Add the name of the JAR file to the Greenplum Database server configuration parameter `pljava_classpath`. The parameter lists the installed JAR files. For information about the parameter, see the *Greenplum Database Reference Guide*.

## Installing the Greenplum PL/Java Extension

Before you install the PL/Java extension, make sure that your Greenplum database is running, you have sourced `greenplum_path.sh`, and that the `$MASTER_DATA_DIRECTORY` and `$GPHOME` variables are set.

1. Download the PL/Java extension package from [VMware Tanzu Network](#) then copy it to the master host.
2. Follow the instructions in [Verifying the Greenplum Database Software Download](#) to verify the integrity of the **Greenplum Procedural Languages PL/Java** software.
3. Install the software extension package by running the `gppkg` command. This example installs the PL/Java extension package on a Linux system:

```
$ gppkg -i pljava-1.4.3-gp5-rhel<osversion>_x86_64.gppkg
```

4. Ensure that the environment variables `JAVA_HOME` and `LD_LIBRARY_PATH` are set properly in `$GPHOME/greenplum_path.sh` on all Greenplum Database hosts.
  - o Set the `JAVA_HOME` variable to the directory where your Java Runtime is installed. For example, for Oracle JRE this directory would be `/usr/java/latest`. For OpenJDK, the directory is `/usr/lib/jvm`. This example changes the environment variable to use `/usr/lib/jvm`.

```
export JAVA_HOME=/usr/lib/jvm
```

- o Set the `LD_LIBRARY_PATH` to include the directory with the Java server runtime libraries. PL/Java depends on `libjvm.so` and the shared object should be in your `LD_LIBRARY_PATH`. By default, `libjvm.so` is available in `$JAVA_HOME/lib/server` with JDK 11, or in `$JAVA_HOME/jre/lib/amd64/server` with JDK 8. This example adds the JDK 11 directory to the environment variable.

```
export LD_LIBRARY_PATH=$GPHOME/lib:$GPHOME/ext/python/lib:$JAVA_HOME/lib/server:$LD_LIBRARY_PATH
```

This example `gpscp` command copies the file to all hosts specified in the file `gphosts_file`.

```
$ gpscp -f gphosts_file $GPHOME/greenplum_path.sh
=:$GPHOME/greenplum_path.sh
```

5. Reload `greenplum_path.sh`.

```
$ source $GPHOME/greenplum_path.sh
```

6. Restart Greenplum Database.

```
$ gpstop -r
```

## Enabling PL/Java and Installing JAR Files

Perform the following steps as the Greenplum Database administrator `gpadmin`.

1. Enable PL/Java in a database by running the `CREATE EXTENSION` command to register the language. For example, this command enables PL/Java in the `testdb` database:

```
$ psql -d testdb -c 'CREATE EXTENSION pljava;'
```

**Note:** The PL/Java `install.sql` script, used in previous releases to register the language, is deprecated.

2. Copy your Java archives (JAR files) to the same directory on all Greenplum Database hosts. This example uses the Greenplum Database `gpscp` utility to copy the file `myclasses.jar` to the directory `$GPHOME/lib/postgresql/java/`:

```
$ gpscp -f gphosts_file myclasses.jar
=:/usr/local/greenplum-db/lib/postgresql/java/
```

The file `gphosts_file` contains a list of the Greenplum Database hosts.

3. Set the `pljava_classpath` server configuration parameter in the master `postgresql.conf` file. For this example, the parameter value is a colon (:) separated list of the JAR files. For example:

```
$ gpconfig -c pljava_classpath -v 'examples.jar:myclasses.jar'
```

The file `examples.jar` is installed when you install the PL/Java extension package with the `gppkg` utility.

**Note:** If you install JAR files in a directory other than `$GPHOME/lib/postgresql/java/`, you must specify the absolute path to the JAR file. Each JAR file must be in the same location on all Greenplum Database hosts. For more information about specifying the location of JAR files, see the information about the `pljava_classpath` server configuration parameter in the *Greenplum Database Reference Guide*.

4. Reload the `postgresql.conf` file.

```
$ gpstop -u
```

5. (optional) Greenplum provides an `examples.sql` file containing sample PL/Java functions that you can use for testing. Run the commands in this file to create the test functions (which use the Java classes in `examples.jar`).

```
$ psql -f $GPHOME/share/postgresql/pljava/examples.sql
```

## Uninstalling PL/Java

- [Remove PL/Java Support for a Database](#)
- [Uninstall the Java JAR files and Software Package](#)

### Remove PL/Java Support for a Database

Use the `DROP EXTENSION` command to remove support for PL/Java from a database. For example, this command deactivates the PL/Java language in the `testdb` database:

```
$ psql -d testdb -c 'DROP EXTENSION pljava;'
```

The default command fails if any existing objects (such as functions) depend on the language. Specify the `CASCADE` option to also drop all dependent objects, including functions that you created with PL/Java.

**Note:** The PL/Java `uninstall.sql` script, used in previous releases to remove the language registration, is deprecated.

### Uninstall the Java JAR files and Software Package

If no databases have PL/Java as a registered language, remove the Java JAR files and uninstall the Greenplum PL/Java extension with the `gppkg` utility.

1. Remove the `pljava_classpath` server configuration parameter from the `postgresql.conf` file on all Greenplum Database hosts. For example:

```
$ gpconfig -r pljava_classpath
```

2. Remove the JAR files from the directories where they were installed on all Greenplum Database hosts. For information about JAR file installation directories, see [Enabling PL/Java and Installing JAR Files](#).
3. Use the Greenplum `gppkg` utility with the `-r` option to uninstall the PL/Java extension. This example uninstalls the PL/Java extension on a Linux system:

```
$ gppkg -r pljava-1.4.3
```

You can run the `gppkg` utility with the options `-q --all` to list the installed extensions and their versions.

4. Remove any updates you made to `greenplum_path.sh` for PL/Java.
5. Reload `greenplum_path.sh` and restart the database

```
$ source $GPHOME/greenplum_path.sh
$ gpstop -r
```

## Writing PL/Java functions

Information about writing functions with PL/Java.

- [SQL Declaration](#)
- [Type Mapping](#)
- [NULL Handling](#)
- [Complex Types](#)
- [Returning Complex Types](#)
- [Returning Complex Types](#)
- [Functions That Return Sets](#)
- [Returning a SETOF <scalar type>](#)
- [Returning a SETOF <complex type>](#)

### SQL Declaration

A Java function is declared with the name of a class and a static method on that class. The class will be resolved using the classpath that has been defined for the schema where the function is declared. If no classpath has been defined for that schema, the public schema is used. If no classpath is found there either, the class is resolved using the system classloader.

The following function can be declared to access the static method `getProperty` on `java.lang.System` class:

```
CREATE FUNCTION getsysprop(VARCHAR)
  RETURNS VARCHAR
```

```
AS 'java.lang.System.getProperty'
LANGUAGE java;
```

Run the following command to return the Java `user.home` property:

```
SELECT getsysprop('user.home');
```

## Type Mapping

Scalar types are mapped in a straight forward way. This table lists the current mappings.

| PostgreSQL    | Java  |
|---------------|---|
| bool          | boolean   |
| char          | byte  |
| int2          | short   |
| int4          | int   |
| int8          | long  |
| varchar       | java.lang.String  |
| text          | java.lang.String  |
| bytea         | byte[ ]   |
| date          | java.sql.Date   |
| time          | java.sql.Time (stored value treated as local time)      |
| timetz        | java.sql.Time   |
| timestamptz   | java.sql.Timestamp (stored value treated as local time) |
| timestamptz   | java.sql.Timestamp                                      |
| complex       | java.sql.ResultSet                                      |
| setof complex | java.sql.ResultSet                                      |

All other types are mapped to `java.lang.String` and will utilize the standard `textin/textout` routines registered for respective type.

## NULL Handling

The scalar types that map to Java primitives can not be passed as `NULL` values. To pass `NULL` values, those types can have an alternative mapping. You enable this mapping by explicitly denoting it in the method reference.

```
CREATE FUNCTION trueIfEvenOrNull(integer)
  RETURNS bool
  AS 'foo.fee.Fum.trueIfEvenOrNull(java.lang.Integer)'
  LANGUAGE java;
```

The Java code would be similar to this:

```

package foo.fee;
public class Fum
{
    static boolean trueIfEvenOrNull(Integer value)
    {
        return (value == null)
            ? true
            : (value.intValue() % 2) == 0;
    }
}

```

The following two statements both yield true:

```

SELECT trueIfEvenOrNull(NULL);
SELECT trueIfEvenOrNull(4);

```

In order to return `NULL` values from a Java method, you use the object type that corresponds to the primitive (for example, you return `java.lang.Integer` instead of `int`). The PL/Java resolve mechanism finds the method regardless. Since Java cannot have different return types for methods with the same name, this does not introduce any ambiguity.

## Complex Types

A complex type will always be passed as a read-only `java.sql.ResultSet` with exactly one row. The `ResultSet` is positioned on its row so a call to `next()` should not be made. The values of the complex type are retrieved using the standard getter methods of the `ResultSet`.

Example:

```

CREATE TYPE complexTest
    AS(base integer, incbase integer, ctime timestamptz);
CREATE FUNCTION useComplexTest(complexTest)
    RETURNS VARCHAR
    AS 'foo.fee.Fum.useComplexTest'
    IMMUTABLE LANGUAGE java;

```

In the Java class `Fum`, we add the following static method:

```

public static String useComplexTest(ResultSet complexTest)
    throws SQLException
{
    int base = complexTest.getInt(1);
    int incbase = complexTest.getInt(2);
    Timestamp ctime = complexTest.getTimestamp(3);
    return "Base = \" + base +
        "\", incbase = \" + incbase +
        "\", ctime = \" + ctime + "\"";
}

```

## Returning Complex Types

Java does not stipulate any way to create a `ResultSet`. Hence, returning a `ResultSet` is not an option. The SQL-2003 draft suggests that a complex return value should be handled as an IN/OUT parameter. PL/Java implements a `ResultSet` that way. If you declare a function that returns a

complex type, you will need to use a Java method with boolean return type with a last parameter of type `java.sql.ResultSet`. The parameter will be initialized to an empty updateable `ResultSet` that contains exactly one row.

Assume that the `complexTest` type in previous section has been created.

```
CREATE FUNCTION createComplexTest(int, int)
  RETURNS complexTest
  AS 'foo.fee.Fum.createComplexTest'
  IMMUTABLE LANGUAGE java;
```

The PL/Java method resolve will now find the following method in the `Fum` class:

```
public static boolean complexReturn(int base, int increment,
  ResultSet receiver)
  throws SQLException
{
  receiver.updateInt(1, base);
  receiver.updateInt(2, base + increment);
  receiver.updateTimestamp(3, new
    Timestamp(System.currentTimeMillis()));
  return true;
}
```

The return value denotes if the receiver should be considered as a valid tuple (true) or NULL (false).

## Functions That Return Sets

When returning result sets, you should not build a result set before returning it, because building a large result set would consume a large amount of resources. It is better to produce one row at a time. Incidentally, that is what the Greenplum Database backend expects a function with SETOF return to do. You can return a SETOF a scalar type such as an `int`, `float` or `varchar`, or you can return a SETOF a complex type.

## Returning a SETOF <scalar type>

In order to return a set of a scalar type, you need create a Java method that returns something that implements the `java.util.Iterator` interface. Here is an example of a method that returns a SETOF `varchar`:

```
CREATE FUNCTION javatest.getSystemProperties()
  RETURNS SETOF varchar
  AS 'foo.fee.Bar.getNames'
  IMMUTABLE LANGUAGE java;
```

This simple Java method returns an iterator:

```
package foo.fee;
import java.util.Iterator;

public class Bar
{
  public static Iterator getNames()
  {
    ArrayList names = new ArrayList();
```

```

        names.add("Lisa");
        names.add("Bob");
        names.add("Bill");
        names.add("Sally");
        return names.iterator();
    }
}

```

## Returning a SETOF <complex type>

A method returning a SETOF <complex type> must use either the interface `org.postgresql.pljava.ResultSetProvider` or `org.postgresql.pljava.ResultSetHandle`. The reason for having two interfaces is that they cater for optimal handling of two distinct use cases. The former is for cases when you want to dynamically create each row that is to be returned from the SETOF function. The latter makes sense in cases where you want to return the result of a query after it runs.

### Using the ResultSetProvider Interface

This interface has two methods. The boolean `assignRowValues(java.sql.ResultSet tupleBuilder, int rowNum)` and the `void close()` method. The Greenplum Database query evaluator will call the `assignRowValues` repeatedly until it returns false or until the evaluator decides that it does not need any more rows. Then it calls `close`.

You can use this interface the following way:

```

CREATE FUNCTION javatest.listComplexTests(int, int)
RETURNS SETOF complexTest
AS 'foo.fee.Fum.listComplexTest'
IMMUTABLE LANGUAGE java;

```

The function maps to a static java method that returns an instance that implements the `ResultSetProvider` interface.

```

public class Fum implements ResultSetProvider
{
    private final int m_base;
    private final int m_increment;
    public Fum(int base, int increment)
    {
        m_base = base;
        m_increment = increment;
    }
    public boolean assignRowValues(ResultSet receiver, int
currentRow)
    throws SQLException
    {
        // Stop when we reach 12 rows.
        //
        if(currentRow >= 12)
            return false;
        receiver.updateInt(1, m_base);
        receiver.updateInt(2, m_base + m_increment * currentRow);
        receiver.updateTimestamp(3, new
Timestamp(System.currentTimeMillis()));
    }
}

```

```

    return true;
}
public void close()
{
    // Nothing needed in this example
}
public static ResultSetProvider listComplexTests(int base,
int increment)
throws SQLException
{
    return new Fum(base, increment);
}
}

```

The `listComplexTests` method is called once. It may return `NULL` if no results are available or an instance of the `ResultSetProvider`. Here the Java class `Fum` implements this interface so it returns an instance of itself. The method `assignRowValues` will then be called repeatedly until it returns false. At that time, `close` will be called.

### Using the `ResultSetHandle` Interface

This interface is similar to the `ResultSetProvider` interface in that it has a `close()` method that will be called at the end. But instead of having the evaluator call a method that builds one row at a time, this method has a method that returns a `ResultSet`. The query evaluator will iterate over this set and deliver the `ResultSet` contents, one tuple at a time, to the caller until a call to `next()` returns false or the evaluator decides that no more rows are needed.

Here is an example that runs a query using a statement that it obtained using the default connection. The SQL suitable for the deployment descriptor looks like this:

```

CREATE FUNCTION javatest.listSupers()
RETURNS SETOF pg_user
AS 'org.postgresql.pljava.example.Users.listSupers'
LANGUAGE java;
CREATE FUNCTION javatest.listNonSupers()
RETURNS SETOF pg_user
AS 'org.postgresql.pljava.example.Users.listNonSupers'
LANGUAGE java;

```

And in the Java package `org.postgresql.pljava.example` a class `Users` is added:

```

public class Users implements ResultSetHandle
{
    private final String m_filter;
    private Statement m_statement;
    public Users(String filter)
    {
        m_filter = filter;
    }
    public ResultSet getResultSet()
    throws SQLException
    {
        m_statement =
            DriverManager.getConnection("jdbc:default:connection").createStatement();
        return m_statement.executeQuery("SELECT * FROM pg_user

```

```

        WHERE " + m_filter);
    }

    public void close()
    throws SQLException
    {
        m_statement.close();
    }

    public static ResultSetHandle listSupers()
    {
        return new Users("usesuper = true");
    }

    public static ResultSetHandle listNonSupers()
    {
        return new Users("usesuper = false");
    }
}

```

## Using JDBC

PL/Java contains a JDBC driver that maps to the PostgreSQL SPI functions. A connection that maps to the current transaction can be obtained using the following statement:

```

Connection conn =
    DriverManager.getConnection("jdbc:default:connection");

```

After obtaining a connection, you can prepare and run statements similar to other JDBC connections. These are limitations for the PL/Java JDBC driver:

- The transaction cannot be managed in any way. Thus, you cannot use methods on the connection such as:
  - `commit()`
  - `rollback()`
  - `setAutoCommit()`
  - `setTransactionIsolation()`
- Savepoints are available with some restrictions. A savepoint cannot outlive the function in which it was set and it must be rolled back or released by that same function.
- A `ResultSet` returned from `executeQuery()` are always `FETCH_FORWARD` and `CONCUR_READ_ONLY`.
- Metadata is only available in PL/Java 1.1 or higher.
- `CallableStatement` (for stored procedures) is not implemented.
- The types `Clob` or `Blob` are not completely implemented, they need more work. The types `byte[]` and `String` can be used for `bytea` and `text` respectively.

## Exception Handling

You can catch and handle an exception in the Greenplum Database backend just like any other exception. The backend `ErrorData` structure is exposed as a property in a class called `org.postgresql.pljava.ServerException` (derived from `java.sql.SQLException`) and the Java try/catch mechanism is synchronized with the backend mechanism.

**Important:** You will not be able to continue running backend functions until your function has returned and the error has been propagated when the backend has generated an exception unless you have used a savepoint. When a savepoint is rolled back, the exceptional condition is reset and you can continue your execution.

## Savepoints

Greenplum Database savepoints are exposed using the `java.sql.Connection` interface. Two restrictions apply.

- A savepoint must be rolled back or released in the function where it was set.
- A savepoint must not outlive the function where it was set.

## Logging

PL/Java uses the standard Java Logger. Hence, you can write things like:

```
Logger.getAnonymousLogger().info( "Time is " + new
Date(System.currentTimeMillis()));
```

At present, the logger uses a handler that maps the current state of the Greenplum Database configuration setting `log_min_messages` to a valid Logger level and that outputs all messages using the Greenplum Database backend function `eelog()`.

**Note:** The `log_min_messages` setting is read from the database the first time a PL/Java function in a session is run. On the Java side, the setting does not change after the first PL/Java function execution in a specific session until the Greenplum Database session that is working with PL/Java is restarted.

The following mapping apply between the Logger levels and the Greenplum Database backend levels.

| java.util.logging.Level | Greenplum Database Level |
|-------------------------|--------------------------|
| SEVERE ERROR            | ERROR                    |
| WARNING                 | WARNING                  |
| CONFIG                  | LOG                      |
| INFO                    | INFO                     |
| FINE                    | DEBUG1                   |
| FINER                   | DEBUG2                   |
| FINEST                  | DEBUG3                   |

## Security

- [Installation](#)
- [Trusted Language](#)

## Installation

Only a database superuser can install PL/Java. The PL/Java utility functions are installed using SECURITY DEFINER so that they run with the access permissions that were granted to the creator of the functions.

## Trusted Language

PL/Java is a *trusted* language. The trusted PL/Java language has no access to the file system as stipulated by PostgreSQL definition of a trusted language. Any database user can create and access functions in a trusted language.

PL/Java also installs a language handler for the language `javau`. This version is *not trusted* and only a superuser can create new functions that use it. Any user can call the functions.

To install both the trusted and untrusted languages, register the extension by running the `'CREATE EXTENSION pljava'` command when [Enabling PL/Java and Installing JAR Files](#).

To install only the trusted language, register the extension by running the `'CREATE EXTENSION pljavat'` command when [Enabling PL/Java and Installing JAR Files](#).

## Some PL/Java Issues and Solutions

When writing the PL/Java, mapping the JVM into the same process-space as the Greenplum Database backend code, some concerns have been raised regarding multiple threads, exception handling, and memory management. Here are brief descriptions explaining how these issues were resolved.

- [Multi-threading](#)
- [Exception Handling](#)
- [Java Garbage Collector Versus palloc\(\) and Stack Allocation](#)

## Multi-threading

Java is inherently multi-threaded. The Greenplum Database backend is not. There is nothing stopping a developer from utilizing multiple `Threads` class in the Java code. Finalizers that call out to the backend might have been spawned from a background Garbage Collection thread. Several third party Java-packages that are likely to be used make use of multiple threads. How can this model coexist with the Greenplum Database backend in the same process?

### Solution

The solution is simple. PL/Java defines a special object called the `Backend.THREADLOCK`. When PL/Java is initialized, the backend immediately grabs this objects monitor (i.e. it will synchronize on this object). When the backend calls a Java function, the monitor is released and then immediately

regained when the call returns. All calls from Java out to backend code are synchronized on the same lock. This ensures that only one thread at a time can call the backend from Java, and only at a time when the backend is awaiting the return of a Java function call.

## Exception Handling

Java makes frequent use of try/catch/finally blocks. Greenplum Database sometimes use an exception mechanism that calls `longjmp` to transfer control to a known state. Such a jump would normally effectively bypass the JVM.

### Solution

The backend now allows errors to be caught using the macros `PG_TRY/PG_CATCH/PG_END_TRY` and in the catch block, the error can be examined using the `ErrorData` structure. PL/Java implements a `java.sql.SQLException` subclass called `org.postgresql.pljava.ServerException`. The `ErrorData` can be retrieved and examined from that exception. A catch handler is allowed to issue a rollback to a savepoint. After a successful rollback, execution can continue.

## Java Garbage Collector Versus `palloc()` and Stack Allocation

Primitive types are always be passed by value. This includes the `String` type (this is a must since Java uses double byte characters). Complex types are often wrapped in Java objects and passed by reference. For example, a Java object can contain a pointer to a `palloc`'ed or stack allocated memory and use native JNI calls to extract and manipulate data. Such data will become stale once a call has ended. Further attempts to access such data will at best give very unpredictable results but more likely cause a memory fault and a crash.

### Solution

The PL/Java contains code that ensures that stale pointers are cleared when the `MemoryContext` or stack where they were allocated goes out of scope. The Java wrapper objects might live on but any attempt to use them will result in a stale native handle exception.

## Example

The following simple Java example creates a JAR file that contains a single method and runs the method.

**Note:** The example requires Java SDK to compile the Java file.

The following method returns a substring.

```
{
public static String substring(String text, int beginIndex,
    int endIndex)
    {
        return text.substring(beginIndex, endIndex);
    }
}
```

Enter the java code in a text file `example.class`.

Contents of the file `manifest.txt`:

```
Manifest-Version: 1.0
Main-Class: Example
Specification-Title: "Example"
Specification-Version: "1.0"
Created-By: 1.6.0_35-b10-428-11M3811
Build-Date: 01/20/2013 10:09 AM
```

Compile the java code:

```
javac *.java
```

Create a JAR archive named `analytics.jar` that contains the class file and the manifest file `MANIFEST` file in the JAR.

```
jar cfm analytics.jar manifest.txt *.class
```

Upload the jar file to the Greenplum master host.

Run the `gpscp` utility to copy the jar file to the Greenplum Java directory. Use the `-f` option to specify the file that contains a list of the master and segment hosts.

```
gpscp -f gphosts_file analytics.jar
=:/usr/local/greenplum-db/lib/postgresql/java/
```

Use the `gpconfig` utility to set the Greenplum `pljava_classpath` server configuration parameter. The parameter lists the installed jar files.

```
gpconfig -c pljava_classpath -v 'analytics.jar'
```

Run the `gpstop` utility with the `-u` option to reload the configuration files.

```
gpstop -u
```

From the `psql` command line, run the following command to show the installed jar files.

```
show pljava_classpath
```

The following SQL commands create a table and define a Java function to test the method in the jar file:

```
create table temp (a varchar) distributed randomly;
insert into temp values ('my string');
--Example function
create or replace function java_substring(varchar, int, int)
returns varchar as 'Example.substring' language java;
--Example execution
select java_substring(a, 1, 5) from temp;
```

You can place the contents in a file, `mysample.sql` and run the command from a `psql` command line:

```
> \i mysample.sql
```

The output is similar to this:

```
java_substring
-----
 y st
(1 row)
```

## PL/Perl Language

This chapter includes the following information:

- [About Greenplum PL/Perl](#)
- [Greenplum Database PL/Perl Limitations](#)
- [Trusted/Untrusted Language](#)
- [Developing Functions with PL/Perl](#)

## About Greenplum PL/Perl

With the Greenplum Database PL/Perl extension, you can write user-defined functions in Perl that take advantage of its advanced string manipulation operators and functions. PL/Perl provides both trusted and untrusted variants of the language.

PL/Perl is embedded in your Greenplum Database distribution. Greenplum Database PL/Perl requires Perl to be installed on the system of each database host.

Refer to the [PostgreSQL PL/Perl documentation](#) for additional information.

## Greenplum Database PL/Perl Limitations

Limitations of the Greenplum Database PL/Perl language include:

- Greenplum Database does not support PL/Perl triggers.
- PL/Perl functions cannot call each other directly.
- SPI is not yet fully implemented.
- If you fetch very large data sets using `spi_exec_query()`, you should be aware that these will all go into memory. You can avoid this problem by using `spi_query()/spi_fetchrow()`. A similar problem occurs if a set-returning function passes a large set of rows back to Greenplum Database via a `return` statement. Use `return_next` for each row returned to avoid this problem.

- When a session ends normally, not due to a fatal error, PL/Perl runs any `END` blocks that you have defined. No other actions are currently performed. (File handles are not automatically flushed and objects are not automatically destroyed.)

## Trusted/Untrusted Language

PL/Perl includes trusted and untrusted language variants.

The PL/Perl trusted language is named `plperl`. The trusted PL/Perl language restricts file system operations, as well as `require`, `use`, and other statements that could potentially interact with the operating system or database server process. With these restrictions in place, any Greenplum Database user can create and run functions in the trusted `plperl` language.

The PL/Perl untrusted language is named `plperlu`. You cannot restrict the operation of functions you create with the `plperlu` untrusted language. Only database superusers have privileges to create untrusted PL/Perl user-defined functions. And only database superusers and other database users that are explicitly granted the permissions can run untrusted PL/Perl user-defined functions.

PL/Perl has limitations with respect to communication between interpreters and the number of interpreters running in a single process. Refer to the PostgreSQL [Trusted and Untrusted PL/Perl](#) documentation for additional information.

## Enabling and Removing PL/Perl Support

You must register the PL/Perl language with a database before you can create and run a PL/Perl user-defined function within that database. To remove PL/Perl support, you must explicitly remove the extension from each database in which it was registered. You must be a database superuser or owner to register or remove trusted languages in Greenplum databases.

**Note:** Only database superusers may register or remove support for the *untrusted* PL/Perl language `plperlu`.

Before you enable or remove PL/Perl support in a database, ensure that:

- Your Greenplum Database is running.
- You have sourced `greenplum_path.sh`.
- You have set the `$MASTER_DATA_DIRECTORY` and `$GPHOME` environment variables.

### Enabling PL/Perl Support

For each database in which you want to enable PL/Perl, register the language using the SQL `CREATE EXTENSION` command. For example, run the following command as the `gpadmin` user to register the trusted PL/Perl language for the database named `testdb`:

```
$ psql -d testdb -c 'CREATE EXTENSION plperl;'
```

### Removing PL/Perl Support

To remove support for PL/Perl from a database, run the SQL `DROP EXTENSION` command. For example, run the following command as the `gpadmin` user to remove support for the trusted PL/Perl language from the database named `testdb`:

```
$ psql -d testdb -c 'DROP EXTENSION plperl;'
```

The default command fails if any existing objects (such as functions) depend on the language. Specify the `CASCADE` option to also drop all dependent objects, including functions that you created with PL/Perl.

## Developing Functions with PL/Perl

You define a PL/Perl function using the standard SQL `CREATE FUNCTION` syntax. The body of a PL/Perl user-defined function is ordinary Perl code. The PL/Perl interpreter wraps this code inside a Perl subroutine.

You can also create an anonymous code block with PL/Perl. An anonymous code block, called with the SQL `DO` command, receives no arguments, and whatever value it might return is discarded. Otherwise, a PL/Perl anonymous code block behaves just like a function. Only database superusers create an anonymous code block with the untrusted `plperl` language.

The syntax of the `CREATE FUNCTION` command requires that you write the PL/Perl function body as a string constant. While it is more convenient to use dollar-quoting, you can choose to use escape string syntax (`E' '`) provided that you double any single quote marks and backslashes used in the body of the function.

PL/Perl arguments and results are handled as they are in Perl. Arguments you pass in to a PL/Perl function are accessed via the `@_` array. You return a result value with the `return` statement, or as the last expression evaluated in the function. A PL/Perl function cannot directly return a non-scalar type because you call it in a scalar context. You can return non-scalar types such as arrays, records, and sets in a PL/Perl function by returning a reference.

PL/Perl treats null argument values as "undefined". Adding the `STRICT` keyword to the `LANGUAGE` subclause instructs Greenplum Database to immediately return null when any of the input arguments are null. When created as `STRICT`, the function itself need not perform null checks.

The following PL/Perl function utilizes the `STRICT` keyword to return the greater of two integers, or null if any of the inputs are null:

```
CREATE FUNCTION perl_max (integer, integer) RETURNS integer AS $$
    if ($_[0] > $_[1]) { return $_[0]; }
    return $_[1];
$$ LANGUAGE plperl STRICT;

SELECT perl_max( 1, 3 );
 perl_max
-----
        3
(1 row)

SELECT perl_max( 1, null );
 perl_max
-----
(1 row)
```

PL/Perl considers anything in a function argument that is not a reference to be a string, the standard Greenplum Database external text representation. The argument values supplied to a PL/Perl function are simply the input arguments converted to text form (just as if they had been displayed by a `SELECT` statement). In cases where the function argument is not an ordinary numeric or text type, you must convert the Greenplum Database type to a form that is more usable by Perl. Conversely, the `return` and `return_next` statements accept any string that is an acceptable input format for the function's declared return type.

Refer to the PostgreSQL [PL/Perl Functions and Arguments](#) documentation for additional information, including composite type and result set manipulation.

## Built-in PL/Perl Functions

PL/Perl includes built-in functions to access the database, including those to prepare and perform queries and manipulate query results. The language also includes utility functions for error logging and string manipulation.

The following example creates a simple table with an integer and a text column. It creates a PL/Perl user-defined function that takes an input string argument and invokes the `spi_exec_query()` built-in function to select all columns and rows of the table. The function returns all rows in the query results where the `v` column includes the function input string.

```
CREATE TABLE test (
    i int,
    v varchar
);
INSERT INTO test (i, v) VALUES (1, 'first line');
INSERT INTO test (i, v) VALUES (2, 'line2');
INSERT INTO test (i, v) VALUES (3, '3rd line');
INSERT INTO test (i, v) VALUES (4, 'different');

CREATE OR REPLACE FUNCTION return_match(varchar) RETURNS SETOF test AS $$
    # store the input argument
    $ss = $_[0];

    # run the query
    my $rv = spi_exec_query('select i, v from test;');

    # retrieve the query status
    my $status = $rv->{status};

    # retrieve the number of rows returned in the query
    my $nrows = $rv->{processed};

    # loop through all rows, comparing column v value with input argument
    foreach my $rn (0 .. $nrows - 1) {
        my $row = $rv->{rows}[$rn];
        my $textstr = $row->{v};
        if( index($textstr, $ss) != -1 ) {
            # match! return the row.
            return_next($row);
        }
    }
    return undef;
$$ LANGUAGE plperl EXECUTE ON MASTER ;
```

```
SELECT return_match( 'iff' );
   return_match
-----
(4,different)
(1 row)
```

Refer to the PostgreSQL PL/Perl [Built-in Functions](#) documentation for a detailed discussion of available functions.

## Global Values in PL/Perl

You can use the global hash map `$_SHARED` to share data, including code references, between PL/Perl function calls for the lifetime of the current session.

The following example uses `$_SHARED` to share data between the user-defined `set_var()` and `get_var()` PL/Perl functions:

```
CREATE OR REPLACE FUNCTION set_var(name text, val text) RETURNS text AS $$
    if ($_SHARED{$_[0]} = $_[1]) {
        return 'ok';
    } else {
        return "cannot set shared variable $_[0] to $_[1]";
    }
}
$$ LANGUAGE plperl;

CREATE OR REPLACE FUNCTION get_var(name text) RETURNS text AS $$
    return $_SHARED{$_[0]};
$$ LANGUAGE plperl;

SELECT set_var('key1', 'value1');
   set_var
-----
      ok
(1 row)

SELECT get_var('key1');
   get_var
-----
  value1
(1 row)
```

For security reasons, PL/Perl creates a separate Perl interpreter for each role. This prevents accidental or malicious interference by one user with the behavior of another user's PL/Perl functions. Each such interpreter retains its own value of the `$_SHARED` variable and other global state. Two PL/Perl functions share the same value of `$_SHARED` if and only if they are run by the same SQL role.

There are situations where you must take explicit steps to ensure that PL/Perl functions can share data in `$_SHARED`. For example, if an application runs under multiple SQL roles (via `SECURITY DEFINER` functions, use of `SET ROLE`, etc.) in a single session, make sure that functions that need to communicate are owned by the same user, and mark these functions as `SECURITY DEFINER`.

## Notes

Additional considerations when developing PL/Perl functions:

- PL/Perl internally utilizes the UTF-8 encoding. It converts any arguments provided in other encodings to UTF-8, and converts return values from UTF-8 back to the original encoding.
- Nesting named PL/Perl subroutines retains the same dangers as in Perl.
- Only the untrusted PL/Perl language variant supports module import. Use `plperl` with care.
- Any module that you use in a `plperl` function must be available from the same location on all Greenplum Database hosts.

## PL/pgSQL Language

This section contains an overview of the Greenplum Database PL/pgSQL language.

- [About Greenplum Database PL/pgSQL](#)
- [PL/pgSQL Plan Caching](#)
- [PL/pgSQL Examples](#)
- [References](#)

## About Greenplum Database PL/pgSQL

Greenplum Database PL/pgSQL is a loadable procedural language that is installed and registered by default with Greenplum Database. You can create user-defined functions using SQL statements, functions, and operators.

With PL/pgSQL you can group a block of computation and a series of SQL queries inside the database server, thus having the power of a procedural language and the ease of use of SQL. Also, with PL/pgSQL you can use all the data types, operators and functions of Greenplum Database SQL.

The PL/pgSQL language is a subset of Oracle PL/SQL. Greenplum Database PL/pgSQL is based on Postgres PL/pgSQL. The Postgres PL/pgSQL documentation is at <https://www.postgresql.org/docs/9.4/plpgsql.html>

When using PL/pgSQL functions, function attributes affect how Greenplum Database creates query plans. You can specify the attribute `IMMUTABLE`, `STABLE`, or `VOLATILE` as part of the `LANGUAGE` clause to classify the type of function. For information about the creating functions and function attributes, see the `CREATE FUNCTION` command in the *Greenplum Database Reference Guide*.

You can run PL/SQL code blocks as anonymous code blocks. See the `DO` command in the *Greenplum Database Reference Guide*.

## Greenplum Database SQL Limitations

When using Greenplum Database PL/pgSQL, limitations include

- Triggers are not supported
- Cursors are forward moving only (not scrollable)

- Updatable cursors (`UPDATE...WHERE CURRENT OF` and `DELETE...WHERE CURRENT OF`) are not supported.
- Parallel retrieve cursors (`DECLARE...PARALLEL RETRIEVE`) are not supported.

For information about Greenplum Database SQL conformance, see [Summary of Greenplum Features](#) in the *Greenplum Database Reference Guide*.

## The PL/pgSQL Language

PL/pgSQL is a block-structured language. The complete text of a function definition must be a block. A block is defined as:

```
[ <label> ]
[ DECLARE
  declarations ]
BEGIN
  statements
END [ <label> ];
```

Each declaration and each statement within a block is terminated by a semicolon (;). A block that appears within another block must have a semicolon after `END`, as shown in the previous block. The `END` that concludes a function body does not require a semicolon.

A label is required only if you want to identify the block for use in an `EXIT` statement, or to qualify the names of variables declared in the block. If you provide a label after `END`, it must match the label at the block's beginning.

**Important:** Do not confuse the use of the `BEGIN` and `END` keywords for grouping statements in PL/pgSQL with the database commands for transaction control. The PL/pgSQL `BEGIN` and `END` keywords are only for grouping; they do not start or end a transaction. Functions are always run within a transaction established by an outer query — they cannot start or commit that transaction, since there would be no context for them to run in. However, a PL/pgSQL block that contains an `EXCEPTION` clause effectively forms a subtransaction that can be rolled back without affecting the outer transaction. For more about the `EXCEPTION` clause, see the PostgreSQL documentation on trapping errors at <https://www.postgresql.org/docs/9.4/plpgsql-control-structures.html#PLPGSQL-ERROR-TRAPPING>.

Keywords are case-insensitive. Identifiers are implicitly converted to lowercase unless double-quoted, just as they are in ordinary SQL commands.

Comments work the same way in PL/pgSQL code as in ordinary SQL:

- A double dash (--) starts a comment that extends to the end of the line.
- A /\* starts a block comment that extends to the matching occurrence of \*/.

Block comments nest.

Any statement in the statement section of a block can be a subblock. Subblocks can be used for logical grouping or to localize variables to a small group of statements.

Variables declared in a subblock mask any similarly-named variables of outer blocks for the duration of the subblock. You can access the outer variables if you qualify their names with their block's label. For example this function declares a variable named `quantity` several times:

```

CREATE FUNCTION testfunc() RETURNS integer AS $$
<< outerblock >>
DECLARE
    quantity integer := 30;
BEGIN
    RAISE NOTICE 'Quantity here is %', quantity; -- Prints 30
    quantity := 50;
    --
    -- Create a subblock
    --
    DECLARE
        quantity integer := 80;
    BEGIN
        RAISE NOTICE 'Quantity here is %', quantity; -- Prints 80
        RAISE NOTICE 'Outer quantity here is %', outerblock.quantity; -- Prints 50
    END;
    RAISE NOTICE 'Quantity here is %', quantity; -- Prints 50
    RETURN quantity;
END;
$$ LANGUAGE plpgsql;

```

## Running SQL Commands

You can run SQL commands with PL/pgSQL statements such as `EXECUTE`, `PERFORM`, and `SELECT ... INTO`. For information about the PL/pgSQL statements, see <https://www.postgresql.org/docs/9.4/plpgsql-statements.html>.

**Note:** The PL/pgSQL statement `SELECT INTO` is not supported in the `EXECUTE` statement.

## PL/pgSQL Plan Caching

A PL/pgSQL function's volatility classification has implications on how Greenplum Database caches plans that reference the function. Refer to [Function Volatility and Plan Caching](#) in the *Greenplum Database Administrator Guide* for information on plan caching considerations for Greenplum Database function volatility categories.

When a PL/pgSQL function runs for the first time in a database session, the PL/pgSQL interpreter parses the function's SQL expressions and commands. The interpreter creates a prepared execution plan as each expression and SQL command is first run in the function. The PL/pgSQL interpreter reuses the execution plan for a specific expression and SQL command for the life of the database connection. While this reuse substantially reduces the total amount of time required to parse and generate plans, errors in a specific expression or command cannot be detected until run time when that part of the function is run.

Greenplum Database will automatically re-plan a saved query plan if there is any schema change to any relation used in the query, or if any user-defined function used in the query is redefined. This makes the re-use of a prepared plan transparent in most cases.

The SQL commands that you use in a PL/pgSQL function must refer to the same tables and columns on every execution. You cannot use a parameter as the name of a table or a column in an SQL command.

PL/pgSQL caches a separate query plan for each combination of actual argument types in which you invoke a polymorphic function to ensure that data type differences do not cause unexpected

failures.

Refer to the PostgreSQL [Plan Caching](#) documentation for a detailed discussion of plan caching considerations in the PL/pgSQL language.

## PL/pgSQL Examples

The following are examples of PL/pgSQL user-defined functions.

### Example: Aliases for Function Parameters

Parameters passed to functions are named with identifiers such as `$1`, `$2`. Optionally, aliases can be declared for `$n` parameter names for increased readability. Either the alias or the numeric identifier can then be used to refer to the parameter value.

There are two ways to create an alias. The preferred way is to give a name to the parameter in the `CREATE FUNCTION` command, for example:

```
CREATE FUNCTION sales_tax(subtotal real) RETURNS real AS $$
BEGIN
    RETURN subtotal * 0.06;
END;
$$ LANGUAGE plpgsql;
```

You can also explicitly declare an alias, using the declaration syntax:

```
name ALIAS FOR $n;
```

This example, creates the same function with the `DECLARE` syntax.

```
CREATE FUNCTION sales_tax(real) RETURNS real AS $$
DECLARE
    subtotal ALIAS FOR $1;
BEGIN
    RETURN subtotal * 0.06;
END;
$$ LANGUAGE plpgsql;
```

### Example: Using the Data Type of a Table Column

When declaring a variable, you can use the `%TYPE` construct to specify the data type of a variable or table column. This is the syntax for declaring a variable whose type is the data type of a table column:

```
name table.column_name%TYPE;
```

You can use the `%TYPE` construct to declare variables that will hold database values. For example, suppose you have a column named `user_id` in your `users` table. To declare a variable named `my_userid` with the same data type as the `users.user_id` column:

```
my_userid users.user_id%TYPE;
```

`%TYPE` is particularly valuable in polymorphic functions, since the data types needed for internal variables may change from one call to the next. Appropriate variables can be created by applying `%TYPE` to the function's arguments or result placeholders.

## Example: Composite Type Based on a Table Row

A variable of a composite type is called a row variable. The following syntax declares a composite variable based on table row:

```
name table_name%ROWTYPE;
```

Such a row variable can hold a whole row of a `SELECT` or `FOR` query result, so long as that query's column set matches the declared type of the variable. The individual fields of the row value are accessed using the usual dot notation, for example `rowvar.column`.

Parameters to a function can be composite types (complete table rows). In that case, the corresponding identifier `$n` will be a row variable, and fields can be selected from it, for example `$1.user_id`.

Only the user-defined columns of a table row are accessible in a row-type variable, not the OID or other system columns. The fields of the row type inherit the table's field size or precision for data types such as `char(n)`.

The next example function uses a row variable composite type. Before creating the function, create the table that is used by the function with this command.

```
CREATE TABLE table1 (
  f1 text,
  f2 numeric,
  f3 integer
) distributed by (f1);
```

This `INSERT` command adds data to the table.

```
INSERT INTO table1 values
 ('test1', 14.1, 3),
 ('test2', 52.5, 2),
 ('test3', 32.22, 6),
 ('test4', 12.1, 4);
```

This function uses a column `%TYPE` variable and `%ROWTYPE` composite variable based on `table1`.

```
CREATE OR REPLACE FUNCTION t1_calc( name text) RETURNS integer
AS $$
DECLARE
  t1_row    table1%ROWTYPE;
  calc_int  table1.f3%TYPE;
BEGIN
  SELECT * INTO t1_row FROM table1 WHERE table1.f1 = $1 ;
  calc_int = (t1_row.f2 * t1_row.f3)::integer ;
  RETURN calc_int ;
END;
$$ LANGUAGE plpgsql VOLATILE;
```

**Note:** The previous function is classified as a `VOLATILE` function because function values could change within a single table scan.

The following `SELECT` command uses the function.

```
select t1_calc( 'test1' );
```

**Note:** The example PL/pgSQL function uses `SELECT` with the `INTO` clause. It is different from the SQL command `SELECT INTO`. If you want to create a table from a `SELECT` result inside a PL/pgSQL function, use the SQL command `CREATE TABLE AS`.

## Example: Using a Variable Number of Arguments

You can declare a PL/pgSQL function to accept variable numbers of arguments, as long as all of the optional arguments are of the same data type. You must mark the last argument of the function as `VARIADIC` and declare the argument using an array type. You can refer to a function that includes `VARIADIC` arguments as a variadic function.

For example, this variadic function returns the minimum value of a variable array of numerics:

```
CREATE FUNCTION mleast (VARIADIC numeric[])
  RETURNS numeric AS $$
  DECLARE minval numeric;
  BEGIN
    SELECT min($1[i]) FROM generate_subscripts( $1, 1) g(i) INTO minval;
    RETURN minval;
  END;
$$ LANGUAGE plpgsql;
CREATE FUNCTION

SELECT mleast(10, -1, 5, 4.4);
 mleast
-----
      -1
(1 row)
```

Effectively, all of the actual arguments at or beyond the `VARIADIC` position are gathered up into a one-dimensional array.

You can pass an already-constructed array into a variadic function. This is particularly useful when you want to pass arrays between variadic functions. Specify `VARIADIC` in the function call as follows:

```
SELECT mleast(VARIADIC ARRAY[10, -1, 5, 4.4]);
```

This prevents PL/pgSQL from expanding the function's variadic parameter into its element type.

## Example: Using Default Argument Values

You can declare PL/pgSQL functions with default values for some or all input arguments. The default values are inserted whenever the function is called with fewer than the declared number of arguments. Because arguments can only be omitted from the end of the actual argument list, you must provide default values for all arguments after an argument defined with a default value.

For example:

```

CREATE FUNCTION use_default_args(a int, b int DEFAULT 2, c int DEFAULT 3)
    RETURNS int AS $$
DECLARE
    sum int;
BEGIN
    sum := $1 + $2 + $3;
    RETURN sum;
END;
$$ LANGUAGE plpgsql;

SELECT use_default_args(10, 20, 30);
 use_default_args
-----
                60
(1 row)

SELECT use_default_args(10, 20);
 use_default_args
-----
                33
(1 row)

SELECT use_default_args(10);
 use_default_args
-----
                15
(1 row)

```

You can also use the = sign in place of the keyword `DEFAULT`.

## Example: Using Polymorphic Data Types

PL/pgSQL supports the polymorphic *anyelement*, *anyarray*, *anyenum*, and *anynonarray* types. Using these types, you can create a single PL/pgSQL function that operates on multiple data types. Refer to [Greenplum Database Data Types](#) for additional information on polymorphic type support in Greenplum Database.

A special parameter named `$0` is created when the return type of a PL/pgSQL function is declared as a polymorphic type. The data type of `$0` identifies the return type of the function as deduced from the actual input types.

In this example, you create a polymorphic function that returns the sum of two values:

```

CREATE FUNCTION add_two_values(v1 anyelement,v2 anyelement)
    RETURNS anyelement AS $$
DECLARE
    sum ALIAS FOR $0;
BEGIN
    sum := v1 + v2;
    RETURN sum;
END;
$$ LANGUAGE plpgsql;

```

Run `add_two_values()` providing integer input values:

```
SELECT add_two_values(1, 2);
 add_two_values
-----
                3
(1 row)
```

The return type of `add_two_values()` is integer, the type of the input arguments. Now execute `add_two_values()` providing float input values:

```
SELECT add_two_values (1.1, 2.2);
 add_two_values
-----
                3.3
(1 row)
```

The return type of `add_two_values()` in this case is float.

You can also specify `VARIADIC` arguments in polymorphic functions.

## Example: Anonymous Block

This example runs the statements in the `t1_calc()` function from a previous example as an anonymous block using the `DO` command. In the example, the anonymous block retrieves the input value from a temporary table.

```
CREATE TEMP TABLE list AS VALUES ('test1') DISTRIBUTED RANDOMLY;

DO $$
DECLARE
    t1_row    table1%ROWTYPE;
    calc_int  table1.f3%TYPE;
BEGIN
    SELECT * INTO t1_row FROM table1, list WHERE table1.f1 = list.column1 ;
    calc_int = (t1_row.f2 * t1_row.f3)::integer ;
    RAISE NOTICE 'calculated value is %', calc_int ;
END $$ LANGUAGE plpgsql ;
```

## PL/Python Language

This section contains an overview of the Greenplum Database PL/Python Language.

- [About Greenplum PL/Python](#)
- [Enabling and Removing PL/Python support](#)
- [Developing Functions with PL/Python](#)
- [Installing Python Modules](#)
- [Examples](#)
- [References](#)

## About Greenplum PL/Python

PL/Python is a loadable procedural language. With the Greenplum Database PL/Python extensions, you can write Greenplum Database user-defined functions in Python that take advantage of Python features and modules to quickly build robust database applications.

You can run PL/Python code blocks as anonymous code blocks. See the [DO](#) command in the *Greenplum Database Reference Guide*.

The Greenplum Database PL/Python extensions are installed by default with Greenplum Database. Two extensions are provided:

- `plpythonu` supports developing functions using Python 2.7. Greenplum Database installs a version of Python 2.7 for `plpythonu` at `$GPHOME/ext/python`.
- `plpython3u`, introduced with Greenplum 6.22, supports developing functions using Python 3.9. Greenplum Database installs a compatible Python at `$GPHOME/ext/python3.9`.

## Greenplum Database PL/Python Limitations

- Greenplum Database does not support PL/Python triggers.
- PL/Python is available only as a Greenplum Database untrusted language.
- Updatable cursors (`UPDATE...WHERE CURRENT OF` and `DELETE...WHERE CURRENT OF`) are not supported.
- Within a single Greenplum session, all PL/Python functions must be called using either `plpythonu` or `plpython3u`. You must start a new session before you can call a function created with different PL/Python version (for example, in order to call a `plpythonu` function after calling a `plpython3u` function, or vice versa).

## Enabling and Removing PL/Python support

The PL/Python language is installed with Greenplum Database. To create and run a PL/Python user-defined function (UDF) in a database, you must register the PL/Python language with the database.

## Enabling PL/Python Support

Greenplum installs compatible versions of Python 2.7 and 3.9 in `$GPHOME/ext`.

For each database that requires its use, register the PL/Python language with the SQL command `CREATE EXTENSION`. Separate extensions are provided for Python 2.7 and Python 3.9 support, and you can install either or both extensions to a database.

Because PL/Python is an untrusted language, only superusers can register PL/Python with a database.

For example, run this command as the `gpadmin` user to register PL/Python with Python 2.7 support in the database named `testdb`:

```
$ psql -d testdb -c 'CREATE EXTENSION plpythonu;'
```

Run this command as the `gpadmin` user to register PL/Python with Python 3.9 support:

```
$ psql -d testdb -c 'CREATE EXTENSION plpython3u;'
```

PL/Python is registered as an untrusted language.

## Removing PL/Python Support

For a database that no longer requires the PL/Python language, remove support for PL/Python with the SQL command `DROP EXTENSION`. Because PL/Python is an untrusted language, only superusers can remove support for the PL/Python language from a database. For example, running this command as the `gpadmin` user removes support for PL/Python for Python 2.7 from the database named `testdb`:

```
$ psql -d testdb -c 'DROP EXTENSION plpythonu;'
```

Run this command as the `gpadmin` user to remove support for PL/Python for Python 3.9:

```
$ psql -d testdb -c 'DROP EXTENSION plpython3u;'
```

The default command fails if any existing objects (such as functions) depend on the language. Specify the `CASCADE` option to also drop all dependent objects, including functions that you created with PL/Python.

## Developing Functions with PL/Python

The body of a PL/Python user-defined function is a Python script. When the function is called, its arguments are passed as elements of the array `args[]`. Named arguments are also passed as ordinary variables to the Python script. The result is returned from the PL/Python function with `return` statement, or `yield` statement in case of a result-set statement.

PL/Python translates Python's `None` into the SQL `null` value.

## Data Type Mapping

The Greenplum to Python data type mapping follows.

| Greenplum Primitive Type     | Python Data Type |
|------------------------------|------------------|
| boolean <sup>1</sup>         | bool             |
| bytea                        | bytes            |
| smallint, bigint, oid        | int              |
| real, double                 | float            |
| numeric                      | decimal          |
| <i>other primitive types</i> | string           |
| SQL null value               | None             |

<sup>1</sup> When the UDF return type is `boolean`, the Greenplum Database evaluates the return value for truth according to Python rules. That is, `0` and empty string are `false`, but notably `'f'` is `true`.

Example:

```
CREATE OR REPLACE FUNCTION pybool_func(a int) RETURNS boolean AS $$
# container: plc_python3_shared
    if (a > 0):
        return True
    else:
        return False
$$ LANGUAGE plpythonu;

SELECT pybool_func(-1);

 pybool_func
-----
 f
(1 row)
```

## Arrays and Lists

You pass SQL array values into PL/Python functions with a Python list. Similarly, PL/Python functions return SQL array values as a Python list. In the typical PL/Python usage pattern, you will specify an array with `[]`.

The following example creates a PL/Python function that returns an array of integers:

```
CREATE FUNCTION return_py_int_array()
    RETURNS int[]
AS $$
    return [1, 11, 21, 31]
$$ LANGUAGE plpythonu;

SELECT return_py_int_array();
 return_py_int_array
-----
 {1,11,21,31}
(1 row)
```

PL/Python treats multi-dimensional arrays as lists of lists. You pass a multi-dimensional array to a PL/Python function using nested Python lists. When a PL/Python function returns a multi-dimensional array, the inner lists at each level must all be of the same size.

The following example creates a PL/Python function that takes a multi-dimensional array of integers as input. The function displays the type of the provided argument, and returns the multi-dimensional array:

```
CREATE FUNCTION return_multidim_py_array(x int4[])
  RETURNS int4[]
AS $$
  plpy.info(x, type(x))
  return x
$$ LANGUAGE plpythonu;

SELECT * FROM return_multidim_py_array(ARRAY[[1,2,3], [4,5,6]]);
INFO:  ([[1, 2, 3], [4, 5, 6]], <type 'list'>)
CONTEXT:  PL/Python function "return_multidim_py_type"
         return_multidim_py_array
         -----
         {{1,2,3},{4,5,6}}
         (1 row)
```

PL/Python also accepts other Python sequences, such as tuples, as function arguments for backwards compatibility with Greenplum versions where multi-dimensional arrays were not supported. In such cases, the Python sequences are always treated as one-dimensional arrays because they are ambiguous with composite types.

## Composite Types

You pass composite-type arguments to a PL/Python function using Python mappings. The element names of the mapping are the attribute names of the composite types. If an attribute has the null value, its mapping value is `None`.

You can return a composite type result as a sequence type (tuple or list). You must specify a composite type as a tuple, rather than a list, when it is used in a multi-dimensional array. You cannot return an array of composite types as a list because it would be ambiguous to determine whether the list represents a composite type or another array dimension. In the typical usage pattern, you will specify composite type tuples with `()`.

In the following example, you create a composite type and a PL/Python function that returns an array of the composite type:

```
CREATE TYPE type_record AS (
  first text,
  second int4
);

CREATE FUNCTION composite_type_as_list()
  RETURNS type_record[]
AS $$
  return [[('first', 1), ('second', 1)], [('first', 2), ('second', 2)], [('first', 3),
('second', 3)]];
$$ LANGUAGE plpythonu;
```

```

SELECT * FROM composite_type_as_list();
               composite_type_as_list
-----
{"(first,1)","(second,1)","(first,2)","(second,2)","(first,3)","(second,3)"}
(1 row)

```

Refer to the PostgreSQL [Arrays, Lists](#) documentation for additional information on PL/Python handling of arrays and composite types.

## Set-Returning Functions

A Python function can return a set of scalar or composite types from any sequence type (for example: tuple, list, set).

In the following example, you create a composite type and a Python function that returns a `SETOF` of the composite type:

```

CREATE TYPE greeting AS (
    how text,
    who text
);

CREATE FUNCTION greet (how text)
    RETURNS SETOF greeting
AS $$
    # return tuple containing lists as composite types
    # all other combinations work also
    return ( {"how": how, "who": "World"}, {"how": how, "who": "Greenplum"} )
$$ LANGUAGE plpythonu;

select greet('hello');
       greet
-----
(hello,World)
(hello,Greenplum)
(2 rows)

```

## Running and Preparing SQL Queries

The PL/Python `plpy` module provides two Python functions to run an SQL query and prepare an execution plan for a query, `plpy.execute` and `plpy.prepare`. Preparing the execution plan for a query is useful if you run the query from multiple Python functions.

PL/Python also supports the `plpy.subtransaction()` function to help manage `plpy.execute` calls in an explicit subtransaction. See [Explicit Subtransactions](#) in the PostgreSQL documentation for additional information about `plpy.subtransaction()`.

### `plpy.execute`

Calling `plpy.execute` with a query string and an optional limit argument causes the query to be run and the result to be returned in a Python result object. The result object emulates a list or dictionary object. The rows returned in the result object can be accessed by row number and column name. The result set row numbering starts with 0 (zero). The result object can be modified. The result object has these additional methods:

- `nrows` that returns the number of rows returned by the query.
- `status` which is the `SPI_execute()` return value.

For example, this Python statement in a PL/Python user-defined function runs a query.

```
rv = plpy.execute("SELECT * FROM my_table", 5)
```

The `plpy.execute` function returns up to 5 rows from `my_table`. The result set is stored in the `rv` object. If `my_table` has a column `my_column`, it would be accessed as:

```
my_col_data = rv[i]["my_column"]
```

Since the function returns a maximum of 5 rows, the index `i` can be an integer between 0 and 4.

### `plpy.prepare`

The function `plpy.prepare` prepares the execution plan for a query. It is called with a query string and a list of parameter types, if you have parameter references in the query. For example, this statement can be in a PL/Python user-defined function:

```
plan = plpy.prepare("SELECT last_name FROM my_users WHERE
first_name = $1", [ "text" ])
```

The string `text` is the data type of the variable that is passed for the variable `$1`. After preparing a statement, you use the function `plpy.execute` to run it:

```
rv = plpy.execute(plan, [ "Fred" ], 5)
```

The third argument is the limit for the number of rows returned and is optional.

When you prepare an execution plan using the PL/Python module the plan is automatically saved. See the Postgres Server Programming Interface (SPI) documentation for information about the execution plans <https://www.postgresql.org/docs/9.4/spi.html>.

To make effective use of saved plans across function calls you use one of the Python persistent storage dictionaries SD or GD.

The global dictionary SD is available to store data between function calls. This variable is private static data. The global dictionary GD is public data, available to all Python functions within a session. Use GD with care.

Each function gets its own execution environment in the Python interpreter, so that global data and function arguments from `myfunc` are not available to `myfunc2`. The exception is the data in the GD dictionary, as mentioned previously.

This example uses the SD dictionary:

```
CREATE FUNCTION usesavedplan() RETURNS trigger AS $$
  if SD.has_key("plan"):
    plan = SD["plan"]
  else:
    plan = plpy.prepare("SELECT 1")
    SD["plan"] = plan
```

```
# rest of function

$$ LANGUAGE plpythonu;
```

## Handling Python Errors and Messages

The Python module `plpy` implements these functions to manage errors and messages:

- `plpy.debug`
- `plpy.log`
- `plpy.info`
- `plpy.notice`
- `plpy.warning`
- `plpy.error`
- `plpy.fatal`
- `plpy.debug`

The message functions `plpy.error` and `plpy.fatal` raise a Python exception which, if uncaught, propagates out to the calling query, causing the current transaction or subtransaction to be cancelled. The functions `raise plpy.ERROR(msg)` and `raise plpy.FATAL(msg)` are equivalent to calling `plpy.error` and `plpy.fatal`, respectively. The other message functions only generate messages of different priority levels.

Whether messages of a particular priority are reported to the client, written to the server log, or both is controlled by the Greenplum Database server configuration parameters `log_min_messages` and `client_min_messages`. For information about the parameters see the *Greenplum Database Reference Guide*.

## Using the dictionary GD To Improve PL/Python Performance

In terms of performance, importing a Python module is an expensive operation and can affect performance. If you are importing the same module frequently, you can use Python global variables to load the module on the first invocation and not require importing the module on subsequent calls. The following PL/Python function uses the GD persistent storage dictionary to avoid importing a module if it has already been imported and is in the GD.

```
psql=#
CREATE FUNCTION pytest() returns text as $$
    if 'mymodule' not in GD:
        import mymodule
        GD['mymodule'] = mymodule
    return GD['mymodule'].sumd([1,2,3])
$$;
```

## Installing Python Modules

When you install a Python module for development with PL/Python, the Greenplum Database Python environment must have the module added to it across all segment hosts and mirror hosts in

the cluster. When expanding Greenplum Database, you must add the Python modules to the new segment hosts.

Greenplum Database provides a collection of data science-related Python modules that you can use to easily develop PL/Python functions in Greenplum. The modules are provided as two `.gppkg` format files that can be installed into a Greenplum cluster using the `gppkg` utility, with one package supporting development with Python 2.7 and the other supporting development with Python 3.9. See [Python Data Science Module Packages](#) for installation instructions and descriptions of the provided modules.

To develop with modules that are not part of the Python Data Science Module packages, you can use Greenplum utilities such as `gpssh` and `gpscp` to run commands or copy files to all hosts in the Greenplum cluster. These sections describe how to use those utilities to install and use additional Python modules:

- [Verifying the Python Environment](#)
- [Installing Python pip](#)
- [Installing Python Packages for Python 2.7](#)
- [Installing Python Packages for Python 3.9](#)
- [Building and Installing Python Modules Locally](#)
- [Testing Installed Python Modules](#)

## Verifying the Python Environment

As part of the Greenplum Database installation, the `gpadmin` user environment is configured to use Python that is installed with Greenplum Database. To check the Python environment, you can use the `which` command:

```
which python
```

The command returns the location of the Python installation. All Greenplum installations include Python 2.7 installed as `$GPHOME/ext/python` and Python 3.9 installed as `$GPHOME/ext/python3.9`:

```
which python3.9
```

When running shell commands on remote hosts with `gpssh`, specify the `-s` option to source the `greenplum_path.sh` file before running commands on the remote hosts. For example, this command should display the Python installed with Greenplum Database on each host specified in the `gpdb_hosts` file.

```
gpssh -s -f gpdb_hosts which python
```

To display the list of currently installed Python 2.7 modules, run this command.

```
python -c "help('modules')"
```

You can optionally run `gpssh` in interactive mode to display Python modules on remote hosts. This example starts `gpssh` in interactive mode and lists the Python modules on the Greenplum Database host `sdw1`.

```
$ gpssh -s -h sdw1
=> python -c "help('modules')"
. . .
=> exit
$
```

## Installing Python pip

The Python utility `pip` installs Python packages that contain Python modules and other resource files from versioned archive files.

Run this command to install `pip` for Python 2.7:

```
python -m ensurepip --default-pip
```

For Python 3.9, use:

```
python3.9 -m ensurepip --default-pip
```

The command runs the `ensurepip` module to bootstrap (install and configure) the `pip` utility from the local Python installation.

You can run this command to ensure the `pip`, `setuptools` and `wheel` projects are current. Current Python projects ensure that you can install Python packages from source distributions or pre-built distributions (wheels).

```
python -m pip install --upgrade pip setuptools wheel
```

You can use `gpssh` to run the commands on the Greenplum Database hosts. This example runs `gpssh` in interactive mode to install `pip` on the hosts listed in the file `gpdb_hosts`.

```
$ gpssh -s -f gpdb_hosts
=> python -m ensurepip --default-pip
[centos6-mdw1] Ignoring indexes: https://pypi.python.org/simple
[centos6-mdw1] Collecting setuptools
[centos6-mdw1] Collecting pip
[centos6-mdw1] Installing collected packages: setuptools, pip
[centos6-mdw1] Successfully installed pip-8.1.1 setuptools-20.10.1
[centos6-sdw1] Ignoring indexes: https://pypi.python.org/simple
[centos6-sdw1] Collecting setuptools
[centos6-sdw1] Collecting pip
[centos6-sdw1] Installing collected packages: setuptools, pip
[centos6-sdw1] Successfully installed pip-8.1.1 setuptools-20.10.1
=> exit
$
```

The `=>` is the inactive prompt for `gpssh`. The utility displays the output from each host. The `exit` command exits from `gpssh` interactive mode.

This `gpssh` command runs a single command on all hosts listed in the file `gpdb_hosts`.

```
gpssh -s -f gpdb_hosts python -m pip install --upgrade pip setuptools wheel
```

The utility displays the output from each host.

For more information about installing Python packages, see <https://packaging.python.org/tutorials/installing-packages/>.

## Installing Python Packages for Python 2.7

After installing `pip`, you can install Python packages. This command installs the `numpy` and `scipy` packages for Python 2.7:

```
python -m pip install --user numpy scipy
```

For Python 3.9, use the `python3.9` command instead:

```
python3.9 -m pip install --user numpy scipy
```

The `--user` option attempts to avoid conflicts when installing Python packages.

You can use `gpssh` to run the command on the Greenplum Database hosts.

For information about these and other Python packages, see [References](#).

## Installing Python Packages for Python 3.9

By default, `greenplum_path.sh` changes the `PYTHONPATH` and `PYTHONHOME` environment variables for use with the installed Python 2.7 environment. In order to install modules using `pip` with Python 3.9, you must first `unset` those parameters. For example to install `numpy` and `scipy` for Python 3.9:

```
gpssh -s -f gpdb_hosts
=> unset PYTHONHOME
=> unset PYTHONPATH
=> $GPHOME/ext/python3.9 -m pip install numpy scipy
```

You can optionally install Python 3.9 modules to a non-standard location by using the `--prefix` option with `pip`. For example:

```
gpssh -s -f gpdb_hosts
=> unset PYTHONHOME
=> unset PYTHONPATH
=> $GPHOME/ext/python3.9 -m pip install --prefix=/home/gpadmin/my_python numpy scipy
```

If you use this option, keep in mind that the `PYTHONPATH` environment variable setting is cleared before initializing or executing functions using `plpython3u`. If you want to use modules installed to a custom location, you must configure the paths to those modules using the Greenplum configuration parameter `plpython3.python_path` instead of `PYTHONPATH`. For example:

```
$ psql -d testdb
testdb=# load 'plpython3';
testdb=# SET plpython3.python_path='/home/gpadmin/my_python';
```

Greenplum uses the value of `plpython3.python_path` to set `PLPYTHONPATH` in the environment used to create or call `plpython3u` functions.

**Note:** `plpython3.python_path` is provided as part of the `plpython3u` extension, so you *must* load the extension (with `load 'plpython3';`) before you can set this configuration parameter in a session.

Ensure that you configure `plpython3.python_path` *before* you create or call `plpython3` functions in a session. If you set or change the parameter after `plpython3u` is initialized you receive the error:

```
ERROR: SET PYTHONPATH failed, the GUC value can only be changed before initializing the python interpreter.
```

To set a default value for the configuration parameter, use `gpconfig` instead:

```
gpconfig -c plpython3.python_path \
  -v "'/home/gpadmin/my_python'" \
  --skipvalidation
gpstop -u
```

## Building and Installing Python Modules Locally

If you are building a Python module, you must ensure that the build creates the correct executable. For example on a Linux system, the build should create a 64-bit executable.

Before building a Python module to be installed, ensure that the appropriate software to build the module is installed and properly configured. The build environment is required only on the host where you build the module.

You can use the Greenplum Database utilities `gpssh` and `gpscp` to run commands on Greenplum Database hosts and to copy files to the hosts.

## Testing Installed Python Modules

You can create a simple PL/Python user-defined function (UDF) to validate that Python a module is available in the Greenplum Database. This example tests the NumPy module.

This PL/Python UDF imports the NumPy module. The function returns `SUCCESS` if the module is imported, and `FAILURE` if an import error occurs.

```
CREATE OR REPLACE FUNCTION plpy_test(x int)
returns text
as $$
  try:
    from numpy import *
    return 'SUCCESS'
  except ImportError, e:
    return 'FAILURE'
$$ language plpythonu;
```

(If you are using Python 3.9, replace `plpythonu` with `plpython3u` in the above command.)

Create a table that contains data on each Greenplum Database segment instance. Depending on the size of your Greenplum Database installation, you might need to generate more data to ensure data is distributed to all segment instances.

```
CREATE TABLE DIST AS (SELECT x FROM generate_series(1,50) x ) DISTRIBUTED RANDOMLY ;
```

This `SELECT` command runs the UDF on the segment hosts where data is stored in the primary segment instances.

```
SELECT gp_segment_id, plpy_test(x) AS status
FROM dist
GROUP BY gp_segment_id, status
ORDER BY gp_segment_id, status;
```

The `SELECT` command returns `SUCCESS` if the UDF imported the Python module on the Greenplum Database segment instance. If the `SELECT` command returns `FAILURE`, you can find the segment host of the segment instance host. The Greenplum Database system table `gp_segment_configuration` contains information about mirroring and segment configuration. This command returns the host name for a segment ID.

```
SELECT hostname, content AS seg_ID FROM gp_segment_configuration
WHERE content = <seg_id> ;
```

If `FAILURE` is returned, these are some possible causes:

- A problem accessing required libraries. For the NumPy example, a Greenplum Database might have a problem accessing the OpenBLAS libraries or the Python libraries on a segment host.

Make sure you get no errors when running command on the segment host as the `gpadmin` user. This `gpssh` command tests importing the `numpy` module on the segment host `mdw1`.

```
gpssh -s -h mdw1 python -c "import numpy"
```

- If the Python `import` command does not return an error, environment variables might not be configured in the Greenplum Database environment. For example, the Greenplum Database might not have been restarted after installing the Python Package on the host system.

## Examples

This PL/Python function example uses Python 3.9 and returns the value of pi using the `numpy` module:

```
CREATE OR REPLACE FUNCTION testpi()
RETURNS float
AS $$
import numpy
return numpy.pi
$$ LANGUAGE plpython3u;
```

Use `SELECT` to call the function:

```
SELECT testpi();
       testpi
-----
 3.14159265358979
(1 row)
```

This PL/Python UDF returns the maximum of two integers:

```
CREATE FUNCTION pymax (a integer, b integer)
  RETURNS integer
AS $$
  if (a is None) or (b is None):
    return None
  if a > b:
    return a
  return b
$$ LANGUAGE plpythonu;
```

You can use the `STRICT` property to perform the null handling instead of using the two conditional statements.

```
CREATE FUNCTION pymax (a integer, b integer)
  RETURNS integer AS $$
return max(a,b)
$$ LANGUAGE plpythonu STRICT ;
```

You can run the user-defined function `pymax` with `SELECT` command. This example runs the UDF and shows the output.

```
SELECT ( pymax(123, 43));
column1
-----
      123
(1 row)
```

This example that returns data from an SQL query that is run against a table. These two commands create a simple table and add data to the table.

```
CREATE TABLE sales (id int, year int, qtr int, day int, region text)
  DISTRIBUTED BY (id) ;

INSERT INTO sales VALUES
(1, 2014, 1,1, 'usa'),
(2, 2002, 2,2, 'europe'),
(3, 2014, 3,3, 'asia'),
(4, 2014, 4,4, 'usa'),
(5, 2014, 1,5, 'europe'),
(6, 2014, 2,6, 'asia'),
(7, 2002, 3,7, 'usa') ;
```

This PL/Python UDF runs a `SELECT` command that returns 5 rows from the table. The Python function returns the `REGION` value from the row specified by the input value. In the Python function, the row numbering starts from 0. Valid input for the function is an integer between 0 and 4.

```
CREATE OR REPLACE FUNCTION mpyptest(a integer)
  RETURNS setof text
AS $$
  rv = plpy.execute("SELECT * FROM sales ORDER BY id", 5)
  region =[]
  region.append(rv[a]["region"])
  return region
$$ language plpythonu EXECUTE ON MASTER;
```

Running this `SELECT` statement returns the `REGION` column value from the third row of the result set.

```
SELECT mypytest(2) ;
```

This command deletes the UDF from the database.

```
DROP FUNCTION mypytest(integer) ;
```

This example runs the PL/Python function in the previous example as an anonymous block with the `DO` command. In the example, the anonymous block retrieves the input value from a temporary table.

```
CREATE TEMP TABLE mytemp AS VALUES (2) DISTRIBUTED RANDOMLY;

DO $$
  temprow = plpy.execute("SELECT * FROM mytemp", 1)
  myval = temprow[0]["column1"]
  rv = plpy.execute("SELECT * FROM sales ORDER BY id", 5)
  region = rv[myval]["region"]
  plpy.notice("region is %s" % region)
$$ language plpythonu;
```

## PL/R Language

This chapter contains the following information:

- [About Greenplum Database PL/R](#)
- [Installing R](#)
- [Installing PL/R](#)
- [Uninstalling PL/R](#)

- [Enabling PL/R Language Support](#)
- [Examples](#)
- [Downloading and Installing R Packages](#)
- [Displaying R Library Information](#)
- [Loading R Modules at Startup](#)
- [References](#)

## About Greenplum Database PL/R

PL/R is a procedural language. With the Greenplum Database PL/R extension you can write database functions in the R programming language and use R packages that contain R functions and data sets.

For information about supported PL/R versions, see the *Greenplum Database Release Notes*.

## Installing R

For RHEL and CentOS, installing the PL/R package installs R in `$GPHOME/ext/R-<version>` and updates `$GPHOME/greenplum_path.sh` for Greenplum Database to use R.

To use PL/R on Ubuntu host systems, you must install and configure R on all Greenplum Database host systems before installing PL/R.

**Note:** You can use the `gpssh` utility to run bash shell commands on multiple remote hosts.

1. To install R, run these `apt` commands on all host systems.

```
$ sudo apt update && sudo apt install r-base
```

Installing `r-base` also installs dependent packages including `r-base-core`.

2. To configure Greenplum Database to use R, add the `R_HOME` environment variable to `$GPHOME/greenplum_path.sh` on all hosts. This example command returns the R home directory.

```
$ R RHOME
/usr/lib/R
```

Using the previous R home directory as an example, add this line to the file on all hosts.

```
export R_HOME=/usr/lib/R
```

3. Source `$GPHOME/greenplum_path.sh` and restart Greenplum Database. For example, run these commands on the Greenplum Database master host.

```
$ source $GPHOME/greenplum_path.sh
$ gpstop -r
```

## Installing PL/R

The PL/R extension is available as a package. Download the package from [VMware Tanzu Network](#) and install it with the Greenplum Package Manager (`gppkg`).

The `gppkg` utility installs Greenplum Database extensions, along with any dependencies, on all hosts across a cluster. It also automatically installs extensions on new hosts in the case of system expansion and segment recovery.

## Installing the Extension Package

Before you install the PL/R extension, make sure that your Greenplum Database is running, you have sourced `greenplum_path.sh`, and that the `$MASTER_DATA_DIRECTORY` and `$GPHOME` variables are set.

1. Download the PL/R extension package from [VMware Tanzu Network](#).
2. Follow the instructions in [Verifying the Greenplum Database Software Download](#) to verify the integrity of the **Greenplum Procedural Languages PL/R** software.
3. Copy the PL/R package to the Greenplum Database master host.
4. Install the software extension package by running the `gppkg` command. This example installs the PL/R extension on a Linux system:

```
$ gppkg -i plr-3.0.3-gp6-rhel7_x86_64.gppkg
```

5. Source the file `$GPHOME/greenplum_path.sh`.
6. Restart Greenplum Database.

```
$ gpstop -r
```

## Enabling PL/R Language Support

For each database that requires its use, register the PL/R language with the SQL command `CREATE EXTENSION`. Because PL/R is an untrusted language, only superusers can register PL/R with a database. For example, run this command as the `gpadmin` user to register the language with the database named `testdb`:

```
$ psql -d testdb -c 'CREATE EXTENSION plr;'
```

PL/R is registered as an untrusted language.

## Uninstalling PL/R

- [Remove PL/R Support for a Database](#)
- [Uninstall the Extension Package](#)
- [Uninstall R \(Ubuntu\)](#)

When you remove PL/R language support from a database, the PL/R routines that you created in the database will no longer work.

### Remove PL/R Support for a Database

For a database that no longer requires the PL/R language, remove support for PL/R with the SQL command `DROP EXTENSION`. Because PL/R is an untrusted language, only superusers can remove support for the PL/R language from a database. For example, run this command as the `gpadmin` user to remove support for PL/R from the database named `testdb`:

```
$ psql -d testdb -c 'DROP EXTENSION plr;'
```

The default command fails if any existing objects (such as functions) depend on the language. Specify the `CASCADE` option to also drop all dependent objects, including functions that you created with PL/R.

## Uninstall the Extension Package

If no databases have PL/R as a registered language, uninstall the Greenplum PL/R extension with the `gppkg` utility. This example uninstalls PL/R package version 3.0.3.

```
$ gppkg -r plr-3.0.3
```

On RHEL and CentOS systems, uninstalling the extension uninstalls the R software that was installed with the extension.

You can run the `gppkg` utility with the options `-q --all` to list the installed extensions and their versions.

For Ubuntu systems, remove the `R_HOME` environment variable from `greenplum_path.sh` on all Greenplum Database host systems.

Source the file `$GPHOME/greenplum_path.sh` and restart the database.

```
$ gpstop -r
```

## Uninstall R (Ubuntu)

For Ubuntu systems, remove R from all Greenplum Database host systems. These commands remove R from an Ubuntu system.

```
$ sudo apt remove r-base
$ sudo apt remove r-base-core
```

Removing `r-base` does not uninstall the R executable. Removing `r-base-core` uninstalls the R executable.

## Examples

The following are simple PL/R examples.

### Example 1: Using PL/R for single row operators

This function generates an array of numbers with a normal distribution using the R function `rnorm()`.

```
CREATE OR REPLACE FUNCTION r_norm(n integer, mean float8,
  std_dev float8) RETURNS float8[ ] AS
$$
  x<-rnorm(n,mean,std_dev)
  return(x)
$$
LANGUAGE 'plr';
```

The following `CREATE TABLE` command uses the `r_norm()` function to populate the table. The `r_norm()` function creates an array of 10 numbers.

```
CREATE TABLE test_norm_var
  AS SELECT id, r_norm(10,0,1) as x
  FROM (SELECT generate_series(1,30:: bigint) AS ID) foo
  DISTRIBUTED BY (id);
```

## Example 2: Returning PL/R data.frames in Tabular Form

Assuming your PL/R function returns an R `data.frame` as its output, unless you want to use arrays of arrays, some work is required to see your `data.frame` from PL/R as a simple SQL table:

- Create a `TYPE` in a Greenplum database with the same dimensions as your R `data.frame`:

```
CREATE TYPE t1 AS ...
```

- Use this `TYPE` when defining your PL/R function

```
... RETURNS SET OF t1 AS ...
```

Sample SQL for this is given in the next example.

## Example 3: Hierarchical Regression using PL/R

The SQL below defines a `TYPE` and runs hierarchical regression using PL/R:

```
--Create TYPE to store model results
DROP TYPE IF EXISTS wj_model_results CASCADE;
CREATE TYPE wj_model_results AS (
  cs text, coefext float, ci_95_lower float, ci_95_upper float,
  ci_90_lower float, ci_90_upper float, ci_80_lower float,
  ci_80_upper float);

--Create PL/R function to run model in R
DROP FUNCTION IF EXISTS wj_plr_RE(float [ ], text [ ]);
CREATE FUNCTION wj_plr_RE(response float [ ], cs text [ ])
RETURNS SETOF wj_model_results AS
$$
  library(arm)
  y<- log(response)
  cs<- cs
  d_temp<- data.frame(y,cs)
  m0 <- lmer (y ~ 1 + (1 | cs), data=d_temp)
  cs_unique<- sort(unique(cs))
  n_cs_unique<- length(cs_unique)
  temp_m0<- data.frame(matrix(0,n_cs_unique, 7))
```

```

for (i in 1:n_cs_unique){temp_m0[i,]<-
  c(exp(coef(m0)$cs[i,1] + c(0,-1.96,1.96,-1.65,1.65,
    -1.28,1.28)*se.ranef(m0)$cs[i]))}
names(temp_m0)<- c("Coefest", "CI_95_Lower",
  "CI_95_Upper", "CI_90_Lower", "CI_90_Upper",
  "CI_80_Lower", "CI_80_Upper")
temp_m0_v2<- data.frames(cs_unique, temp_m0)
return(temp_m0_v2)
}
LANGUAGE 'plr';

--Run modeling plr function and store model results in a
--table
DROP TABLE IF EXISTS wj_model_results_roi;
CREATE TABLE wj_model_results_roi AS SELECT *
FROM wj_plr_RE('{1,1,1}', '{"a", "b", "c"}');

```

## Downloading and Installing R Packages

R packages are modules that contain R functions and data sets. You can install R packages to extend R and PL/R functionality in Greenplum Database.

Greenplum Database provides a collection of data science-related R libraries that can be used with the Greenplum Database PL/R language. You can download these libraries in `.gppkg` format from [VMware Tanzu Network](#). For information about the libraries, see [R Data Science Library Package](#).

**Note:** If you expand Greenplum Database and add segment hosts, you must install the R packages in the R installation of the new hosts.

1. For an R package, identify all dependent R packages and each package web URL. The information can be found by selecting the given package from the following navigation page:

[https://cran.r-project.org/web/packages/available\\_packages\\_by\\_name.html](https://cran.r-project.org/web/packages/available_packages_by_name.html)

As an example, the page for the R package `arm` indicates that the package requires the following R libraries: `Matrix`, `lattice`, `lme4`, `R2WinBUGS`, `coda`, `abind`, `foreign`, and `MASS`.

You can also try installing the package with R `CMD INSTALL` command to determine the dependent packages.

For the R installation included with the Greenplum Database PL/R extension, the required R packages are installed with the PL/R extension. However, the `Matrix` package requires a newer version.

2. From the command line, use the `wget` utility to download the `tar.gz` files for the `arm` package to the Greenplum Database master host:

```
wget https://cran.r-project.org/src/contrib/Archive/arm/arm_1.5-03.tar.gz
```

```
wget https://cran.r-project.org/src/contrib/Archive/Matrix/Matrix_0.9996875-1.tar.gz
```

3. Use the `gpscp` utility and the `hosts_all` file to copy the `tar.gz` files to the same directory on all nodes of the Greenplum Database cluster. The `hosts_all` file contains a list of all the Greenplum Database segment hosts. You might require root access to do this.

```
gpscp -f hosts_all Matrix_0.9996875-1.tar.gz =:/home/gpadmin
```

```
gpscp -f /hosts_all arm_1.5-03.tar.gz =:/home/gpadmin
```

- Use the `gpssh` utility in interactive mode to log into each Greenplum Database segment host (`gpssh -f all_hosts`). Install the packages from the command prompt using the `R CMD INSTALL` command. Note that this may require root access. For example, this R install command installs the packages for the arm package.

```
$R_HOME/bin/R CMD INSTALL Matrix_0.9996875-1.tar.gz arm_1.5-03.tar.gz
```

- Ensure that the package is installed in the `$R_HOME/library` directory on all the segments (the `gpssh` can be used to install the package). For example, this `gpssh` command list the contents of the R library directory.

```
gpssh -s -f all_hosts "ls $R_HOME/library"
```

The `gpssh` option `-s` sources the `greenplum_path.sh` file before running commands on the remote hosts.

- Test if the R package can be loaded.

This function performs a simple test to determine if an R package can be loaded:

```
CREATE OR REPLACE FUNCTION R_test_require(fname text)
RETURNS boolean AS
$BODY$
    return(require(fname,character.only=T))
$BODY$
LANGUAGE 'plr';
```

This SQL command checks if the R package arm can be loaded:

```
SELECT R_test_require('arm');
```

## Displaying R Library Information

You can use the R command line to display information about the installed libraries and functions on the Greenplum Database host. You can also add and remove libraries from the R installation. To start the R command line on the host, log into the host as the `gadmin` user and run the script R from the directory `$GPHOME/ext/R-3.3.3/bin`.

This R function lists the available R packages from the R command line:

```
> library()
```

Display the documentation for a particular R package

```
> library(help="<package_name>")
> help(package="<package_name>")
```

Display the help file for an R function:

```
> help("<function_name>")
> ?<function_name>
```

To see what packages are installed, use the R command `installed.packages()`. This will return a matrix with a row for each package that has been installed. Below, we look at the first 5 rows of this matrix.

```
> installed.packages()
```

Any package that does not appear in the installed packages matrix must be installed and loaded before its functions can be used.

An R package can be installed with `install.packages()`:

```
> install.packages("<package_name>")
> install.packages("mypkg", dependencies = TRUE, type="source")
```

Load a package from the R command line.

```
> library(" <package_name> ")
```

An R package can be removed with `remove.packages`

```
> remove.packages("<package_name>")
```

You can use the R command `-e` option to run functions from the command line. For example, this command displays help on the R package MASS.

```
$ R -e 'help("MASS")'
```

## Loading R Modules at Startup

PL/R can automatically load saved R code during interpreter initialization. To use this feature, you create the `plr_modules` database table and then insert the R modules you want to auto-load into the table. If the table exists, PL/R will load the code it contains into the interpreter.

In a Greenplum Database system, table rows are usually distributed so that each row exists at only one segment instance. The R interpreter at each segment instance, however, needs to load all of the modules, so a normally distributed table will not work. You must create the `plr_modules` table as a *replicated table* in the default schema so that all rows in the table are present at every segment instance. For example:

```
CREATE TABLE public.plr_modules {
  modseq int4,
  modsrc text
} DISTRIBUTED REPLICATED;
```

See <https://www.joeconway.com/plr/doc/plr-module-funcs.html> for more information about using the PL/R auto-load feature.

## Greenplum Database R Client

This chapter contains the following information:

- [About Greenplum R](#)
- [Supported Platforms](#)
- [Prerequisites](#)
- [Installing the Greenplum R Client](#)
- [Example Data Sets](#)
- [Using the Greenplum R Client](#)
- [Limitations](#)
- [Function Summary](#)

## About Greenplum R

The Greenplum R Client (GreenplumR) is an interactive in-database data analytics tool for Greenplum Database. The client provides an R interface to tables and views, and requires no SQL knowledge to operate on these database objects.

You can use GreenplumR with the Greenplum PL/R procedural language to run an R function on data stored in Greenplum Database. GreenplumR parses the R function and creates a user-defined function (UDF) for execution in Greenplum. Greenplum runs the UDF in parallel on the segment hosts.

You can similarly use GreenplumR with Greenplum PL/Container 3 (Beta), to run an R function against Greenplum data in a high-performance R sandbox runtime environment.

No analytic data is loaded into R when you use GreenplumR, a key requirement when dealing with large data sets. Only the R function and minimal data is transferred between R and Greenplum.

## Supported Platforms

GreenplumR supports the following component versions:

| GreenplumR Version | R Version | Greenplum Version | PL/R Version | PL/Container Version |
|--------------------|-----------|-------------------|--------------|----------------------|
| 1,1,0, 1.0.0       | 3.6+      | 6.1+              | 3.0.2+       | 3.0.0 (Beta)         |

## Prerequisites

You can use GreenplumR with Greenplum Database and the PL/R and PL/Container procedural languages. Before you install and run GreenplumR on a client system:

- Ensure that your Greenplum Database installation is running version 6.1 or newer.
- Ensure that your client development system has connectivity to the Greenplum Database master host.
- Ensure that R version 3.6.0 or newer is installed on your client system, and that you set the `$R_HOME` environment variable appropriately.
- Determine the procedural language(s) you plan to use with GreenplumR, and ensure that the language(s) is installed and configured in your Greenplum Database cluster. Refer to [PL/R Language](#) and [PL/Container Language \(3.0 Beta\)](#) for language installation and configuration instructions.
- Verify that you have registered the procedural language(s) in each database in which you plan to use GreenplumR to read data from or write data to Greenplum. For example, the following command lists the extensions and languages registered in the database named `testdb`:

```
$ psql -h gpmaster -d testdb -c '\dx'
```

| List of installed extensions |          |            |  |
|------------------------------|----------|------------|--|
| Name                         | Version  | Schema     | Description  |
| plcontainer                  | 1.0.0    | public     | GPDB execution sandboxing for Python and R                 |
| plpgsql                      | 1.0      | pg_catalog | PL/pgSQL procedural language                               |
| plr                          | 8.3.0.16 | public     | load R interpreter and run R script from within a database |

Check for the `plr` and/or `plcontainer` extension `Name`.

## Installing the Greenplum R Client

GreenplumR is an R package. You obtain the package from VMware Tanzu Network (or the GreenplumR [github](#) repository) and install the package within the R console.

1. Download the package from the *Greenplum Procedural Languages* filegroup on [VMware Tanzu Network](#). The naming format of the downloaded file is `greenplumR-<version>-gp6.tar.gz`.

Note the file system location of the downloaded file.

2. Follow the instructions in [Verifying the Greenplum Database Software Download](#) to verify the integrity of the **Greenplum Procedural Languages GreenplumR** software.
3. Install the dependent R packages: `ini`, `shiny`, and `RPostgreSQL`. For example, enter the R console and run the following, or equivalent, command:

```
user@clientsys$ R
> install.packages(c("ini", "shiny", "RPostgreSQL"))
```

You may be prompted to select a CRAN download mirror. And, depending on your client system configuration, you may be prompted to use or create a personal library.

After downloading, R builds and installs these and dependent packages.

4. Install the GreenplumR R package:

```
> install.packages("/path/to/greenplumR-<version>-gp6.tar.gz", repos = NULL, type = "source")
```

5. Install the `Rdpack` documentation package:

```
> install.packages("Rdpack")
```

## Example Data Sets

GreenplumR includes the `abalone` and `null.data` sample datasets. Refer to the reference pages for more information:

```
> help( abalone )
> help( null.data )
```

## Using the Greenplum R Client

You use GreenplumR to perform in-database analytics. Typical operations that you may perform include:

- Loading the GreenplumR package.
- Connecting to and disconnecting from Greenplum Database.
- Examining database objects.
- Analyzing and manipulating data.
- Running R functions in Greenplum Database.

## Loading GreenplumR

Use the R `library()` function to load GreenplumR:

```
user@clientsys$ R
> library("GreenplumR")
```

## Connecting to Greenplum Database

The `db.connect()` and `db.connect.dsn()` GreenplumR functions establish a connection to Greenplum Database. The `db.disconnect()` function closes a database connection.

The GreenplumR connect and disconnect function signatures follow:

```

db.connect( host = "localhost", user = Sys.getenv("USER"),
           dbname = user, password = "", port = 5432, conn.pkg = "RPostgreSQL",
           default.schemas = NULL, verbose = TRUE, quick = FALSE )

db.connect.dsn( dsn.key, db.ini = "~/db.ini", default.schemas = NULL,
              verbose = TRUE, quick = FALSE )

db.disconnect( conn.id = 1, verbose = TRUE, force = FALSE )

```

When you connect to Greenplum Database, you provide the master host, port, database name, user name, password, and other information via function arguments or a data source name (DSN) file. If you do not specify an argument or value, GreenplumR uses the default.

The `db.connect[.dsn]()` functions return an integer connection identifier. You specify this identifier when you operate on tables or views in the database. You also specify this identifier when you close the connection.

The `db.disconnect()` function returns a logical that identifies whether or not the connection was successfully disconnected.

To list and display information about active Greenplum connections, use the `db.list()` function.

#### Example:

```

## connect to Greenplum database named testdb on host gpmaster
> cid_to_testdb <- db.connect( host = "gpmaster", port=5432, dbname = "testdb" )
Loading required package: DBI
Created a connection to database with ID 1
[1] 1

> db.list()
Database Connection Info
## -----
[Connection ID 1]
Host      : gpmaster
User      : gpadmin
Database  : testdb
DBMS     : Greenplum 6

> db.disconnect( cid_to_testdb )
Connection 1 is disconnected!
[1] TRUE

```

## Examining Database Objects

The `db.objects()` function lists the tables and views in the database identified by a specific connection identifier. The function signature is:

```
db.objects( search = NULL, conn.id = 1 )
```

If you choose, you can specify a filter string to narrow the returned results. For example, to list the tables and views in the `public` schema in the database identified by the default connection identifier, invoke the function as follows:

```
> db.objects( search = "public." )
```

## Analyzing and Manipulating Data

The fundamental data structure of R is the `data.frame`. A data frame is a collection of variables represented as a list of vectors. GreenplumR operates on `db.data.frame` objects, and exposes functions to convert to and manipulate objects of this type:

- `as.db.data.frame()` - writes data in a file or a `data.frame` into a Greenplum table. You can also use the function to write the results of a query into a table, or to create a local `db.data.frame`.
- `db.data.frame()` - creates a temporary R object that references a view or table in a Greenplum database. No data is loaded into R when you use this function.

### Example:

```
## create a db.data.frame from the abalone example data set;
## abalone is a data.frame
> abdf1 <- as.db.data.frame(abalone, conn.id = cid_to_testdb, verbose = FALSE)

## sort on the id column and preview the first 5 rows
> lk( sort( abdf1, INDICES=abdf1$id ), 5 )
  id sex length diameter height  whole  shucked viscera shell rings
1  1  M  0.455   0.365  0.095 0.5140  0.2245  0.1010 0.150   15
2  2  M  0.350   0.265  0.090 0.2255  0.0995  0.0485 0.070    7
3  3  F  0.530   0.420  0.135 0.6770  0.2565  0.1415 0.210    9
4  4  M  0.440   0.365  0.125 0.5160  0.2155  0.1140 0.155   10
5  5  I  0.330   0.255  0.080 0.2050  0.0895  0.0395 0.055    7

## write the data frame to a Greenplum table named abalone_from_r;
## use most of the function defaults
> as.db.data.frame( abdf1, table.name = "public.abalone_from_r" )
The data contained in table "pg_temp_93"."gp_temp_5bdf4ec7_42f9_9f9799_a0d76231be8f" which is wrapped by abdf1 is copied into "public"."abalone_from_r" in database testdb on gpmaster !
Table      : "public"."abalone_from_r"
Database   : testdb
Host       : gpmaster
Connection : 1

## list database objects, should display the newly created table
> db.objects( search = "public." )
[1] "public.abalone_from_r"
```

## Running R Functions in Greenplum Database

GreenplumR supports two functions that allow you to run an R function, in-database, on every row of a Greenplum Database table: `db.gpapply()` and `db.gptapply()`. You can use the Greenplum PL/R or PL/Container procedural language as the vehicle in which to run the function.

The function signatures follow:

```
db.gpapply( X, MARGIN = NULL, FUN = NULL, output.name = NULL, output.signature = NULL,
            clear.existing = FALSE, case.sensitive = FALSE, output.distributeOn = NUL
```

```
L,
        debugger.mode = FALSE, runtime.id = "plc_r_shared", language = "plcontainer",
input.signature = NULL, ... )

db.gptapply( X, INDEX, FUN = NULL, output.name = NULL, output.signature = NULL,
            clear.existing = FALSE, case.sensitive = FALSE,
            output.distributeOn = NULL, debugger.mode = FALSE,
            runtime.id = "plc_r_shared", language = "plcontainer",
            input.signature = NULL, ... )
```

Use the second variant of the function when the table data is indexed.

By default, `db.gp[t]apply()` passes a single data frame input argument to the R function `FUN`. If you define `FUN` to take a list of arguments, you must specify the function argument name to Greenplum table column name mapping in `input.signature`. You must specify this mapping in table column order.

### Example 1:

Create a Greenplum table named `table1` in the database named `testdb`. This table has a single integer-type field. Populate the table with some data:

```
user@clientsys$ psql -h gpmaster -d testdb
testdb=# CREATE TABLE table1( id int );
testdb=# INSERT INTO table1 SELECT generate_series(1,13);
testdb=# \q
```

Create an R function that increments an integer. Run the function on `table1` in Greenplum using the PL/R procedural language. Then write the new values to a table named `table1_r_inc`:

```
user@clientsys$ R
> ## create a reference to table1
> t1 <- db.data.frame("public.table1")

> ## create an R function that increment an integer by 1
> fn.function_plus_one <- function(num)
{
  return (num[[1]] + 1)
}

> ## create the function output signature
> .sig <- list( "num" = "int" )

> ## run the function in Greenplum and print
> x <- db.gpapply( t1, output.name = NULL, FUN = fn.function_plus_one,
  output.signature = .sig, clear.existing = TRUE, case.sensitive = TRUE, language = "plr" )
> print(x)
  num
1   2
2   6
3  12
4  13
5   3
6   4
7   5
8   7
```

```

9      8
10     9
11    10
12    11
13    14

> ## run the function in Greenplum and write to the output table
> db.gpapply(t1, output.name = "public.table1_r_inc", FUN = fn.function_plus_one,
  output.signature = .sig, clear.existing = TRUE, case.sensitive = TRUE,
  language = "plr" )

## list database objects, should display the newly created table
> db.objects( search = "public.")
[1] "public.abalone_from_r"          "public.table1_r_inc"

```

**Example 2:**

Create a Greenplum table named `table2` in the database named `testdb`. This table has two integer-type fields. Populate the table with some data:

```

user@clientsys$ psql -h gpmaster -d testdb
testdb=# CREATE TABLE table2( c1 int, c2 int );
testdb=# INSERT INTO table2 VALUES (1, 2);
testdb=#\q

```

Create an R function that takes two integer arguments, manipulates the arguments, and returns both. Run the function on the data in `table2` in Greenplum using the PL/R procedural language, writing the new values to a table named `table2_r_upd`:

```

user@clientsys$ R
> ## create a reference to table2
> t2 <- db.data.frame("public.table2")

> ## create the R function
> fn.func_with_two_args <- function(a, b)
{
  a <- a * 20
  b <- a + 66
  c <- list(a, b)
  return (as.data.frame(c))
}

> ## create the function input signature, mapping function argument name to
> ## table column name
> input.sig <- list('a' = 'c1', 'b' = 'c2')

> ## create the function output signature
> return.sig <- list('a' = 'int', 'b' = 'int')

> ## run the function in Greenplum and write to the output table
> db.gpapply(t2, output.name = "public.table2_r_upd", FUN = fn.func_with_two_args,
  output.signature = return.sig, clear.existing = TRUE, case.sensitive = TRUE,
  language = "plr", input.signature = input.sig )

```

View the contents of the Greenplum table named `table2_r_upd`:

```

user@clientsys$ psql -h gpmaster -d testdb
testdb=# SELECT * FROM table2_r_upd;
 a | b
----+----
 20 | 86
(1 row)
testdb=# \q

```

## Limitations

GreenplumR has the following limitations:

- The `db.gpapply()` and `db.gptapply()` functions currently operate only on `conn.id = 1`.
- The GreenplumR function reference pages are not yet published. You can find `html` versions of the reference pages in your R library `R/<platform>-library/3.6/GreenplumR/html` directory. Open the `00Index.html` file in the browser of your choice and select the function of interest.
- The `GreenplumR()` graphical user interface is currently unsupported.

## Function Summary

GreenplumR provides several functions. To obtain reference information for GreenplumR functions while running the R console, invoke the `help()` function. For example, to display the reference information for the GreenplumR `db.data.frame()` function:

```
> help( db.data.frame )
```

GreenplumR functions include:

Table 2. GreenplumR Functions

| Category               | Name   | Description  |
|------------------------|--|--|
| Aggregate Functions    | <code>mean()</code> , <code>sum()</code> ,<br><code>count()</code> , <code>max()</code> ,<br><code>min()</code> , <code>sd()</code> ,<br><code>var()</code> ,<br><code>colMeans()</code> ,<br><code>colSums()</code> ,<br><code>colAgg()</code> ,<br><code>db.array()</code> | Functions that perform a calculation on multiple values and return a single value. |
| Connectivity Functions | <code>connection info</code>   | Extract connection information.  |
|                        | <code>db.connect()</code>  | Create a database connection.  |
|                        | <code>db.connect.dsn()</code>  | Create a database connection using a DSN.  |
|                        | <code>db.disconnect()</code>   | Disconnect a database connection.  |
|                        | <code>db.list()</code>   | List database connections.   |

| Category                  | Name  | Description   |
|---------------------------|---|---|
| Database Object Functions | as.db.data.frame()  | Create a db.data.frame from a file or data.frame, optionally writing the data to a Greenplum table.     |
|                           | db.data.frame()   | Create a data frame that references a view or table in the database.                                    |
|                           | db.objects()  | List the table and view objects in the database.  |
|                           | db.existsObject()   | Identifies whether a table or view exists in the database.  |
| Mathematical Functions    | exp(), abs(), log(), log10(), sign(), sqrt(), factorial(), sin(), cos(), tan(), asin(), acos(), atan(), atan2() | Mathematical functions that take db.obj as an argument.   |
| Greenplum Functions       | db.gpapply()  | Wrap an R function with a UDF and run it on every row of data in a Greenplum table.                     |
|                           | db.gptapply()   | Wrap an R function with a UDF and run it on every row of data grouped by an index in a Greenplum table. |

## Inserting, Updating, and Deleting Data

This section provides information about manipulating data and concurrent access in Greenplum Database.

This topic includes the following subtopics:

- [About Concurrency Control in Greenplum Database](#)
- [Inserting Rows](#)
- [Updating Existing Rows](#)
- [Deleting Rows](#)
- [Working With Transactions](#)
- [Global Deadlock Detector](#)
- [Vacuuming the Database](#)
- [Running Out of Locks](#)

**Parent topic:** [Greenplum Database Administrator Guide](#)

### About Concurrency Control in Greenplum Database

Greenplum Database and PostgreSQL do not use locks for concurrency control. They maintain data consistency using a multiversion model, Multiversion Concurrency Control (MVCC). MVCC achieves transaction isolation for each database session, and each query transaction sees a snapshot of data. This ensures the transaction sees consistent data that is not affected by other concurrent transactions.

Because MVCC does not use explicit locks for concurrency control, lock contention is minimized and Greenplum Database maintains reasonable performance in multiuser environments. Locks acquired for querying (reading) data do not conflict with locks acquired for writing data.

Greenplum Database provides multiple lock modes to control concurrent access to data in tables. Most Greenplum Database SQL commands automatically acquire the appropriate locks to ensure that referenced tables are not dropped or modified in incompatible ways while a command runs. For applications that cannot adapt easily to MVCC behavior, you can use the `LOCK` command to acquire explicit locks. However, proper use of MVCC generally provides better performance.

| Lock Mode                    | Associated SQL Commands   | Conflicts With  |
|------------------------------|---|---|
| ACCESS<br>SHARE              | <code>SELECT</code>   | ACCESS EXCLUSIVE  |
| ROW SHARE                    | <code>SELECT...FOR lock_strength</code>   | EXCLUSIVE, ACCESS EXCLUSIVE   |
| ROW<br>EXCLUSIVE             | <code>INSERT, COPY</code>   | SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE   |
| SHARE<br>UPDATE<br>EXCLUSIVE | <code>VACUUM (without FULL), ANALYZE</code>   | SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE   |
| SHARE                        | <code>CREATE INDEX</code>   | ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE                                 |
| SHARE ROW<br>EXCLUSIVE       |   | ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE                          |
| EXCLUSIVE                    | <code>DELETE, UPDATE, SELECT...FOR lock_strength, REFRESH MATERIALIZED VIEW CONCURRENTLY</code>                                 | ROW SHARE, ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE               |
| ACCESS<br>EXCLUSIVE          | <code>ALTER TABLE, DROP TABLE, TRUNCATE, REINDEX, CLUSTER, REFRESH MATERIALIZED VIEW (without CONCURRENTLY), VACUUM FULL</code> | ACCESS SHARE, ROW SHARE, ROW EXCLUSIVE, SHARE UPDATE EXCLUSIVE, SHARE, SHARE ROW EXCLUSIVE, EXCLUSIVE, ACCESS EXCLUSIVE |

**Note:** By default Greenplum Database acquires the more restrictive `EXCLUSIVE` lock (rather than `ROW EXCLUSIVE` in PostgreSQL) for `UPDATE`, `DELETE`, and `SELECT...FOR UPDATE` operations on heap tables. When the Global Deadlock Detector is enabled the lock mode for `UPDATE` and `DELETE` operations on heap tables is `ROW EXCLUSIVE`. See [Global Deadlock Detector](#). Greenplum always holds a table-level lock with `SELECT...FOR UPDATE` statements.

## Inserting Rows

Use the `INSERT` command to create rows in a table. This command requires the table name and a value for each column in the table; you may optionally specify the column names in any order. If you do not specify column names, list the data values in the order of the columns in the table, separated by commas.

For example, to specify the column names and the values to insert:

```
INSERT INTO products (name, price, product_no) VALUES ('Cheese', 9.99, 1);
```

To specify only the values to insert:

```
INSERT INTO products VALUES (1, 'Cheese', 9.99);
```

Usually, the data values are literals (constants), but you can also use scalar expressions. For example:

```
INSERT INTO films SELECT * FROM tmp_films WHERE date_prod <
'2016-05-07';
```

You can insert multiple rows in a single command. For example:

```
INSERT INTO products (product_no, name, price) VALUES
(1, 'Cheese', 9.99),
(2, 'Bread', 1.99),
(3, 'Milk', 2.99);
```

To insert data into a partitioned table, you specify the root partitioned table, the table created with the `CREATE TABLE` command. You also can specify a leaf child table of the partitioned table in an `INSERT` command. An error is returned if the data is not valid for the specified leaf child table. Specifying a child table that is not a leaf child table in the `INSERT` command is not supported.

To insert large amounts of data, use external tables or the `COPY` command. These load mechanisms are more efficient than `INSERT` for inserting large quantities of rows. See [Loading and Unloading Data](#) for more information about bulk data loading.

The storage model of append-optimized tables is optimized for bulk data loading. Greenplum does not recommend single row `INSERT` statements for append-optimized tables. For append-optimized tables, Greenplum Database supports a maximum of 127 concurrent `INSERT` transactions into a single append-optimized table.

## Updating Existing Rows

The `UPDATE` command updates rows in a table. You can update all rows, a subset of all rows, or individual rows in a table. You can update each column separately without affecting other columns.

To perform an update, you need:

- The name of the table and columns to update
- The new values of the columns
- One or more conditions specifying the row or rows to be updated.

For example, the following command updates all products that have a price of 5 to have a price of 10:

```
UPDATE products SET price = 10 WHERE price = 5;
```

Using `UPDATE` in Greenplum Database has the following restrictions:

- While GPORCA supports updates to Greenplum distribution key columns, the Postgres Planner does not.
- If mirrors are enabled, you cannot use `STABLE` or `VOLATILE` functions in an `UPDATE` statement.
- Greenplum Database partitioning columns cannot be updated.

## Deleting Rows

The `DELETE` command deletes rows from a table. Specify a `WHERE` clause to delete rows that match certain criteria. If you do not specify a `WHERE` clause, all rows in the table are deleted. The result is a valid, but empty, table. For example, to remove all rows from the products table that have a price of 10:

```
DELETE FROM products WHERE price = 10;
```

To delete all rows from a table:

```
DELETE FROM products;
```

Using `DELETE` in Greenplum Database has similar restrictions to using `UPDATE`:

- If mirrors are enabled, you cannot use `STABLE` or `VOLATILE` functions in an `UPDATE` statement.

## Truncating a Table

Use the `TRUNCATE` command to quickly remove all rows in a table. For example:

```
TRUNCATE mytable;
```

This command empties a table of all rows in one operation. Note that `TRUNCATE` does not scan the table, therefore it does not process inherited child tables or `ON DELETE` rewrite rules. The command truncates only rows in the named table.

## Working With Transactions

Transactions allow you to bundle multiple SQL statements in one all-or-nothing operation.

The following are the Greenplum Database SQL transaction commands:

- `BEGIN` or `START TRANSACTION` starts a transaction block.
- `END` or `COMMIT` commits the results of a transaction.
- `ROLLBACK` abandons a transaction without making any changes.
- `SAVEPOINT` marks a place in a transaction and enables partial rollback. You can roll back commands run after a savepoint while maintaining commands run before the savepoint.
- `ROLLBACK TO SAVEPOINT` rolls back a transaction to a savepoint.
- `RELEASE SAVEPOINT` destroys a savepoint within a transaction.

## Transaction Isolation Levels

Greenplum Database accepts the standard SQL transaction levels as follows:

- `READ UNCOMMITTED` and `READ COMMITTED` behave like the standard `READ COMMITTED`.
- `REPEATABLE READ` and `SERIALIZABLE` behave like `REPEATABLE READ`.

The following information describes the behavior of the Greenplum transaction levels.

### Read Uncommitted and Read Committed

Greenplum Database does not allow any command to see an uncommitted update in another concurrent transaction, so `READ UNCOMMITTED` behaves the same as `READ COMMITTED`. `READ COMMITTED` provides fast, simple, partial transaction isolation. `SELECT`, `UPDATE`, and `DELETE` commands operate on a snapshot of the database taken when the query started.

A `SELECT` query:

- Sees data committed before the query starts.
- Sees updates run within the transaction.
- Does not see uncommitted data outside the transaction.
- Can possibly see changes that concurrent transactions made if the concurrent transaction is committed after the initial read in its own transaction.

Successive `SELECT` queries in the same transaction can see different data if other concurrent transactions commit changes between the successive queries. `UPDATE` and `DELETE` commands find only rows committed before the commands started.

`READ COMMITTED` transaction isolation allows concurrent transactions to modify or lock a row before `UPDATE` or `DELETE` find the row. `READ COMMITTED` transaction isolation may be inadequate for applications that perform complex queries and updates and require a consistent view of the database.

### Repeatable Read and Serializable

`SERIALIZABLE` transaction isolation, as defined by the SQL standard, ensures that transactions that run concurrently produce the same results as if they were run one after another. If you specify `SERIALIZABLE` Greenplum Database falls back to `REPEATABLE READ`. `REPEATABLE READ` transactions prevent dirty reads, non-repeatable reads, and phantom reads without expensive locking, but Greenplum Database does not detect all serializability interactions that can occur during concurrent transaction execution. Concurrent transactions should be examined to identify interactions that are not prevented by disallowing concurrent updates of the same data. You can prevent these interactions by using explicit table locks or by requiring the conflicting transactions to update a dummy row introduced to represent the conflict.

With `REPEATABLE READ` transactions, a `SELECT` query:

- Sees a snapshot of the data as of the start of the transaction (not as of the start of the current query within the transaction).
- Sees only data committed before the query starts.
- Sees updates run within the transaction.

- Does not see uncommitted data outside the transaction.
- Does not see changes that concurrent transactions make.
- Successive `SELECT` commands within a single transaction always see the same data.
- `UPDATE`, `DELETE`, `SELECT FOR UPDATE`, and `SELECT FOR SHARE` commands find only rows committed before the command started. If a concurrent transaction has updated, deleted, or locked a target row, the `REPEATABLE READ` transaction waits for the concurrent transaction to commit or roll back the change. If the concurrent transaction commits the change, the `REPEATABLE READ` transaction rolls back. If the concurrent transaction rolls back its change, the `REPEATABLE READ` transaction can commit its changes.

The default transaction isolation level in Greenplum Database is `READ COMMITTED`. To change the isolation level for a transaction, declare the isolation level when you `BEGIN` the transaction or use the `SET TRANSACTION` command after the transaction starts.

## Global Deadlock Detector

The Greenplum Database Global Deadlock Detector background worker process collects lock information on all segments and uses a directed algorithm to detect the existence of local and global deadlocks. This algorithm allows Greenplum Database to relax concurrent update and delete restrictions on heap tables. (Greenplum Database still employs table-level locking on AO/CO tables, restricting concurrent `UPDATE`, `DELETE`, and `SELECT...FOR lock_strength` operations.)

By default, the Global Deadlock Detector is deactivated and Greenplum Database runs the concurrent `UPDATE` and `DELETE` operations on a heap table serially. You can activate these concurrent updates and have the Global Deadlock Detector determine when a deadlock exists by setting the server configuration parameter `gp_enable_global_deadlock_detector`.

When the Global Deadlock Detector is enabled, the background worker process is automatically started on the master host when you start Greenplum Database. You configure the interval at which the Global Deadlock Detector collects and analyzes lock waiting data via the `gp_global_deadlock_detector_period` server configuration parameter.

If the Global Deadlock Detector determines that a deadlock exists, it breaks the deadlock by cancelling one or more backend processes associated with the youngest transaction(s) involved.

When the Global Deadlock Detector determines a deadlock exists for the following types of transactions, only one of the transactions will succeed. The other transactions will fail with an error indicating that concurrent updates to the same row is not allowed.

- Concurrent transactions on the same row of a heap table where the first transaction is an update operation and a later transaction runs an update or delete and the query plan contains a motion operator.
- Concurrent update transactions on the same distribution key of a heap table that are run by the Postgres Planner.
- Concurrent update transactions on the same row of a hash table that are run by the GPORCA optimizer.

**Note:** Greenplum Database uses the interval specified in the `deadlock_timeout` server configuration parameter for local deadlock detection. Because the local and global deadlock

detection algorithms differ, the cancelled process(es) may differ depending upon which detector (local or global) Greenplum Database triggers first.

**Note:** If the `lock_timeout` server configuration parameter is turned on and set to a value smaller than `deadlock_timeout` and `gp_global_deadlock_detector_period`, Greenplum Database will cancel a statement before it would ever trigger a deadlock check in that session.

To view lock waiting information for all segments, run the `gp_dist_wait_status()` user-defined function. You can use the output of this function to determine which transactions are waiting on locks, which transactions are holding locks, the lock types and mode, the waiter and holder session identifiers, and which segments are running the transactions. Sample output of the `gp_dist_wait_status()` function follows:

```
SELECT * FROM pg_catalog.gp_dist_wait_status();
-[ RECORD 1 ]-----+-----
segid          | 0
waiter_dxid    | 11
holder_dxid    | 12
holdTillEndXact | t
waiter_lpid    | 31249
holder_lpid    | 31458
waiter_lockmode | ShareLock
waiter_locktype | transactionid
waiter_sessionid | 8
holder_sessionid | 9
-[ RECORD 2 ]-----+-----
segid          | 1
waiter_dxid    | 12
holder_dxid    | 11
holdTillEndXact | t
waiter_lpid    | 31467
holder_lpid    | 31250
waiter_lockmode | ShareLock
waiter_locktype | transactionid
waiter_sessionid | 9
holder_sessionid | 8
```

When it cancels a transaction to break a deadlock, the Global Deadlock Detector reports the following error message:

```
ERROR: canceling statement due to user request: "cancelled by global deadlock detector"
```

## Global Deadlock Detector UPDATE and DELETE Compatibility

The Global Deadlock Detector can manage concurrent updates for these types of `UPDATE` and `DELETE` commands on heap tables:

- Simple `UPDATE` of a single table. Update a non-distribution key with the Postgres Planner. The command does not contain a `FROM` clause, or a sub-query in the `WHERE` clause.

```
UPDATE t SET c2 = c2 + 1 WHERE c1 > 10;
```

- Simple **DELETE** of a single table. The command does not contain a sub-query in the **FROM** or **WHERE** clauses.

```
DELETE FROM t WHERE c1 > 10;
```

- Split **UPDATE**. For the Postgres Planner, the **UPDATE** command updates a distribution key.

```
UPDATE t SET c = c + 1; -- c is a distribution key
```

For GPORCA, the **UPDATE** command updates a distribution key or references a distribution key.

```
UPDATE t SET b = b + 1 WHERE c = 10; -- c is a distribution key
```

- Complex **UPDATE**. The **UPDATE** command includes multiple table joins.

```
UPDATE t1 SET c = t1.c+1 FROM t2 WHERE t1.c = t2.c;
```

Or the command contains a sub-query in the **WHERE** clause.

```
UPDATE t SET c = c + 1 WHERE c > ALL(SELECT * FROM t1);
```

- Complex **DELETE**. A complex **DELETE** command is similar to a complex **UPDATE**, and involves multiple table joins or a sub-query.

```
DELETE FROM t USING t1 WHERE t.c > t1.c;
```

The following table shows the concurrent **UPDATE** or **DELETE** commands that are managed by the Global Deadlock Detector. For example, concurrent simple **UPDATE** commands on the same table row are managed by the Global Deadlock Detector. For a concurrent complex **UPDATE** and a simple **UPDATE**, only one **UPDATE** is performed, and an error is returned for the other **UPDATE**.

| Command               | Simple <b>UPDATE</b> | Simple <b>DELETE</b> | Split <b>UPDATE</b> | Complex <b>UPDATE</b> | Complex <b>DELETE</b> |
|-----------------------|----------------------|----------------------|---------------------|-----------------------|-----------------------|
| Simple <b>UPDATE</b>  | YES                  | YES                  | NO                  | NO                    | NO                    |
| Simple <b>DELETE</b>  | YES                  | YES                  | NO                  | YES                   | YES                   |
| Split <b>UPDATE</b>   | NO                   | NO                   | NO                  | NO                    | NO                    |
| Complex <b>UPDATE</b> | NO                   | YES                  | NO                  | NO                    | NO                    |
| Complex <b>DELETE</b> | NO                   | YES                  | NO                  | NO                    | YES                   |

## Vacuuming the Database

Deleted or updated data rows occupy physical space on disk even though new transactions cannot see them. Periodically running the **VACUUM** command removes these expired rows. For example:

```
VACUUM mytable;
```

The `VACUUM` command collects table-level statistics such as the number of rows and pages. Vacuum all tables after loading data, including append-optimized tables. For information about recommended routine vacuum operations, see [Routine Vacuum and Analyze](#).

**Important:** The `VACUUM`, `VACUUM FULL`, and `VACUUM ANALYZE` commands should be used to maintain the data in a Greenplum database especially if updates and deletes are frequently performed on your database data. See the `VACUUM` command in the *Greenplum Database Reference Guide* for information about using the command.

## Running Out of Locks

Greenplum Database can potentially run out of locks when a database operation accesses multiple tables in a single transaction. Backup and restore are examples of such operations.

When Greenplum Database runs out of locks, the error message that you may observe references a shared memory error:

```
... "WARNING","53200","out of shared memory",,,,,,"LOCK TABLE ...  
... "ERROR","53200","out of shared memory",,"You might need to increase max_locks_per_  
transaction.",,,,,,"LOCK TABLE ...
```

**Note:** "shared memory" in this context refers to the shared memory of the internal object: the lock slots. "Out of shared memory" does *not* refer to exhaustion of system- or Greenplum-level memory resources.

As the hint describes, consider increasing the `max_locks_per_transaction` server configuration parameter when you encounter this error.

# Managing a Greenplum System

This section describes basic system administration tasks performed by a Greenplum Database system administrator.

- **About the Greenplum Database Release Version Number**  
Greenplum Database version numbers and the way they change identify what has been modified from one Greenplum Database release to the next.
- **Starting and Stopping Greenplum Database**  
In a Greenplum Database DBMS, the database server instances (the master and all segments) are started or stopped across all of the hosts in the system in such a way that they can work together as a unified DBMS.
- **Accessing the Database**  
This topic describes the various client tools you can use to connect to Greenplum Database, and how to establish a database session.
- **Configuring the Greenplum Database System**  
Server configuration parameters affect the behavior of Greenplum Database.
- **Enabling Compression**  
You can configure Greenplum Database to use data compression with some database features and with some utilities.
- **Configuring Proxies for the Greenplum Interconnect**  
You can configure a Greenplum system to use proxies for interconnect communication to reduce the use of connections and ports during query processing.
- **Enabling High Availability and Data Consistency Features**  
The fault tolerance and the high-availability features of Greenplum Database can be configured.
- **Backing Up and Restoring Databases**  
This topic describes how to use Greenplum backup and restore features.
- **Expanding a Greenplum System**  
To scale up performance and storage capacity, expand your Greenplum Database system by adding hosts to the system. In general, adding nodes to a Greenplum cluster achieves a linear scaling of performance and storage capacity.
- **Migrating Data with gpcopy**  
You can use the `gpcopy` utility to transfer data between databases in different Greenplum Database clusters.
- **Monitoring a Greenplum System**  
You can monitor a Greenplum Database system using a variety of tools included with the system or available as add-ons.

- **Routine System Maintenance Tasks**

To keep a Greenplum Database system running efficiently, the database must be regularly cleared of expired data and the table statistics must be updated so that the query optimizer has accurate information.

- **Recommended Monitoring and Maintenance Tasks**

This section lists monitoring and maintenance activities recommended to ensure high availability and consistent performance of your Greenplum Database cluster.

**Parent topic:** [Greenplum Database Administrator Guide](#)

## About the Greenplum Database Release Version Number

Greenplum Database version numbers and the way they change identify what has been modified from one Greenplum Database release to the next.

A Greenplum Database release version number takes the format x.y.z, where:

- x identifies the Major version number
- y identifies the Minor version number
- z identifies the Patch version number

Greenplum Database releases that have the same Major release number are guaranteed to be backwards compatible. Greenplum Database increments the Major release number when the catalog changes or when incompatible feature changes or new features are introduced. Previously deprecated functionality may be removed in a major release.

The Minor release number for a given Major release increments when backwards compatible new features are introduced or when a Greenplum Database feature is deprecated. (Previously deprecated functionality will never be removed in a minor release.)

Greenplum Database increments the Patch release number for a given Minor release for backwards-compatible bug fixes.

**Parent topic:** [Managing a Greenplum System](#)

## Starting and Stopping Greenplum Database

In a Greenplum Database DBMS, the database server instances (the master and all segments) are started or stopped across all of the hosts in the system in such a way that they can work together as a unified DBMS.

Because a Greenplum Database system is distributed across many machines, the process for starting and stopping a Greenplum Database system is different than the process for starting and stopping a regular PostgreSQL DBMS.

Use the `gpstart` and `gpstop` utilities to start and stop Greenplum Database, respectively. These utilities are located in the `$GPHOME/bin` directory on your Greenplum Database master host.

**Important:** Do not issue a `kill` command to end any Postgres process. Instead, use the database command `pg_cancel_backend()`.

Issuing a `kill -9` or `kill -11` can introduce database corruption and prevent root cause analysis from being performed.

For information about `gpstart` and `gpstop`, see the *Greenplum Database Utility Guide*.

**Parent topic:** [Managing a Greenplum System](#)

## Starting Greenplum Database

Start an initialized Greenplum Database system by running the `gpstart` utility on the master instance.

Use the `gpstart` utility to start a Greenplum Database system that has already been initialized by the `gpinitssystem` utility, but has been stopped by the `gpstop` utility. The `gpstart` utility starts Greenplum Database by starting all the Postgres database instances on the Greenplum Database cluster. `gpstart` orchestrates this process and performs the process in parallel.

Run `gpstart` on the master host to start Greenplum Database:

```
$ gpstart
```

## Restarting Greenplum Database

Stop the Greenplum Database system and then restart it.

The `gpstop` utility with the `-r` option can stop and then restart Greenplum Database after the shutdown completes.

To restart Greenplum Database, enter the following command on the master host:

```
$ gpstop -r
```

## Reloading Configuration File Changes Only

Reload changes to Greenplum Database configuration files without interrupting the system.

The `gpstop` utility can reload changes to the `pg_hba.conf` configuration file and to *runtime* parameters in the master `postgresql.conf` file without service interruption. Active sessions pick up changes when they reconnect to the database. Many server configuration parameters require a full system restart (`gpstop -r`) to activate. For information about server configuration parameters, see the *Greenplum Database Reference Guide*.

Reload configuration file changes without shutting down the Greenplum Database system using the `gpstop` utility:

```
$ gpstop -u
```

## Starting the Master in Maintenance Mode

Start only the master to perform maintenance or administrative tasks without affecting data on the segments.

Maintenance mode should only be used with direction from VMware Technical Support. For example, you could connect to a database only on the master instance in maintenance mode and

edit system catalog settings. For more information about system catalog tables, see the *Greenplum Database Reference Guide*.

1. Run `gpstart` using the `-m` option:

```
$ gpstart -m
```

2. Connect to the master in maintenance mode to do catalog maintenance. For example:

```
$ PGOPTIONS='-c gp_role=utility' psql postgres
```

3. After completing your administrative tasks, stop the master in maintenance mode. Then, restart it in production mode.

```
$ gpstop -m
$ gpstart
```

**Warning:**

Incorrect use of maintenance mode connections can result in an inconsistent system state. Only Technical Support should perform this operation.

## Stopping Greenplum Database

The `gpstop` utility stops or restarts your Greenplum Database system and always runs on the master host. When activated, `gpstop` stops all `postgres` processes in the system, including the master and all segment instances. The `gpstop` utility uses a default of up to 64 parallel worker threads to bring down the Postgres instances that make up the Greenplum Database cluster. The system waits for any active transactions to finish before shutting down. If after two minutes there are still active connections, `gpstop` will prompt you to either continue waiting in smart mode, stop in fast mode, or stop in immediate mode. To stop Greenplum Database immediately, use fast mode.

**Important:** Immediate shut down mode is not recommended. This mode stops all database processes without allowing the database server to complete transaction processing or clean up any temporary or in-process work files.

- To stop Greenplum Database:

```
$ gpstop
```

- To stop Greenplum Database in fast mode:

```
$ gpstop -M fast
```

By default, you are not allowed to shut down Greenplum Database if there are any client connections to the database. Use the `-M fast` option to roll back all in progress transactions and terminate any connections before shutting down.

## Stopping Client Processes

Greenplum Database launches a new backend process for each client connection. A Greenplum Database user with `SUPERUSER` privileges can cancel and terminate these client backend processes.

Canceling a backend process with the `pg_cancel_backend()` function ends a specific queued or active client query. Terminating a backend process with the `pg_terminate_backend()` function terminates a client connection to a database.

The `pg_cancel_backend()` function has two signatures:

- `pg_cancel_backend( pid int4 )`
- `pg_cancel_backend( pid int4, msg text )`

The `pg_terminate_backend()` function has two similar signatures:

- `pg_terminate_backend( pid int4 )`
- `pg_terminate_backend( pid int4, msg text )`

If you provide a `msg`, Greenplum Database includes the text in the cancel message returned to the client. `msg` is limited to 128 bytes; Greenplum Database truncates anything longer.

The `pg_cancel_backend()` and `pg_terminate_backend()` functions return `true` if successful, and `false` otherwise.

To cancel or terminate a backend process, you must first identify the process ID of the backend. You can obtain the process ID from the `pid` column of the `pg_stat_activity` view. For example, to view the process information associated with all running and queued queries:

```
=# SELECT username, pid, waiting, state, query, datname
   FROM pg_stat_activity;
```

Sample partial query output:

| username | pid   | waiting | state  | query                  | datname |
|----------|-------|---------|--------|------------------------|---------|
| sammy    | 31861 | f       | idle   | SELECT * FROM testtbl; | testdb  |
| billy    | 31905 | t       | active | SELECT * FROM topten;  | testdb  |

Use the output to identify the process id (`pid`) of the query or client connection.

For example, to cancel the waiting query identified in the sample output above and include `'Admin canceled long-running query.'` as the message returned to the client:

```
=# SELECT pg_cancel_backend(31905 , 'Admin canceled long-running query. ');
ERROR: canceling statement due to user request: "Admin canceled long-running query."
```

## Managing Greenplum Database Access

Securing Greenplum Database includes protecting access to the database through network configuration, database user authentication, and encryption.

- **Configuring Client Authentication**  
This topic explains how to configure client connections and authentication for Greenplum Database.
- **Managing Roles and Privileges**  
The Greenplum Database authorization mechanism stores roles and permissions to access

database objects in the database and is administered using SQL statements or command-line utilities.

**Parent topic:** [Greenplum Database Administrator Guide](#)

## Configuring Client Authentication

This topic explains how to configure client connections and authentication for Greenplum Database.

When a Greenplum Database system is first initialized, the system contains one predefined *superuser* role. This role will have the same name as the operating system user who initialized the Greenplum Database system. This role is referred to as `gpadmin`. By default, the system is configured to only allow local connections to the database from the `gpadmin` role. If you want to allow any other roles to connect, or if you want to allow connections from remote hosts, you have to configure Greenplum Database to allow such connections. This section explains how to configure client connections and authentication to Greenplum Database.

- **Using LDAP Authentication with TLS/SSL**  
You can control access to Greenplum Database with an LDAP server and, optionally, secure the connection with encryption by adding parameters to `pg_hba.conf` file entries.
- **Using Kerberos Authentication**  
You can control access to Greenplum Database with a Kerberos authentication server.
- **Configuring Kerberos for Linux Clients**  
You can configure Linux client applications to connect to a Greenplum Database system that is configured to authenticate with Kerberos.
- **Configuring Kerberos For Windows Clients**  
You can configure Microsoft Windows client applications to connect to a Greenplum Database system that is configured to authenticate with Kerberos.

**Parent topic:** [Managing Greenplum Database Access](#)

## Allowing Connections to Greenplum Database

Client access and authentication is controlled by the standard PostgreSQL host-based authentication file, `pg_hba.conf`. For detailed information about this file, see [The `pg\_hba.conf` File](#) in the PostgreSQL documentation.

In Greenplum Database, the `pg_hba.conf` file of the master instance controls client access and authentication to your Greenplum Database system. The Greenplum Database segments also have `pg_hba.conf` files, but these are already correctly configured to allow only client connections from the master host. The segments never accept outside client connections, so there is no need to alter the `pg_hba.conf` file on segments.

The general format of the `pg_hba.conf` file is a set of records, one per line. Greenplum Database ignores blank lines and any text after the `#` comment character. A record consists of a number of fields that are separated by spaces or tabs. Fields can contain white space if the field value is quoted. Records cannot be continued across lines. Each remote client access record has the following format:

```
host database role address authentication-method
```

Each UNIX-domain socket access record is in this format:

```
local database role authentication-method
```

The following table describes meaning of each field.

Table 1. pg\_hba.conf Fields

| Field     | Description  |
|-----------|--|
| local     | Matches connection attempts using UNIX-domain sockets. Without a record of this type, UNIX-domain socket connections are disallowed.   |
| host      | Matches connection attempts made using TCP/IP. Remote TCP/IP connections will not be possible unless the server is started with an appropriate value for the <code>listen_addresses</code> server configuration parameter.   |
| hostssl   | Matches connection attempts made using TCP/IP, but only when the connection is made with SSL encryption. SSL must be enabled at server start time by setting the <code>ssl</code> server configuration parameter.  |
| hostnossl | Matches connection attempts made over TCP/IP that do not use SSL.  |
| database  | Specifies which database names this record matches. The value <code>all</code> specifies that it matches all databases. Multiple database names can be supplied by separating them with commas. A separate file containing database names can be specified by preceding the file name with a <code>@</code> .  |
| role      | Specifies which database role names this record matches. The value <code>all</code> specifies that it matches all roles. If the specified role is a group and you want all members of that group to be included, precede the role name with a <code>+</code> . Multiple role names can be supplied by separating them with commas. A separate file containing role names can be specified by preceding the file name with a <code>@</code> . |

| Field                 | Description   |
|-----------------------|---|
| address               | <p>Specifies the client machine addresses that this record matches. This field can contain an IP address, an IP address range, or a host name.</p> <p>An IP address range is specified using standard numeric notation for the range's starting address, then a slash (/) and a CIDR mask length. The mask length indicates the number of high-order bits of the client IP address that must match. Bits to the right of this should be zero in the given IP address. There must not be any white space between the IP address, the /, and the CIDR mask length.</p> <p>Typical examples of an IPv4 address range specified this way are <code>172.20.143.89/32</code> for a single host, or <code>172.20.143.0/24</code> for a small network, or <code>10.6.0.0/16</code> for a larger one. An IPv6 address range might look like <code>::1/128</code> for a single host (in this case the IPv6 loopback address) or <code>fe80::7a31:c1ff:0000:0000/96</code> for a small network. <code>0.0.0.0/0</code> represents all IPv4 addresses, and <code>::0/0</code> represents all IPv6 addresses. To specify a single host, use a mask length of 32 for IPv4 or 128 for IPv6. In a network address, do not omit trailing zeroes.</p> <p>An entry given in IPv4 format will match only IPv4 connections, and an entry given in IPv6 format will match only IPv6 connections, even if the represented address is in the IPv4-in-IPv6 range.</p> <div style="border: 1px solid #ccc; padding: 10px; margin: 10px 0;">  <p><b>Note:</b></p> <p>Entries in IPv6 format will be rejected if the host system C library does not have support for IPv6 addresses.</p> </div> <p>If a host name is specified (an address that is not an IP address or IP range is treated as a host name), that name is compared with the result of a reverse name resolution of the client IP address (for example, reverse DNS lookup, if DNS is used). Host name comparisons are case insensitive. If there is a match, then a forward name resolution (for example, forward DNS lookup) is performed on the host name to check whether any of the addresses it resolves to are equal to the client IP address. If both directions match, then the entry is considered to match.</p> <p>Some host name databases allow associating an IP address with multiple host names, but the operating system only returns one host name when asked to resolve an IP address. The host name that is used in <code>pg_hba.conf</code> must be the one that the address-to-name resolution of the client IP address returns, otherwise the line will not be considered a match.</p> <p>When host names are specified in <code>pg_hba.conf</code>, you should ensure that name resolution is reasonably fast. It can be of advantage to set up a local name resolution cache such as <code>nscd</code>. Also, you can enable the server configuration parameter <code>log_hostname</code> to see the client host name instead of the IP address in the log.</p> |
| IP-address<br>IP-mask | <p>These fields can be used as an alternative to the CIDR address notation. Instead of specifying the mask length, the actual mask is specified in a separate column. For example, <code>255.0.0.0</code> represents an IPv4 CIDR mask length of 8, and <code>255.255.255.255</code> represents a CIDR mask length of 32.</p>   |
| authentication-method | <p>Specifies the authentication method to use when connecting. Greenplum supports the <a href="#">authentication methods</a> supported by PostgreSQL 9.4.</p>   |

**CAUTION:** For a more secure system, consider removing records for remote connections that use trust authentication from the `pg_hba.conf` file. Trust authentication grants any user who can connect to the server access to the database using any role they specify. You can safely replace trust authentication with ident authentication for local UNIX-socket connections. You can also use

ident authentication for local and remote TCP clients, but the client host must be running an ident service and you must trust the integrity of that machine.

## Editing the `pg_hba.conf` File

Initially, the `pg_hba.conf` file is set up with generous permissions for the `gpadmin` user and no database access for other Greenplum Database roles. You will need to edit the `pg_hba.conf` file to enable users' access to databases and to secure the `gpadmin` user. Consider removing entries that have trust authentication, since they allow anyone with access to the server to connect with any role they choose. For local (UNIX socket) connections, use ident authentication, which requires the operating system user to match the role specified. For local and remote TCP connections, ident authentication requires the client's host to run an indent service. You can install an ident service on the master host and then use ident authentication for local TCP connections, for example `127.0.0.1/28`. Using ident authentication for remote TCP connections is less secure because it requires you to trust the integrity of the ident service on the client's host.

This example shows how to edit the `pg_hba.conf` file of the master to allow remote client access to all databases from all roles using encrypted password authentication.

### Editing `pg_hba.conf`

1. Open the file `$MASTER_DATA_DIRECTORY/pg_hba.conf` in a text editor.
2. Add a line to the file for each type of connection you want to allow. Records are read sequentially, so the order of the records is significant. Typically, earlier records will have tight connection match parameters and weaker authentication methods, while later records will have looser match parameters and stronger authentication methods. For example:

```
# allow the gpadmin user local access to all databases
# using ident authentication
local  all  gpadmin  ident          sameuser
host   all  gpadmin  127.0.0.1/32  ident
host   all  gpadmin  ::1/128       ident
# allow the 'dba' role access to any database from any
# host with IP address 192.168.x.x and use md5 encrypted
# passwords to authenticate the user
# Note that to use SHA-256 encryption, replace md5 with
# password in the line below
host   all  dba    192.168.0.0/32  md5
# allow all roles access to any database from any
# host and use ldap to authenticate the user. Greenplum role
# names must match the LDAP common name.
host   all  all    192.168.0.0/32  ldap ldapserver=usldap1 ldapport=1389 ldapp
refix="cn=" ldapsuffix=",ou=People,dc=company,dc=com"
```

3. Save and close the file.
4. Reload the `pg_hba.conf` configuration file for your changes to take effect:

```
$ gpstop -u
```

**Note:** Note that you can also control database access by setting object privileges as described in [Managing Object Privileges](#). The `pg_hba.conf` file just controls who can initiate a database session

and how those connections are authenticated.

## Limiting Concurrent Connections

Greenplum Database allocates some resources on a per-connection basis, so setting the maximum number of connections allowed is recommended.

To limit the number of active concurrent sessions to your Greenplum Database system, you can configure the `max_connections` server configuration parameter. This is a *local* parameter, meaning that you must set it in the `postgresql.conf` file of the master, the standby master, and each segment instance (primary and mirror). The recommended value of `max_connections` on segments is 5-10 times the value on the master.

When you set `max_connections`, you must also set the dependent parameter `max_prepared_transactions`. This value must be at least as large as the value of `max_connections` on the master, and segment instances should be set to the same value as the master.

For example:

- In `$MASTER_DATA_DIRECTORY/postgresql.conf` (including standby master):

```
max_connections=100
max_prepared_transactions=100
```

- In `SEGMENT_DATA_DIRECTORY/postgresql.conf` for all segment instances:

```
max_connections=500
max_prepared_transactions=100
```

The following steps set the parameter values with the Greenplum Database utility `gpconfig`.

For information about `gpconfig`, see the *Greenplum Database Utility Guide*.

### To change the number of allowed connections

1. Log into the Greenplum Database master host as the Greenplum Database administrator and source the file `$GPHOME/greenplum_path.sh`.
2. Set the value of the `max_connections` parameter. This `gpconfig` command sets the value on the segments to 1000 and the value on the master to 200.

```
$ gpconfig -c max_connections -v 1000 -m 200
```

The value on the segments must be greater than the value on the master. The recommended value of `max_connections` on segments is 5-10 times the value on the master.

3. Set the value of the `max_prepared_transactions` parameter. This `gpconfig` command sets the value to 200 on the master and all segments.

```
$ gpconfig -c max_prepared_transactions -v 200
```

The value of `max_prepared_transactions` must be greater than or equal to `max_connections` on the master.

4. Stop and restart your Greenplum Database system.

```
$ gpstop -r
```

5. You can check the value of parameters on the master and segments with the `gpconfig -s` option. This `gpconfig` command displays the values of the `max_connections` parameter.

```
$ gpconfig -s max_connections
```

**Note:** Raising the values of these parameters may cause Greenplum Database to request more shared memory. To mitigate this effect, consider decreasing other memory-related parameters such as `gp_cached_segworkers_threshold`.

## Encrypting Client/Server Connections

Enable SSL for client connections to Greenplum Database to encrypt the data passed over the network between the client and the database.

Greenplum Database has native support for SSL connections between the client and the master server. SSL connections prevent third parties from snooping on the packets, and also prevent man-in-the-middle attacks. SSL should be used whenever the client connection goes through an insecure link, and must be used whenever client certificate authentication is used.

Enabling Greenplum Database in SSL mode requires the following items.

- OpenSSL installed on both the client and the master server hosts (master and standby master).
- The SSL files `server.key` (server private key) and `server.crt` (server certificate) should be correctly generated for the master host and standby master host.
  - The private key should not be protected with a passphrase. The server does not prompt for a passphrase for the private key, and Greenplum Database start up fails with an error if one is required.
  - On a production system, there should be a key and certificate pair for the master host and a pair for the standby master host with a subject CN (Common Name) for the master host and standby master host. A self-signed certificate can be used for testing, but a certificate signed by a certificate authority (CA) should be used in production, so the client can verify the identity of the server. Either a global or local CA can be used. If all the clients are local to the organization, a local CA is recommended.
- Ensure that Greenplum Database can access `server.key` and `server.crt`, and any additional authentication files such as `root.crt` (for trusted certificate authorities). When starting in

SSL mode, the Greenplum Database master looks for `server.key` and `server.crt`. As the default, Greenplum Database does not start if the files are not in the master data directory (`$MASTER_DATA_DIRECTORY`). Also, if you use other SSL authentication files such as `root.crt` (trusted certificate authorities), the files must be on the master host.

If Greenplum Database master mirroring is enabled with SSL client authentication, SSL authentication files must be on both the master host and standby master host and *should not be placed* in the default directory `$MASTER_DATA_DIRECTORY`. When master mirroring is enabled, an `initstandby` operation copies the contents of the `$MASTER_DATA_DIRECTORY` from the master to the standby master and the incorrect SSL key, and cert files (the master files, and not the standby master files) will prevent standby master start up.

You can specify a different directory for the location of the SSL server files with the `postgresql.conf` parameters `sslcert`, `sslkey`, `sslrootcert`, and `sslcr1`. For more information about the parameters, see [SSL Client Authentication](#) in the *Security Configuration Guide*.

Greenplum Database can be started with SSL enabled by setting the server configuration parameter `ssl=on` in the `postgresql.conf` file on the master and standby master hosts. This `gpconfig` command sets the parameter:

```
gpconfig -c ssl -m on -v off
```

Setting the parameter requires a server restart. This command restarts the system: `gpstop -ra`.

## Creating a Self-signed Certificate without a Passphrase for Testing Only

To create a quick self-signed certificate for the server for testing, use the following OpenSSL command:

```
# openssl req -new -text -out server.req
```

Enter the information requested by the prompts. Be sure to enter the local host name as *Common Name*. The challenge password can be left blank.

The program will generate a key that is passphrase protected, and does not accept a passphrase that is less than four characters long.

To use this certificate with Greenplum Database, remove the passphrase with the following commands:

```
# openssl rsa -in privkey.pem -out server.key
# rm privkey.pem
```

Enter the old passphrase when prompted to unlock the existing key.

Then, enter the following command to turn the certificate into a self-signed certificate and to copy the key and certificate to a location where the server will look for them.

```
# openssl req -x509 -in server.req -text -key server.key -out server.crt
```

Finally, change the permissions on the key with the following command. The server will reject the file if the permissions are less restrictive than these.

```
# chmod og-rwx server.key
```

For more details on how to create your server private key and certificate, refer to the [OpenSSL documentation](#).

## Using LDAP Authentication with TLS/SSL

You can control access to Greenplum Database with an LDAP server and, optionally, secure the connection with encryption by adding parameters to `pg_hba.conf` file entries.

Greenplum Database supports LDAP authentication with the TLS/SSL protocol to encrypt communication with an LDAP server:

- LDAP authentication with STARTTLS and TLS protocol – STARTTLS starts with a clear text connection (no encryption) and upgrades it to a secure connection (with encryption).
- LDAP authentication with a secure connection and TLS/SSL (LDAPS) – Greenplum Database uses the TLS or SSL protocol based on the protocol that is used by the LDAP server.

If no protocol is specified, Greenplum Database communicates with the LDAP server with a clear text connection.

To use LDAP authentication, the Greenplum Database master host must be configured as an LDAP client. See your LDAP documentation for information about configuring LDAP clients.

## Enabling LDAP Authentication with STARTTLS and TLS

To enable STARTTLS with the TLS protocol, in the `pg_hba.conf` file, add an `ldap` line and specify the `ldaptls` parameter with the value 1. The default port is 389. In this example, the authentication method parameters include the `ldaptls` parameter.

```
ldap ldapserver=myldap.com ldaptls=1 ldapprefix="uid=" ldapsuffix=",ou=People,dc=example,dc=com"
```

Specify a non-default port with the `ldapport` parameter. In this example, the authentication method includes the `ldaptls` parameter and the `ldapport` parameter to specify the port 550.

```
ldap ldapserver=myldap.com ldaptls=1 ldapport=550 ldapprefix="uid=" ldapsuffix=",ou=People,dc=example,dc=com"
```

## Enabling LDAP Authentication with a Secure Connection and TLS/SSL

To enable a secure connection with TLS/SSL, add `ldaps://` as the prefix to the LDAP server name specified in the `ldapserver` parameter. The default port is 636.

This example `ldapserver` parameter specifies a secure connection and the TLS/SSL protocol for the LDAP server `myldap.com`.

```
ldapserver=ldaps://myldap.com
```

To specify a non-default port, add a colon (:) and the port number after the LDAP server name. This example `ldapserver` parameter includes the `ldaps://` prefix and the non-default port 550.

```
ldapserver=ldaps://myldap.com:550
```

## Configuring Authentication with a System-wide OpenLDAP System

If you have a system-wide OpenLDAP system and logins are configured to use LDAP with TLS or SSL in the `pg_hba.conf` file, logins may fail with the following message:

```
could not start LDAP TLS session: error code '-11'
```

To use an existing OpenLDAP system for authentication, Greenplum Database must be set up to use the LDAP server's CA certificate to validate user certificates. Follow these steps on both the master and standby hosts to configure Greenplum Database:

1. Copy the base64-encoded root CA chain file from the Active Directory or LDAP server to the Greenplum Database master and standby master hosts. This example uses the directory `/etc/pki/tls/certs`.
2. Change to the directory where you copied the CA certificate file and, as the root user, generate the hash for OpenLDAP:

```
# cd /etc/pki/tls/certs
# openssl x509 -noout -hash -in <ca-certificate-file>
# ln -s <ca-certificate-file> <ca-certificate-file>.0
```

3. Configure an OpenLDAP configuration file for Greenplum Database with the CA certificate directory and certificate file specified.

As the root user, edit the OpenLDAP configuration file `/etc/openldap/ldap.conf`:

```
SASL_NOCANON on
URI ldaps://ldapA.example.priv ldaps://ldapB.example.priv ldaps://ldapC.examp
le.priv
BASE dc=example,dc=priv
TLS_CACERTDIR /etc/pki/tls/certs
TLS_CACERT /etc/pki/tls/certs/<ca-certificate-file>
```

**Note:** For certificate validation to succeed, the hostname in the certificate must match a hostname in the URI property. Otherwise, you must also add `TLS_REQCERT allow` to the file.

4. As the `gpadmin` user, edit `/usr/local/greenplum-db/greenplum_path.sh` and add the following line.

```
export LDAPCONF=/etc/openldap/ldap.conf
```

## Notes

Greenplum Database logs an error if the following are specified in an `pg_hba.conf` file entry:

- If both the `ldaps://` prefix and the `ldaptls=1` parameter are specified.
- If both the `ldaps://` prefix and the `ldapport` parameter are specified.

Enabling encrypted communication for LDAP authentication only encrypts the communication between Greenplum Database and the LDAP server.

See [Encrypting Client/Server Connections](#) for information about encrypting client connections.

## Examples

These are example entries from an `pg_hba.conf` file.

This example specifies LDAP authentication with no encryption between Greenplum Database and the LDAP server.

```
host all plainuser 0.0.0.0/0 ldap ldapserver=myldap.com ldapprefix="uid=" ldapsuffix="",ou=People,dc=example,dc=com"
```

This example specifies LDAP authentication with the STARTTLS and TLS protocol between Greenplum Database and the LDAP server.

```
host all tlsuser 0.0.0.0/0 ldap ldapserver=myldap.com ldaptls=1 ldapprefix="uid=" ldapsuffix="",ou=People,dc=example,dc=com"
```

This example specifies LDAP authentication with a secure connection and TLS/SSL protocol between Greenplum Database and the LDAP server.

```
host all ldapsuser 0.0.0.0/0 ldap ldapserver=ldaps://myldap.com ldapprefix="uid=" ldapsuffix="",ou=People,dc=example,dc=com"
```

**Parent topic:** [Configuring Client Authentication](#)

## Using Kerberos Authentication

You can control access to Greenplum Database with a Kerberos authentication server.

Greenplum Database supports the Generic Security Service Application Program Interface (GSSAPI) with Kerberos authentication. GSSAPI provides automatic authentication (single sign-on) for systems that support it. You specify the Greenplum Database users (roles) that require Kerberos authentication in the Greenplum Database configuration file `pg_hba.conf`. The login fails if Kerberos authentication is not available when a role attempts to log in to Greenplum Database.

Kerberos provides a secure, encrypted authentication service. It does not encrypt data exchanged between the client and database and provides no authorization services. To encrypt data exchanged over the network, you must use an SSL connection. To manage authorization for access to Greenplum databases and objects such as schemas and tables, you use settings in the `pg_hba.conf` file and privileges given to Greenplum Database users and roles within the database. For information about managing authorization privileges, see [Managing Roles and Privileges](#).

For more information about Kerberos, see <http://web.mit.edu/kerberos/>.

## Prerequisites

Before configuring Kerberos authentication for Greenplum Database, ensure that:

- You can identify the KDC server you use for Kerberos authentication and the Kerberos realm for your Greenplum Database system. If you have not yet configured your MIT Kerberos KDC server, see [Installing and Configuring a Kerberos KDC Server](#) for example instructions.
- System time on the Kerberos Key Distribution Center (KDC) server and Greenplum Database master is synchronized. (For example, install the `ntp` package on both servers.)
- Network connectivity exists between the KDC server and the Greenplum Database master host.
- Java 1.7.0\_17 or later is installed on all Greenplum Database hosts. Java 1.7.0\_17 is required to use Kerberos-authenticated JDBC on Red Hat Enterprise Linux 6.x or 7.x.

## Procedure

Following are the tasks to complete to set up Kerberos authentication for Greenplum Database.

- [Creating Greenplum Database Principals in the KDC Database](#)
- [Installing the Kerberos Client on the Master Host](#)
- [Configuring Greenplum Database to use Kerberos Authentication](#)
- [Mapping Kerberos Principals to Greenplum Database Roles](#)
- [Configuring JDBC Kerberos Authentication for Greenplum Database](#)
- [Configuring Kerberos for Linux Clients](#)
- [Configuring Kerberos For Windows Clients](#)

**Parent topic:** [Configuring Client Authentication](#)

## Creating Greenplum Database Principals in the KDC Database

Create a service principal for the Greenplum Database service and a Kerberos admin principal that allows managing the KDC database as the `gadmin` user.

1. Log in to the Kerberos KDC server as the root user.

```
$ ssh root@<kdc-server>
```

2. Create a principal for the Greenplum Database service.

```
# kadmin.local -q "addprinc -randkey postgres/mdw@GPDB.KRB"
```

The `-randkey` option prevents the command from prompting for a password.

The `postgres` part of the principal names matches the value of the Greenplum Database `krb_srvname` server configuration parameter, which is `postgres` by default.

The host name part of the principal name must match the output of the `hostname` command on the Greenplum Database master host. If the `hostname` command shows the fully qualified domain name (FQDN), use it in the principal name, for example `postgres/mdw.example.com@GPDB.KRB`.

The `GPDB.KRB` part of the principal name is the Kerberos realm name.

3. Create a principal for the `gpadmin/admin` role.

```
# kadmin.local -q "addprinc gpadmin/admin@GPDB.KRB"
```

This principal allows you to manage the KDC database when you are logged in as `gpadmin`. Make sure that the Kerberos `kadm.acl` configuration file contains an ACL to grant permissions to this principal. For example, this ACL grants all permissions to any admin user in the `GPDB.KRB` realm.

```
*/admin@GPDB.KRB *
```

4. Create a keytab file with `kadmin.local`. The following example creates a keytab file `gpdb-kerberos.keytab` in the current directory with authentication information for the Greenplum Database service principal and the `gpadmin/admin` principal.

```
# kadmin.local -q "ktadd -k gpdb-kerberos.keytab postgres/mdw@GPDB.KRB gpadmin/admin@GPDB.KRB"
```

5. Copy the keytab file to the master host.

```
# scp gpdb-kerberos.keytab gpadmin@mdw:~
```

## Installing the Kerberos Client on the Master Host

Install the Kerberos client utilities and libraries on the Greenplum Database master.

1. Install the Kerberos packages on the Greenplum Database master.

```
$ sudo yum install krb5-libs krb5-workstation
```

2. Copy the `/etc/krb5.conf` file from the KDC server to `/etc/krb5.conf` on the Greenplum Master host.

## Configuring Greenplum Database to use Kerberos Authentication

Configure Greenplum Database to use Kerberos.

1. Log in to the Greenplum Database master host as the `gpadmin` user.

```
$ ssh gpadmin@<master>
```

```
$ source /usr/local/greenplum-db/greenplum_path.sh
```

2. Set the ownership and permissions of the keytab file you copied from the KDC server.

```
$ chown gpadmin:gpadmin /home/gpadmin/gpdb-kerberos.keytab
$ chmod 400 /home/gpadmin/gpdb-kerberos.keytab
```

3. Configure the location of the keytab file by setting the Greenplum Database `krb_server_keyfile` server configuration parameter. This `gpconfig` command specifies the folder `/home/gpadmin` as the location of the keytab file `gpdb-kerberos.keytab`.

```
$ gpconfig -c krb_server_keyfile -v '/home/gpadmin/gpdb-kerberos.keytab'
```

4. Modify the Greenplum Database file `pg_hba.conf` to enable Kerberos support. For example, adding the following line to `pg_hba.conf` adds GSSAPI and Kerberos authentication support for connection requests from all users and hosts on the same network to all Greenplum Database databases.

```
host all all 0.0.0.0/0 gss include_realm=0 krb_realm=GPDB.KRB
```

Setting the `krb_realm` option to a realm name ensures that only users from that realm can successfully authenticate with Kerberos. Setting the `include_realm` option to `0` excludes the realm name from the authenticated user name. For information about the `pg_hba.conf` file, see [The `pg\_hba.conf` file](#) in the PostgreSQL documentation.

5. Restart Greenplum Database after updating the `krb_server_keyfile` parameter and the `pg_hba.conf` file.

```
$ gpstop -ar
```

6. Create the `gpadmin/admin` Greenplum Database superuser role.

```
$ createuser gpadmin/admin --superuser
```

The Kerberos keys for this database role are in the keyfile you copied from the KDC server.

7. Create a ticket using `kinit` and show the tickets in the Kerberos ticket cache with `klist`.

```
$ LD_LIBRARY_PATH= kinit -k -t /home/gpadmin/gpdb-kerberos.keytab gpadmin/admin
@GPDB.KRB
$ LD_LIBRARY_PATH= klist
Ticket cache: FILE:/tmp/krb5cc_1000
Default principal: gpadmin/admin@GPDB.KRB
```

| Valid starting      | Expires             | Service principal        |
|---------------------|---------------------|--------------------------|
| 06/13/2018 17:37:35 | 06/14/2018 17:37:35 | krbtgt/GPDB.KRB@GPDB.KRB |

**Note:** When you set up the Greenplum Database environment by sourcing the `greenplum-db_path.sh` script, the `LD_LIBRARY_PATH` environment variable is set to include the Greenplum Database `lib` directory, which includes Kerberos libraries. This may cause Kerberos utility commands such as `kinit` and `klist` to fail due to version conflicts. The solution is to run Kerberos utilities before you source the `greenplum-db_path.sh` file or

temporarily unset the `LD_LIBRARY_PATH` variable when you run Kerberos utilities, as shown in the example.

- As a test, log in to the postgres database with the `gpadmin/admin` role:

```
$ psql -U "gpadmin/admin" -h mdw postgres
psql (9.4.20)
Type "help" for help.

postgres=# select current_user;
 current_user
-----
 gpadmin/admin
(1 row)
```

**Note:** When you start `psql` on the master host, you must include the `-h <master-hostname>` option to force a TCP connection because Kerberos authentication does not work with local connections.

If a Kerberos principal is not a Greenplum Database user, a message similar to the following is displayed from the `psql` command line when the user attempts to log in to the database:

```
psql: krb5_sendauth: Bad response
```

The principal must be added as a Greenplum Database user.

## Mapping Kerberos Principals to Greenplum Database Roles

To connect to a Greenplum Database system with Kerberos authentication enabled, a user first requests a ticket-granting ticket from the KDC server using the `kinit` utility with a password or a keytab file provided by the Kerberos admin. When the user then connects to the Kerberos-enabled Greenplum Database system, the user's Kerberos principle name will be the Greenplum Database role name, subject to transformations specified in the options field of the `gss` entry in the Greenplum Database `pg_hba.conf` file:

- If the `krb_realm=<realm>` option is present, Greenplum Database only accepts Kerberos principals who are members of the specified realm.
- If the `include_realm=0` option is specified, the Greenplum Database role name is the Kerberos principal name without the Kerberos realm. If the `include_realm=1` option is instead specified, the Kerberos realm is not stripped from the Greenplum Database rolename. The role must have been created with the Greenplum Database `CREATE ROLE` command.
- If the `map=<map-name>` option is specified, the Kerberos principal name is compared to entries labeled with the specified `<map-name>` in the `$MASTER_DATA_DIRECTORY/pg_ident.conf` file and replaced with the Greenplum Database role name specified in the first matching entry.

A user name map is defined in the `$MASTER_DATA_DIRECTORY/pg_ident.conf` configuration file. This example defines a map named `mymap` with two entries.

```
# MAPNAME      SYSTEM-USERNAME      GP-USERNAME
```

```
mymap      /^admin@GPDB.KRB$      gpadmin
mymap      /^(.*)_gp)@GPDB.KRB$  \1
```

The map name is specified in the `pg_hba.conf` Kerberos entry in the options field:

```
host all all 0.0.0.0/0 gss include_realm=0 krb_realm=GPDB.KRB map=mymap
```

The first map entry matches the Kerberos principal `admin@GPDB.KRB` and replaces it with the Greenplum Database `gpadmin` role name. The second entry uses a wildcard to match any Kerberos principal in the `GPDB-KRB` realm with a name ending with the characters `_gp` and replaces it with the initial portion of the principal name. Greenplum Database applies the first matching map entry in the `pg_ident.conf` file, so the order of entries is significant.

For more information about using username maps see [Username maps](#) in the PostgreSQL documentation.

## Configuring JDBC Kerberos Authentication for Greenplum Database

Enable Kerberos-authenticated JDBC access to Greenplum Database.

You can configure Greenplum Database to use Kerberos to run user-defined Java functions.

1. Ensure that Kerberos is installed and configured on the Greenplum Database master. See [Installing the Kerberos Client on the Master Host](#).
2. Create the file `.java.login.config` in the folder `/home/gpadmin` and add the following text to the file:

```
pgjdbc {
  com.sun.security.auth.module.Krb5LoginModule required
  doNotPrompt=true
  useTicketCache=true
  debug=true
  client=true;
};
```

3. Create a Java application that connects to Greenplum Database using Kerberos authentication. The following example database connection URL uses a PostgreSQL JDBC driver and specifies parameters for Kerberos authentication:

```
jdbc:postgresql://mdw:5432/mytest?kerberosServerName=postgres
&jaasApplicationName=pgjdbc&user=gpadmin/gpdb-kdc
```

The parameter names and values specified depend on how the Java application performs Kerberos authentication.

4. Test the Kerberos login by running a sample Java application from Greenplum Database.

## Installing and Configuring a Kerberos KDC Server

Steps to set up a Kerberos Key Distribution Center (KDC) server on a Red Hat Enterprise Linux host for use with Greenplum Database.

If you do not already have a KDC, follow these steps to install and configure a KDC server on a Red Hat Enterprise Linux host with a `GPDB.KRB` realm. The host name of the KDC server in this example is `gpdb-kdc`.

1. Install the Kerberos server and client packages:

```
$ sudo yum install krb5-libs krb5-server krb5-workstation
```

2. Edit the `/etc/krb5.conf` configuration file. The following example shows a Kerberos server configured with a default `GPDB.KRB` realm.

```
[logging]
default = FILE:/var/log/krb5libs.log
kdc = FILE:/var/log/krb5kdc.log
admin_server = FILE:/var/log/kadmind.log

[libdefaults]
default_realm = GPDB.KRB
dns_lookup_realm = false
dns_lookup_kdc = false
ticket_lifetime = 24h
renew_lifetime = 7d
forwardable = true
default_tgs_etypes = aes128-cts des3-hmac-sha1 des-cbc-crc des-cbc-md5
default_tkt_etypes = aes128-cts des3-hmac-sha1 des-cbc-crc des-cbc-md5
permitted_etypes = aes128-cts des3-hmac-sha1 des-cbc-crc des-cbc-md5

[realms]
GPDB.KRB = {
    kdc = gpdb-kdc:88
    admin_server = gpdb-kdc:749
    default_domain = gpdb.krb
}

[domain_realm]
.gpdb.krb = GPDB.KRB
gpdb.krb = GPDB.KRB

[appdefaults]
pam = {
    debug = false
    ticket_lifetime = 36000
    renew_lifetime = 36000
    forwardable = true
    krb4_convert = false
}
```

The `kdc` and `admin_server` keys in the `[realms]` section specify the host (`gpdb-kdc`) and port where the Kerberos server is running. IP numbers can be used in place of host names.

If your Kerberos server manages authentication for other realms, you would instead add the `GPDB.KRB` realm in the `[realms]` and `[domain_realm]` section of the `kdc.conf` file. See the [Kerberos documentation](#) for information about the `kdc.conf` file.

3. To create the Kerberos database, run the `kdb5_util`.

```
# kdb5_util create -s
```

The `kdb5_util create` command creates the database to store keys for the Kerberos realms that are managed by this KDC server. The `-s` option creates a stash file. Without the stash file, every time the KDC server starts it requests a password.

4. Add an administrative user to the KDC database with the `kadmin.local` utility. Because it does not itself depend on Kerberos authentication, the `kadmin.local` utility allows you to add an initial administrative user to the local Kerberos server. To add the user `gpadmin` as an administrative user to the KDC database, run the following command:

```
# kadmin.local -q "addprinc gpadmin/admin"
```

Most users do not need administrative access to the Kerberos server. They can use `kadmin` to manage their own principals (for example, to change their own password). For information about `kadmin`, see the [Kerberos documentation](#).

5. If needed, edit the `/var/kerberos/krb5kdc/kadm5.acl` file to grant the appropriate permissions to `gpadmin`.
6. Start the Kerberos daemons:

```
# /sbin/service krb5kdc start#
/sbin/service kadmin start
```

7. To start Kerberos automatically upon restart:

```
# /sbin/chkconfig krb5kdc on
# /sbin/chkconfig kadmin on
```

## Configuring Kerberos for Linux Clients

You can configure Linux client applications to connect to a Greenplum Database system that is configured to authenticate with Kerberos.

If your JDBC application on Red Hat Enterprise Linux uses Kerberos authentication when it connects to your Greenplum Database, your client system must be configured to use Kerberos authentication. If you are not using Kerberos authentication to connect to a Greenplum Database, Kerberos is not needed on your client system.

- [Requirements](#)
- [Setting Up Client System with Kerberos Authentication](#)
- [Running a Java Application](#)

For information about enabling Kerberos authentication with Greenplum Database, see the chapter "Setting Up Kerberos Authentication" in the *Greenplum Database Administrator Guide*.

**Parent topic:** [Configuring Client Authentication](#)

## Requirements

The following are requirements to connect to a Greenplum Database that is enabled with Kerberos authentication from a client system with a JDBC application.

- [Prerequisites](#)
- [Required Software on the Client Machine](#)

## Prerequisites

- Kerberos must be installed and configured on the Greenplum Database master host.
 

**Important:** Greenplum Database must be configured so that a remote user can connect to Greenplum Database with Kerberos authentication. Authorization to access Greenplum Database is controlled by the `pg_hba.conf` file. For details, see "Editing the `pg_hba.conf` File" in the *Greenplum Database Administration Guide*, and also see the *Greenplum Database Security Configuration Guide*.
- The client system requires the Kerberos configuration file `krb5.conf` from the Greenplum Database master.
- The client system requires a Kerberos keytab file that contains the authentication credentials for the Greenplum Database user that is used to log into the database.
- The client machine must be able to connect to Greenplum Database master host.

If necessary, add the Greenplum Database master host name and IP address to the system `hosts` file. On Linux systems, the `hosts` file is in `/etc`.

## Required Software on the Client Machine

- The Kerberos `kinit` utility is required on the client machine. The `kinit` utility is available when you install the Kerberos packages:
  - `krb5-libs`
  - `krb5-workstation`

**Note:** When you install the Kerberos packages, you can use other Kerberos utilities such as `klist` to display Kerberos ticket information.

Java applications require this additional software:

- Java JDK
 

Java JDK 1.7.0\_17 is supported on Red Hat Enterprise Linux 6.x.
- Ensure that `JAVA_HOME` is set to the installation directory of the supported Java JDK.

## Setting Up Client System with Kerberos Authentication

To connect to Greenplum Database with Kerberos authentication requires a Kerberos ticket. On client systems, tickets are generated from Kerberos keytab files with the `kinit` utility and are stored in a cache file.

1. Install a copy of the Kerberos configuration file `krb5.conf` from the Greenplum Database master. The file is used by the Greenplum Database client software and the Kerberos utilities.

Install `krb5.conf` in the directory `/etc`.

If needed, add the parameter `default_ccache_name` to the `[libdefaults]` section of the `krb5.ini` file and specify location of the Kerberos ticket cache file on the client system.

2. Obtain a Kerberos keytab file that contains the authentication credentials for the Greenplum Database user.
3. Run `kinit` specifying the keytab file to create a ticket on the client machine. For this example, the keytab file `gpdb-kerberos.keytab` is in the current directory. The ticket cache file is in the `gpadmin` user home directory.

```
> kinit -k -t gpdb-kerberos.keytab -c /home/gpadmin/cache.txt
gpadmin/kerberos-gpdb@KRB.EXAMPLE.COM
```

## Running psql

From a remote system, you can access a Greenplum Database that has Kerberos authentication enabled.

### To connect to Greenplum Database with psql

1. As the `gpadmin` user, open a command window.
2. Start `psql` from the command window and specify a connection to the Greenplum Database specifying the user that is configured with Kerberos authentication.

The following example logs into the Greenplum Database on the machine `kerberos-gpdb` as the `gpadmin` user with the Kerberos credentials `gpadmin/kerberos-gpdb`:

```
$ psql -U "gpadmin/kerberos-gpdb" -h kerberos-gpdb postgres
```

## Running a Java Application

Accessing Greenplum Database from a Java application with Kerberos authentication uses the Java Authentication and Authorization Service (JAAS)

1. Create the file `.java.login.config` in the user home folder.

For example, on a Linux system, the home folder is similar to `/home/gpadmin`.

Add the following text to the file:

```
pgjdbc {
    com.sun.security.auth.module.Krb5LoginModule required
    doNotPrompt=true
    useTicketCache=true
    ticketCache = "/home/gpadmin/cache.txt"
    debug=true
    client=true;
};
```

2. Create a Java application that connects to Greenplum Database using Kerberos authentication and run the application as the user.

This example database connection URL uses a PostgreSQL JDBC driver and specifies parameters for Kerberos authentication.

```
jdbc:postgresql://kerberos-gpdb:5432/mytest?
kerberosServerName=postgres&jaasApplicationName=pgjdbc&
user=gpadmin/kerberos-gpdb
```

The parameter names and values specified depend on how the Java application performs Kerberos authentication.

## Configuring Kerberos For Windows Clients

You can configure Microsoft Windows client applications to connect to a Greenplum Database system that is configured to authenticate with Kerberos.

When a Greenplum Database system is configured to authenticate with Kerberos, you can configure Kerberos authentication for the Greenplum Database client utilities `gpload` and `psql` on a Microsoft Windows system. The Greenplum Database clients authenticate with Kerberos directly.

This section contains the following information.

- [Installing and Configuring Kerberos on a Windows System](#)
- [Running the psql Utility](#)
- [Example gpload YAML File](#)
- [Creating a Kerberos Keytab File](#)
- [Issues and Possible Solutions](#)

These topics assume that the Greenplum Database system is configured to authenticate with Kerberos. For information about configuring Greenplum Database with Kerberos authentication, refer to [Using Kerberos Authentication](#).

**Parent topic:** [Configuring Client Authentication](#)

## Installing and Configuring Kerberos on a Windows System

The `kinit`, `kdestroy`, and `klist` MIT Kerberos Windows client programs and supporting libraries are installed on your system when you install the Greenplum Database Client and Load Tools package:

- `kinit` - generate a Kerberos ticket
- `kdestroy` - destroy active Kerberos tickets
- `klist` - list Kerberos tickets

You must configure Kerberos on the Windows client to authenticate with Greenplum Database:

1. Copy the Kerberos configuration file `/etc/krb5.conf` from the Greenplum Database master to the Windows system, rename it to `krb5.ini`, and place it in the default Kerberos location on the Windows system, `C:\ProgramData\MIT\Kerberos5\krb5.ini`. This directory may be hidden. This step requires administrative privileges on the Windows client system. You may also choose to place the `/etc/krb5.ini` file in a custom location. If you choose to do this,

you must configure and set a system environment variable named `KRB5_CONFIG` to the custom location.

2. Locate the `[libdefaults]` section of the `krb5.ini` file, and remove the entry identifying the location of the Kerberos credentials cache file, `default_ccache_name`. This step requires administrative privileges on the Windows client system.

This is an example configuration file with `default_ccache_name` removed. The `[logging]` section is also removed.

```
[libdefaults]
debug = true
default_etypes = aes256-cts-hmac-sha1-96
default_realm = EXAMPLE.LOCAL
dns_lookup_realm = false
dns_lookup_kdc = false
ticket_lifetime = 24h
renew_lifetime = 7d
forwardable = true

[realms]
EXAMPLE.LOCAL = {
    kdc = bocdc.example.local
    admin_server = bocdc.example.local
}

[domain_realm]
.example.local = EXAMPLE.LOCAL
example.local = EXAMPLE.LOCAL
```

3. Set up the Kerberos credential cache file. On the Windows system, set the environment variable `KRB5CCNAME` to specify the file system location of the cache file. The file must be named `krb5cache`. This location identifies a file, not a directory, and should be unique to each login on the server. When you set `KRB5CCNAME`, you can specify the value in either a local user environment or within a session. For example, the following command sets `KRB5CCNAME` in the session:

```
set KRB5CCNAME=%USERPROFILE%\krb5cache
```

4. Obtain your Kerberos principal and password or keytab file from your system administrator.
5. Generate a Kerberos ticket using a password or a keytab. For example, to generate a ticket using a password:

```
kinit [<principal>]
```

To generate a ticket using a keytab (as described in [Creating a Kerberos Keytab File](#)):

```
kinit -k -t <keytab_filepath> [<principal>]
```

6. Set up the Greenplum clients environment:

```
set PGGSSLIB=gssapi
"c:\Program Files\Greenplum\greenplum-clients\greenplum_clients_path.bat"
```

## Running the psql Utility

After you configure Kerberos and generate the Kerberos ticket on a Windows system, you can run the Greenplum Database command line client `psql`.

If you get warnings indicating that the Console code page differs from Windows code page, you can run the Windows utility `chcp` to change the code page. This is an example of the warning and fix:

```
psql -h prod1.example.local warehouse
psql (9.4.20)
WARNING: Console code page (850) differs from Windows code page (1252)
8-bit characters might not work correctly. See psql reference
page "Notes for Windows users" for details.
Type "help" for help.

warehouse=# \q

chcp 1252
Active code page: 1252

psql -h prod1.example.local warehouse
psql (9.4.20)
Type "help" for help.
```

## Creating a Kerberos Keytab File

You can create and use a Kerberos `keytab` file to avoid entering a password at the command line or listing a password in a script file when you connect to a Greenplum Database system, perhaps when automating a scheduled Greenplum task such as `gpload`. You can create a keytab file with the Java JRE keytab utility `ktab`. If you use AES256-CTS-HMAC-SHA1-96 encryption, you need to download and install the Java extension *Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files for JDK/JRE* from Oracle.

**Note:** You must enter the password to create a keytab file. The password is visible onscreen as you enter it.

This example runs the Java `ktab.exe` program to create a keytab file (`-a` option) and list the keytab name and entries (`-l -e -t` options).

```
C:\Users\dev1>"\Program Files\Java\jre1.8.0_77\bin"\ktab -a dev1
Password for dev1@EXAMPLE.LOCAL:<your_password>
Done!
Service key for dev1 is saved in C:\Users\dev1\krb5.keytab

C:\Users\dev1>"\Program Files\Java\jre1.8.0_77\bin"\ktab -l -e -t
Keytab name: C:\Users\dev1\krb5.keytab
KVNO Timestamp Principal
-----
 4 13/04/16 19:14 dev1@EXAMPLE.LOCAL (18:AES256 CTS mode with HMAC SHA1-96)
 4 13/04/16 19:14 dev1@EXAMPLE.LOCAL (17:AES128 CTS mode with HMAC SHA1-96)
 4 13/04/16 19:14 dev1@EXAMPLE.LOCAL (16:DES3 CBC mode with SHA1-KD)
 4 13/04/16 19:14 dev1@EXAMPLE.LOCAL (23:RC4 with HMAC)
```

You can then generate a Kerberos ticket using a keytab with the following command:

```
kinit -kt dev1.keytab dev1
```

or

```
kinit -kt %USERPROFILE%\krb5.keytab dev1
```

## Example gpload YAML File

When you initiate a `gpload` job to a Greenplum Database system using Kerberos authentication, you omit the `USER:` property and value from the YAML control file.

This example `gpload` YAML control file named `test.yaml` does not include a `USER:` entry:

```
---
VERSION: 1.0.0.1
DATABASE: warehouse
HOST: prod1.example.local
PORT: 5432

GLOAD:
  INPUT:
    - SOURCE:
        PORT_RANGE: [18080,18080]
        FILE:
          - /Users/dev1/Downloads/test.csv
    - FORMAT: text
    - DELIMITER: ','
    - QUOTE: '''
    - ERROR_LIMIT: 25
    - LOG_ERRORS: true
  OUTPUT:
    - TABLE: public.test
    - MODE: INSERT
  PRELOAD:
    - REUSE_TABLES: true
```

These commands run `kinit` using a keytab file, run `gpload.bat` with the `test.yaml` file, and then display successful `gpload` output.

```
kinit -kt %USERPROFILE%\krb5.keytab dev1

gpload.bat -f test.yaml
2016-04-10 16:54:12|INFO|gpload session started 2016-04-10 16:54:12
2016-04-10 16:54:12|INFO|started gpfdist -p 18080 -P 18080 -f "/Users/dev1/Downloads/t
est.csv" -t 30
2016-04-10 16:54:13|INFO|running time: 0.23 seconds
2016-04-10 16:54:13|INFO|rows Inserted = 3
2016-04-10 16:54:13|INFO|rows Updated = 0
2016-04-10 16:54:13|INFO|data formatting errors = 0
2016-04-10 16:54:13|INFO|gpload succeeded
```

## Issues and Possible Solutions

- This message indicates that Kerberos cannot find your Kerberos credentials cache file:

```
Credentials cache I/O operation failed XXX
(Kerberos error 193)
krb5_cc_default() failed
```

To ensure that Kerberos can find the file, set the environment variable `KRB5CCNAME` and run `kinit`.

```
set KRB5CCNAME=%USERPROFILE%\krb5cache
kinit
```

- This `kinit` message indicates that the `kinit -k -t` command could not find the keytab.

```
kinit: Generic preauthentication failure while getting initial credentials
```

Confirm that the full path and filename for the Kerberos keytab file is correct.

## Managing Roles and Privileges

The Greenplum Database authorization mechanism stores roles and permissions to access database objects in the database and is administered using SQL statements or command-line utilities.

Greenplum Database manages database access permissions using *roles*. The concept of roles subsumes the concepts of *users* and *groups*. A role can be a database user, a group, or both. Roles can own database objects (for example, tables) and can assign privileges on those objects to other roles to control access to the objects. Roles can be members of other roles, thus a member role can inherit the object privileges of its parent role.

Every Greenplum Database system contains a set of database roles (users and groups). Those roles are separate from the users and groups managed by the operating system on which the server runs. However, for convenience you may want to maintain a relationship between operating system user names and Greenplum Database role names, since many of the client applications use the current operating system user name as the default.

In Greenplum Database, users log in and connect through the master instance, which then verifies their role and access privileges. The master then issues commands to the segment instances behind the scenes as the currently logged in role.

Roles are defined at the system level, meaning they are valid for all databases in the system.

In order to bootstrap the Greenplum Database system, a freshly initialized system always contains one predefined *superuser* role (also referred to as the system user). This role will have the same name as the operating system user that initialized the Greenplum Database system. Customarily, this role is named `gppadmin`. In order to create more roles you first have to connect as this initial role.

**Parent topic:** [Managing Greenplum Database Access](#)

## Security Best Practices for Roles and Privileges

- **Secure the `gppadmin` system user.** Greenplum requires a UNIX user id to install and initialize the Greenplum Database system. This system user is referred to as `gppadmin` in the Greenplum documentation. This `gppadmin` user is the default database superuser in

Greenplum Database, as well as the file system owner of the Greenplum installation and its underlying data files. This default administrator account is fundamental to the design of Greenplum Database. The system cannot run without it, and there is no way to limit the access of this `gpadmin` user id. Use roles to manage who has access to the database for specific purposes. You should only use the `gpadmin` account for system maintenance tasks such as expansion and upgrade. Anyone who logs on to a Greenplum host as this user id can read, alter or delete any data; including system catalog data and database access rights. Therefore, it is very important to secure the `gpadmin` user id and only provide access to essential system administrators. Administrators should only log in to Greenplum as `gpadmin` when performing certain system maintenance tasks (such as upgrade or expansion). Database users should never log on as `gpadmin`, and ETL or production workloads should never run as `gpadmin`.

- **Assign a distinct role to each user that logs in.** For logging and auditing purposes, each user that is allowed to log in to Greenplum Database should be given their own database role. For applications or web services, consider creating a distinct role for each application or service. See [Creating New Roles \(Users\)](#).
- **Use groups to manage access privileges.** See [Role Membership](#).
- **Limit users who have the SUPERUSER role attribute.** Roles that are superusers bypass all access privilege checks in Greenplum Database, as well as resource queuing. Only system administrators should be given superuser rights. See [Altering Role Attributes](#).

## Creating New Roles (Users)

A user-level role is considered to be a database role that can log in to the database and initiate a database session. Therefore, when you create a new user-level role using the `CREATE ROLE` command, you must specify the `LOGIN` privilege. For example:

```
=# CREATE ROLE jsmith WITH LOGIN;
```

A database role may have a number of attributes that define what sort of tasks that role can perform in the database. You can set these attributes when you create the role, or later using the `ALTER ROLE` command. See [Table 1](#) for a description of the role attributes you can set.

## Altering Role Attributes

A database role may have a number of attributes that define what sort of tasks that role can perform in the database.

| Attributes   | Description   |
|--|---|
| <code>SUPERUSER</code> or <code>NOSUPERUSER</code>   | Determines if the role is a superuser. You must yourself be a superuser to create a new superuser. <code>NOSUPERUSER</code> is the default. |
| <code>CREATEDB</code> or <code>NOCREATEDB</code>     | Determines if the role is allowed to create databases. <code>NOCREATEDB</code> is the default.  |
| <code>CREATEROLE</code> or <code>NOCREATEROLE</code> | Determines if the role is allowed to create and manage other roles. <code>NOCREATEROLE</code> is the default.                               |

| Attributes   | Description  |
|--|--|
| <code>INHERIT</code> or<br><code>NOINHERIT</code>                  | Determines whether a role inherits the privileges of roles it is a member of. A role with the <code>INHERIT</code> attribute can automatically use whatever database privileges have been granted to all roles it is directly or indirectly a member of. <code>INHERIT</code> is the default.  |
| <code>LOGIN</code> or <code>NOLOGIN</code>                         | Determines whether a role is allowed to log in. A role having the <code>LOGIN</code> attribute can be thought of as a user. Roles without this attribute are useful for managing database privileges (groups). <code>NOLOGIN</code> is the default.  |
| <code>CONNECTION<br/>LIMIT<br/>*connlimit*</code>                  | If role can log in, this specifies how many concurrent connections the role can make. -1 (the default) means no limit.   |
| <code>CREATEEXTTABLE</code><br>or<br><code>NOCREATEEXTTABLE</code> | Determines whether a role is allowed to create external tables. <code>NOCREATEEXTTABLE</code> is the default. For a role with the <code>CREATEEXTTABLE</code> attribute, the default external table <code>type</code> is <code>readable</code> and the default <code>protocol</code> is <code>gpfdist</code> . Note that external tables that use the <code>file</code> or <code>execute</code> protocols can only be created by superusers.   |
| <code>PASSWORD<br/>'*password*'</code>                             | Sets the role's password. If you do not plan to use password authentication you can omit this option. If no password is specified, the password will be set to null and password authentication will always fail for that user. A null password can optionally be written explicitly as <code>PASSWORD NULL</code> .   |
| <code>ENCRYPTED</code> or<br><code>UNENCRYPTED</code>              | Controls whether a new password is stored as a hash string in the <code>pg_authid</code> system catalog. If neither <code>ENCRYPTED</code> nor <code>UNENCRYPTED</code> is specified, the default behavior is determined by the <code>password_encryption</code> configuration parameter, which is <code>on</code> by default. If the supplied <code>*password*</code> string is already in hashed format, it is stored as-is, regardless of whether <code>ENCRYPTED</code> or <code>UNENCRYPTED</code> is specified.<br><br>See <a href="#">Protecting Passwords in Greenplum Database</a> for additional information about protecting login passwords. |
| <code>VALID UNTIL<br/>'timestamp'</code>                           | Sets a date and time after which the role's password is no longer valid. If omitted the password will be valid for all time.   |
| <code>RESOURCE QUEUE<br/>queue_name</code>                         | Assigns the role to the named resource queue for workload management. Any statement that role issues is then subject to the resource queue's limits. Note that the <code>RESOURCE QUEUE</code> attribute is not inherited; it must be set on each user-level ( <code>LOGIN</code> ) role.  |
| <code>DENY<br/>deny_interval<br/>or DENY<br/>deny_point</code>     | Restricts access during an interval, specified by day or day and time. For more information see <a href="#">Time-based Authentication</a> .  |

You can set these attributes when you create the role, or later using the `ALTER ROLE` command. For example:

```
=# ALTER ROLE jsmith WITH PASSWORD 'passwd123';
=# ALTER ROLE admin VALID UNTIL 'infinity';
=# ALTER ROLE jsmith LOGIN;
=# ALTER ROLE jsmith RESOURCE QUEUE adhoc;
=# ALTER ROLE jsmith DENY DAY 'Sunday';
```

A role can also have role-specific defaults for many of the server configuration settings. For example, to set the default schema search path for a role:

```
=# ALTER ROLE admin SET search_path TO myschema, public;
```

## Role Membership

It is frequently convenient to group users together to ease management of object privileges: that way, privileges can be granted to, or revoked from, a group as a whole. In Greenplum Database this is done by creating a role that represents the group, and then granting membership in the group role to individual user roles.

Use the `CREATE ROLE` SQL command to create a new group role. For example:

```
=# CREATE ROLE admin CREATEROLE CREATEDB;
```

Once the group role exists, you can add and remove members (user roles) using the `GRANT` and `REVOKE` commands. For example:

```
=# GRANT admin TO john, sally;
=# REVOKE admin FROM bob;
```

For managing object privileges, you would then grant the appropriate permissions to the group-level role only (see [Table 2](#)). The member user roles then inherit the object privileges of the group role. For example:

```
=# GRANT ALL ON TABLE mytable TO admin;
=# GRANT ALL ON SCHEMA myschema TO admin;
=# GRANT ALL ON DATABASE mydb TO admin;
```

The role attributes `LOGIN`, `SUPERUSER`, `CREATEDB`, `CREATEROLE`, `CREATEEXTTABLE`, and `RESOURCE QUEUE` are never inherited as ordinary privileges on database objects are. User members must actually `SET ROLE` to a specific role having one of these attributes in order to make use of the attribute. In the above example, we gave `CREATEDB` and `CREATEROLE` to the `admin` role. If `sally` is a member of `admin`, then `sally` could issue the following command to assume the role attributes of the parent role:

```
=> SET ROLE admin;
```

## Managing Object Privileges

When an object (table, view, sequence, database, function, language, schema, or tablespace) is created, it is assigned an owner. The owner is normally the role that ran the creation statement. For most kinds of objects, the initial state is that only the owner (or a superuser) can do anything with the object. To allow other roles to use it, privileges must be granted. Greenplum Database supports the following privileges for each object type:

Table 2. Object Privileges

| Object Type | Privileges |
|-------------|------------|
|-------------|------------|

| Object Type                    | Privileges   |
|--------------------------------|--|
| Tables, External Tables, Views | SELECT<br>INSERT<br>UPDATE<br>DELETE<br>REFERENCES<br>TRIGGER<br>TRUNCATE<br>ALL |
| Columns                        | SELECT<br>INSERT<br>UPDATE<br>REFERENCES<br>ALL                                  |
| Sequences                      | USAGE<br>SELECT<br>UPDATE<br>ALL   |
| Databases                      | CREATE<br>CONNECT<br>TEMPORARY<br>TEMP<br>ALL                                    |
| Domains                        | USAGE<br>ALL   |
| Foreign Data Wrappers          | USAGE<br>ALL   |
| Foreign Servers                | USAGE<br>ALL   |
| Functions                      | EXECUTE<br>ALL   |

| Object Type          | Privileges              |
|----------------------|-------------------------|
| Procedural Languages | USAGE<br>ALL            |
| Schemas              | CREATE<br>USAGE<br>ALL  |
| Tablespaces          | CREATE<br>ALL           |
| Types                | USAGE<br>ALL            |
| Protocols            | SELECT<br>INSERT<br>ALL |

**Note:** You must grant privileges for each object individually. For example, granting `ALL` on a database does not grant full access to the objects within that database. It only grants all of the database-level privileges (`CONNECT`, `CREATE`, `TEMPORARY`) to the database itself.

Use the `GRANT` SQL command to give a specified role privileges on an object. For example, to grant the role named `jsmith` insert privileges on the table named `mytable`:

```
=# GRANT INSERT ON mytable TO jsmith;
```

Similarly, to grant `jsmith` select privileges only to the column named `coll` in the table named `table2`:

```
=# GRANT SELECT (coll) on TABLE table2 TO jsmith;
```

To revoke privileges, use the `REVOKE` command. For example:

```
=# REVOKE ALL PRIVILEGES ON mytable FROM jsmith;
```

You can also use the `DROP OWNED` and `REASSIGN OWNED` commands for managing objects owned by deprecated roles (Note: only an object's owner or a superuser can drop an object or reassign ownership). For example:

```
=# REASSIGN OWNED BY sally TO bob;
=# DROP OWNED BY visitor;
```

## Simulating Row Level Access Control

Greenplum Database does not support row-level access or row-level, labeled security. You can simulate row-level access by using views to restrict the rows that are selected. You can simulate row-level labels by adding an extra column to the table to store sensitivity information, and then using views to control row-level access based on this column. You can then grant roles access to the views rather than to the base table.

## Encrypting Data

Greenplum Database is installed with an optional module of encryption/decryption functions called `pgcrypto`. The `pgcrypto` functions allow database administrators to store certain columns of data in encrypted form. This adds an extra layer of protection for sensitive data, as data stored in Greenplum Database in encrypted form cannot be read by anyone who does not have the encryption key, nor can it be read directly from the disks.

**Note:** The `pgcrypto` functions run inside the database server, which means that all the data and passwords move between `pgcrypto` and the client application in clear-text. For optimal security, consider also using SSL connections between the client and the Greenplum master server.

To use `pgcrypto` functions, register the `pgcrypto` extension in each database in which you want to use the functions. For example:

```
$ psql -d testdb -c "CREATE EXTENSION pgcrypto"
```

See `pgcrypto` in the PostgreSQL documentation for more information about individual functions.

## Protecting Passwords in Greenplum Database

In its default configuration, Greenplum Database saves MD5 hashes of login users' passwords in the `pg_authid` system catalog rather than saving clear text passwords. Anyone who is able to view the `pg_authid` table can see hash strings, but no passwords. This also ensures that passwords are obscured when the database is dumped to backup files.

Greenplum Database supports SHA-256 and SCRAM-SHA-256 password hash algorithms as well. The `password_hash_algorithm` server configuration parameter value and `pg_hba.conf` settings determine how passwords are hashed and what authentication method is in effect.

| <code>password_hash_algorithm</code><br>Parameter Value | <code>pg_hba.conf</code><br>Authentication Method | Comments  |
|---|---|---|
| MD5   | md5   | The default Greenplum Database password hash algorithm.   |
| SCRAM-SHA-256   | scram-sha-256                                     | The most secure method, <b>but is not supported by Greenplum Database version 6.20.x and older clients.</b> |
| SHA-256   | password  | Clear text passwords are sent over the network, SSL-secured client connections are recommended.             |

The password hash function runs when the password is set by using any of the following commands:

- `CREATE USER name WITH ENCRYPTED PASSWORD 'password'`

- `CREATE ROLE name WITH LOGIN ENCRYPTED PASSWORD 'password'`
- `ALTER USER name WITH ENCRYPTED PASSWORD 'password'`
- `ALTER ROLE name WITH ENCRYPTED PASSWORD 'password'`

The `ENCRYPTED` keyword may be omitted when the `password_encryption` system configuration parameter is `on`, which is the default value. The `password_encryption` configuration parameter determines whether clear text or hashed passwords are saved when the `ENCRYPTED` or `UNENCRYPTED` keyword is not present in the command.

**Note:** The SQL command syntax and `password_encryption` configuration variable include the term *encrypt*, but the passwords are not technically encrypted. They are *hashed* and therefore cannot be decrypted.

Although it is not recommended, passwords may be saved in clear text in the database by including the `UNENCRYPTED` keyword in the command or by setting the `password_encryption` configuration variable to `off`. Note that changing the configuration value has no effect on existing passwords, only newly-created or updated passwords.

To set `password_encryption` globally, run these commands in a shell as the `gpadmin` user:

```
$ gpconfig -c password_encryption -v 'off'
$ gpstop -u
```

To set `password_encryption` in a session, use the SQL `SET` command:

```
=# SET password_encryption = 'on';
```

## About MD5 Password Hashing

In its default configuration, Greenplum Database saves MD5 hashes of login users' passwords.

The hash is calculated on the concatenated clear text password and role name. The MD5 hash produces a 32-byte hexadecimal string prefixed with the characters `md5`. The hashed password is saved in the `rolpassword` column of the `pg_authid` system table.

The default `md5` authentication method hashes the password twice before sending it to Greenplum Database, once on the password and role name and then again with a salt value shared between the client and server, so the clear text password is never sent on the network.

## About SCRAM-SHA-256 Password Hashing

Passwords may be hashed using the SCRAM-SHA-256 hash algorithm instead of the default MD5 hash algorithm. When a password is encrypted with SCRAM-SHA-256, it has the format:

```
SCRAM-SHA-256$<iteration count>:<salt>$<StoredKey>:<ServerKey>
```

where `<salt>`, `<StoredKey>`, and `<ServerKey>` are in base64-encoded format. This format is the same as that specified by RFC 5803.

To enable SCRAM-SHA-256 hashing, change the `password_hash_algorithm` configuration parameter from its default value, `MD5`, to `SCRAM-SHA-256`. The parameter can be set either globally or

at the session level. To set `password_hash_algorithm` globally, execute these commands in a shell as the `gpadmin` user:

```
$ gpconfig -c password_hash_algorithm -v 'SCRAM-SHA-256'
$ gpstop -u
```

To set `password_hash_algorithm` in a session, use the SQL `SET` command:

```
=# SET password_hash_algorithm = 'SCRAM-SHA-256';
```

## About SHA-256 Password Hashing

Passwords may be hashed using the SHA-256 hash algorithm instead of the default MD5 hash algorithm. The algorithm produces a 64-byte hexadecimal string prefixed with the characters `sha256`.

**Note:** Although SHA-256 uses a stronger cryptographic algorithm and produces a longer hash string for password hashing, it does not include SHA-256 password hashing over the network during client authentication. To use SHA-256 password hashing, the authentication method must be set to `password` in the `pg_hba.conf` configuration file so that clear text passwords are sent to Greenplum Database. SHA-256 password hashing cannot be used with the `md5` authentication method. **Because clear text passwords are sent over the network, it is very important to use SSL-secured client connections when you use SHA-256.**

To enable SHA-256 hashing, change the `password_hash_algorithm` configuration parameter from its default value, `MD5`, to `SHA-256`. The parameter can be set either globally or at the session level. To set `password_hash_algorithm` globally, execute these commands in a shell as the `gpadmin` user:

```
$ gpconfig -c password_hash_algorithm -v 'SHA-256'
$ gpstop -u
```

To set `password_hash_algorithm` in a session, use the SQL `SET` command:

```
=# SET password_hash_algorithm = 'SHA-256';
```

## Time-based Authentication

Greenplum Database enables the administrator to restrict access to certain times by role. Use the `CREATE ROLE` or `ALTER ROLE` commands to specify time-based constraints.

For details, refer to the *Greenplum Database Security Configuration Guide*.

## Accessing the Database

This topic describes the various client tools you can use to connect to Greenplum Database, and how to establish a database session.

- [Establishing a Database Session](#)
- [Supported Client Applications](#)
- [Greenplum Database Client Applications](#)

- [Connecting with psql](#)
- [Database Application Interfaces](#)
- [Troubleshooting Connection Problems](#)

Parent topic: [Managing a Greenplum System](#)

## Establishing a Database Session

Users can connect to Greenplum Database using a PostgreSQL-compatible client program, such as `psql`. Users and administrators *always* connect to Greenplum Database through the *master*; the segments cannot accept client connections.

In order to establish a connection to the Greenplum Database master, you will need to know the following connection information and configure your client program accordingly.

| Connection Parameter | Description  | Environment Variable      |
|----------------------|--|---------------------------|
| Application name     | The application name that is connecting to the database. The default value, held in the <code>application_name</code> connection parameter is <code>psql</code> .  | <code>\$PGAPPNAME</code>  |
| Database name        | The name of the database to which you want to connect. For a newly initialized system, use the <code>postgres</code> database to connect for the first time.   | <code>\$PGDATABASE</code> |
| Host name            | The host name of the Greenplum Database master. The default host is the local host.  | <code>\$PGHOST</code>     |
| Port                 | The port number that the Greenplum Database master instance is running on. The default is 5432.  | <code>\$PGPORT</code>     |
| User name            | The database user (role) name to connect as. This is not necessarily the same as your OS user name. Check with your Greenplum administrator if you are not sure what your database user name is. Note that every Greenplum Database system has one superuser account that is created automatically at initialization time. This account has the same name as the OS name of the user who initialized the Greenplum system (typically <code>gpadmin</code> ). | <code>\$PGUSER</code>     |

[Connecting with psql](#) provides example commands for connecting to Greenplum Database.

Parent topic: [Accessing the Database](#)

## Supported Client Applications

Users can connect to Greenplum Database using various client applications:

- A number of [Greenplum Database Client Applications](#) are provided with your Greenplum installation. The `psql` client application provides an interactive command-line interface to Greenplum Database.
- Using standard [Database Application Interfaces](#), such as ODBC and JDBC, users can create their own client applications that interface to Greenplum Database.
- Most client tools that use standard database interfaces, such as ODBC and JDBC, can be configured to connect to Greenplum Database.

Parent topic: [Accessing the Database](#)

## Greenplum Database Client Applications

Greenplum Database comes installed with a number of client utility applications located in the `$GPHOME/bin` directory of your Greenplum Database master host installation. The following are the most commonly used client utility applications:

| Name                    | Usage                                  |
|-------------------------|--|
| <code>createdb</code>   | create a new database                  |
| <code>createuser</code> | define a new database role             |
| <code>dropdb</code>     | remove a database                      |
| <code>dropuser</code>   | remove a role                          |
| <code>psql</code>       | PostgreSQL interactive terminal        |
| <code>reindexdb</code>  | reindex a database                     |
| <code>vacuumdb</code>   | garbage-collect and analyze a database |

When using these client applications, you must connect to a database through the Greenplum master instance. You will need to know the name of your target database, the host name and port number of the master, and what database user name to connect as. This information can be provided on the command-line using the options `-d`, `-h`, `-p`, and `-U` respectively. If an argument is found that does not belong to any option, it will be interpreted as the database name first.

All of these options have default values which will be used if the option is not specified. The default host is the local host. The default port number is 5432. The default user name is your OS system user name, as is the default database name. Note that OS user names and Greenplum Database user names are not necessarily the same.

If the default values are not correct, you can set the environment variables `PGDATABASE`, `PGHOST`, `PGPORT`, and `PGUSER` to the appropriate values, or use a `psql ~/.pgpass` file to contain frequently-used passwords.

For information about Greenplum Database environment variables, see the *Greenplum Database Reference Guide*. For information about `psql`, see the *Greenplum Database Utility Guide*.

**Parent topic:** [Accessing the Database](#)

### Connecting with psql

Depending on the default values used or the environment variables you have set, the following examples show how to access a database via `psql`:

```
$ psql -d gpdatabase -h master_host -p 5432 -U `gpadmin`
```

```
$ psql gpdatabase
```

```
$ psql
```

If a user-defined database has not yet been created, you can access the system by connecting to the `postgres` database. For example:

```
$ psql postgres
```

After connecting to a database, `psql` provides a prompt with the name of the database to which `psql` is currently connected, followed by the string `=>` (or `=#` if you are the database superuser). For example:

```
gpdatabase=>
```

At the prompt, you may type in SQL commands. A SQL command must end with a `;` (semicolon) in order to be sent to the server and run. For example:

```
=> SELECT * FROM mytable;
```

See the *Greenplum Reference Guide* for information about using the `psql` client application and SQL commands and syntax.

## Using the PgBouncer Connection Pooler

The PgBouncer utility manages connection pools for PostgreSQL and Greenplum Database connections.

The following topics describe how to set up and use PgBouncer with Greenplum Database. Refer to the [PgBouncer web site](#) for information about using PgBouncer with PostgreSQL.

- [Overview](#)
- [Migrating PgBouncer](#)
- [Configuring PgBouncer](#)
- [Starting PgBouncer](#)
- [Managing PgBouncer](#)

**Parent topic:** [Accessing the Database](#)

## Overview

A database connection pool is a cache of database connections. Once a pool of connections is established, connection pooling eliminates the overhead of creating new database connections, so clients connect much faster and the server load is reduced.

The PgBouncer connection pooler, from the PostgreSQL community, is included in your Greenplum Database installation. PgBouncer is a light-weight connection pool manager for Greenplum and PostgreSQL. PgBouncer maintains a pool for connections for each database and user combination. PgBouncer either creates a new database connection for a client or reuses an existing connection for the same user and database. When the client disconnects, PgBouncer returns the connection to the pool for re-use.

In order not to compromise transaction semantics for connection pooling, PgBouncer supports several types of pooling when rotating connections:

- *Session pooling* - Most polite method. When a client connects, a server connection will be assigned to it for the whole duration the client stays connected. When the client disconnects, the server connection will be put back into the pool. This is the default method.
- *Transaction pooling* - A server connection is assigned to a client only during a transaction. When PgBouncer notices that transaction is over, the server connection will be put back into the pool.
- *Statement pooling* - Most aggressive method. The server connection will be put back into the pool immediately after a query completes. Multi-statement transactions are disallowed in this mode as they would break.

You can set a default pool mode for the PgBouncer instance. You can override this mode for individual databases and users.

PgBouncer supports the standard connection interface shared by PostgreSQL and Greenplum Database. The Greenplum Database client application (for example, `psql`) connects to the host and port on which PgBouncer is running rather than the Greenplum Database master host and port.

PgBouncer includes a `psql`-like administration console. Authorized users can connect to a virtual database to monitor and manage PgBouncer. You can manage a PgBouncer daemon process via the admin console. You can also use the console to update and reload PgBouncer configuration at runtime without stopping and restarting the process.

PgBouncer natively supports TLS.

## Migrating PgBouncer

When you migrate to a new Greenplum Database version, you must migrate your PgBouncer instance to that in the new Greenplum Database installation.

- **If you are migrating to a Greenplum Database version 5.8.x or earlier**, you can migrate PgBouncer without dropping connections. Launch the new PgBouncer process with the `-R` option and the configuration file that you started the process with:

```
$ pgbouncer -R -d pgbouncer.ini
```

The `-R` (reboot) option causes the new process to connect to the console of the old process through a Unix socket and issue the following commands:

```
SUSPEND;
SHOW FDS;
SHUTDOWN;
```

When the new process detects that the old process is gone, it resumes the work with the old connections. This is possible because the `SHOW FDS` command sends actual file descriptors to the new process. If the transition fails for any reason, kill the new process and the old process will resume.

- **If you are migrating to a Greenplum Database version 5.9.0 or later**, you must shut down the PgBouncer instance in your old installation and reconfigure and restart PgBouncer in your new installation.
- If you used stunnel to secure PgBouncer connections in your old installation, you must configure SSL/TLS in your new installation using the built-in TLS capabilities of PgBouncer 1.8.1 and later.
- If you currently use the built-in PAM LDAP integration, you may choose to migrate to the new native LDAP PgBouncer integration introduced in Greenplum Database version 6.22; refer to [Configuring LDAP-based Authentication for PgBouncer](#) for configuration information.

## Configuring PgBouncer

You configure PgBouncer and its access to Greenplum Database via a configuration file. This configuration file, commonly named `pgbouncer.ini`, provides location information for Greenplum databases. The `pgbouncer.ini` file also specifies process, connection pool, authorized users, and authentication configuration for PgBouncer.

Sample `pgbouncer.ini` file contents:

```
[databases]
postgres = host=127.0.0.1 port=5432 dbname=postgres
pgb_mydb = host=127.0.0.1 port=5432 dbname=mydb

[pgbouncer]
pool_mode = session
listen_port = 6543
listen_addr = 127.0.0.1
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = gpadmin
```

Refer to the [pgbouncer.ini](#) reference page for the PgBouncer configuration file format and the list of configuration properties it supports.

When a client connects to PgBouncer, the connection pooler looks up the the configuration for the requested database (which may be an alias for the actual database) that was specified in the `pgbouncer.ini` configuration file to find the host name, port, and database name for the database connection. The configuration file also identifies the authentication mode in effect for the database.

PgBouncer requires an authentication file, a text file that contains a list of Greenplum Database users and passwords. The contents of the file are dependent on the `auth_type` you configure in the `pgbouncer.ini` file. Passwords may be either clear text or MD5-encoded strings. You can also configure PgBouncer to query the destination database to obtain password information for users that are not in the authentication file.

## PgBouncer Authentication File Format

PgBouncer requires its own user authentication file. You specify the name of this file in the `auth_file` property of the `pgbouncer.ini` configuration file. `auth_file` is a text file in the following format:

```
"username1" "password" ...
"username2" "md5abcdef012342345" ...
"username2" "SCRAM-SHA-256${iterations}:${salt}:${storedkey}:${serverkey}"
```

`auth_file` contains one line per user. Each line must have at least two fields, both of which are enclosed in double quotes (" "). The first field identifies the Greenplum Database user name. The second field is either a plain-text password, an MD5-encoded password, or a SCRAM secret. PgBouncer ignores the remainder of the line.

(The format of `auth_file` is similar to that of the `pg_auth` text file that Greenplum Database uses for authentication information. PgBouncer can work directly with this Greenplum Database authentication file.)

Use an MD5 encoded password. The format of an MD5 encoded password is:

```
"md5" + MD5_encoded(<password><username>)
```

You can also obtain the MD5-encoded passwords of all Greenplum Database users from the `pg_shadow` view.

PostgreSQL SCRAM secret format:

```
SCRAM-SHA-256${iterations}:${salt}:${storedkey}:${serverkey}
```

See the PostgreSQL documentation and RFC 5803 for details on this.

The passwords or secrets stored in the authentication file serve two purposes. First, they are used to verify the passwords of incoming client connections, if a password-based authentication method is configured. Second, they are used as the passwords for outgoing connections to the backend server, if the backend server requires password-based authentication (unless the password is specified directly in the database's connection string). The latter works if the password is stored in plain text or MD5-hashed.

SCRAM secrets can only be used for logging into a server if the client authentication also uses SCRAM, the PgBouncer database definition does not specify a user name, and the SCRAM secrets are identical in PgBouncer and the PostgreSQL server (same salt and iterations, not merely the same password). This is due to an inherent security property of SCRAM: The stored SCRAM secret cannot by itself be used for deriving login credentials.

The authentication file can be written by hand, but it's also useful to generate it from some other list of users and passwords. See `./etc/mkauth.py` for a sample script to generate the authentication file from the `pg_shadow` system table. Alternatively, use

```
auth_query
```

instead of `auth_file` to avoid having to maintain a separate authentication file.

## Configuring HBA-based Authentication for PgBouncer

PgBouncer supports HBA-based authentication. To configure HBA-based authentication for PgBouncer, you set `auth_type=hba` in the `pgbouncer.ini` configuration file. You also provide the filename of the HBA-format file in the `auth_hba_file` parameter of the `pgbouncer.ini` file.

Contents of an example PgBouncer HBA file named `hba_bouncer.conf`:

```
local      all      bouncer      trust
host      all      bouncer      127.0.0.1/32  trust
```

Example excerpt from the related `pgbouncer.ini` configuration file:

```
[databases]
p0 = port=15432 host=127.0.0.1 dbname=p0 user=bouncer pool_size=2
p1 = port=15432 host=127.0.0.1 dbname=p1 user=bouncer
...

[pgbouncer]
...
auth_type = hba
auth_file = userlist.txt
auth_hba_file = hba_bouncer.conf
...
```

Refer to the [HBA file format](#) discussion in the PgBouncer documentation for information about PgBouncer support of the HBA authentication file format.

## Configuring LDAP-based Authentication for PgBouncer

Starting in Greenplum Database version 6.22, PgBouncer supports native LDAP authentication between the `psql` client and the `pgbouncer` process. Configuring this LDAP-based authentication is similar to configuring HBA-based authentication for PgBouncer:

- Specify `auth-type=hba` in the `pgbouncer.ini` configuration file.
- Provide the file name of an HBA-format file in the `auth_hba_file` parameter of the `pgbouncer.ini` file, and specify the LDAP parameters (server address, base DN, bind DN, bind password, search attribute, etc.) in the file.

**Note:** You may, but are not required to, specify LDAP user names and passwords in the `auth-file`. When you do *not* specify these strings in the `auth-file`, LDAP user password changes require no PgBouncer configuration changes.

If you enable LDAP authentication between `psql` and `pgbouncer` and you use `md5`, `password`, or `scram-sha-256` for authentication between PgBouncer and Greenplum Database, ensure that you configure the latter password independently.

Excerpt of an example PgBouncer HBA file named `hba_bouncer_for_ldap.conf` that specifies LDAP authentication follows:

```
host all user1 0.0.0.0/0 ldap ldapserver=<ldap-server-address> ldapbasedn="CN=Users,DC=greenplum,DC=org" ldapbinddn="CN=Administrator,CN=Users,DC=greenplum,DC=org" ldapbindpasswd="ChangeMe1!!" ldapsearchattribute="SomeAttrName"
```

Refer to the Greenplum Database [LDAP Authentication](#) discussion for more information on configuring an HBA file for LDAP.

Example excerpt from the related `pgbouncer.ini` configuration file:

```
[databases]
* = port = 6000 host=127.0.0.1

[pgbouncer]
listen_addr = 0.0.0.0
listen_port = 6432

auth_type = hba
auth_hba_file = hba_bouncer_for_ldap.conf
...
```

## Starting PgBouncer

You can run PgBouncer on the Greenplum Database master or on another server. If you install PgBouncer on a separate server, you can easily switch clients to the standby master by updating the PgBouncer configuration file and reloading the configuration using the PgBouncer Administration Console.

Follow these steps to set up PgBouncer.

1. Create a PgBouncer configuration file. For example, add the following text to a file named `pgbouncer.ini`:

```
[databases]
postgres = host=127.0.0.1 port=5432 dbname=postgres
pgb_mydb = host=127.0.0.1 port=5432 dbname=mydb

[pgbouncer]
pool_mode = session
listen_port = 6543
listen_addr = 127.0.0.1
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = gpadmin
```

The file lists databases and their connection details. The file also configures the PgBouncer instance. Refer to the `pgbouncer.ini` reference page for information about the format and content of a PgBouncer configuration file.

2. Create an authentication file. The filename should be the name you specified for the `auth_file` parameter of the `pgbouncer.ini` file, `users.txt`. Each line contains a user name and password. The format of the password string matches the `auth_type` you configured in the PgBouncer configuration file. If the `auth_type` parameter is `plain`, the password string is a clear text password, for example:

```
"gpadmin" "gpadmin1234"
```

If the `auth_type` in the following example is `md5`, the authentication field must be MD5-encoded. The format for an MD5-encoded password is:

```
"md5" + MD5_encoded(<password><username>)
```

3. Launch `pgbouncer`:

```
$ $GPHOME/bin/pgbouncer -d pgbouncer.ini
```

The `-d` option runs PgBouncer as a background (daemon) process. Refer to the [pgbouncer](#) reference page for the `pgbouncer` command syntax and options.

4. Update your client applications to connect to `pgbouncer` instead of directly to Greenplum Database server. For example, to connect to the Greenplum database named `mydb` configured above, run `psql` as follows:

```
$ psql -p 6543 -U someuser pgb_mydb
```

The `-p` option value is the `listen_port` that you configured for the PgBouncer instance.

## Managing PgBouncer

PgBouncer provides a `psql`-like administration console. You log in to the PgBouncer Administration Console by specifying the PgBouncer port number and a virtual database named `pgbouncer`. The console accepts SQL-like commands that you can use to monitor, reconfigure, and manage PgBouncer.

For complete documentation of PgBouncer Administration Console commands, refer to the [pgbouncer-admin](#) command reference.

Follow these steps to get started with the PgBouncer Administration Console.

1. Use `psql` to log in to the `pgbouncer` virtual database:

```
$ psql -p 6543 -U username pgbouncer
```

The username that you specify must be listed in the `admin_users` parameter in the `pgbouncer.ini` configuration file. You can also log in to the PgBouncer Administration Console with the current Unix username if the `pgbouncer` process is running under that user's UID.

2. To view the available PgBouncer Administration Console commands, run the `SHOW help` command:

```
pgbouncer=# SHOW help;
NOTICE:  Console usage
DETAIL:
   SHOW HELP | CONFIG | DATABASES | FDS | POOLS | CLIENTS | SERVERS | SOCKETS | LISTS | VERSION
 | ...
   SET key = arg
   RELOAD
   PAUSE
   SUSPEND
   RESUME
   SHUTDOWN
   [...]
```

3. If you update PgBouncer configuration by editing the `pgbouncer.ini` configuration file, you use the `RELOAD` command to reload the file:

```
pgbouncer=# RELOAD;
```

## Mapping PgBouncer Clients to Greenplum Database Server Connections

To map a PgBouncer client to a Greenplum Database server connection, use the PgBouncer Administration Console `SHOW CLIENTS` and `SHOW SERVERS` commands:

1. Use `ptr` and `link` to map the local client connection to the server connection.
2. Use the `addr` and the `port` of the client connection to identify the TCP connection from the client.
3. Use `local_addr` and `local_port` to identify the TCP connection to the server.

## Database Application Interfaces

You may want to develop your own client applications that interface to Greenplum Database. PostgreSQL provides a number of database drivers for the most commonly used database application programming interfaces (APIs), which can also be used with Greenplum Database. These drivers are available as a separate download. Each driver (except libpq, which comes with PostgreSQL) is an independent PostgreSQL development project and must be downloaded, installed and configured to connect to Greenplum Database. The following drivers are available:

| API             | PostgreSQL Driver                | Download Link   |
|-----------------|----------------------------------|---|
| ODBC            | Greenplum DataDirect ODBC Driver | <a href="https://network.pivotal.io/products/pivotal-gpdb">https://network.pivotal.io/products/pivotal-gpdb</a> . |
| ODBC            | psqlODBC                         | <a href="https://odbc.postgresql.org/">https://odbc.postgresql.org/</a>   |
| JDBC            | Greenplum DataDirect JDBC Driver | <a href="https://network.pivotal.io/products/pivotal-gpdb">https://network.pivotal.io/products/pivotal-gpdb</a>   |
| JDBC            | pgjdbc                           | <a href="https://jdbc.postgresql.org/">https://jdbc.postgresql.org/</a>   |
| Perl DBI        | pgperl                           | <a href="https://metacpan.org/release/DBD-Pg">https://metacpan.org/release/DBD-Pg</a>                             |
| Python DBI      | pygresql                         | <a href="http://www.pygresql.org/">http://www.pygresql.org/</a>   |
| libpq C Library | libpq                            | <a href="https://www.postgresql.org/docs/9.4/libpq.html">https://www.postgresql.org/docs/9.4/libpq.html</a>       |

General instructions for accessing a Greenplum Database with an API are:

1. Download your programming language platform and respective API from the appropriate source. For example, you can get the Java Development Kit (JDK) and JDBC API from Oracle.
2. Write your client application according to the API specifications. When programming your application, be aware of the SQL support in Greenplum Database so you do not include any unsupported SQL syntax.

Download the appropriate driver and configure connectivity to your Greenplum Database master instance.

## Troubleshooting Connection Problems

A number of things can prevent a client application from successfully connecting to Greenplum Database. This topic explains some of the common causes of connection problems and how to correct them.

| Problem  | Solution   |
|--|--|
| No <code>pg_hba.conf</code> entry for host or user | To enable Greenplum Database to accept remote client connections, you must configure your Greenplum Database master instance so that connections are allowed from the client hosts and database users that will be connecting to Greenplum Database. This is done by adding the appropriate entries to the <code>pg_hba.conf</code> configuration file (located in the master instance's data directory). For more detailed information, see <a href="#">Allowing Connections to Greenplum Database</a> .  |
| Greenplum Database is not running                  | If the Greenplum Database master instance is down, users will not be able to connect. You can verify that the Greenplum Database system is up by running the <code>gpstate</code> utility on the Greenplum master host.  |
| Network problems<br><br>Interconnect timeouts      | <p>If users connect to the Greenplum master host from a remote client, network problems can prevent a connection (for example, DNS host name resolution problems, the host system is down, and so on.). To ensure that network problems are not the cause, connect to the Greenplum master host from the remote client host. For example: <code>ping hostname</code></p> <p>If the system cannot resolve the host names and IP addresses of the hosts involved in Greenplum Database, queries and connections will fail. For some operations, connections to the Greenplum Database master use <code>localhost</code> and others use the actual host name, so you must be able to resolve both. If you encounter this error, first make sure you can connect to each host in your Greenplum Database array from the master host over the network. In the <code>/etc/hosts</code> file of the master and all segments, make sure you have the correct host names and IP addresses for all hosts involved in the Greenplum Database array. The <code>127.0.0.1</code> IP must resolve to <code>localhost</code>.</p> |
| Too many clients already                           | By default, Greenplum Database is configured to allow a maximum of 250 concurrent user connections on the master and 750 on a segment. A connection attempt that causes that limit to be exceeded will be refused. This limit is controlled by the <code>max_connections</code> parameter in the <code>postgresql.conf</code> configuration file of the Greenplum Database master. If you change this setting for the master, you must also make appropriate changes at the segments.  |

## Configuring the Greenplum Database System

Server configuration parameters affect the behavior of Greenplum Database. They are part of the PostgreSQL "Grand Unified Configuration" system, so they are sometimes called "GUCs." Most of the Greenplum Database server configuration parameters are the same as the PostgreSQL configuration parameters, but some are Greenplum-specific.

- [About Greenplum Database Master and Local Parameters](#)
- [Setting Configuration Parameters](#)
- [Viewing Server Configuration Parameter Settings](#)
- [Configuration Parameter Categories](#)

Parent topic: [Managing a Greenplum System](#)

## About Greenplum Database Master and Local Parameters

Server configuration files contain parameters that configure server behavior. The Greenplum Database configuration file, `postgresql.conf`, resides in the data directory of the database instance.

The master and each segment instance have their own `postgresql.conf` file. Some parameters are *local*: each segment instance examines its `postgresql.conf` file to get the value of that parameter. Set local parameters on the master and on each segment instance.

Other parameters are *master* parameters that you set on the master instance. The value is passed down to (or in some cases ignored by) the segment instances at query run time.

See the *Greenplum Database Reference Guide* for information about *local* and *master* server configuration parameters.

**Parent topic:** [Configuring the Greenplum Database System](#)

## Setting Configuration Parameters

Many configuration parameters limit who can change them and where or when they can be set. For example, to change certain parameters, you must be a Greenplum Database superuser. Other parameters can be set only at the system level in the `postgresql.conf` file or require a system restart to take effect.

Many configuration parameters are *session* parameters. You can set session parameters at the system level, the database level, the role level or the session level. Database users can change most session parameters within their session, but some require superuser permissions.

See the *Greenplum Database Reference Guide* for information about setting server configuration parameters.

- [Setting a Local Configuration Parameter](#)
- [Setting a Master Configuration Parameter](#)

**Parent topic:** [Configuring the Greenplum Database System](#)

## Setting a Local Configuration Parameter

To change a local configuration parameter across multiple segments, update the parameter in the `postgresql.conf` file of each targeted segment, both primary and mirror. Use the `gpconfig` utility to set a parameter in all Greenplum `postgresql.conf` files. For example:

```
$ gpconfig -c gp_vmem_protect_limit -v 4096
```

Restart Greenplum Database to make the configuration changes effective:

```
$ gpstop -r
```

**Parent topic:** [Setting Configuration Parameters](#)

## Setting a Master Configuration Parameter

To set a master configuration parameter, set it at the Greenplum Database master instance. If it is also a *session* parameter, you can set the parameter for a particular database, role or session. If a parameter is set at multiple levels, the most granular level takes precedence. For example, session overrides role, role overrides database, and database overrides system.

- [Setting Parameters at the System Level](#)
- [Setting Parameters at the Database Level](#)
- [Setting Parameters at the Role Level](#)
- [Setting Parameters in a Session](#)

Parent topic: [Setting Configuration Parameters](#)

## Setting Parameters at the System Level

Master parameter settings in the master `postgresql.conf` file are the system-wide default. To set a master parameter:

1. Edit the `$MASTER_DATA_DIRECTORY/postgresql.conf` file.
2. Find the parameter to set, uncomment it (remove the preceding `#` character), and type the desired value.
3. Save and close the file.
4. For *session* parameters that do not require a server restart, upload the `postgresql.conf` changes as follows:

```
$ gpstop -u
```

5. For parameter changes that require a server restart, restart Greenplum Database as follows:

```
$ gpstop -r
```

For details about the server configuration parameters, see the *Greenplum Database Reference Guide*.

Parent topic: [Setting a Master Configuration Parameter](#)

## Setting Parameters at the Database Level

Use `ALTER DATABASE` to set parameters at the database level. For example:

```
=# ALTER DATABASE mydatabase SET search_path TO myschema;
```

When you set a session parameter at the database level, every session that connects to that database uses that parameter setting. Settings at the database level override settings at the system level.

Parent topic: [Setting a Master Configuration Parameter](#)

## Setting Parameters at the Role Level

Use `ALTER ROLE` to set a parameter at the role level. For example:

```
=# ALTER ROLE bob SET search_path TO bobschema;
```

When you set a session parameter at the role level, every session initiated by that role uses that parameter setting. Settings at the role level override settings at the database level.

**Parent topic:** [Setting a Master Configuration Parameter](#)

## Setting Parameters in a Session

Any session parameter can be set in an active database session using the `SET` command. For example:

```
=# SET statement_mem TO '200MB';
```

The parameter setting is valid for the rest of that session or until you issue a `RESET` command. For example:

```
=# RESET statement_mem;
```

Settings at the session level override those at the role level.

**Parent topic:** [Setting a Master Configuration Parameter](#)

## Viewing Server Configuration Parameter Settings

The SQL command `SHOW` allows you to see the current server configuration parameter settings. For example, to see the settings for all parameters:

```
$ psql -c 'SHOW ALL;'
```

`SHOW` lists the settings for the master instance only. To see the value of a particular parameter across the entire system (master and all segments), use the `gpconfig` utility. For example:

```
$ gpconfig --show max_connections
```

**Parent topic:** [Configuring the Greenplum Database System](#)

## Configuration Parameter Categories

Configuration parameters affect categories of server behaviors, such as resource consumption, query tuning, and authentication. Refer to [Parameter Categories](#) in the *Greenplum Database Reference Guide* for a list of Greenplum server configuration parameter categories.

**Parent topic:** [Configuring the Greenplum Database System](#)

## Enabling Compression

You can configure Greenplum Database to use data compression with some database features and with some utilities. Compression reduces disk usage and improves I/O across the system, however,

it adds some performance overhead when compressing and decompressing data.

You can configure support for data compression with these features and utilities. See the specific feature or utility for information about support for compression.

- Append-optimized tables support compressing table data. See [CREATE TABLE](#).
- User-defined data types can be defined to compress data. See [CREATE TYPE](#).
- The external table protocols [gpfdist \(gpfdists\)](#), [s3](#), and [pxf](#) support compression when accessing external data. For information about external tables, see [CREATE EXTERNAL TABLE](#).
- Workfiles (temporary spill files that are created when running a query that requires more memory than it is allocated) can be compressed. See the server configuration parameter [gp\\_workfile\\_compression](#).
- The Greenplum Database utilities [gpbackup](#), [gprestore](#), [gpcopy](#), [gpload](#), and [gplogfilter](#) support compression.

For some compression algorithms (such as `zlib`) Greenplum Database requires software packages installed on the host system. For information about required software packages, see the *Greenplum Database Installation Guide*.

**Parent topic:** [Managing a Greenplum System](#)

## Configuring Proxies for the Greenplum Interconnect

You can configure a Greenplum system to use proxies for interconnect communication to reduce the use of connections and ports during query processing.

The Greenplum *interconnect* (the networking layer) refers to the inter-process communication between segments and the network infrastructure on which this communication relies. For information about the Greenplum architecture and interconnect, see [About the Greenplum Architecture](#).

In general, when running a query, a QD (query dispatcher) on the Greenplum master creates connections to one or more QE (query executor) processes on segments, and a QE can create connections to other QEs. For a description of Greenplum query processing and parallel query processing, see [About Greenplum Query Processing](#).

By default, connections between the QD on the master and QEs on segment instances and between QEs on different segment instances require a separate network port. You can configure a Greenplum system to use proxies when Greenplum communicates between the QD and QEs and between QEs on different segment instances. The interconnect proxies require only one network connection for Greenplum internal communication between two segment instances, so it consumes fewer connections and ports than `TCP` mode, and has better performance than `UDPIFC` mode in a high-latency network.

To enable interconnect proxies for the Greenplum system, set these system configuration parameters.

- List the proxy ports with the parameter [gp\\_interconnect\\_proxy\\_addresses](#). You must specify a proxy port for the master, standby master, and all segment instances.
- Set the parameter [gp\\_interconnect\\_type](#) to `proxy`.

**Note:** When expanding a Greenplum Database system, you must deactivate interconnect proxies before adding new hosts and segment instances to the system, and you must update the `gp_interconnect_proxy_addresses` parameter with the newly-added segment instances before you re-enable interconnect proxies.

**Parent topic:** [Managing a Greenplum System](#)

## Example

This example sets up a Greenplum system to use proxies for the Greenplum interconnect when running queries. The example sets the `gp_interconnect_proxy_addresses` parameter and tests the proxies before setting the `gp_interconnect_type` parameter for the Greenplum system.

- [Setting the Interconnect Proxy Addresses](#)
- [Testing the Interconnect Proxies](#)
- [Setting Interconnect Proxies for the System](#)

## Setting the Interconnect Proxy Addresses

Set the `gp_interconnect_proxy_addresses` parameter to specify the proxy ports for the master and segment instances. The syntax for the value has the following format and you must specify the parameter value as a single-quoted string.

```
<db_id>:<cont_id>:<seg_address>:<port>[, ... ]
```

For the master, standby master, and segment instance, the first three fields, `db_id`, `cont_id`, and `seg_address` can be found in the `gp_segment_configuration` catalog table. The fourth field, `port`, is the proxy port for the Greenplum master or a segment instance.

- `db_id` is the `dbid` column in the catalog table.
- `cont_id` is the `content` column in the catalog table.
- `seg_address` is the IP address or hostname corresponding to the `address` column in the catalog table.
- `port` is the TCP/IP port for the segment instance proxy that you specify.

**Important:** If a segment instance hostname is bound to a different IP address at runtime, you must run `gpstop -u` to re-load the `gp_interconnect_proxy_addresses` value.

This is an example PL/Python function that displays or sets the segment instance proxy port values for the `gp_interconnect_proxy_addresses` parameter. To create and run the function, you must enable PL/Python in the database with the `CREATE EXTENSION plpythonu` command.

```
--
-- A PL/Python function to setup the interconnect proxy addresses.
-- Requires the Python modules os and socket.
--
-- Usage:
--   select my_setup_ic_proxy(-1000, '');           -- display IC proxy values for
segments
--   select my_setup_ic_proxy(-1000, 'update proxy'); -- update the gp_interconnect_p
proxy_addresses parameter
```

```

--
-- The first argument, "delta", is used to calculate the proxy port with this formula:
--
--   proxy_port = postmaster_port + delta
--
-- The second argument, "action", is used to update the gp_interconnect_proxy_addresses
parameter.
-- The parameter is not updated unless "action" is 'update proxy'.
-- Note that running "gpstop -u" is required for the update to take effect.
-- A Greenplum system restart will also work.
--
create or replace function my_setup_ic_proxy(delta int, action text)
returns table(dbid smallint, content smallint, address text, port int) as $$
import os
import socket

results = []
value = ''

segs = plpy.execute('''SELECT dbid, content, port, address
                        FROM gp_segment_configuration
                        ORDER BY 1''')

for seg in segs:
    dbid = seg['dbid']
    content = seg['content']
    port = seg['port']
    address = seg['address']

    # decide the proxy port
    port = port + delta

    # append to the result list
    results.append((dbid, content, address, port))

    # build the value for the GUC
    if value:
        value += ','
    value += '{}:({}):({}):({})'.format(dbid, content, address, port)

if action.lower() == 'update proxy':
    os.system('gpconfig --skipvalidation -c gp_interconnect_proxy_addresses -v
''{}}'''.format(value))
    plpy.notice('the settings are applied, please reload with 'gpstop -u' to take
effect.')
else:
    plpy.notice('if the settings are correct, re-run with 'update proxy' to apply.')
return results
$$ language plpythonu execute on master;

```

**Note:** When you run the function, you should connect to the database using the Greenplum interconnect type `UDPIFC` or `TCP`. This example uses `psql` to connect to the database `mytest` with the interconnect type `UDPIFC`.

```
PGOPTIONS="-c gp_interconnect_type=udpifc" psql -d mytest
```

Running this command lists the segment instance values for the `gp_interconnect_proxy_addresses` parameter.

```
select my_setup_ic_proxy(-1000, '');
```

This command runs the function to set the parameter.

```
select my_setup_ic_proxy(-1000, 'update proxy');
```

As an alternative, you can run the `gpconfig` utility to set the `gp_interconnect_proxy_addresses` parameter. To set the value as a string, the value is a single-quoted string that is enclosed in double quotes. The example Greenplum system consists of a master and a single segment instance.

```
gpconfig --skipvalidation -c gp_interconnect_proxy_addresses -v "'1:-1:192.168.180.50:35432,2:0:192.168.180.54:35000'"
```

After setting the `gp_interconnect_proxy_addresses` parameter, reload the `postgresql.conf` file with the `gpstop -u` command. This command does not stop and restart the Greenplum system.

## Testing the Interconnect Proxies

To test the proxy ports configured for the system, you can set the `PGOPTIONS` environment variable when you start a `psql` session in a command shell. This command sets the environment variable to enable interconnect proxies, starts `psql`, and logs into the database `mytest`.

```
PGOPTIONS="-c gp_interconnect_type=proxy" psql -d mytest
```

You can run queries in the shell to test the system. For example, you can run a query that accesses all the primary segment instances. This query displays the segment IDs and number of rows on the segment instance from the table `sales`.

```
# SELECT gp_segment_id, COUNT(*) FROM sales GROUP BY gp_segment_id ;
```

## Setting Interconnect Proxies for the System

After you have tested the interconnect proxies for the system, set the server configuration parameter for the system with the `gpconfig` utility.

```
gpconfig -c gp_interconnect_type -v proxy
```

Reload the `postgresql.conf` file with the `gpstop -u` command. This command does not stop and restart the Greenplum system.

## Enabling High Availability and Data Consistency Features

The fault tolerance and the high-availability features of Greenplum Database can be configured.

**Important:** When data loss is not acceptable for a Greenplum Database cluster, Greenplum master and segment mirroring is recommended. If mirroring is not enabled then Greenplum stores only one copy of the data, so the underlying storage media provides the only guarantee for data availability and correctness in the event of a hardware failure.

The VMware Tanzu Greenplum on vSphere virtualized environment ensures the enforcement of anti-affinity rules required for Greenplum mirroring solutions and fully supports mirrorless

deployments. Other virtualized or containerized deployment environments are generally not supported for production use unless both Greenplum master and segment mirroring are enabled.

For information about the utilities that are used to enable high availability, see the *Greenplum Database Utility Guide*.

- [Overview of Greenplum Database High Availability](#)
- [Enabling Mirroring in Greenplum Database](#)
- [How Greenplum Database Detects a Failed Segment](#)
- [Understanding Segment Recovery](#)
- [Recovering from Segment Failures](#)
- [Recovering a Failed Master](#)

**Parent topic:** [Managing a Greenplum System](#)

## Overview of Greenplum Database High Availability

A Greenplum Database system can be made highly available by providing a fault-tolerant hardware platform, by enabling Greenplum Database high-availability features, and by performing regular monitoring and maintenance procedures to ensure the health of all system components.

Hardware components will eventually fail, whether due to normal wear or an unexpected circumstance. Loss of power can lead to temporarily unavailable components. A system can be made highly available by providing redundant standbys for components that can fail so that services can continue uninterrupted when a failure does occur. In some cases, the cost of redundancy is higher than users' tolerance for interruption in service. When this is the case, the goal is to ensure that full service is able to be restored, and can be restored within an expected timeframe.

With Greenplum Database, fault tolerance and data availability is achieved with:

- [Hardware level RAID storage protection](#)
- [Data storage checksums](#)
- [Greenplum segment mirroring](#)
- [Master mirroring](#)
- [Dual clusters](#)
- [Database backup and restore](#)

### Hardware level RAID

A best practice Greenplum Database deployment uses hardware level RAID to provide high performance redundancy for single disk failure without having to go into the database level fault tolerance. This provides a lower level of redundancy at the disk level.

### Data storage checksums

Greenplum Database uses checksums to verify that data loaded from disk to memory has not been corrupted on the file system.

Greenplum Database has two kinds of storage for user data: heap and append-optimized. Both storage models use checksums to verify data read from the file system and, with the default settings, they handle checksum verification errors in a similar way.

Greenplum Database master and segment database processes update data on pages in the memory they manage. When a memory page is updated and flushed to disk, checksums are computed and saved with the page. When a page is later retrieved from disk, the checksums are verified and the page is only permitted to enter managed memory if the verification succeeds. A failed checksum verification is an indication of corruption in the file system and causes Greenplum Database to generate an error, cancelling the transaction.

The default checksum settings provide the best level of protection from undetected disk corruption propagating into the database and to mirror segments.

Heap checksum support is enabled by default when the Greenplum Database cluster is initialized with the `gpinitssystem` management utility. Although it is strongly discouraged, a cluster can be initialized without heap checksum support by setting the `HEAP_CHECKSUM` parameter to off in the `gpinitssystem` cluster configuration file. See [gpinitssystem](#).

Once initialized, it is not possible to change heap checksum support for a cluster without reinitializing the system and reloading databases.

You can check the read-only server configuration parameter `data_checksums` to see if heap checksums are enabled in a cluster:

```
$ gpconfig -s data_checksums
```

When a Greenplum Database cluster starts up, the `gpstart` utility checks that heap checksums are consistently enabled or deactivated on the master and all segments. If there are any differences, the cluster fails to start. See [gpstart](#).

In cases where it is necessary to ignore heap checksum verification errors so that data can be recovered, setting the `ignore_checksum_failure` system configuration parameter to on causes Greenplum Database to issue a warning when a heap checksum verification fails, but the page is then permitted to load into managed memory. If the page is updated and saved to disk, the corrupted data could be replicated to the mirror segment. Because this can lead to data loss, setting `ignore_checksum_failure` to on should only be done to enable data recovery.

For append-optimized storage, checksum support is one of several storage options set at the time an append-optimized table is created with the `CREATE TABLE` command. The default storage options are specified in the `gp_default_storage_options` server configuration parameter. The `checksum` storage option is activated by default and deactivating it is strongly discouraged.

If you choose to deactivate checksums for an append-optimized table, you can either

- change the `gp_default_storage_options` configuration parameter to include `checksum=false` before creating the table, or
- add the `checksum=false` option to the `WITH storage_options` clause of the `CREATE TABLE` statement.

Note that the `CREATE TABLE` statement allows you to set storage options, including checksums, for individual partition files.

See the [CREATE TABLE](#) command reference and the `gp_default_storage_options` configuration parameter reference for syntax and examples.

## Segment Mirroring

Greenplum Database stores data in multiple segment instances, each of which is a Greenplum Database PostgreSQL instance. The data for each table is spread between the segments based on the distribution policy that is defined for the table in the DDL at the time the table is created. When segment mirroring is enabled, for each segment instance there is a *primary* and *mirror* pair. The mirror segment is kept up to date with the primary segment using Write-Ahead Logging (WAL)-based streaming replication. See [Overview of Segment Mirroring](#).

The mirror instance for each segment is usually initialized with the `gpinitssystem` utility or the `gpexpand` utility. As a best practice, the mirror runs on a different host than the primary instance to protect from a single machine failure. There are different strategies for assigning mirrors to hosts. When choosing the layout of the primaries and mirrors, it is important to consider the failure scenarios to ensure that processing skew is minimized in the case of a single machine failure.

## Master Mirroring

There are two master instances in a highly available cluster, a *primary* and a *standby*. As with segments, the master and standby should be deployed on different hosts so that the cluster can tolerate a single host failure. Clients connect to the primary master and queries can be run only on the primary master. The standby master is kept up to date with the primary master using Write-Ahead Logging (WAL)-based streaming replication. See [Overview of Master Mirroring](#).

If the master fails, the administrator runs the `gpactivatestandby` utility to have the standby master take over as the new primary master. You can configure a virtual IP address for the master and standby so that client programs do not have to switch to a different network address when the current master changes. If the master host fails, the virtual IP address can be swapped to the actual acting master.

## Dual Clusters

An additional level of redundancy can be provided by maintaining two Greenplum Database clusters, both storing the same data.

Two methods for keeping data synchronized on dual clusters are "dual ETL" and "backup/restore."

Dual ETL provides a complete standby cluster with the same data as the primary cluster. ETL (extract, transform, and load) refers to the process of cleansing, transforming, validating, and loading incoming data into a data warehouse. With dual ETL, this process is run twice in parallel, once on each cluster, and is validated each time. It also allows data to be queried on both clusters, doubling the query throughput. Applications can take advantage of both clusters and also ensure that the ETL is successful and validated on both clusters.

To maintain a dual cluster with the backup/restore method, create backups of the primary cluster and restore them on the secondary cluster. This method takes longer to synchronize data on the secondary cluster than the dual ETL strategy, but requires less application logic to be developed.

Populating a second cluster with backups is ideal in use cases where data modifications and ETL are performed daily or less frequently.

## Backup and Restore

Making regular backups of the databases is recommended except in cases where the database can be easily regenerated from the source data. Backups should be taken to protect from operational, software, and hardware errors.

Use the `gpbackup` utility to backup Greenplum databases. `gpbackup` performs the backup in parallel across segments, so backup performance scales up as hardware is added to the cluster.

When designing a backup strategy, a primary concern is where to store the backup data. The data each segment manages can be backed up on the segment's local storage, but should not be stored there permanently—the backup reduces disk space available to the segment and, more importantly, a hardware failure could simultaneously destroy the segment's live data and the backup. After performing a backup, the backup files should be moved from the primary cluster to separate, safe storage. Alternatively, the backup can be made directly to separate storage.

Using a Greenplum Database storage plugin with the `gpbackup` and `gprestore` utilities, you can send a backup to, or retrieve a backup from a remote location or a storage appliance. Greenplum Database storage plugins support connecting to locations including Amazon Simple Storage Service (Amazon S3) locations and Dell EMC Data Domain storage appliances.

Using the Backup/Restore Storage Plugin API you can create a custom plugin that the `gpbackup` and `gprestore` utilities can use to integrate a custom backup storage system with the Greenplum Database.

For information about using `gpbackup` and `gprestore`, see [VMware Tanzu Greenplum Backup and Restore Documentation](#).

- [Overview of Segment Mirroring](#)
- [Overview of Master Mirroring](#)

**Parent topic:** [Enabling High Availability and Data Consistency Features](#)

## Overview of Segment Mirroring

When Greenplum Database High Availability is enabled, there are two types of segment instances: *primary* and *mirror*. Each primary segment has one corresponding mirror segment. A primary segment instance receives requests from the master to make changes to the segment data and then replicates those changes to the corresponding mirror. If Greenplum Database detects that a primary segment has failed or become unavailable, it changes the role of its mirror segment to primary segment and the role of the unavailable primary segment to mirror segment. Transactions in progress when the failure occurred roll back and must be restarted. The administrator must then recover the mirror segment, allow the mirror to synchronize with the current primary segment, and then exchange the primary and mirror segments so they are in their preferred roles.

If segment mirroring is not enabled, the Greenplum Database system shuts down if a segment instance fails. Administrators must manually recover all failed segments before Greenplum Database operations can resume.

When segment mirroring is enabled for an existing system, the primary segment instances continue to provide service to users while a snapshot of the primary segments are taken. While the snapshots are taken and deployed on the mirror segment instances, changes to the primary segment are also recorded. After the snapshot has been deployed on the mirror segment, the mirror segment is synchronized and kept current using Write-Ahead Logging (WAL)-based streaming replication. Greenplum Database WAL replication uses the `walsender` and `walreceiver` replication processes. The `walsender` process is a primary segment process. The `walreceiver` is a mirror segment process.

When database changes occur, the logs that capture the changes are streamed to the mirror segment to keep it current with the corresponding primary segments. During WAL replication, database changes are written to the logs before being applied, to ensure data integrity for any in-process operations.

When Greenplum Database detects a primary segment failure, the WAL replication process stops and the mirror segment automatically starts as the active primary segment. If a mirror segment fails or becomes inaccessible while the primary is active, the primary segment tracks database changes in logs that are applied to the mirror when it is recovered. For information about segment fault detection and the recovery process, see [How Greenplum Database Detects a Failed Segment and Recovering from Segment Failures](#).

These Greenplum Database system catalog tables contain mirroring and replication information.

- The catalog table `gp_segment_configuration` contains the current configuration and state of primary and mirror segment instances and the master and standby master instance.
- The catalog view `gp_stat_replication` contains replication statistics of the `walsender` processes that are used for Greenplum Database master and segment mirroring.

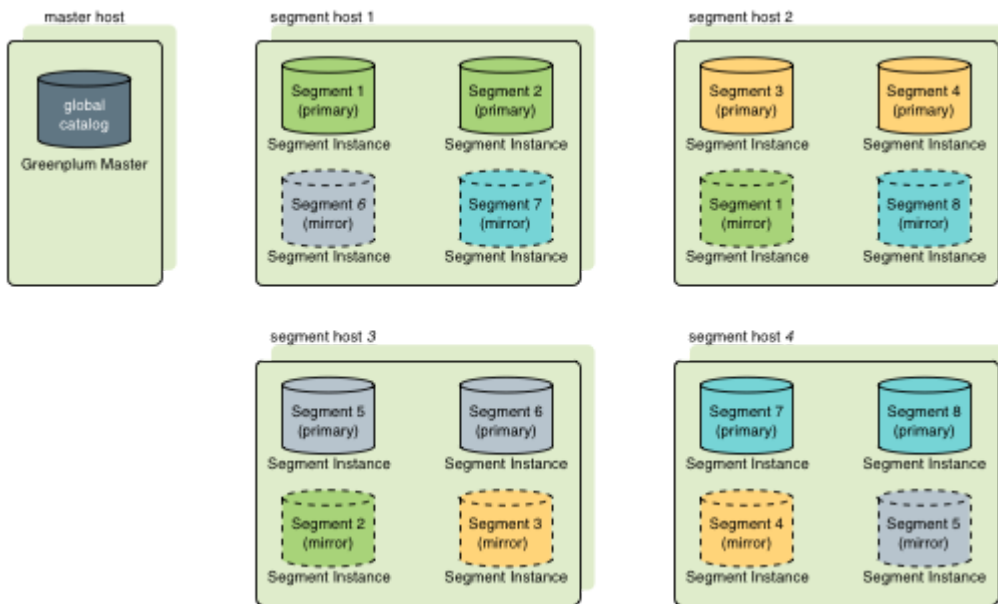

## About Segment Mirroring Configurations

Mirror segment instances can be placed on hosts in the cluster in different configurations. As a best practice, a primary segment and the corresponding mirror are placed on different hosts. Each host must have the same number of primary and mirror segments. When you create segment mirrors with the Greenplum Database utilities `gpinitssystem` or `gpaddmirrors` you can specify the segment mirror configuration, group mirroring (the default) or spread mirroring. With `gpaddmirrors`, you can create custom mirroring configurations with a `gpaddmirrors` configuration file and specify the file on the command line.

*Group mirroring* is the default mirroring configuration when you enable mirroring during system initialization. The mirror segments for each host's primary segments are placed on one other host. If a single host fails, the number of active primary segments doubles on the host that backs the failed host. [Figure 1](#) illustrates a group mirroring configuration.

*Spread mirroring* can be specified during system initialization. This configuration spreads each host's mirrors over multiple hosts so that if any single host fails, no other host will have more than one mirror promoted to an active primary segment. Spread mirroring is possible only if there are more hosts than segments per host. [Figure 2](#) illustrates the placement of mirrors in a spread segment mirroring configuration.

**Note:** You must ensure you have the appropriate number of host systems for your mirroring configuration when you create a system or when you expand a system. For example, to create a system that is configured with spread mirroring requires more hosts than segment instances per host, and a system that is configured with group mirroring requires at least two new hosts when expanding the system. For information about segment mirroring configurations, see [Segment Mirroring Configurations](#). For information about expanding systems with segment mirroring enabled, see [Planning Mirror Segments](#).

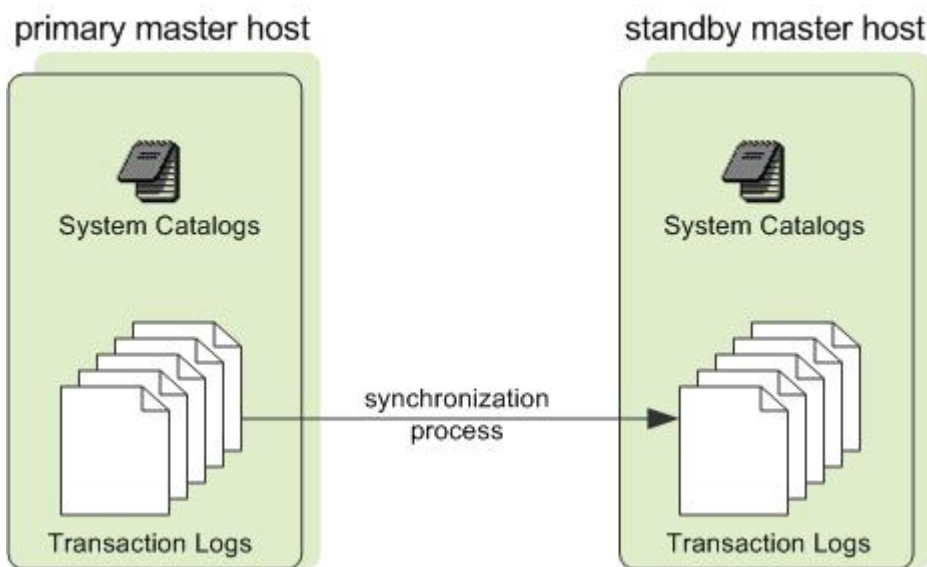

**Parent topic:** [Overview of Greenplum Database High Availability](#)

## Overview of Master Mirroring

You can deploy a backup or mirror of the master instance on a separate host machine. The backup master instance, called the *standby master*, serves as a warm standby if the primary master becomes nonoperational. You create a standby master from the primary master while the primary is online.

When you enable master mirroring for an existing system, the primary master continues to provide service to users while a snapshot of the primary master instance is taken. While the snapshot is taken and deployed on the standby master, changes to the primary master are also recorded. After the snapshot has been deployed on the standby master, the standby master is synchronized and kept current using Write-Ahead Logging (WAL)-based streaming replication. Greenplum Database WAL replication uses the `walsender` and `walreceiver` replication processes. The `walsender` process is a primary master process. The `walreceiver` is a standby master process.

Since the master does not house user data, only system catalog tables are synchronized between the primary and standby masters. When these tables are updated, the replication logs that capture the changes are streamed to the standby master to keep it current with the primary. During WAL replication, all database modifications are written to replication logs before being applied, to ensure data integrity for any in-process operations.

This is how Greenplum Database handles a master failure.

- If the primary master fails, the Greenplum Database system shuts down and the master replication process stops. The administrator runs the `gpactivatestandby` utility to have the standby master take over as the new primary master. Upon activation of the standby master, the replicated logs reconstruct the state of the primary master at the time of the last successfully committed transaction. The activated standby master then functions as the Greenplum Database master, accepting connections on the port specified when standby master was initialized. See [Recovering a Failed Master](#).
- If the standby master fails or becomes inaccessible while the primary master is active, the primary master tracks database changes in logs that are applied to the standby master when it is recovered.

These Greenplum Database system catalog tables contain mirroring and replication information.

- The catalog table `gp_segment_configuration` contains the current configuration and state of primary and mirror segment instances and the master and standby master instance.
- The catalog view `gp_stat_replication` contains replication statistics of the `walsender` processes that are used for Greenplum Database master and segment mirroring.

Parent topic: [Overview of Greenplum Database High Availability](#)

## Enabling Mirroring in Greenplum Database

You can configure your Greenplum Database system with mirroring at setup time using `gpinitssystem` or enable mirroring later using `gpaddmirrors` and `gpinitstandby`. This topic assumes you are adding mirrors to an existing system that was initialized without mirrors.

- [Enabling Segment Mirroring](#)
- [Enabling Master Mirroring](#)

Parent topic: [Enabling High Availability and Data Consistency Features](#)

## Enabling Segment Mirroring

Mirror segments allow database queries to fail over to a backup segment if the primary segment is unavailable. By default, mirrors are configured on the same array of hosts as the primary segments. You may choose a completely different set of hosts for your mirror segments so they do not share machines with any of your primary segments.

**Important:** During the online data replication process, Greenplum Database should be in a quiescent state, workloads and other queries should not be running.

## To add segment mirrors to an existing system (same hosts as primaries)

1. Allocate the data storage area for mirror data on all segment hosts. The data storage area must be different from your primary segments' file system location.
2. Use `gpssh-exkeys` to ensure that the segment hosts can SSH and SCP to each other without a password prompt.
3. Run the `gpaddmirrors` utility to enable mirroring in your Greenplum Database system. For example, to add 10000 to your primary segment port numbers to calculate the mirror segment port numbers:

```
$ gpaddmirrors -p 10000
```

Where `-p` specifies the number to add to your primary segment port numbers. Mirrors are added with the default group mirroring configuration.

## To add segment mirrors to an existing system (different hosts from primaries)

1. Ensure the Greenplum Database software is installed on all hosts. See the *Greenplum Database Installation Guide* for detailed installation instructions.
2. Allocate the data storage area for mirror data, and tablespaces if needed, on all segment hosts.
3. Use `gpssh-exkeys` to ensure the segment hosts can SSH and SCP to each other without a password prompt.
4. Create a configuration file that lists the host names, ports, and data directories on which to create mirrors. To create a sample configuration file to use as a starting point, run:

```
$ gpaddmirrors -o <filename>
```

The format of the mirror configuration file is:

```
<row_id>=<contentID>|<address>|<port>|<data_dir>
```

Where `row_id` is the row in the file, `contentID` is the segment instance content ID, `address` is the host name or IP address of the segment host, `port` is the communication port, and `data_dir` is the segment instance data directory.

For example, this is contents of a mirror configuration file for two segment hosts and two segment instances per host:

```
0=2|sdw1-1|41000|/data/mirror1/gp2
1=3|sdw1-2|41001|/data/mirror2/gp3
2=0|sdw2-1|41000|/data/mirror1/gp0
3=1|sdw2-2|41001|/data/mirror2/gp1
```

5. Run the `gpaddmirrors` utility to enable mirroring in your Greenplum Database system:

```
$ gpaddmirrors -i <mirror_config_file>
```

The `-i` option specifies the mirror configuration file you created.

**Parent topic:** [Enabling Mirroring in Greenplum Database](#)

## Enabling Master Mirroring

You can configure a new Greenplum Database system with a standby master using `gpinitssystem` or enable it later using `gpinitstandby`. This topic assumes you are adding a standby master to an existing system that was initialized without one.

For information about the utilities `gpinitssystem` and `gpinitstandby`, see the *Greenplum Database Utility Guide*.

## To add a standby master to an existing system

1. Ensure the standby master host is installed and configured: `gpadmin` system user created, Greenplum Database binaries installed, environment variables set, SSH keys exchanged, and that the data directories and tablespace directories, if needed, are created.

2. Run the `gpinitstandby` utility on the currently active *primary* master host to add a standby master host to your Greenplum Database system. For example:

```
$ gpinitstandby -s smdw
```

Where `-s` specifies the standby master host name.

To switch operations to a standby master, see [Recovering a Failed Master](#).

## To check the status of the master mirroring process (optional)

You can run the `gpstate` utility with the `-f` option to display details of the standby master host.

```
$ gpstate -f
```

The standby master status should be passive, and the WAL sender state should be streaming.

For information about the `gpstate` utility, see the *Greenplum Database Utility Guide*.

**Parent topic:** [Enabling Mirroring in Greenplum Database](#)

## How Greenplum Database Detects a Failed Segment

With segment mirroring enabled, Greenplum Database automatically fails over to a mirror segment instance when a primary segment instance goes down. Provided one segment instance is online per portion of data, users may not realize a segment is down. If a transaction is in progress when a fault occurs, the in-progress transaction rolls back and restarts automatically on the reconfigured set of segments. The `gpstate` utility can be used to identify failed segments. The utility displays information from the catalog tables including `gp_segment_configuration`.

If the entire Greenplum Database system becomes nonoperational due to a segment failure (for example, if mirroring is not enabled or not enough segments are online to access all user data), users will see errors when trying to connect to a database. The errors returned to the client program may indicate the failure. For example:

```
ERROR: All segment databases are unavailable
```

## How a Segment Failure is Detected and Managed

On the Greenplum Database master host, the Postgres `postmaster` process forks a fault probe process, `ftsprobe`. This is also known as the FTS (Fault Tolerance Server) process. The `postmaster` process restarts the FTS if it fails.

The FTS runs in a loop with a sleep interval between each cycle. On each loop, the FTS probes each primary segment instance by making a TCP socket connection to the segment instance using the hostname and port registered in the `gp_segment_configuration` table. If the connection succeeds, the segment performs a few simple checks and reports back to the FTS. The checks include running a `stat` system call on critical segment directories and checking for internal faults in

the segment instance. If no issues are detected, a positive reply is sent to the FTS and no action is taken for that segment instance.

If the connection cannot be made, or if a reply is not received in the timeout period, then a retry is attempted for the segment instance. If the configured maximum number of probe attempts fail, the FTS probes the segment's mirror to ensure that it is up, and then updates the `gp_segment_configuration` table, marking the primary segment "down" and setting the mirror to act as the primary. The FTS updates the `gp_configuration_history` table with the operations performed.

When there is only an active primary segment and the corresponding mirror is down, the primary goes into the *Not In Sync* state and continues logging database changes, so the mirror can be synchronized without performing a full copy of data from the primary to the mirror.

## Configuring FTS Behavior

There is a set of server configuration parameters that affect FTS behavior:

### `gp_fts_probe_interval`

How often, in seconds, to begin a new FTS loop. For example if the setting is 60 and the probe loop takes 10 seconds, the FTS process sleeps 50 seconds. If the setting is 60 and probe loop takes 75 seconds, the process sleeps 0 seconds. The default is 60, and the maximum is 3600.

### `gp_fts_probe_timeout`

Probe timeout between master and segment, in seconds. The default is 20, and the maximum is 3600.

### `gp_fts_probe_retries`

The number of attempts to probe a segment. For example if the setting is 5 there will be 4 retries after the first attempt fails. Default: 5

### `gp_log_fts`

Logging level for FTS. The value may be "off", "terse", "verbose", or "debug". The "verbose" setting can be used in production to provide useful data for troubleshooting. The "debug" setting should not be used in production. Default: "terse"

### `gp_segment_connect_timeout`

The maximum time (in seconds) allowed for a mirror to respond. Default: 600 (10 minutes)

In addition to the fault checking performed by the FTS, a primary segment that is unable to send data to its mirror can change the status of the mirror to down. The primary queues up the data and after `gp_segment_connect_timeout` seconds pass, indicates a mirror failure, causing the mirror to be marked down and the primary to go into *Not In Sync* mode.

- [Checking for Failed Segments](#)

**Parent topic:** [Enabling High Availability and Data Consistency Features](#)

## Checking for Failed Segments

With mirroring enabled, you can have failed segment instances in the system without interruption of service or any indication that a failure has occurred. You can verify the status of your system

using the `gpstate` utility, by examining the contents of the `gp_segment_configuration` catalog table, or by checking log files.

## Check for failed segments using gpstate

The `gpstate` utility provides the status of each individual component of a Greenplum Database system, including primary segments, mirror segments, master, and standby master.

On the master host, run the `gpstate` utility with the `-e` option to show segment instances with error conditions:

```
$ gpstate -e
```

If the utility lists `Segments with Primary and Mirror Roles Switched`, the segment is not in its *preferred role* (the role to which it was assigned at system initialization). This means the system is in a potentially unbalanced state, as some segment hosts may have more active segments than is optimal for top system performance.

Segments that display the `Config status` as `Down` indicate the corresponding mirror segment is down.

See [Recovering from Segment Failures](#) for instructions to fix this situation.

## Check for failed segments using the gp\_segment\_configuration table

To get detailed information about failed segments, you can check the `gp_segment_configuration` catalog table. For example:

```
$ psql postgres -c "SELECT * FROM gp_segment_configuration WHERE status='d';"
```

For failed segment instances, note the host, port, preferred role, and data directory. This information will help determine the host and segment instances to troubleshoot. To display information about mirror segment instances, run:

```
$ gpstate -m
```

## Check for failed segments by examining log files

Log files can provide information to help determine an error's cause. The master and segment instances each have their own log file in `log` of the data directory. The master log file contains the most information and you should always check it first.

Use the `gplogfilter` utility to check the Greenplum Database log files for additional information. To check the segment log files, run `gplogfilter` on the segment hosts using `gpssh`.

## To check the log files

1. Use `gplogfilter` to check the master log file for `WARNING`, `ERROR`, `FATAL` or `PANIC` log level messages:

```
$ gplogfilter -t
```

2. Use `gpssh` to check for `WARNING`, `ERROR`, `FATAL`, or `PANIC` log level messages on each segment instance. For example:

```
$ gpssh -f seg_hosts_file -e 'source
/usr/local/greenplum-db/greenplum_path.sh ; gplogfilter -t
/data1/primary/*/log/gpdb*.log' > seglog.out
```

**Parent topic:** [How Greenplum Database Detects a Failed Segment](#)

## Understanding Segment Recovery

This topic provides background information about concepts and principles of segment recovery. If you have down segments and need immediate help recovering them, see the instructions in [Recovering from Segment Failures](#). For information on how Greenplum Database detects that segments are down and an explanation of the Fault Tolerance Server (FTS) that manages down segment tracking, see [How Greenplum Database Detects a Failed Segment](#).

This topic is divided into the following sections:

- [Segment Recovery Basics](#)
- [Segment Recovery: Flow of Events](#)
- [Simple Failover and Recovery Example](#)
- [Incremental versus Full Recovery](#)

**Parent topic:** [Enabling High Availability and Data Consistency Features](#)

## Segment Recovery Basics

If the master cannot connect to a segment instance, it marks that segment as down in the Greenplum Database `gp_segment_configuration` table. The segment instance remains offline until an administrator takes steps to bring the segment back online. The process for recovering a down segment instance or host depends on the cause of the failure and on whether or not mirroring is enabled. A segment instance can be marked as down for a number of reasons:

- A segment host is unavailable; for example, due to network or hardware failures.
- A segment instance is not running; for example, there is no `postgres` database listener process.
- The data directory of the segment instance is corrupt or missing; for example, data is not accessible, the file system is corrupt, or there is a disk failure.

In order to bring the down segment instance back into operation again, you must correct the problem that made it fail in the first place, and then – if you have mirroring enabled – you can attempt to recover the segment instance from its mirror using the `gprecoverseg` utility.

## Segment Recovery: Flow of Events

## When a Primary Segment Goes Down

The following summarizes the flow of events that follow a **primary** segment going down:

1. A primary segment goes down.
2. The Fault Tolerance Server (FTS) detects this and marks the segment as down in the `gp_segment_configuration` table.
3. The mirror segment is promoted to primary and starts functioning as primary. The previous primary is demoted to mirror.
4. The user fixes the underlying problem.
5. The user runs `gprecoverseg` to bring back the (formerly primary) mirror segment.
6. The WAL synchronization process ensures that the mirror segment data is synchronized with the primary segment data. Users can check the state of this syncing with `gpstate -e`.
7. Greenplum Database marks the segments as up (u) in the `gp_segment_configuration` table.
8. If segments are not in their preferred roles, user runs `gprecoverseg -r` to restore them to their preferred roles.

## When a Mirror Segment Goes Down

The following summarizes the flow of events that follow a **mirror** segment going down:

1. A mirror segment goes down.
2. The Fault Tolerance Server (FTS) detects this and marks the segment as down in the `gp_segment_configuration` table.
3. The user fixes the underlying problem.
4. The user runs `gprecoverseg` to bring back the (formerly mirror) mirror segment.
5. The syncing process occurs: the mirror comes into sync with its primary via WAL syncing. You can check the state of this syncing with `gpstate -e`.

## Rebalancing After Recovery

After a segment instance has been recovered, the segments may not be in their preferred roles, which can cause processing to be skewed. The `gp_segment_configuration` table has the columns `role` (current role) and `preferred_role` (original role at the beginning). When a segment's `role` and `preferred_role` do not match the system may not be balanced. To rebalance the cluster and bring all the segments into their preferred roles, run the `gprecoverseg -r` command.

## Simple Failover and Recovery Example

Consider a single primary-mirror segment instance pair where the primary segment has failed over to the mirror. The following table shows the segment instance preferred role, role, mode, and status from the `gp_segment_configuration` table before beginning recovery of the failed primary segment.

You can also run `gpstate -e` to display any issues with a primary or mirror segment instances.

| Segment Type | preferred_role | role       | mode           | status  |
|--------------|----------------|------------|----------------|---------|
| Primary      | p(primary)     | m(mirror)  | n(Not In Sync) | d(down) |
| Mirror       | m(mirror)      | p(primary) | n(Not In Sync) | u(up)   |

The primary segment is down and segment instances are not in their preferred roles. The mirror segment is up and its role is now primary. However, it is not synchronized with its mirror (the former primary segment) because that segment is down. You must potentially fix either issues with the host the down segment is running on, issues with the segment instance itself, or both. You then use `gprecoverseg` to prepare failed segment instances for recovery and initiate synchronization between the primary and mirror instances.

After `gprecoverseg` has completed, the segments are in the states shown in the following table where the primary-mirror segment pair is up with the primary and mirror roles reversed from their preferred roles.

**Note:** There might be a lag between when `gprecoverseg` completes and when the segment status is set to `u` (up).

| Segment Type | preferred_role      | role            | mode            | status |
|--------------|---------------------|-----------------|-----------------|--------|
| Primary      | p(primary)          | m(mirror)       | s(Synchronized) | u(up)  |
| Mirror       | m(mirror)p(primary) | s(Synchronized) | u(up)           |        |

The `gprecoverseg -r` command rebalances the system by returning the segment roles to their preferred roles.

| Segment Type | preferred_role | role       | mode            | status |
|--------------|----------------|------------|-----------------|--------|
| Primary      | p(primary)     | p(primary) | s(Synchronized) | u(up)  |
| Mirror       | m(mirror)      | m(mirror)  | s(Synchronized) | u(up)  |

## Incremental versus Full Recovery

Greenplum database can perform two types of recovery: incremental or full. The default is incremental.

By default, `gprecoverseg` performs an incremental recovery, placing the mirror into *Synchronizing* mode, which starts to replay the recorded changes from the primary onto the mirror. If the incremental recovery cannot be completed, the recovery fails and you should run `gprecoverseg` again with the `-F` option, to perform full recovery. This causes the primary to copy all of its data to the mirror.

**Note:** After a failed incremental recovery attempt you must perform a full recovery.

Whenever possible, you should perform an incremental recovery rather than a full recovery, as incremental recovery is substantially faster.

For a more detailed explanation of the differences between incremental and full recovery, see the article "[VMware Tanzu Greenplum 6's gprecoverseg explained](#)" in the VMware Tanzu Support Hub.

## Recovering from Segment Failures

This topic walks you through what to do when one or more segments or hosts are down and you want to recover the down segments. The recovery path you follow depends primarily which of these 3 scenarios fits your circumstances:

- you want to recover in-place to the current host
- you want to recover to a different host, within the cluster
- you want to recover to a new host, outside of the cluster

The steps you follow within these scenarios can vary, depending on:

- whether you want to do an incremental or a full recovery
- whether you want to recover all segments or just a subset of segments

**Note:** Incremental recovery is only possible when recovering segments to the current host (in-place recovery).

This topic is divided into the following sections:

- [Prerequisites](#)
- [Recovery Scenarios](#)
- [Post-Recovery Tasks](#)

**Parent topic:** [Enabling High Availability and Data Consistency Features](#)

### Prerequisites

- Mirroring is enabled for all segments.
- You've already identified which segments have failed. If necessary, see the topic [Checking for Failed Segments](#).
- The master host can connect to the segment host.
- All networking or hardware issues that caused the segment to fail have been resolved.

### Recovery Scenarios

This section documents the steps for the 3 distinct segment recovery scenarios. Follow the link to instructions that walk you through each scenario.

- [Recover In-Place to Current Host](#)
  - [Incremental Recovery](#)
  - [Full Recovery](#)
- [Recover to A Different Host within the Cluster](#)
- [Recover to A New Host, Outside of the Cluster](#)

### Recover In-Place to Current Host

When recovering in-place to the current host, you may choose between incremental recovery (the default) and full recovery.

## Incremental Recovery

Follow these steps for incremental recovery:

1. To recover all segments, run `gprecoverseg` with no options:

```
gprecoverseg
```

2. To recover a subset of segments:

1. Manually create a `recover_config_file` file in a location of your choice, where each segment to recover has its own line with format

```
failedAddress|failedPort|failedDataDirectory
```

For multiple segments, create a new line for each segment you want to recover, specifying the address, port number and data directory for each down segment. For example:

```
failedAddress1|failedPort1|failedDataDirectory1
failedAddress2|failedPort2|failedDataDirectory2
failedAddress3|failedPort3|failedDataDirectory3
```

2. Alternatively, generate a sample recovery file using the following command; you may edit the resulting file if necessary:

```
$ gprecoverseg -o /home/gpadmin/recover_config_file
```

3. Pass the `recover_config_file` to the `gprecoverseg -i` command:

```
$ gprecoverseg -i /home/gpadmin/recover_config_file
```

3. Perform the post-recovery tasks summarized in the section [Post-Recovery Tasks](#).

## Full Recovery

1. To recover all segments, run `gprecoverseg -F`:

```
gprecoverseg -F
```

2. To recover specific segments:

1. Manually create a `recover_config_file` file in a location of your choice, where each segment to recover has its own line with following format:

```
failedAddress1|failedPort1|failedDataDirectory1<SPACE>failedAddress2|failedPort2|failedDataDirectory2
```

Note the literal **SPACE** separating the lines.

2. Alternatively, generate a sample recovery file using the following command and edit the resulting file to match your desired recovery configuration:

```
$ gprecoverseg -o /home/gpadmin/recover_config_file
```

3. Run the following command, passing in the config file generated in the previous step:

```
$ gprecoverseg -i recover_config_file
```

3. Perform the post-recovery tasks summarized in the section [Post-Recovery Tasks](#).

## Recover to A Different Host within the Cluster

**Note:** Only full recovery is possible when recovering to a different host in the cluster.

Follow these steps to recover all segments or just a subset of segments to a different host in the cluster:

1. Manually create a `recover_config_file` file in a location of your choice, where each segment to recover has its own line with following format:

```
failedAddress|failedPort|failedDataDirectory<SPACE>newAddress|newPort|newDataDirectory
```

Note the literal **SPACE** separating the details of the down segment from the details of where the segment will be recovered to.

Alternatively, generate a sample recovery file using the following command and edit the resulting file to match your desired recovery configuration:

```
$ gprecoverseg -o -p /home/gpadmin/recover_config_file
```

2. Run the following command, passing in the config file generated in the previous step:

```
$ gprecoverseg -i recover_config_file
```

3. Perform the post-recovery tasks summarized in the section [Post-Recovery Tasks](#).

## Recover to A New Host, Outside of the Cluster

Follow these steps if you are planning to do a hardware refresh on the host the segments are running on.

**Note:** Only full recovery is possible when recovering to a new host.

### Requirements for New Host

The new host must:

- have the same Greenplum Database software installed and configured as the failed host
- have the same hardware and OS configuration as the failed host (same hostname, OS version, OS configuration parameters applied, locales, gpadmin user account, data directory locations created, ssh keys exchanged, number of network interfaces, network interface naming convention, and so on)

- have sufficient disk space to accommodate the segments
- be able to connect password-less with all other existing segments and Greenplum master.

### Steps to Recover to a New Host

1. Bring up the new host
2. Run the following command to recover all segments to the new host:

```
gprecoverseg -p <new_host_name>
```

You may also specify more than one host. However, be sure you do not trigger a double-fault scenario when recovering to two hosts at a time.

```
gprecoverseg -p <new_host_name1>,<new_host_name2>
```

**Note:** In the case of multiple failed segment hosts, you can specify the hosts to recover to with a comma-separated list. However, it is strongly recommended to recover to one host at a time. If you must recover to more than one host at a time, then it is critical to ensure that a double fault scenario does not occur, in which both the segment primary and corresponding mirror are offline.

3. Perform the post-recovery tasks summarized in the section [Post-Recovery Tasks](#).

## Post-Recovery Tasks

Follow these steps once `gprecoverseg` has completed:

1. Validate segment status and preferred roles:

```
select * from gp_segment_configuration
```

2. Monitor mirror synchronization progress:

```
gpstate -e
```

3. If necessary, run the following command to return segments to their preferred roles:

```
gprecoverseg -r
```

## Recovering a Failed Master

If the primary master fails, the Greenplum Database system is not accessible and WAL replication stops. Use `gpactivatestandby` to activate the standby master. Upon activation of the standby master, Greenplum Database reconstructs the master host state at the time of the last successfully committed transaction.

These steps assume a standby master host is configured for the system. See [Enabling Master Mirroring](#).

## To activate the standby master

1. Run the `gpactivatestandby` utility from the standby master host you are activating. For example:

```
$ export PGPORT=5432
$ gpactivatestandby -d /data/master/gpseg-1
```

Where `-d` specifies the data directory of the master host you are activating.

After you activate the standby, it becomes the *active* or *primary* master for your Greenplum Database array.

2. After the utility completes, run `gpstate` with the `-b` option to display a summary of the system status:

```
$ gpstate -b
```

The master instance status should be `Active`. When a standby master is not configured, the command displays `No master standby configured` for the standby master status. If you configured a new standby master, its status is `Passive`.

3. Optional: If you have not already done so while activating the prior standby master, you can run `gpinitstandby` on the active master host to configure a new standby master.

**Important:** You must initialize a new standby master to continue providing master mirroring.

For information about restoring the original master and standby master configuration, see [Restoring Master Mirroring After a Recovery](#).

- [Restoring Master Mirroring After a Recovery](#)

**Parent topic:** [Enabling High Availability and Data Consistency Features](#)

## Restoring Master Mirroring After a Recovery

After you activate a standby master for recovery, the standby master becomes the primary master. You can continue running that instance as the primary master if it has the same capabilities and dependability as the original master host.

You must initialize a new standby master to continue providing master mirroring unless you have already done so while activating the prior standby master. Run `gpinitstandby` on the active master host to configure a new standby master. See [Enabling Master Mirroring](#).

You can restore the primary and standby master instances on the original hosts. This process swaps the roles of the primary and standby master hosts, and it should be performed only if you strongly prefer to run the master instances on the same hosts they occupied prior to the recovery scenario.

**Important:** Restoring the primary and standby master instances to their original hosts is not an online operation. The master host must be stopped to perform the operation.

For information about the Greenplum Database utilities, see the *Greenplum Database Utility Guide*.

**Parent topic:** [Recovering a Failed Master](#)

## To restore the master mirroring after a recovery

1. Ensure the original master host is in dependable running condition; ensure the cause of the original failure is fixed.
2. On the original master host, move or remove the data directory, `gpseg-1`. This example moves the directory to `backup_gpseg-1`:

```
$ mv /data/master/gpseg-1 /data/master/backup_gpseg-1
```

You can remove the backup directory once the standby is successfully configured.

3. Initialize a standby master on the original master host. For example, run this command from the current master host, `smdw`:

```
$ gpinitstandby -s mdw
```

4. After the initialization completes, check the status of standby master, `mdw`. Run `gpstate` with the `-f` option to check the standby master status:

```
$ gpstate -f
```

The standby master status should be `passive`, and the WAL sender state should be `streaming`.

## To restore the master and standby instances on original hosts (optional)

**Note:** Before performing the steps in this section, be sure you have followed the steps to restore master mirroring after a recovery, as described in the [To restore the master mirroring after a recovery](#) previous section.

1. Stop the Greenplum Database master instance on the standby master. For example:

```
$ gpstop -m
```

2. Run the `gpactivatestandby` utility from the original master host, `mdw`, that is currently a standby master. For example:

```
$ gpactivatestandby -d $MASTER_DATA_DIRECTORY
```

Where the `-d` option specifies the data directory of the host you are activating.

3. After the utility completes, run `gpstate` with the `-b` option to display a summary of the system status:

```
$ gpstate -b
```

The master instance status should be `Active`. When a standby master is not configured, the command displays `No master standby configured` for the standby master state.

4. On the standby master host, move or remove the data directory, `gpseg-1`. This example moves the directory:

```
$ mv /data/master/gpseg-1 /data/master/backup_gpseg-1
```

You can remove the backup directory once the standby is successfully configured.

5. After the original master host runs the primary Greenplum Database master, you can initialize a standby master on the original standby master host. For example:

```
$ gpinitstandby -s smdw
```

After the command completes, you can run the `gpstate -f` command on the primary master host, to check the standby master status.

## To check the status of the master mirroring process (optional)

You can run the `gpstate` utility with the `-f` option to display details of the standby master host.

```
$ gpstate -f
```

The standby master status should be `passive`, and the WAL sender state should be `streaming`.

For information about the `gpstate` utility, see the *Greenplum Database Utility Guide*.

## Backing Up and Restoring Databases

Performing backups regularly ensures that you can restore your data or rebuild your Greenplum Database system if data corruption or a system failure occurs. You can also use backups to migrate data from one Greenplum Database system to another.

Greenplum Database supports parallel and non-parallel methods for backing up and restoring databases. Parallel operations scale regardless of the number of segments in your system, because segment hosts each write their data to local disk storage simultaneously. With non-parallel backup and restore operations, the data must be sent over the network from the segments to the master, which writes all of the data to its storage. In addition to restricting I/O to one host, non-parallel backup requires that the master have sufficient local disk storage to store the entire database.

## Parallel Backup with `gpbackup` and `gprestore`

`gpbackup` and `gprestore` are the recommended Greenplum Database backup and restore utilities. `gpbackup` utilizes `ACCESS SHARE` locks at the individual table level, instead of `EXCLUSIVE` locks on the `pg_class` catalog table. This enables you to run DML statements during the backup, such as `CREATE`, `ALTER`, `DROP`, and `TRUNCATE` operations, as long as those operations do not target the current backup set. Backup files created with `gpbackup` are designed to provide future capabilities for restoring individual database objects along with their dependencies, such as functions and required user-defined datatypes.

`gpbackup`, `gprestore`, and related utilities are provided as a separate download, [VMware Tanzu™ Greenplum® Backup and Restore](#). Follow the instructions in the [VMware Tanzu Greenplum Backup and Restore Documentation](#) to install and use these utilities.

## Non-Parallel Backup with `pg_dump`

The PostgreSQL `pg_dump` and `pg_dumpall` non-parallel backup utilities can be used to create a single dump file on the master host that contains all data from all active segments.

The PostgreSQL non-parallel utilities should be used only for special cases. They are much slower than using the Greenplum backup utilities since all of the data must pass through the master. Additionally, it is often the case that the master host has insufficient disk space to save a backup of an entire distributed Greenplum database.

The `pg_restore` utility requires compressed dump files created by `pg_dump` or `pg_dumpall`. To perform a non-parallel restore using parallel backup files, you can copy the backup files from each segment host to the master host, and then load them through the master.

Another non-parallel method for backing up Greenplum Database data is to use the `COPY TO SQL` command to copy all or a portion of a table out of the database to a delimited text file on the master host.

## Expanding a Greenplum System

To scale up performance and storage capacity, expand your Greenplum Database system by adding hosts to the system. In general, adding nodes to a Greenplum cluster achieves a linear scaling of performance and storage capacity.

Data warehouses typically grow over time as additional data is gathered and the retention periods increase for existing data. At times, it is necessary to increase database capacity to consolidate different data warehouses into a single database. Additional computing capacity (CPU) may also be needed to accommodate newly added analytics projects. Although it is wise to provide capacity for growth when a system is initially specified, it is not generally possible to invest in resources long

before they are required. Therefore, you should expect to run a database expansion project periodically.

Because of the Greenplum MPP architecture, when you add resources to the system, the capacity and performance are the same as if the system had been originally implemented with the added resources. Unlike data warehouse systems that require substantial downtime in order to dump and restore the data, expanding a Greenplum Database system is a phased process with minimal downtime. Regular and ad hoc workloads can continue while data is redistributed and transactional consistency is maintained. The administrator can schedule the distribution activity to fit into ongoing operations and can pause and resume as needed. Tables can be ranked so that datasets are redistributed in a prioritized sequence, either to ensure that critical workloads benefit from the expanded capacity sooner, or to free disk space needed to redistribute very large tables.

The expansion process uses standard Greenplum Database operations so it is transparent and easy for administrators to troubleshoot. Segment mirroring and any replication mechanisms in place remain active, so fault-tolerance is uncompromised and disaster recovery measures remain effective.

After the expansion is completed, you must perform different tasks depending on your environment.

**Parent topic:** [Managing a Greenplum System](#)

## System Expansion Overview

You can perform a Greenplum Database expansion to add segment instances and segment hosts with minimal downtime. In general, adding nodes to a Greenplum cluster achieves a linear scaling of performance and storage capacity.

Data warehouses typically grow over time, often at a continuous pace, as additional data is gathered and the retention period increases for existing data. At times, it is necessary to increase database capacity to consolidate disparate data warehouses into a single database. The data warehouse may also require additional computing capacity (CPU) to accommodate added analytics projects. It is good to provide capacity for growth when a system is initially specified, but even if

you anticipate high rates of growth, it is generally unwise to invest in capacity long before it is required. Database expansion, therefore, is a project that you should expect to have to run periodically.

When you expand your database, you should expect the following qualities:

- Scalable capacity and performance. When you add resources to a Greenplum Database, the capacity and performance are the same as if the system had been originally implemented with the added resources.
- Uninterrupted service during expansion. Regular workloads, both scheduled and ad-hoc, are not interrupted.
- Transactional consistency.
- Fault tolerance. During the expansion, standard fault-tolerance mechanisms—such as segment mirroring—remain active, consistent, and effective.
- Replication and disaster recovery. Any existing replication mechanisms continue to function during expansion. Restore mechanisms needed in case of a failure or catastrophic event remain effective.
- Transparency of process. The expansion process employs standard Greenplum Database mechanisms, so administrators can diagnose and troubleshoot any problems.
- Configurable process. Expansion can be a long running process, but it can be fit into a schedule of ongoing operations. The expansion schema's tables allow administrators to prioritize the order in which tables are redistributed, and the expansion activity can be paused and resumed.

The planning and physical aspects of an expansion project are a greater share of the work than expanding the database itself. It will take a multi-discipline team to plan and run the project. For on-premise installations, space must be acquired and prepared for the new servers. The servers must be specified, acquired, installed, cabled, configured, and tested. For cloud deployments, similar plans should also be made. [Planning New Hardware Platforms](#) describes general considerations for deploying new hardware.

After you provision the new hardware platforms and set up their networks, configure the operating systems and run performance tests using Greenplum utilities. The Greenplum Database software distribution includes utilities that are helpful to test and burn-in the new servers before beginning the software phase of the expansion. See [Preparing and Adding Hosts](#) for steps to prepare the new hosts for Greenplum Database.

Once the new servers are installed and tested, the software phase of the Greenplum Database expansion process begins. The software phase is designed to be minimally disruptive, transactionally consistent, reliable, and flexible.

- The first step of the software phase of expansion process is preparing the Greenplum Database system: adding new segment hosts and initializing new segment instances. This phase can be scheduled to occur during a period of low activity to avoid disrupting ongoing business operations. During the initialization process, the following tasks are performed:
  - Greenplum Database software is installed.
  - Databases and database objects are created in the new segment instances on the new segment hosts.

- The *gpexpand* schema is created in the postgres database. You can use the tables and view in the schema to monitor and control the expansion process. After the system has been updated, the new segment instances on the new segment hosts are available.
- New segments are immediately available and participate in new queries and data loads. The existing data, however, is skewed. It is concentrated on the original segments and must be redistributed across the new total number of primary segments.
- Because some of the table data is skewed, some queries might be less efficient because more data motion operations might be needed.
- The last step of the software phase is redistributing table data. Using the expansion control tables in the *gpexpand* schema as a guide, tables are redistributed. For each table:
  - The *gpexpand* utility redistributes the table data, across all of the servers, old and new, according to the distribution policy.
  - The table's status is updated in the expansion control tables.
  - After data redistribution, the query optimizer creates more efficient execution plans when data is not skewed. When all tables have been redistributed, the expansion is complete.

**Important:** The *gprestore* utility cannot restore backups you made before the expansion with the *gpbackup* utility, so back up your databases immediately after the system expansion is complete.

Redistributing table data is a long-running process that creates a large volume of network and disk activity. It can take days to redistribute some very large databases. To minimize the effects of the increased activity on business operations, system administrators can pause and resume expansion activity on an ad hoc basis, or according to a predetermined schedule. Datasets can be prioritized so that critical applications benefit first from the expansion.

In a typical operation, you run the *gpexpand* utility four times with different options during the complete expansion process.

1. To create an expansion input file:

```
gpexpand -f <hosts_file>
```

2. To initialize segments and create the expansion schema:

```
gpexpand -i <input_file>
```

*gpexpand* creates a data directory, copies user tables from all existing databases on the new segments, and captures metadata for each table in an expansion schema for status tracking. After this process completes, the expansion operation is committed and irrevocable.

3. To redistribute table data:

```
gpexpand -d <duration>
```

During initialization, *gpexpand* adds and initializes new segment instances. To complete system expansion, you must run *gpexpand* to redistribute data tables across the newly

added segment instances. Depending on the size and scale of your system, redistribution can be accomplished in a single session during low-use hours, or you can divide the process into batches over an extended period. Each table or partition is unavailable for read or write operations during redistribution. As each table is redistributed across the new segments, database performance should incrementally improve until it exceeds pre-expansion performance levels.

You may need to run `gpexpand` several times to complete the expansion in large-scale systems that require multiple redistribution sessions. `gpexpand` can benefit from explicit table redistribution ranking; see [Planning Table Redistribution](#).

Users can access Greenplum Database during initialization, but they may experience performance degradation on systems that rely heavily on hash distribution of tables. Normal operations such as ETL jobs, user queries, and reporting can continue, though users might experience slower response times.

4. To remove the expansion schema:

```
gpexpand -c
```

For information about the `gpexpand` utility and the other utilities that are used for system expansion, see the *Greenplum Database Utility Guide*.

**Parent topic:** [Expanding a Greenplum System](#)

## Planning Greenplum System Expansion

Careful planning will help to ensure a successful Greenplum expansion project.

The topics in this section help to ensure that you are prepared to perform a system expansion.

- [System Expansion Checklist](#) is a checklist you can use to prepare for and perform the system expansion process.
- [Planning New Hardware Platforms](#) covers planning for acquiring and setting up the new hardware.
- [Planning New Segment Initialization](#) provides information about planning to initialize new segment hosts with `gpexpand`.
- [Planning Table Redistribution](#) provides information about planning the data redistribution after the new segment hosts have been initialized.

**Important:** When expanding a Greenplum Database system, you must deactivate Greenplum interconnect proxies before adding new hosts and segment instances to the system, and you must update the `gp_interconnect_proxy_addresses` parameter with the newly-added segment instances before you re-enable interconnect proxies. For example, these commands deactivate Greenplum interconnect proxies by setting the interconnect to the default (`UDPIFC`) and reloading the `postgresql.conf` file to update the Greenplum system configuration.

```
gpconfig -r gp_interconnect_type
gpstop -u
```

For information about Greenplum interconnect proxies, see [Configuring Proxies for the Greenplum Interconnect](#).

**Parent topic:** [Expanding a Greenplum System](#)

## System Expansion Checklist

This checklist summarizes the tasks for a Greenplum Database system expansion.

Table 1. Greenplum Database System Expansion Checklist

### Online Pre-Expansion Tasks

\* System is up and available

|                          |   |
|--------------------------|---|
| <input type="checkbox"/> | Plan for ordering, building, and networking new hardware platforms, or provisioning cloud resources.  |
| <input type="checkbox"/> | Devise a database expansion plan. Map the number of segments per host, schedule the downtime period for testing performance and creating the expansion schema, and schedule the intervals for table redistribution. |
| <input type="checkbox"/> | Perform a complete schema dump.   |
| <input type="checkbox"/> | Install Greenplum Database binaries on new hosts.   |
| <input type="checkbox"/> | Copy SSH keys to the new hosts ( <code>gpssh-exkeys</code> ).   |
| <input type="checkbox"/> | Validate disk I/O and memory bandwidth of the new hardware or cloud resources ( <code>gpcheckperf</code> ).   |
| <input type="checkbox"/> | Validate that the master data directory has no extremely large files in the <code>log</code> directory.   |

### Offline Pre-Expansion Tasks

\* The system is unavailable to all user activity during this process.

|                          |   |
|--------------------------|---|
| <input type="checkbox"/> | Validate that there are no catalog issues ( <code>gpcheckcat</code> ).  |
| <input type="checkbox"/> | Validate disk I/O and memory bandwidth of the combined existing and new hardware or cloud resources ( <code>gpcheckperf</code> ). |

### Online Segment Instance Initialization

\* System is up and available

|                          |   |
|--------------------------|---|
| <input type="checkbox"/> | Prepare an expansion input file ( <code>gpexpand</code> ).  |
| <input type="checkbox"/> | Initialize new segments into the system and create an expansion schema ( <code>gpexpand -i input_file</code> ). |

### Online Expansion and Table Redistribution

\* System is up and available

|                          |  |
|--------------------------|--|
| <input type="checkbox"/> | Before you start table redistribution, stop any automated snapshot processes or other processes that consume disk space. |
|--------------------------|--|

Redistribute tables through the expanded system (`gpexpand`).

Remove expansion schema (`gpexpand -c`).

**Important:** Run `analyze` to update distribution statistics.

During the expansion, use `gpexpand -a`, and post-expansion, use `analyze`.

---

### Back Up Databases

\* System is up and available

Back up databases using the `gpbackup` utility. Backups you created before you began the system expansion cannot be restored to the newly expanded system because the `gprestore` utility can only restore backups to a Greenplum Database system with the same number of segments.

---

## Planning New Hardware Platforms

A deliberate, thorough approach to deploying compatible hardware greatly minimizes risk to the expansion process.

Hardware resources and configurations for new segment hosts should match those of the existing hosts. Work with *VMware Support* before making a hardware purchase to expand Greenplum Database.

The steps to plan and set up new hardware platforms vary for each deployment. Some considerations include how to:

- Prepare the physical space for the new hardware; consider cooling, power supply, and other physical factors.
- Determine the physical networking and cabling required to connect the new and existing hardware.
- Map the existing IP address spaces and developing a networking plan for the expanded system.
- Capture the system configuration (users, profiles, NICs, and so on) from existing hardware to use as a detailed list for ordering new hardware.
- Create a custom build plan for deploying hardware with the desired configuration in the particular site and environment.

After selecting and adding new hardware to your network environment, ensure you perform the tasks described in [Preparing and Adding Hosts](#).

## Planning New Segment Initialization

Expanding Greenplum Database can be performed when the system is up and available. Run `gpexpand` to initialize new segment instances into the system and create an expansion schema.

The time required depends on the number of schema objects in the Greenplum system and other factors related to hardware performance. In most environments, the initialization of new segments requires less than thirty minutes offline.

These utilities cannot be run while `gpexpand` is performing segment initialization.

- `gpbackup`
- `gpcheckcat`
- `gpconfig`
- `gppkg`
- `gprestore`

**Important:** After you begin initializing new segments, you can no longer restore the system using backup files created for the pre-expansion system. When initialization successfully completes, the expansion is committed and cannot be rolled back.

## Planning Mirror Segments

If your existing system has mirror segments, the new segments must have mirroring configured. If there are no mirrors configured for existing segments, you cannot add mirrors to new hosts with the `gpexpand` utility. For more information about segment mirroring configurations that are available during system initialization, see [About Segment Mirroring Configurations](#).

For Greenplum Database systems with mirror segments, ensure you add enough new host machines to accommodate new mirror segments. The number of new hosts required depends on your mirroring strategy:

- **Group Mirroring** — Add at least two new hosts so the mirrors for the first host can reside on the second host, and the mirrors for the second host can reside on the first. This is the default type of mirroring if you enable segment mirroring during system initialization.
- **Spread Mirroring** — Add at least one more host to the system than the number of segments per host. The number of separate hosts must be greater than the number of segment instances per host to ensure even spreading. You can specify this type of mirroring during system initialization or when you enable segment mirroring for an existing system.
- **Block Mirroring** — Adding one or more blocks of host systems. For example add a block of four or eight hosts. Block mirroring is a custom mirroring configuration. For more information about block mirroring, see [Segment Mirroring Configurations](#).

## Increasing Segments Per Host

By default, new hosts are initialized with as many primary segments as existing hosts have. You can increase the segments per host or add new segments to existing hosts.

For example, if existing hosts currently have two segments per host, you can use `gpexpand` to initialize two additional segments on existing hosts for a total of four segments and initialize four new segments on new hosts.

The interactive process for creating an expansion input file prompts for this option; you can also specify new segment directories manually in the input configuration file. For more information, see [Creating an Input File for System Expansion](#).

## About the Expansion Schema

At initialization, the `gpexpand` utility creates an expansion schema named `gpexpand` in the postgres database.

The expansion schema stores metadata for each table in the system so its status can be tracked throughout the expansion process. The expansion schema consists of two tables and a view for tracking expansion operation progress:

- `gpexpand.status`
- `gpexpand.status_detail`
- `gpexpand.expansion_progress`

Control expansion process aspects by modifying `gpexpand.status_detail`. For example, removing a record from this table prevents the system from expanding the table across new segments. Control the order in which tables are processed for redistribution by updating the `rank` value for a record. For more information, see [Ranking Tables for Redistribution](#).

## Planning Table Redistribution

Table redistribution is performed while the system is online. For many Greenplum systems, table redistribution completes in a single `gpexpand` session scheduled during a low-use period. Larger systems may require multiple sessions and setting the order of table redistribution to minimize performance impact. Complete the table redistribution in one session if possible.

**Important:** To perform table redistribution, your segment hosts must have enough disk space to temporarily hold a copy of your largest table. All tables are unavailable for read and write operations during redistribution.

The performance impact of table redistribution depends on the size, storage type, and partitioning design of a table. For any given table, redistributing it with `gpexpand` takes as much time as a `CREATE TABLE AS SELECT` operation would. When redistributing a terabyte-scale fact table, the expansion utility can use much of the available system resources, which could affect query performance or other database workloads.

## Table Redistribution Method

Greenplum Database uses a *rebuild* table distribution method to redistribute data during an expansion. Greenplum:

1. Creates a new table.
2. Copies all of the data from the old table to the new table.
3. Replaces the old table.

The rebuild method is similar to creating a new table with a `CREATE TABLE AS SELECT` command. During data redistribution, Greenplum Database acquires an `ACCESS EXCLUSIVE` lock on the table.

## Managing Redistribution in Large-Scale Greenplum Systems

When planning the redistribution phase, consider the impact of the `ACCESS EXCLUSIVE` lock taken on each table. User activity on a table can delay its redistribution, but also tables are unavailable for user activity during redistribution.

You can manage the order in which tables are redistributed by adjusting their ranking. See [Ranking Tables for Redistribution](#). Manipulating the redistribution order can help adjust for limited disk space and restore optimal query performance for high-priority queries sooner.

### Systems with Abundant Free Disk Space

In systems with abundant free disk space (required to store a copy of the largest table), you can focus on restoring optimum query performance as soon as possible by first redistributing important tables that queries use heavily. Assign high ranking to these tables, and schedule redistribution operations for times of low system usage. Run one redistribution process at a time until large or critical tables have been redistributed.

### Systems with Limited Free Disk Space

If your existing hosts have limited disk space, you may prefer to first redistribute smaller tables (such as dimension tables) to clear space to store a copy of the largest table. Available disk space on the original segments increases as each table is redistributed across the expanded system. When enough free space exists on all segments to store a copy of the largest table, you can redistribute large or critical tables. Redistribution of large tables requires exclusive locks; schedule this procedure for off-peak hours.

Also consider the following:

- Run multiple parallel redistribution processes during off-peak hours to maximize available system resources.
- When running multiple processes, operate within the connection limits for your Greenplum system. For information about limiting concurrent connections, see [Limiting Concurrent Connections](#).

## Redistributing Append-Optimized and Compressed Tables

`gpexpand` redistributes append-optimized and compressed append-optimized tables at different rates than heap tables. The CPU capacity required to compress and decompress data tends to increase the impact on system performance. For similar-sized tables with similar data, you may find overall performance differences like the following:

- Uncompressed append-optimized tables expand 10% faster than heap tables.
- Append-optimized tables that are defined to use data compression expand at a significantly slower rate than uncompressed append-optimized tables, potentially up to 80% slower.
- Systems with data compression such as ZFS/LZJB take longer to redistribute.

**Important:** If your system hosts use data compression, use identical compression settings on the new hosts to avoid disk space shortage.

## Redistributing Partitioned Tables

Because the expansion utility can process each individual partition on a large table, an efficient partition design reduces the performance impact of table redistribution. Only the child tables of a partitioned table are set to a random distribution policy. The read/write lock for redistribution applies to only one child table at a time.

## Redistributing Indexed Tables

Because the `gpexpand` utility must re-index each indexed table after redistribution, a high level of indexing has a large performance impact. Systems with intensive indexing have significantly slower rates of table redistribution.

## Preparing and Adding Hosts

Verify your new host systems are ready for integration into the existing Greenplum system.

To prepare new host systems for expansion, install the Greenplum Database software binaries, exchange the required SSH keys, and run performance tests.

Run performance tests first on the new hosts and then all hosts. Run the tests on all hosts with the system offline so user activity does not distort results.

Generally, you should run performance tests when an administrator modifies host networking or other special conditions in the system. For example, if you will run the expanded system on two network clusters, run tests on each cluster.

**Note:** Preparing host systems for use by a Greenplum Database system assumes that the new hosts' operating system has been properly configured to match the existing hosts, described in [Configuring Your Systems](#).

**Parent topic:** [Expanding a Greenplum System](#)

## Adding New Hosts to the Trusted Host Environment

New hosts must exchange SSH keys with the existing hosts to enable Greenplum administrative utilities to connect to all segments without a password prompt. Perform the key exchange process twice with the `gpssh-exkeys` utility.

First perform the process as `root`, for administration convenience, and then as the user `gpadmin`, for management utilities. Perform the following tasks in order:

1. [To exchange SSH keys as root](#)
2. [To create the gpadmin user](#)
3. [To exchange SSH keys as the gpadmin user](#)

**Note:** The Greenplum Database segment host naming convention is `sdwN` where `sdw` is a prefix and `N` is an integer ( `sdw1`, `sdw2` and so on). For hosts with multiple interfaces, the convention is to append a dash (-) and number to the host name. For example, `sdw1-1` and `sdw1-2` are the two interface names for host `sdw1`.

### To exchange SSH keys as root

1. Create a host file with the existing host names in your array and a separate host file with the new expansion host names. For existing hosts, you can use the same host file used to set up SSH keys in the system. In the files, list all hosts (master, backup master, and segment hosts) with one name per line and no extra lines or spaces. Exchange SSH keys using the configured host names for a given host if you use a multi-NIC configuration. In this example, `mdw` is configured with a single NIC, and `sdw1`, `sdw2`, and `sdw3` are configured with 4 NICs:

```
mdw
sdw1-1
sdw1-2
sdw1-3
sdw1-4
sdw2-1
sdw2-2
sdw2-3
sdw2-4
sdw3-1
sdw3-2
sdw3-3
sdw3-4
```

2. Log in as `root` on the master host, and source the `greenplum_path.sh` file from your Greenplum installation.

```
$ su -
# source /usr/local/greenplum-db/greenplum_path.sh
```

3. Run the `gpssh-exkeys` utility referencing the host list files. For example:

```
# gpssh-exkeys -e /home/gpadmin/<existing_hosts_file> -x
/home/gpadmin/<new_hosts_file>
```

4. `gpssh-exkeys` checks the remote hosts and performs the key exchange between all hosts. Enter the `root` user password when prompted. For example:

```
***Enter password for root@<hostname>: <root_password>
```

## To create the gpadmin user

1. Use `gpssh` to create the `gpadmin` user on all the new segment hosts (if it does not exist already). Use the list of new hosts you created for the key exchange. For example:

```
# gpssh -f <new_hosts_file> '/usr/sbin/useradd gpadmin -d
/home/gpadmin -s /bin/bash'
```

2. Set a password for the new `gpadmin` user. On Linux, you can do this on all segment hosts simultaneously using `gpssh`. For example:

```
# gpssh -f <new_hosts_file> 'echo <gpadmin_password> | passwd
gpadmin --stdin'
```

3. Verify the `gpadmin` user has been created by looking for its home directory:

```
# gpssh -f <new_hosts_file> ls -l /home
```

## To exchange SSH keys as the gpadmin user

1. Log in as `gpadmin` and run the `gpssh-exkeys` utility referencing the host list files. For example:

```
# gpssh-exkeys -e /home/gpadmin/<existing_hosts_file> -x
/home/gpadmin/<new_hosts_file>
```

2. `gpssh-exkeys` will check the remote hosts and perform the key exchange between all hosts. Enter the `gpadmin` user password when prompted. For example:

```
***Enter password for gpadmin@<hostname>: <gpadmin_password>
```

## Validating Disk I/O and Memory Bandwidth

Use the `gpcheckperf` utility to test disk I/O and memory bandwidth.

### To run gpcheckperf

1. Run the `gpcheckperf` utility using the host file for new hosts. Use the `-d` option to specify the file systems you want to test on each host. You must have write access to these directories. For example:

```
$ gpcheckperf -f <new_hosts_file> -d /data1 -d /data2 -v
```

2. The utility may take a long time to perform the tests because it is copying very large files between the hosts. When it is finished, you will see the summary results for the Disk Write, Disk Read, and Stream tests.

For a network divided into subnets, repeat this procedure with a separate host file for each subnet.

## Integrating New Hardware into the System

Before initializing the system with the new segments, shut down the system with `gpstop` to prevent user activity from skewing performance test results. Then, repeat the performance tests using host files that include *all* hosts, existing and new.

### Initializing New Segments

Use the `gpexpand` utility to create and initialize the new segment instances and create the expansion schema.

The first time you run `gpexpand` with a valid input file it creates and initializes segment instances and creates the expansion schema. After these steps are completed, running `gpexpand` detects if the expansion schema has been created and, if so, performs table redistribution.

- [Creating an Input File for System Expansion](#)
- [Running gpexpand to Initialize New Segments](#)
- [Rolling Back a Failed Expansion Setup](#)

**Parent topic:** [Expanding a Greenplum System](#)

## Creating an Input File for System Expansion

To begin expansion, `gpexpand` requires an input file containing information about the new segments and hosts. If you run `gpexpand` without specifying an input file, the utility displays an interactive interview that collects the required information and automatically creates an input file.

If you create the input file using the interactive interview, you may specify a file with a list of expansion hosts in the interview prompt. If your platform or command shell limits the length of the host list, specifying the hosts with `-f` may be mandatory.

## Creating an input file in Interactive Mode

Before you run `gpexpand` to create an input file in interactive mode, ensure you know:

- The number of new hosts (or a hosts file)
- The new hostnames (or a hosts file)
- The mirroring strategy used in existing hosts, if any
- The number of segments to add per host, if any

The utility automatically generates an input file based on this information, `dbid`, `content` ID, and data directory values stored in `gp_segment_configuration`, and saves the file in the current directory.

### To create an input file in interactive mode

1. Log in on the master host as the user who will run your Greenplum Database system; for example, `gpadmin`.
2. Run `gpexpand`. The utility displays messages about how to prepare for an expansion operation, and it prompts you to quit or continue.

Optionally, specify a hosts file using `-f`. For example:

```
$ gpexpand -f /home/gpadmin/<new_hosts_file>
```

3. At the prompt, select `y` to continue.
4. Unless you specified a hosts file using `-f`, you are prompted to enter hostnames. Enter a comma separated list of the hostnames of the new expansion hosts. Do not include interface hostnames. For example:

```
> sdw4, sdw5, sdw6, sdw7
```

To add segments to existing hosts only, enter a blank line at this prompt. Do not specify `localhost` or any existing host name.

5. Enter the mirroring strategy used in your system, if any. Options are `spread|grouped|none`. The default setting is `grouped`.

Ensure you have enough hosts for the selected grouping strategy. For more information about mirroring, see [Planning Mirror Segments](#).

6. Enter the number of new primary segments to add, if any. By default, new hosts are initialized with the same number of primary segments as existing hosts. Increase segments per host by entering a number greater than zero. The number you enter will be the number

of additional segments initialized on all hosts. For example, if existing hosts currently have two segments each, entering a value of `2` initializes two more segments on existing hosts, and four segments on new hosts.

7. If you are adding new primary segments, enter the new primary data directory root for the new segments. Do not specify the actual data directory name, which is created automatically by `gpexpand` based on the existing data directory names.

For example, if your existing data directories are as follows:

```
/gpdata/primary/gp0
/gpdata/primary/gp1
```

then enter the following (one at each prompt) to specify the data directories for two new primary segments:

```
/gpdata/primary
/gpdata/primary
```

When the initialization runs, the utility creates the new directories `gp2` and `gp3` under `/gpdata/primary`.

8. If you are adding new mirror segments, enter the new mirror data directory root for the new segments. Do not specify the data directory name; it is created automatically by `gpexpand` based on the existing data directory names.

For example, if your existing data directories are as follows:

```
/gpdata/mirror/gp0
/gpdata/mirror/gp1
```

enter the following (one at each prompt) to specify the data directories for two new mirror segments:

```
/gpdata/mirror
/gpdata/mirror
```

When the initialization runs, the utility will create the new directories `gp2` and `gp3` under `/gpdata/mirror`.

These primary and mirror root directories for new segments must exist on the hosts, and the user running `gpexpand` must have permissions to create directories in them.

After you have entered all required information, the utility generates an input file and saves it in the current directory. For example:

```
gpexpand_inputfile_yyyymmdd_145134
```

If the Greenplum cluster is configured with tablespaces, the utility automatically generates an additional tablespace mapping file. This file is required for later parsing by the utility so make sure it is present before proceeding with the next step. For example:

```
gpexpand_inputfile_yyyymmdd_145134.ts
```

## Expansion Input File Format

Use the interactive interview process to create your own input file unless your expansion scenario has atypical needs.

The format for expansion input files is:

```
hostname|address|port|datadir|dbid|content|preferred_role
```

For example:

```
sdw5|sdw5-1|50011|/gpdata/primary/gp9|11|9|p
sdw5|sdw5-2|50012|/gpdata/primary/gp10|12|10|p
sdw5|sdw5-2|60011|/gpdata/mirror/gp9|13|9|m
sdw5|sdw5-1|60012|/gpdata/mirror/gp10|14|10|m
```

For each new segment, this format of expansion input file requires the following:

| Parameter      | Valid Values  | Description  |
|----------------|---|--|
| hostname       | Hostname  | Hostname for the segment host.   |
| port           | An available port number  | Database listener port for the segment, incremented on the existing segment <i>port</i> base number.   |
| datadir        | Directory name  | The data directory location for a segment as per the <code>gp_segment_configuration</code> system catalog.   |
| dbid           | Integer. Must not conflict with existing <i>dbid</i> values.    | Database ID for the segment. The values you enter should be incremented sequentially from existing <i>dbid</i> values shown in the system catalog <code>gp_segment_configuration</code> . For example, to add four segment instances to an existing ten-segment array with <i>dbid</i> values of 1-10, list new <i>dbid</i> values of 11, 12, 13 and 14. |
| content        | Integer. Must not conflict with existing <i>content</i> values. | The content ID of the segment. A primary segment and its mirror should have the same content ID, incremented sequentially from existing values. For more information, see <i>content</i> in the reference for <code>gp_segment_configuration</code> .  |
| preferred_role | <code>p</code> or <code>m</code>                                | Determines whether this segment is a primary or mirror. Specify <code>p</code> for primary and <code>m</code> for mirror.  |

## Running gpexpand to Initialize New Segments

After you have created an input file, run `gpexpand` to initialize new segment instances.

### To run gpexpand with an input file

1. Log in on the master host as the user who will run your Greenplum Database system; for example, `gpadmin`.
2. Run the `gpexpand` utility, specifying the input file with `-i`. For example:

```
$ gpexpand -i input_file
```

The utility detects if an expansion schema exists for the Greenplum Database system. If a *gpexpand* schema exists, remove it with `gpexpand -c` before you start a new expansion operation. See [Removing the Expansion Schema](#).

When the new segments are initialized and the expansion schema is created, the utility prints a success message and exits.

When the initialization process completes, you can connect to Greenplum Database and view the expansion schema. The *gpexpand* schema resides in the postgres database. For more information, see [About the Expansion Schema](#).

After segment initialization is complete, [redistribute the tables](#) to balance existing data over the new segments.

## Monitoring the Cluster Expansion State

At any time, you can check the state of cluster expansion by running the `gpstate` utility with the `-x` flag:

```
$ gpstate -x
```

If the expansion schema exists in the postgres database, `gpstate -x` reports on the progress of the expansion. During the first expansion phase, `gpstate` reports on the progress of new segment initialization. During the second phase, `gpstate` reports on the progress of table redistribution, and whether redistribution is paused or active.

You can also query the expansion schema to see expansion status. See [Monitoring Table Redistribution](#) for more information.

## Rolling Back a Failed Expansion Setup

You can roll back an expansion setup operation (adding segment instances and segment hosts) only if the operation fails.

If the expansion fails during the initialization step, while the database is down, you must first restart the database in master-only mode by running the `gpstart -m` command.

Roll back the failed expansion with the following command:

```
gpexpand --rollback
```

## Redistributing Tables

Redistribute tables to balance existing data over the newly expanded cluster.

After creating an expansion schema, you can redistribute tables across the entire system with `gpexpand`. Plan to run this during low-use hours when the utility's CPU usage and table locks have minimal impact on operations. Rank tables to redistribute the largest or most critical tables first.

**Note:** When redistributing data, Greenplum Database must be running in production mode. Greenplum Database cannot be in restricted mode or in master mode. The `gpstart` options `-R` or `-m` cannot be specified to start Greenplum Database.

While table redistribution is underway, any new tables or partitions created are distributed across all segments exactly as they would be under normal operating conditions. Queries can access all segments, even before the relevant data is redistributed to tables on the new segments. The table or partition being redistributed is locked and unavailable for read or write operations. When its redistribution completes, normal operations resume.

- [Ranking Tables for Redistribution](#)
- [Redistributing Tables Using gpexpand](#)
- [Monitoring Table Redistribution](#)

**Parent topic:** [Expanding a Greenplum System](#)

## Ranking Tables for Redistribution

For large systems, you can control the table redistribution order. Adjust tables' `rank` values in the expansion schema to prioritize heavily-used tables and minimize performance impact. Available free disk space can affect table ranking; see [Managing Redistribution in Large-Scale Greenplum Systems](#).

To rank tables for redistribution by updating `rank` values in `gpexpand.status_detail`, connect to Greenplum Database using `psql` or another supported client. Update `gpexpand.status_detail` with commands such as:

```
=> UPDATE gpexpand.status_detail SET rank=10;

=> UPDATE gpexpand.status_detail SET rank=1 WHERE fq_name = 'public.lineitem';
=> UPDATE gpexpand.status_detail SET rank=2 WHERE fq_name = 'public.orders';
```

These commands lower the priority of all tables to 10 and then assign a rank of 1 to `lineitem` and a rank of 2 to `orders`. When table redistribution begins, `lineitem` is redistributed first, followed by `orders` and all other tables in `gpexpand.status_detail`. To exclude a table from redistribution, remove the table from the `gpexpand.status_detail` table.

## Redistributing Tables Using gpexpand

### To redistribute tables with gpexpand

1. Log in on the master host as the user who will run your Greenplum Database system, for example, `gpadmin`.
2. Run the `gpexpand` utility. You can use the `-d` or `-e` option to define the expansion session time period. For example, to run the utility for up to 60 consecutive hours:

```
$ gpexpand -d 60:00:00
```

The utility redistributes tables until the last table in the schema completes or it reaches the specified duration or end time. `gpexpand` updates the status and time in `gpexpand.status` when a session starts and finishes.

**Note:** After completing table redistribution, run the `VACUUM ANALYZE` and `REINDEX` commands on the catalog tables to update table statistics, and rebuild indexes. See [Routine Vacuum and Analyze](#) in

the *Administration Guide* and `VACUUM` in the *Reference Guide*.

## Monitoring Table Redistribution

During the table redistribution process you can query the expansion schema to view:

- a current progress summary, the estimated rate of table redistribution, and the estimated time to completion. Use `gpexpand.expansion_progress`, as described in [Viewing Expansion Status](#).
- per-table status information, using `gpexpand.status_detail`. See [Viewing Table Status](#).

See also [Monitoring the Cluster Expansion State](#) for information about monitoring the overall expansion progress with the `gpstate` utility.

### Viewing Expansion Status

After the first table completes redistribution, `gpexpand.expansion_progress` calculates its estimates and refreshes them based on all tables' redistribution rates. Calculations restart each time you start a table redistribution session with `gpexpand`. To monitor progress, connect to Greenplum Database using `psql` or another supported client; query `gpexpand.expansion_progress` with a command like the following:

```
=# SELECT * FROM gpexpand.expansion_progress;
          name          |          value
-----+-----
 Bytes Left            | 5534842880
 Bytes Done            | 142475264
 Estimated Expansion Rate | 680.75667095996092 MB/s
 Estimated Time to Completion | 00:01:01.008047
 Tables Expanded       | 4
 Tables Left           | 4
(6 rows)
```

### Viewing Table Status

The table `gpexpand.status_detail` stores status, time of last update, and more facts about each table in the schema. To see a table's status, connect to Greenplum Database using `psql` or another supported client and query `gpexpand.status_detail`:

```
=> SELECT status, expansion_started, source_bytes FROM
gpexpand.status_detail WHERE fq_name = 'public.sales';
 status | expansion_started | source_bytes
-----+-----+-----
 COMPLETED | 2017-02-20 10:54:10.043869 | 4929748992
(1 row)
```

## Post Expansion Tasks

After the expansion is completed, you must perform different tasks depending on your environment.

- [Removing the Expansion Schema](#)

- [Setting Up PXF on the New Host](#)

**Parent topic:** [Expanding a Greenplum System](#)

## Removing the Expansion Schema

You must remove the existing expansion schema before you can perform another expansion operation on the Greenplum system.

You can safely remove the expansion schema after the expansion operation is complete and verified. To run another expansion operation on a Greenplum system, first remove the existing expansion schema.

1. Log in on the master host as the user who will be running your Greenplum Database system (for example, `gpadmin`).
2. Run the `gpexpand` utility with the `-c` option. For example:

```
$ gpexpand -c
```

**Note:** Some systems require you to press Enter twice.

## Setting Up PXF on the New Host

If you are using PXF in your Greenplum Database cluster, you must perform some configuration steps on the new hosts.

There are different steps to follow depending on your PXF version and the type of installation.

### PXF 5

- You must **install** the same version of the PXF `rpm` or `deb` on the new hosts.
- Log into the Greenplum Master and run the following commands:

```
gpadmin@gpmaster$ pxf cluster reset
gpadmin@gpmaster$ pxf cluster init
```

### PXF 6

- You must **install** the same version of the PXF `rpm` or `deb` on the new hosts.
- Log into the Greenplum Master and run the following commands:

```
gpadmin@gpmaster$ pxf cluster register
gpadmin@gpmaster$ pxf cluster sync
```

## Migrating Data with `gpcopy`

You can use the `gpcopy` utility to transfer data between databases in different Greenplum Database clusters.

**Note:** `gpcopy` is available only with the commercial release of VMware Tanzu Greenplum.

`gpcopy` is a high-performance utility that can copy metadata and data from one Greenplum database to another Greenplum database. You can migrate the entire contents of a database, or just selected tables. The clusters can have different Greenplum Database versions. For example, you can use `gpcopy` to migrate data from a Greenplum Database version 4.3.26 (or later) system to a 5.9 (or later) or a 6.x Greenplum system, or from a Greenplum Database version 5.9+ system to a Greenplum 6.x system.

**Note:** The `gpcopy` utility is available as a separate download for the commercial release of Tanzu Greenplum. See the [Tanzu Greenplum Data Copy Utility Documentation](#).

**Parent topic:** [Managing a Greenplum System](#)

## Monitoring a Greenplum System

You can monitor a Greenplum Database system using a variety of tools included with the system or available as add-ons.

Observing the Greenplum Database system day-to-day performance helps administrators understand the system behavior, plan workflow, and troubleshoot problems. This chapter discusses tools for monitoring database performance and activity.

Also, be sure to review [Recommended Monitoring and Maintenance Tasks](#) for monitoring activities you can script to quickly detect problems in the system.

**Parent topic:** [Managing a Greenplum System](#)

## Monitoring Database Activity and Performance

Greenplum Database includes an optional system monitoring and management database, `gpperfmon`, that administrators can enable. The `gpperfmon_install` command-line utility creates the `gpperfmon` database and enables data collection agents that collect and store query and system metrics in the database. Administrators can query metrics in the `gpperfmon` database. See the documentation for the `gpperfmon` database in the *Greenplum Database Reference Guide*.

VMware Tanzu Greenplum Command Center, an optional web-based interface, provides cluster status information, graphical administrative tools, real-time query monitoring, and historical cluster and query data. Download the Greenplum Command Center package from [VMware Tanzu Network](#) and view the documentation at the [Greenplum Command Center Documentation](#) web site.

## Monitoring System State

As a Greenplum Database administrator, you must monitor the system for problem events such as a segment going down or running out of disk space on a segment host. The following topics describe how to monitor the health of a Greenplum Database system and examine certain state information for a Greenplum Database system.

- [Checking System State](#)
- [Checking Disk Space Usage](#)
- [Checking for Data Distribution Skew](#)
- [Checking for and Terminating Overflowed Backends](#)

- [Viewing Metadata Information about Database Objects](#)
- [Viewing Session Memory Usage Information](#)
- [Viewing Query Workfile Usage Information](#)

## Checking System State

A Greenplum Database system is comprised of multiple PostgreSQL instances (the master and segments) spanning multiple machines. To monitor a Greenplum Database system, you need to know information about the system as a whole, as well as status information of the individual instances. The `gpstate` utility provides status information about a Greenplum Database system.

### Viewing Master and Segment Status and Configuration

The default `gpstate` action is to check segment instances and show a brief status of the valid and failed segments. For example, to see a quick status of your Greenplum Database system:

```
$ gpstate
```

To see more detailed information about your Greenplum Database array configuration, use `gpstate` with the `-s` option:

```
$ gpstate -s
```

### Viewing Your Mirroring Configuration and Status

If you are using mirroring for data redundancy, you may want to see the list of mirror segment instances in the system, their current synchronization status, and the mirror to primary mapping. For example, to see the mirror segments in the system and their status:

```
$ gpstate -m
```

To see the primary to mirror segment mappings:

```
$ gpstate -c
```

To see the status of the standby master mirror:

```
$ gpstate -f
```

## Checking Disk Space Usage

A database administrator's most important monitoring task is to make sure the file systems where the master and segment data directories reside do not grow to more than 70 percent full. A filled

data disk will not result in data corruption, but it may prevent normal database activity from continuing. If the disk grows too full, it can cause the database server to shut down.

You can use the `gp_disk_free` external table in the `gp_toolkit` administrative schema to check for remaining free space (in kilobytes) on the segment host file systems. For example:

```
=# SELECT * FROM gp_toolkit.gp_disk_free
ORDER BY dfsegment;
```

## Checking Sizing of Distributed Databases and Tables

The `gp_toolkit` administrative schema contains several views that you can use to determine the disk space usage for a distributed Greenplum Database database, schema, table, or index.

For a list of the available sizing views for checking database object sizes and disk space, see the *Greenplum Database Reference Guide*.

### Viewing Disk Space Usage for a Database

To see the total size of a database (in bytes), use the `gp_size_of_database` view in the `gp_toolkit` administrative schema. For example:

```
=> SELECT * FROM gp_toolkit.gp_size_of_database
ORDER BY soddatname;
```

### Viewing Disk Space Usage for a Table

The `gp_toolkit` administrative schema contains several views for checking the size of a table. The table sizing views list the table by object ID (not by name). To check the size of a table by name, you must look up the relation name (`relname`) in the `pg_class` table. For example:

```
=> SELECT relname AS name, sotdsize AS size, sotdtoastsize
AS toast, sotdadditionalsize AS other
FROM gp_toolkit.gp_size_of_table_disk as sotd, pg_class
WHERE sotd.sotdoid=pg_class.oid ORDER BY relname;
```

For a list of the available table sizing views, see the *Greenplum Database Reference Guide*.

### Viewing Disk Space Usage for Indexes

The `gp_toolkit` administrative schema contains a number of views for checking index sizes. To see the total size of all index(es) on a table, use the `gp_size_of_all_table_indexes` view. To see the size of a particular index, use the `gp_size_of_index` view. The index sizing views list tables and indexes by object ID (not by name). To check the size of an index by name, you must look up the relation name (`relname`) in the `pg_class` table. For example:

```
=> SELECT soisize, relname as indexname
FROM pg_class, gp_toolkit.gp_size_of_index
WHERE pg_class.oid=gp_size_of_index.soioid
```

```
AND pg_class.relkind='i';
```

## Checking for Data Distribution Skew

All tables in Greenplum Database are distributed, meaning their data is divided across all of the segments in the system. Unevenly distributed data may diminish query processing performance. A table's distribution policy, set at table creation time, determines how the table's rows are distributed. For information about choosing the table distribution policy, see the following topics:

- [Viewing a Table's Distribution Key](#)
- [Viewing Data Distribution](#)
- [Checking for Query Processing Skew](#)

The `gp_toolkit` administrative schema also contains a number of views for checking data distribution skew on a table. For information about how to check for uneven data distribution, see the *Greenplum Database Reference Guide*.

## Viewing a Table's Distribution Key

To see the columns used as the data distribution key for a table, you can use the `\d+` meta-command in `psql` to examine the definition of a table. For example:

```
=# \d+ sales
\
      Table "retail.sales"
  Column      |      Type      | Modifiers | Description
-----+-----+-----+-----
 sale_id     | integer        |           |
 amt         | float          |           |
 date        | date           |           |
Has OIDs: no
Distributed by: (sale_id)
```

When you create a *replicated* table, Greenplum Database stores all rows in the table on every segment. Replicated tables have no distribution key. Where the `\d+` meta-command reports the distribution key for a normally distributed table, it shows `Distributed Replicated` for a replicated table.

## Viewing Data Distribution

To see the data distribution of a table's rows (the number of rows on each segment), you can run a query such as:

```
=# SELECT gp_segment_id, count(*)
FROM <table_name> GROUP BY gp_segment_id;
```

A table is considered to have a balanced distribution if all segments have roughly the same number of rows.

**Note:** If you run this query on a replicated table, it fails because Greenplum Database does not permit user queries to reference the system column `gp_segment_id` (or the system columns `ctid`, `cmin`, `cmax`, `xmin`, and `xmax`) in replicated tables. Because every segment has all of the tables' rows, replicated tables are evenly distributed by definition.

## Checking for Query Processing Skew

When a query is being processed, all segments should have equal workloads to ensure the best possible performance. If you identify a poorly-performing query, you may need to investigate further using the `EXPLAIN` command. For information about using the `EXPLAIN` command and query profiling, see [Query Profiling](#).

Query processing workload can be skewed if the table's data distribution policy and the query predicates are not well matched. To check for processing skew, you can run a query such as:

```
=# SELECT gp_segment_id, count(*) FROM <table_name>
WHERE <column>=<value>' GROUP BY gp_segment_id;
```

This will show the number of rows returned by segment for the given `WHERE` predicate.

As noted in [Viewing Data Distribution](#), this query will fail if you run it on a replicated table because you cannot reference the `gp_segment_id` system column in a query on a replicated table.

## Avoiding an Extreme Skew Warning

You may receive the following warning message while running a query that performs a hash join operation:

```
Extreme skew in the innerside of Hashjoin
```

This occurs when the input to a hash join operator is skewed. It does not prevent the query from completing successfully. You can follow these steps to avoid skew in the plan:

1. Ensure that all fact tables are analyzed.
2. Verify that any populated temporary table used by the query is analyzed.
3. View the `EXPLAIN ANALYZE` plan for the query and look for the following:
  - o If there are scans with multi-column filters that are producing more rows than estimated, then set the `gp_selectivity_damping_factor` server configuration parameter to 2 or higher and retest the query.
  - o If the skew occurs while joining a single fact table that is relatively small (less than 5000 rows), set the `gp_segments_for_planner` server configuration parameter to 1 and retest the query.
4. Check whether the filters applied in the query match distribution keys of the base tables. If the filters and distribution keys are the same, consider redistributing some of the base tables with different distribution keys.
5. Check the cardinality of the join keys. If they have low cardinality, try to rewrite the query with different joining columns or additional filters on the tables to reduce the number of rows. These changes could change the query semantics.

## Checking for and Terminating Overflowed Backends

Subtransaction overflow arises when a Greenplum Database backend creates more than 64 subtransactions, resulting in a high lookup cost for visibility checks. This slows query performance, but even more so when it occurs in combination with long-running transactions, which result in still more lookups. Terminating suboverflowed backends and/or backends with long-running transactions can help prevent and alleviate performance problems.

Greenplum Database includes an extension -- `gp_subtransaction_overflow` -- and a view -- `gp_suboverflowed_backend` -- that is run over a user-defined function to help users query for suboverflowed backends. Users can use segment id and process id information reported in the view to terminate the offending backends, thereby preventing degradation of performance.

Follow these steps to identify and terminate overflowed backends.

1. Create the extension:

```
CREATE EXTENSION gp_subtransaction_overflow;
```

2. Select all from the view the extension created:

```
select * from gp_suboverflowed_backend`;
```

This returns output similar to the following:

```
segid |   pids
-----+-----
-1 |
  0 | {1731513}
  1 | {1731514}
  2 | {1731515}
(4 rows)
```

3. Connect to the database in utility mode and query `pg_stat_activity` to return the session id for the process id in the output for a segment. For example:

```
select sess_id from pg_stat_activity where pid=1731513;
```

```
sess_id
-----
  10
(1 row)
```

4. Terminate the session, which will terminate all associated backends on all segments:

```
select pg_terminate_backend(pid) from pg_stat_activity where sess_id=10;
```

5. Verify that there are no more suboverflowed backends:

```
select * from gp_suboverflowed_backend`;
```

```
segid |   pids
-----+-----
```

```
-1 |
 0 |
 1 |
 2 |
(4 rows)
```

## Logging Statements that Cause Overflowed Subtransactions

You can optionally set a Greenplum configuration parameter, `gp_log_suboverflow_statement`, to record SQL statements that cause overflowed subtransactions. When this parameter is active, statements that cause overflow are recorded in server logs on the master host and segment hosts with the text: `Statement caused suboverflow: <statement>`.

One way to find these statements is to query the `gp_toolkit.gp_log_system` table. For example, after activating the setting:

```
SET set gp_log_suboverflow_statement = ON;
```

you can find statements that caused overflow with a query such as:

```
SELECT DISTINCT logsegment, logmessage FROM gp_toolkit.gp_log_system
WHERE logmessage LIKE 'Statement caused suboverflow%';
```

| logsegment | logmessage  |
|------------|---|
| seg0       | Statement caused suboverflow: INSERT INTO t_1352_1 VALUES (i) |
| seg1       | Statement caused suboverflow: INSERT INTO t_1352_1 VALUES (i) |
| seg2       | Statement caused suboverflow: INSERT INTO t_1352_1 VALUES (i) |

(3 rows)

## Viewing Metadata Information about Database Objects

Greenplum Database tracks various metadata information in its system catalogs about the objects stored in a database, such as tables, views, indexes and so on, as well as global objects such as roles and tablespaces.

### Viewing the Last Operation Performed

You can use the system views `pg_stat_operations` and `pg_stat_partition_operations` to look up actions performed on an object, such as a table. For example, to see the actions performed on a table, such as when it was created and when it was last vacuumed and analyzed:

```
=> SELECT schemaname as schema, objname as table,
       username as role, actionname as action,
       subtype as type, statime as time
FROM pg_stat_operations
WHERE objname='cust';
```

| schema | table | role | action  | type  | time                          |
|--------|-------|------|---------|-------|-------------------------------|
| sales  | cust  | main | CREATE  | TABLE | 2016-02-09 18:10:07.867977-08 |
| sales  | cust  | main | VACUUM  |       | 2016-02-10 13:32:39.068219-08 |
| sales  | cust  | main | ANALYZE |       | 2016-02-25 16:07:01.157168-08 |

```
(3 rows)
```

## Viewing the Definition of an Object

To see the definition of an object, such as a table or view, you can use the `\d+` meta-command when working in `psql`. For example, to see the definition of a table:

```
=> \d+ <mytable>
```

## Viewing Session Memory Usage Information

You can create and use the `session_level_memory_consumption` view that provides information about the current memory utilization for sessions that are running queries on Greenplum Database. The view contains session information and information such as the database that the session is connected to, the query that the session is currently running, and memory consumed by the session processes.

- [Creating the session\\_level\\_memory\\_consumption View](#)
- [The session\\_level\\_memory\\_consumption View](#)

### Creating the session\_level\_memory\_consumption View

To create the `session_state.session_level_memory_consumption` view in a Greenplum Database, run the script `CREATE EXTENSION gp_internal_tools;` once for each database. For example, to install the view in the database `testdb`, use this command:

```
$ psql -d testdb -c "CREATE EXTENSION gp_internal_tools;"
```

### The session\_level\_memory\_consumption View

The `session_state.session_level_memory_consumption` view provides information about memory consumption and idle time for sessions that are running SQL queries.

When resource queue-based resource management is active, the column `is_runaway` indicates whether Greenplum Database considers the session a runaway session based on the `vmem` memory consumption of the session's queries. Under the resource queue-based resource management scheme, Greenplum Database considers the session a runaway when the queries consume an excessive amount of memory. The Greenplum Database server configuration parameter `runaway_detector_activation_percent` governs the conditions under which Greenplum Database considers a session a runaway session.

The `is_runaway`, `runaway_vmem_mb`, and `runaway_command_cnt` columns are not applicable when resource group-based resource management is active.

| column               | type    | references | description  |
|----------------------|---------|------------|--|
| <code>datname</code> | name    |            | Name of the database that the session is connected to. |
| <code>sess_id</code> | integer |            | Session ID.  |

| column                           | type      | references | description  |
|----------------------------------|-----------|------------|--|
| <code>username</code>            | name      |            | Name of the session user.  |
| <code>query</code>               | text      |            | Current SQL query that the session is running.   |
| <code>segid</code>               | integer   |            | Segment ID.  |
| <code>vmem_mb</code>             | integer   |            | Total vmem memory usage for the session in MB.   |
| <code>is_runaway</code>          | boolean   |            | Session is marked as runaway on the segment.   |
| <code>qe_count</code>            | integer   |            | Number of query processes for the session.   |
| <code>active_qe_count</code>     | integer   |            | Number of active query processes for the session.  |
| <code>dirty_qe_count</code>      | integer   |            | Number of query processes that have not yet released their memory. The value is <code>-1</code> for sessions that are not running. |
| <code>runaway_vmem_mb</code>     | integer   |            | Amount of vmem memory that the session was consuming when it was marked as a runaway session.                                      |
| <code>runaway_command_cnt</code> | integer   |            | Command count for the session when it was marked as a runaway session.   |
| <code>idle_start</code>          | timestamp |            | The last time a query process in this session became idle.   |

## Viewing Query Workfile Usage Information

The Greenplum Database administrative schema `gp_toolkit` contains views that display information about Greenplum Database workfiles. Greenplum Database creates workfiles on disk if it does not have sufficient memory to run the query in memory. This information can be used for troubleshooting and tuning queries. The information in the views can also be used to specify the values for the Greenplum Database configuration parameters `gp_workfile_limit_per_query` and `gp_workfile_limit_per_segment`.

These are the views in the schema `gp_toolkit`:

- The `gp_workfile_entries` view contains one row for each operator using disk space for workfiles on a segment at the current time.
- The `gp_workfile_usage_per_query` view contains one row for each query using disk space for workfiles on a segment at the current time.
- The `gp_workfile_usage_per_segment` view contains one row for each segment. Each row displays the total amount of disk space used for workfiles on the segment at the current time.

For information about using `gp_toolkit`, see [Using gp\\_toolkit](#).

## Viewing the Database Server Log Files

Every database instance in Greenplum Database (master and segments) runs a PostgreSQL database server with its own server log file. Log files are created in the `log` directory of the master and each segment data directory.

## Log File Format

The server log files are written in comma-separated values (CSV) format. Some log entries will not have values for all log fields. For example, only log entries associated with a query worker process will have the `slice_id` populated. You can identify related log entries of a particular query by the query's session identifier (`gp_session_id`) and command identifier (`gp_command_count`).

The following fields are written to the log:

| Number | Field Name         | Data Type                | Description  |
|--------|--------------------|--------------------------|--|
| 1      | event_time         | timestamp with time zone | Time that the log entry was written to the log   |
| 2      | user_name          | varchar(100)             | The database user name   |
| 3      | database_name      | varchar(100)             | The database name  |
| 4      | process_id         | varchar(10)              | The system process ID (prefixed with "p")  |
| 5      | thread_id          | varchar(50)              | The thread count (prefixed with "th")  |
| 6      | remote_host        | varchar(100)             | On the master, the hostname/address of the client machine. On the segment, the hostname/address of the master.                     |
| 7      | remote_port        | varchar(10)              | The segment or master port number  |
| 8      | session_start_time | timestamp with time zone | Time session connection was opened   |
| 9      | transaction_id     | int                      | Top-level transaction ID on the master. This ID is the parent of any subtransactions.  |
| 10     | gp_session_id      | text                     | Session identifier number (prefixed with "con")  |
| 11     | gp_command_count   | text                     | The command number within a session (prefixed with "cmd")  |
| 12     | gp_segment         | text                     | The segment content identifier (prefixed with "seg" for primaries or "mir" for mirrors). The master always has a content ID of -1. |
| 13     | slice_id           | text                     | The slice ID (portion of the query plan being executed)  |
| 14     | distr_tranx_id     | text                     | Distributed transaction ID   |
| 15     | local_tranx_id     | text                     | Local transaction ID   |
| 16     | sub_tranx_id       | text                     | Subtransaction ID  |
| 17     | event_severity     | varchar(10)              | Values include: LOG, ERROR, FATAL, PANIC, DEBUG1, DEBUG2   |
| 18     | sql_state_code     | varchar(10)              | SQL state code associated with the log message   |
| 19     | event_message      | text                     | Log or error message text  |

| Number | Field Name         | Data Type | Description  |
|--------|--------------------|-----------|--|
| 20     | event_detail       | text      | Detail message text associated with an error or warning message  |
| 21     | event_hint         | text      | Hint message text associated with an error or warning message  |
| 22     | internal_query     | text      | The internally-generated query text  |
| 23     | internal_query_pos | int       | The cursor index into the internally-generated query text  |
| 24     | event_context      | text      | The context in which this message gets generated   |
| 25     | debug_query_string | text      | User-supplied query string with full detail for debugging. This string can be modified for internal use. |
| 26     | error_cursor_pos   | int       | The cursor index into the query string   |
| 27     | func_name          | text      | The function in which this message is generated  |
| 28     | file_name          | text      | The internal code file where the message originated  |
| 29     | file_line          | int       | The line of the code file where the message originated   |
| 30     | stack_trace        | text      | Stack trace text associated with this message  |

## Searching the Greenplum Server Log Files

Greenplum Database provides a utility called `gplogfilter` can search through a Greenplum Database log file for entries matching the specified criteria. By default, this utility searches through the Greenplum Database master log file in the default logging location. For example, to display the last three lines of each of the log files under the master directory:

```
$ gplogfilter -n 3
```

To search through all segment log files simultaneously, run `gplogfilter` through the `gpssh` utility. For example, to display the last three lines of each segment log file:

```
$ gpssh -f seg_host_file
```

```
=> source /usr/local/greenplum-db/greenplum_path.sh
=> gplogfilter -n 3 /gpdata/gp*/log/gpdb*.log
```

## Using gp\_toolkit

Use the Greenplum Database administrative schema `gp_toolkit` to query the system catalogs, log files, and operating environment for system status information. The `gp_toolkit` schema contains several views you can access using SQL commands. The `gp_toolkit` schema is accessible to all database users. Some objects require superuser permissions. Use a command similar to the following to add the `gp_toolkit` schema to your schema search path:

```
=> ALTER ROLE myrole SET search_path TO myschema, gp_toolkit;
```

For a description of the available administrative schema views and their usages, see the *Greenplum Database Reference Guide*.

## SQL Standard Error Codes

The following table lists all the defined error codes. Some are not used, but are defined by the SQL standard. The error classes are also shown. For each error class there is a standard error code having the last three characters 000. This code is used only for error conditions that fall within the class but do not have any more-specific code assigned.

The PL/pgSQL condition name for each error code is the same as the phrase shown in the table, with underscores substituted for spaces. For example, code 22012, DIVISION BY ZERO, has condition name DIVISION\_BY\_ZERO. Condition names can be written in either upper or lower case.

**Note:** PL/pgSQL does not recognize warning, as opposed to error, condition names; those are classes 00, 01, and 02.

| Error Code  | Meaning                                    | Constant                                   |
|---|--|--|
| <b>Class 00</b> – Successful Completion                                       |  |  |
| 00000   | SUCCESSFUL COMPLETION                      | successful_completion                      |
| <b>Class 01</b> – Warning   |  |  |
| 01000   | WARNING                                    | warning                                    |
| 0100C   | DYNAMIC RESULT SETS RETURNED               | dynamic_result_sets_returned               |
| 01008   | IMPLICIT ZERO BIT PADDING                  | implicit_zero_bit_padding                  |
| 01003   | NULL VALUE ELIMINATED IN SET FUNCTION      | null_value_eliminated_in_set_function      |
| 01007   | PRIVILEGE NOT GRANTED                      | privilege_not_granted                      |
| 01006   | PRIVILEGE NOT REVOKED                      | privilege_not_revoked                      |
| 01004   | STRING DATA RIGHT TRUNCATION               | string_data_right_truncation               |
| 01P01   | DEPRECATED FEATURE                         | deprecated_feature                         |
| <b>Class 02</b> – No Data (this is also a warning class per the SQL standard) |  |  |
| 02000   | NO DATA                                    | no_data                                    |
| 02001   | NO ADDITIONAL DYNAMIC RESULT SETS RETURNED | no_additional_dynamic_result_sets_returned |
| <b>Class 03</b> – SQL Statement Not Yet Complete                              |  |  |
| 03000   | SQL STATEMENT NOT YET COMPLETE             | sql_statement_not_yet_complete             |

| Error Code                                       | Meaning   | Constant  |
|--|---|---|
| <b>Class 08</b> — Connection Exception           |   |   |
| 08000  | CONNECTION EXCEPTION                              | connection_exception                              |
| 08003  | CONNECTION DOES NOT EXIST                         | connection_does_not_exist                         |

## Routine System Maintenance Tasks

To keep a Greenplum Database system running efficiently, the database must be regularly cleared of expired data and the table statistics must be updated so that the query optimizer has accurate information.

Greenplum Database requires that certain tasks be performed regularly to achieve optimal performance. The tasks discussed here are required, but database administrators can automate them using standard UNIX tools such as `cron` scripts. An administrator sets up the appropriate scripts and checks that they ran successfully. See [Recommended Monitoring and Maintenance Tasks](#) for additional suggested maintenance activities you can implement to keep your Greenplum system running optimally.

**Parent topic:** [Managing a Greenplum System](#)

## Routine Vacuum and Analyze

The design of the MVCC transaction concurrency model used in Greenplum Database means that deleted or updated data rows still occupy physical space on disk even though they are not visible to new transactions. If your database has many updates and deletes, many expired rows exist and the space they use must be reclaimed with the `VACUUM` command. The `VACUUM` command also collects table-level statistics, such as numbers of rows and pages, so it is also necessary to vacuum append-optimized tables, even when there is no space to reclaim from updated or deleted rows.

Vacuuming an append-optimized table follows a different process than vacuuming heap tables. On each segment, a new segment file is created and visible rows are copied into it from the current segment. When the segment file has been copied, the original is scheduled to be dropped and the new segment file is made available. This requires sufficient available disk space for a copy of the visible rows until the original segment file is dropped.

If the ratio of hidden rows to total rows in a segment file is less than a threshold value (10, by default), the segment file is not compacted. The threshold value can be configured with the `gp_appendonly_compaction_threshold` server configuration parameter. `VACUUM FULL` ignores the value of `gp_appendonly_compaction_threshold` and rewrites the segment file regardless of the ratio.

You can use the `__gp_aovisimap_compaction_info()` function in the `gp_toolkit` schema to investigate the effectiveness of a `VACUUM` operation on append-optimized tables.

For information about the `__gp_aovisimap_compaction_info()` function see, "Checking Append-Optimized Tables" in the *Greenplum Database Reference Guide*.

`VACUUM` can be deactivated for append-optimized tables using the `gp_appendonly_compaction` server configuration parameter.

For details about vacuuming a database, see [Vacuuming the Database](#).

For information about the `gp_appendonly_compaction_threshold` server configuration parameter and the `VACUUM` command, see the *Greenplum Database Reference Guide*.

## Transaction ID Management

Greenplum's MVCC transaction semantics depend on comparing transaction ID (XID) numbers to determine visibility to other transactions. Transaction ID numbers are compared using modulo 232 arithmetic, so a Greenplum system that runs more than about two billion transactions can experience transaction ID wraparound, where past transactions appear to be in the future. This means past transactions' outputs become invisible. Therefore, it is necessary to `VACUUM` every table in every database at least once per two billion transactions.

Greenplum Database assigns XID values only to transactions that involve DDL or DML operations, which are typically the only transactions that require an XID.

**Important:** Greenplum Database monitors transaction IDs. If you do not vacuum the database regularly, Greenplum Database will generate a warning and error.

Greenplum Database issues the following warning when a significant portion of the transaction IDs are no longer available and before transaction ID wraparound occurs:

```
WARNING: database "database_name" must be vacuumed within *number\_of\_transactions*
transactions
```

When the warning is issued, a `VACUUM` operation is required. If a `VACUUM` operation is not performed, Greenplum Database stops creating transactions when it reaches a limit prior to when transaction ID wraparound occurs. Greenplum Database issues this error when it stops creating transactions to avoid possible data loss:

```
FATAL: database is not accepting commands to avoid
wraparound data loss in database "database_name"
```

The Greenplum Database configuration parameter `xid_warn_limit` controls when the warning is displayed. The parameter `xid_stop_limit` controls when Greenplum Database stops creating transactions.

### Recovering from a Transaction ID Limit Error

When Greenplum Database reaches the `xid_stop_limit` transaction ID limit due to infrequent `VACUUM` maintenance, it becomes unresponsive. To recover from this situation, perform the following steps as database administrator:

1. Shut down Greenplum Database.
2. Temporarily lower the `xid_stop_limit` by 10,000,000.
3. Start Greenplum Database.
4. Run `VACUUM FREEZE` on all affected databases.
5. Reset the `xid_stop_limit` to its original value.
6. Restart Greenplum Database.

For information about the configuration parameters, see the *Greenplum Database Reference Guide*.

For information about transaction ID wraparound see the [PostgreSQL documentation](#).

## System Catalog Maintenance

Numerous database updates with `CREATE` and `DROP` commands increase the system catalog size and affect system performance. For example, running many `DROP TABLE` statements degrades the overall system performance due to excessive data scanning during metadata operations on catalog tables. The performance loss occurs between thousands to tens of thousands of `DROP TABLE` statements, depending on the system.

You should run a system catalog maintenance procedure regularly to reclaim the space occupied by deleted objects. If a regular procedure has not been run for a long time, you may need to run a more intensive procedure to clear the system catalog. This topic describes both procedures.

### Regular System Catalog Maintenance

It is recommended that you periodically run `REINDEX` and `VACUUM` on the system catalog to clear the space that deleted objects occupy in the system indexes and tables. If regular database operations include numerous `DROP` statements, it is safe and appropriate to run a system catalog maintenance procedure with `VACUUM` daily at off-peak hours. You can do this while the system is available.

These are Greenplum Database system catalog maintenance steps.

1. Perform a `REINDEX` on the system catalog tables to rebuild the system catalog indexes. This removes bloat in the indexes and improves `VACUUM` performance.

**Note:** `REINDEX` causes locking of system catalog tables, which could affect currently running queries. To avoid disrupting ongoing business operations, schedule the `REINDEX` operation during a period of low activity.

2. Perform a `VACUUM` on the system catalog tables.
3. Perform an `ANALYZE` on the system catalog tables to update the catalog table statistics.

This example script performs a `REINDEX`, `VACUUM`, and `ANALYZE` of a Greenplum Database system catalog. In the script, replace `<database-name>` with a database name.

```
#!/bin/bash
DBNAME="<database-name>"
SYSTABLES="' pg_catalog.' || relname || ';' FROM pg_class a, pg_namespace b
WHERE a.relnamespace=b.oid AND b.nspname='pg_catalog' AND a.relkind='r'"

reindexdb --system -d $DBNAME
psql -tc "SELECT 'VACUUM' || $SYSTABLES" $DBNAME | psql -a $DBNAME
analyze db -as pg_catalog -d $DBNAME
```

**Note:** If you are performing catalog maintenance during a maintenance period and you need to stop a process due to time constraints, run the Greenplum Database function `pg_cancel_backend(<PID>)` to safely stop the Greenplum Database process.

### Intensive System Catalog Maintenance

If system catalog maintenance has not been performed in a long time, the catalog can become bloated with dead space; this causes excessively long wait times for simple metadata operations. A wait of more than two seconds to list user tables, such as with the `\d` metacommand from within `psql`, is an indication of catalog bloat.

If you see indications of system catalog bloat, you must perform an intensive system catalog maintenance procedure with `VACUUM FULL` during a scheduled downtime period. During this period, stop all catalog activity on the system; the `VACUUM FULL` system catalog maintenance procedure takes exclusive locks against the system catalog.

Running regular system catalog maintenance procedures can prevent the need for this more costly procedure.

These are steps for intensive system catalog maintenance.

1. Stop all catalog activity on the Greenplum Database system.
2. Perform a `REINDEX` on the system catalog tables to rebuild the system catalog indexes. This removes bloat in the indexes and improves `VACUUM` performance.
3. Perform a `VACUUM FULL` on the system catalog tables. See the following Note.
4. Perform an `ANALYZE` on the system catalog tables to update the catalog table statistics.

**Note:** The system catalog table `pg_attribute` is usually the largest catalog table. If the `pg_attribute` table is significantly bloated, a `VACUUM FULL` operation on the table might require a significant amount of time and might need to be performed separately. The presence of both of these conditions indicate a significantly bloated `pg_attribute` table that might require a long `VACUUM FULL` time:

- The `pg_attribute` table contains a large number of records.
- The diagnostic message for `pg_attribute` is `significant amount of bloat` in the `gp_toolkit.gp_bloat_diag` view.

### Vacuum and Analyze for Query Optimization

Greenplum Database uses a cost-based query optimizer that relies on database statistics. Accurate statistics allow the query optimizer to better estimate selectivity and the number of rows that a

query operation retrieves. These estimates help it choose the most efficient query plan. The `ANALYZE` command collects column-level statistics for the query optimizer.

You can run both `VACUUM` and `ANALYZE` operations in the same command. For example:

```
=# VACUUM ANALYZE mytable;
```

Running the `VACUUM ANALYZE` command might produce incorrect statistics when the command is run on a table with a significant amount of bloat (a significant amount of table disk space is occupied by deleted or obsolete rows). For large tables, the `ANALYZE` command calculates statistics from a random sample of rows. It estimates the number rows in the table by multiplying the average number of rows per page in the sample by the number of actual pages in the table. If the sample contains many empty pages, the estimated row count can be inaccurate.

For a table, you can view information about the amount of unused disk space (space that is occupied by deleted or obsolete rows) in the `gp_toolkit` view `gp_bloat_diag`. If the `bddiag` column for a table contains the value `significant amount of bloat suspected`, a significant amount of table disk space consists of unused space. Entries are added to the `gp_bloat_diag` view after a table has been vacuumed.

To remove unused disk space from the table, you can run the command `VACUUM FULL` on the table. Due to table lock requirements, `VACUUM FULL` might not be possible until a maintenance period.

As a temporary workaround, run `ANALYZE` to compute column statistics and then run `VACUUM` on the table to generate an accurate row count. This example runs `ANALYZE` and then `VACUUM` on the `cust_info` table.

```
ANALYZE cust_info;
VACUUM cust_info;
```

**Important:** If you intend to run queries on partitioned tables with GPORCA enabled (the default), you must collect statistics on the partitioned table root partition with the `ANALYZE` command. For information about GPORCA, see [Overview of GPORCA](#).

**Note:** You can use the Greenplum Database utility `analyzedb` to update table statistics. Tables can be analyzed concurrently. For append optimized tables, `analyzedb` updates statistics only if the statistics are not current. See the [analyzedb](#) utility.

## Routine Reindexing

For B-tree indexes, a freshly-constructed index is slightly faster to access than one that has been updated many times because logically adjacent pages are usually also physically adjacent in a newly built index. Reindexing older indexes periodically can improve access speed. If all but a few index keys on a page have been deleted, there will be wasted space on the index page. A reindex will reclaim that wasted space. In Greenplum Database it is often faster to drop an index (`DROP INDEX`) and then recreate it (`CREATE INDEX`) than it is to use the `REINDEX` command.

For table columns with indexes, some operations such as bulk updates or inserts to the table might perform more slowly because of the updates to the indexes. To enhance performance of bulk

operations on tables with indexes, you can drop the indexes, perform the bulk operation, and then re-create the index.

## Managing Greenplum Database Log Files

- [Database Server Log Files](#)
- [Management Utility Log Files](#)

### Database Server Log Files

Greenplum Database log output tends to be voluminous, especially at higher debug levels, and you do not need to save it indefinitely. Administrators should purge older log files periodically.

Greenplum Database by default has log file rotation enabled for the master and segment database logs. Log files are created in the `log` subdirectory of the master and each segment data directory using the following naming convention: `gpdb-YYYY-MM-DD_hhmmss.csv`. Administrators need to implement scripts or programs to periodically clean up old log files in the `log` directory of the master and each segment instance.

Log rotation can be triggered by the size of the current log file or the age of the current log file. The `log_rotation_size` configuration parameter sets the size of an individual log file that triggers log rotation. When the log file size is equal to or greater than the specified size, the file is closed and a new log file is created. The `log_rotation_size` value is specified in kilobytes. The default is 1048576 kilobytes, or 1GB. If `log_rotation_size` is set to 0, size-based rotation is deactivated.

The `log_rotation_age` configuration parameter specifies the age of a log file that triggers rotation. When the specified amount of time has elapsed since the log file was created, the file is closed and a new log file is created. The default `log_rotation_age`, 1d, creates a new log file 24 hours after the current log file was created. If `log_rotation_age` is set to 0, time-based rotation is deactivated.

For information about viewing the database server log files, see [Viewing the Database Server Log Files](#).

### Management Utility Log Files

Log files for the Greenplum Database management utilities are written to `~/gpAdminLogs` by default. The naming convention for management log files is:

```
<script_name>_<date>.log
```

The log entry format is:

```
<timestamp>:<utility>:<host>:<user>: [INFO|WARN|FATAL] :<message>
```

The log file for a particular utility execution is appended to its daily log file each time that utility is run.

## Recommended Monitoring and Maintenance Tasks

This section lists monitoring and maintenance activities recommended to ensure high availability and consistent performance of your Greenplum Database cluster.

The tables in the following sections suggest activities that a Greenplum System Administrator can perform periodically to ensure that all components of the system are operating optimally. Monitoring activities help you to detect and diagnose problems early. Maintenance activities help you to keep the system up-to-date and avoid deteriorating performance, for example, from bloated system tables or diminishing free disk space.

It is not necessary to implement all of these suggestions in every cluster; use the frequency and severity recommendations as a guide to implement measures according to your service requirements.

## Database State Monitoring Activities

Table 1. Database State Monitoring Activities

| Activity  | Procedure  | Corrective Actions  |
|---|--|---|
| <p>List segments that are currently down. If any rows are returned, this should generate a warning or alert.</p> <p>Recommended frequency: run every 5 to 10 minutes</p> <p>Severity: IMPORTANT</p> | <p>Run the following query in the <code>postgres</code> database:</p> <pre>SELECT * FROM gp_segment_configuration WHERE status = 'd';</pre>  | <p>If the query returns any rows, follow these steps to correct the problem:</p> <ol style="list-style-type: none"> <li>1. Verify that the hosts with down segments are responsive.</li> <li>2. If hosts are OK, check the log files for the primaries and mirrors of the down segments to discover the root cause of the segments going down.</li> <li>3. If no unexpected errors are found, run the <code>gprecoverseg</code> utility to bring the segments back online.</li> </ol> |
| <p>Check for segments that are up and not in sync. If rows are returned, this should generate a warning or alert.</p> <p>Recommended frequency: run every 5 to 10 minutes</p>                       | <p>Execute the following query in the <code>postgres</code> database:</p> <pre>SELECT * FROM gp_segment_configuration WHERE mode = 'n' and status = 'u' and content &lt;&gt; -1;</pre> | <p>If the query returns rows then the segment might be in the process of moving from <code>Not In Sync</code> to <code>Synchronized</code> mode. Use <code>gpstate -e</code> to track progress.</p>   |

| Activity  | Procedure   | Corrective Actions  |
|---|---|---|
| <p>Check for segments that are not operating in their preferred role but are marked as up and <i>Synchronized</i>. If any segments are found, the cluster may not be balanced. If any rows are returned this should generate a warning or alert.</p> <p>Recommended frequency: run every 5 to 10 minutes</p> <p>Severity: IMPORTANT</p> | <p>Execute the following query in the <i>postgres</i> database:</p> <pre data-bbox="687 353 933 645">SELECT * FROM gp_segment_configuration WHERE preferred_role &lt;&gt; role and status = 'u' and mode = 's';</pre> | <p>When the segments are not running in their preferred role, processing might be skewed. Run <i>gprecoverseg -r</i> to bring the segments back into their preferred roles.</p>   |
| <p>Run a distributed query to test that it runs on all segments. One row should be returned for each primary segment.</p> <p>Recommended frequency: run every 5 to 10 minutes</p> <p>Severity: CRITICAL</p>   | <p>Execute the following query in the <i>postgres</i> database:</p> <pre data-bbox="687 795 933 1025">SELECT gp_segment_id, count(*) FROM gp_dist_random('pg_classes') GROUP BY 1;</pre>                              | <p>If this query fails, there is an issue dispatching to some segments in the cluster. This is a rare event. Check the hosts that are not able to be dispatched to ensure there is no hardware or networking issue.</p> |
| <p>Test the state of master mirroring on Greenplum Database. If the value is not "STREAMING", raise an alert or warning.</p> <p>Recommended frequency: run every 5 to 10 minutes</p> <p>Severity: IMPORTANT</p>   | <p>Run the following <i>psql</i> command:</p> <pre data-bbox="687 1160 933 1350">psql &lt;dbname&gt; -c 'SELECT pid, state FROM pg_stat_replication;'</pre>   | <p>Check the log file from the master and standby master for errors. If there are no unexpected errors and the machines are up, run the <i>gpinitstandby</i> utility to bring the standby online.</p>                   |
| <p>Perform a basic check to see if the master is up and functioning.</p> <p>Recommended frequency: run every 5 to 10 minutes</p> <p>Severity: CRITICAL</p>  | <p>Run the following query in the <i>postgres</i> database:</p> <pre data-bbox="687 1512 933 1641">SELECT count(*) FROM gp_segment_configuration;</pre>   | <p>If this query fails, the active master may be down. Try to start the database on the original master if the server is up and running. If that fails, try to activate the standby master as master.</p>               |

## Hardware and Operating System Monitoring

Table 2. Hardware and Operating System Monitoring Activities

| Activity | Procedure | Corrective Actions |
|----------|-----------|--------------------|
|----------|-----------|--------------------|

| Activity  | Procedure   | Corrective Actions   |
|---|---|--|
| <p>Check disk space usage on volumes used for Greenplum Database data storage and the OS.</p> <p>Recommended frequency: every 5 to 30 minutes</p> <p>Severity: CRITICAL</p> | <p>Set up a disk space check.</p> <ul style="list-style-type: none"> <li>Set a threshold to raise an alert when a disk reaches a percentage of capacity. The recommended threshold is 75% full.</li> <li>It is not recommended to run the system with capacities approaching 100%.</li> </ul> | <p>Use <code>VACUUM/VACUUM FULL</code> on user tables to reclaim space occupied by dead rows.</p>  |
| <p>Check for errors or dropped packets on the network interfaces.</p> <p>Recommended frequency: hourly</p> <p>Severity: IMPORTANT</p>                                       | <p>Set up a network interface checks.</p>   | <p>Work with network and OS teams to resolve errors.</p>   |
| <p>Check for RAID errors or degraded RAID performance.</p> <p>Recommended frequency: every 5 minutes</p> <p>Severity: CRITICAL</p>  | <p>Set up a RAID check.</p>   | <ul style="list-style-type: none"> <li>Replace failed disks as soon as possible.</li> <li>Work with system administration team to resolve other RAID or controller errors as soon as possible.</li> </ul>  |
| <p>Check for adequate I/O bandwidth and I/O skew.</p> <p>Recommended frequency: when create a cluster or when hardware issues are suspected.</p>                            | <p>Run the Greenplum <code>gpcheckperf</code> utility.</p>  | <p>The cluster may be under-specified if data transfer rates are not similar to the following:</p> <ul style="list-style-type: none"> <li>2GB per second disk read</li> <li>1 GB per second disk write</li> <li>10 Gigabit per second network read and write</li> </ul> <p>If transfer rates are lower than expected, consult with your data architect regarding performance expectations.</p> <p>If the machines on the cluster display an uneven performance profile, work with the system administration team to fix faulty machines.</p> |

## Catalog Monitoring

Table 3. Catalog Monitoring Activities

| Activity | Procedure | Corrective Actions |
|----------|-----------|--------------------|
|----------|-----------|--------------------|

| Activity  | Procedure  | Corrective Actions                                       |
|---|--|--|
| <p>Run catalog consistency checks in each database to ensure the catalog on each host in the cluster is consistent and in a good state.</p> <p>You may run this command while the database is up and running.</p> <p>Recommended frequency: weekly</p> <p>Severity: IMPORTANT</p> | <p>Run the Greenplum <code>gpcheckcat</code> utility in each database:</p> <pre>gpcheckcat -o</pre> <div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;">  <p><b>Note:</b></p> <p>With the <code>-o</code> option, <code>gpcheckcat</code> runs just 10 of its usual 15 tests.</p> </div> | <p>Run the repair scripts for any issues identified.</p> |

## Data Maintenance

Table 4. Data Maintenance Activities

| Activity | Procedure | Corrective Actions |
|----------|-----------|--------------------|
|----------|-----------|--------------------|

| Activity   | Procedure   | Corrective Actions   |
|--|---|--|
| <p>Check for missing statistics on tables.</p>   | <p>Check the <code>gp_stats_missing</code> view in each database:</p> <pre>SELECT * FROM gp_toolkit.gp _stats_missin g;</pre> | <p>Run <code>ANALYZE</code> on tables that are missing statistics.</p>   |
| <p>Check for tables that have bloat (dead space) in data files that cannot be recovered by a regular <code>VACUUM</code> command.</p> <p>Recommended frequency: weekly or monthly</p> <p>Severity: WARNING</p> | <p>Check the <code>gp_bloat_diag</code> view in each database:</p> <pre>SELECT * FROM gp_toolkit.gp _bloat_diag;</pre>        | <p><code>VACUUM FULL</code> acquires an <code>ACCESS EXCLUSIVE</code> lock on tables. Run <code>VACUUM FULL</code> during a time when users and applications do not require access to the tables, such as during a time of low activity, or during a maintenance window.</p> |

## Database Maintenance

Table 5. Database Maintenance Activities

| Activity  | Procedure  | Corrective Actions   |
|---|--|--|
| <p>Reclaim space occupied by deleted rows in the heap tables so that the space they occupy can be reused.</p> <p>Recommended frequency: daily</p> <p>Severity: CRITICAL</p> | <p>Vacuum user tables:</p> <pre>VACUUM &lt;table&gt;;</pre>  | <p>Vacuum updated tables regularly to prevent bloating.</p>  |
| <p>Update table statistics.</p> <p>Recommended frequency: after loading data and before executing queries</p> <p>Severity: CRITICAL</p>                                     | <p>Analyze user tables. You can use the <code>analyzedb</code> management utility:</p> <pre>analyzedb -d &lt;database&gt; -a</pre> | <p>Analyze updated tables regularly so that the optimizer can produce efficient query execution plans.</p> |
| <p>Backup the database data.</p> <p>Recommended frequency: daily, or as required by your backup plan</p> <p>Severity: CRITICAL</p>  | <p>Run the <code>gpbackup</code> utility to create a backup of the master and segment databases in parallel.</p>                   | <p>Best practice is to have a current backup ready in case the database must be restored.</p>              |

| Activity   | Procedure  | Corrective Actions  |
|--|--|---|
| <p>Vacuum, reindex, and analyze system catalogs to maintain an efficient catalog.</p> <p>Recommended frequency: weekly, or more often if database objects are created and dropped frequently</p> | <ol style="list-style-type: none"> <li>1. <code>VACUUM</code> the system tables in each database.</li> <li>2. Run <code>REINDEX SYSTEM</code> in each database, or use the <code>reindexdb</code> command-line utility with the <code>-s</code> option: <div style="border: 1px solid #ccc; padding: 5px; margin: 5px 0;"> <pre>reindexdb -s &lt;database&gt;</pre> </div> </li> <li>3. <code>ANALYZE</code> each of the system tables: <div style="border: 1px solid #ccc; padding: 5px; margin: 5px 0;"> <pre>analyzedb -s pg_catalog -d &lt;database&gt;</pre> </div> </li> </ol> | <p>The optimizer retrieves information from the system tables to create query plans. If system tables and indexes are allowed to become bloated over time, scanning the system tables increases query execution time. It is important to run <code>ANALYZE</code> after reindexing, because <code>REINDEX</code> leaves indexes with no statistics.</p> |

## Patching and Upgrading

Table 6. Patch and Upgrade Activities

| Activity  | Procedure  | Corrective Actions  |
|---|--|---|
| <p>Ensure any bug fixes or enhancements are applied to the kernel.</p> <p>Recommended frequency: at least every 6 months</p> <p>Severity: IMPORTANT</p> | <p>Follow the vendor's instructions to update the Linux kernel.</p>  | <p>Keep the kernel current to include bug fixes and security fixes, and to avoid difficult future upgrades.</p>   |
| <p>Install Greenplum Database minor releases, for example 5.0.x.</p> <p>Recommended frequency: quarterly</p> <p>Severity: IMPORTANT</p>                 | <p>Follow upgrade instructions in the Greenplum Database <i>Release Notes</i>. Always upgrade to the latest in the series.</p> | <p>Keep the Greenplum Database software current to incorporate bug fixes, performance enhancements, and feature enhancements into your Greenplum cluster.</p> |

# Managing Performance

The topics in this section cover Greenplum Database performance management, including how to monitor performance and how to configure workloads to prioritize resource utilization.

- **Defining Database Performance**  
Managing system performance includes measuring performance, identifying the causes of performance problems, and applying the tools and techniques available to you to remedy the problems.
- **Common Causes of Performance Issues**  
This section explains the troubleshooting processes for common performance issues and potential solutions to these issues.
- **Greenplum Database Memory Overview**  
Memory is a key resource for a Greenplum Database system and, when used efficiently, can ensure high performance and throughput. This topic describes how segment host memory is allocated between segments and the options available to administrators to configure memory.
- **Managing Resources**  
Greenplum Database provides features to help you prioritize and allocate resources to queries according to business requirements and to prevent queries from starting when resources are unavailable.
- **Investigating a Performance Problem**  
This section provides guidelines for identifying and troubleshooting performance problems in a Greenplum Database system.

**Parent topic:** [Greenplum Database Administrator Guide](#)

## Defining Database Performance

Managing system performance includes measuring performance, identifying the causes of performance problems, and applying the tools and techniques available to you to remedy the problems.

Greenplum measures database performance based on the rate at which the database management system (DBMS) supplies information to requesters.

**Parent topic:** [Managing Performance](#)

## Understanding the Performance Factors

Several key performance factors influence database performance. Understanding these factors helps identify performance opportunities and avoid problems:

- [System Resources](#)
- [Workload](#)
- [Throughput](#)
- [Contention](#)
- [Optimization](#)

## System Resources

Database performance relies heavily on disk I/O and memory usage. To accurately set performance expectations, you need to know the baseline performance of the hardware on which your DBMS is deployed. Performance of hardware components such as CPUs, hard disks, disk controllers, RAM, and network interfaces will significantly affect how fast your database performs.

**Note:** Do not install anti-virus software on Greenplum Database hosts as the software might cause extra CPU and IO load that interferes with Greenplum Database operations.

## Workload

The workload equals the total demand from the DBMS, and it varies over time. The total workload is a combination of user queries, applications, batch jobs, transactions, and system commands directed through the DBMS at any given time. For example, it can increase when month-end reports are run or decrease on weekends when most users are out of the office. Workload strongly influences database performance. Knowing your workload and peak demand times helps you plan for the most efficient use of your system resources and enables processing the largest possible workload.

## Throughput

A system's throughput defines its overall capability to process data. DBMS throughput is measured in queries per second, transactions per second, or average response times. DBMS throughput is closely related to the processing capacity of the underlying systems (disk I/O, CPU speed, memory bandwidth, and so on), so it is important to know the throughput capacity of your hardware when setting DBMS throughput goals.

## Contention

Contention is the condition in which two or more components of the workload attempt to use the system in a conflicting way — for example, multiple queries that try to update the same piece of data at the same time or multiple large workloads that compete for system resources. As contention increases, throughput decreases.

## Optimization

DBMS optimizations can affect the overall system performance. SQL formulation, database configuration parameters, table design, data distribution, and so on enable the database query optimizer to create the most efficient access plans.

## Determining Acceptable Performance

When approaching a performance tuning initiative, you should know your system's expected level of performance and define measurable performance requirements so you can accurately evaluate your system's performance. Consider the following when setting performance goals:

- [Baseline Hardware Performance](#)
- [Performance Benchmarks](#)

## Baseline Hardware Performance

Most database performance problems are caused not by the database, but by the underlying systems on which the database runs. I/O bottlenecks, memory problems, and network issues can notably degrade database performance. Knowing the baseline capabilities of your hardware and operating system (OS) will help you identify and troubleshoot hardware-related problems before you explore database-level or query-level tuning initiatives.

See the *Greenplum Database Reference Guide* for information about running the `gpcheckperf` utility to validate hardware and network performance.

## Performance Benchmarks

To maintain good performance or fix performance issues, you should know the capabilities of your DBMS on a defined workload. A benchmark is a predefined workload that produces a known result set. Periodically run the same benchmark tests to help identify system-related performance degradation over time. Use benchmarks to compare workloads and identify queries or applications that need optimization.

Many third-party organizations, such as the Transaction Processing Performance Council (TPC), provide benchmark tools for the database industry. TPC provides TPC-H, a decision support system that examines large volumes of data, runs queries with a high degree of complexity, and gives answers to critical business questions. For more information about TPC-H, go to:

<http://www.tpc.org/tpch>

## Distribution and Skew

Greenplum Database relies on even distribution of data across segments.

In an MPP shared nothing environment, overall response time for a query is measured by the completion time for all segments. The system is only as fast as the slowest segment. If the data is skewed, segments with more data will take more time to complete, so every segment must have an approximately equal number of rows and perform approximately the same amount of processing. Poor performance and out of memory conditions may result if one segment has significantly more data to process than other segments.

Optimal distributions are critical when joining large tables together. To perform a join, matching rows must be located together on the same segment. If data is not distributed on the same join column, the rows needed from one of the tables are dynamically redistributed to the other segments. In some cases a broadcast motion, in which each segment sends its individual rows to all other segments, is performed rather than a redistribution motion, where each segment rehashes the data and sends the rows to the appropriate segments according to the hash key.

**Parent topic:** [Greenplum Database Administrator Guide](#)

## Local (Co-located) Joins

Using a hash distribution that evenly distributes table rows across all segments and results in local joins can provide substantial performance gains. When joined rows are on the same segment, much of the processing can be accomplished within the segment instance. These are called *local* or *co-located* joins. Local joins minimize data movement; each segment operates independently of the other segments, without network traffic or communications between segments.

To achieve local joins for large tables commonly joined together, distribute the tables on the same column. Local joins require that both sides of a join be distributed on the same columns (and in the same order) *and* that all columns in the distribution clause are used when joining tables. The distribution columns must also be the same data type—although some values with different data types may appear to have the same representation, they are stored differently and hash to different values, so they are stored on different segments.

## Data Skew

Data skew may be caused by uneven data distribution due to the wrong choice of distribution keys or single tuple table insert or copy operations. Present at the table level, data skew, is often the root cause of poor query performance and out of memory conditions. Skewed data affects scan (read) performance, but it also affects all other query execution operations, for instance, joins and group by operations.

It is very important to *validate* distributions to *ensure* that data is evenly distributed after the initial load. It is equally important to *continue* to validate distributions after incremental loads.

The following query shows the number of rows per segment as well as the variance from the minimum and maximum numbers of rows:

```
SELECT 'Example Table' AS "Table Name",
       max(c) AS "Max Seg Rows", min(c) AS "Min Seg Rows",
       (max(c)-min(c))*100.0/max(c) AS "Percentage Difference Between Max & Min"
FROM (SELECT count(*) c, gp_segment_id FROM facts GROUP BY 2) AS a;
```

The `gp_toolkit` schema has two views that you can use to check for skew.

- The `gp_toolkit.gp_skew_coefficients` view shows data distribution skew by calculating the coefficient of variation (CV) for the data stored on each segment. The `skccoeff` column shows the coefficient of variation (CV), which is calculated as the standard deviation divided by the average. It takes into account both the average and variability around the average of a data series. The lower the value, the better. Higher values indicate greater data skew.
- The `gp_toolkit.gp_skew_idle_fractions` view shows data distribution skew by calculating the percentage of the system that is idle during a table scan, which is an indicator of computational skew. The `siffraction` column shows the percentage of the system that is idle during a table scan. This is an indicator of uneven data distribution or query processing skew. For example, a value of 0.1 indicates 10% skew, a value of 0.5 indicates 50% skew, and so on. Tables that have more than 10% skew should have their distribution policies evaluated.

## Considerations for Replicated Tables

When you create a replicated table (with the `CREATE TABLE` clause `DISTRIBUTED REPLICATED`), Greenplum Database distributes every table row to every segment instance. Replicated table data is evenly distributed because every segment has the same rows. A query that uses the `gp_segment_id` system column on a replicated table to verify evenly distributed data, will fail because Greenplum Database does not allow queries to reference replicated tables' system columns.

## Processing Skew

Processing skew results when a disproportionate amount of data flows to, and is processed by, one or a few segments. It is often the culprit behind Greenplum Database performance and stability issues. It can happen with operations such join, sort, aggregation, and various OLAP operations. Processing skew happens in flight while a query is running and is not as easy to detect as data skew.

If single segments are failing, that is, not all segments on a host, it may be a processing skew issue. Identifying processing skew is currently a manual process. First look for spill files. If there is skew, but not enough to cause spill, it will not become a performance issue. If you determine skew exists, then find the query responsible for the skew.

The remedy for processing skew in almost all cases is to rewrite the query. Creating temporary tables can eliminate skew. Temporary tables can be randomly distributed to force a two-stage aggregation.

## Common Causes of Performance Issues

This section explains the troubleshooting processes for common performance issues and potential solutions to these issues.

**Parent topic:** [Managing Performance](#)

## Identifying Hardware and Segment Failures

The performance of Greenplum Database depends on the hardware and IT infrastructure on which it runs. Greenplum Database is comprised of several servers (hosts) acting together as one cohesive system (array); as a first step in diagnosing performance problems, ensure that all Greenplum Database segments are online. Greenplum Database's performance will be as fast as the slowest host in the array. Problems with CPU utilization, memory management, I/O processing, or network load affect performance. Common hardware-related issues are:

- **Disk Failure** – Although a single disk failure should not dramatically affect database performance if you are using RAID, disk resynchronization does consume resources on the host with failed disks. The `gpcheckperf` utility can help identify segment hosts that have disk I/O issues.
- **Host Failure** – When a host is offline, the segments on that host are nonoperational. This means other hosts in the array must perform twice their usual workload because they are running the primary segments and multiple mirrors. If mirrors are not enabled, service is interrupted. Service is temporarily interrupted to recover failed segments. The `gpstate` utility helps identify failed segments.

- **Network Failure** – Failure of a network interface card, a switch, or DNS server can bring down segments. If host names or IP addresses cannot be resolved within your Greenplum array, these manifest themselves as interconnect errors in Greenplum Database. The `gpcheckperf` utility helps identify segment hosts that have network issues.
- **Disk Capacity** – Disk capacity on your segment hosts should never exceed 70 percent full. Greenplum Database needs some free space for runtime processing. To reclaim disk space that deleted rows occupy, run `VACUUM` after loads or updates. The `gp_toolkit` administrative schema has many views for checking the size of distributed database objects.

See the *Greenplum Database Reference Guide* for information about checking database object sizes and disk space.

## Managing Workload

A database system has a limited CPU capacity, memory, and disk I/O resources. When multiple workloads compete for access to these resources, database performance degrades. Resource management maximizes system throughput while meeting varied business requirements. Greenplum Database provides resource queues and resource groups to help you manage these system resources.

Resource queues and resource groups limit resource usage and the total number of concurrent queries running in the particular queue or group. By assigning database roles to the appropriate queue or group, administrators can control concurrent user queries and prevent system overload. For more information about resource queues and resource groups, including selecting the appropriate scheme for your Greenplum Database environment, see [Managing Resources](#).

Greenplum Database administrators should run maintenance workloads such as data loads and `VACUUM ANALYZE` operations after business hours. Do not compete with database users for system resources; perform administrative tasks at low-usage times.

## Avoiding Contention

Contention arises when multiple users or workloads try to use the system in a conflicting way; for example, contention occurs when two transactions try to update a table simultaneously. A transaction that seeks a table-level or row-level lock will wait indefinitely for conflicting locks to be released. Applications should not hold transactions open for long periods of time, for example, while waiting for user input.

## Maintaining Database Statistics

Greenplum Database uses a cost-based query optimizer that relies on database statistics. Accurate statistics allow the query optimizer to better estimate the number of rows retrieved by a query to choose the most efficient query plan. Without database statistics, the query optimizer cannot estimate how many records will be returned. The optimizer does not assume it has sufficient memory to perform certain operations such as aggregations, so it takes the most conservative action and does these operations by reading and writing from disk. This is significantly slower than doing them in memory. `ANALYZE` collects statistics about the database that the query optimizer needs.

**Note:** When running an SQL command with GPORCA, Greenplum Database issues a warning if the command performance could be improved by collecting statistics on a column or set of columns referenced by the command. The warning is issued on the command line and information is added to the Greenplum Database log file. For information about collecting statistics on table columns, see the `ANALYZE` command in the *Greenplum Database Reference Guide*

## Identifying Statistics Problems in Query Plans

Before you interpret a query plan for a query using `EXPLAIN` or `EXPLAIN ANALYZE`, familiarize yourself with the data to help identify possible statistics problems. Check the plan for the following indicators of inaccurate statistics:

- **Are the optimizer's estimates close to reality?** Run `EXPLAIN ANALYZE` and see if the number of rows the optimizer estimated is close to the number of rows the query operation returned.
- **Are selective predicates applied early in the plan?** The most selective filters should be applied early in the plan so fewer rows move up the plan tree.
- **Is the optimizer choosing the best join order?** When you have a query that joins multiple tables, make sure the optimizer chooses the most selective join order. Joins that eliminate the largest number of rows should be done earlier in the plan so fewer rows move up the plan tree.

See [Query Profiling](#) for more information about reading query plans.

## Tuning Statistics Collection

The following configuration parameters control the amount of data sampled for statistics collection:

- `default_statistics_target`

These parameters control statistics sampling at the system level. It is better to sample only increased statistics for columns used most frequently in query predicates. You can adjust statistics for a particular column using the command:

```
ALTER TABLE...SET STATISTICS
```

For example:

```
ALTER TABLE sales ALTER COLUMN region SET STATISTICS 50;
```

This is equivalent to changing `default_statistics_target` for a particular column. Subsequent `ANALYZE` operations will then gather more statistics data for that column and produce better query plans as a result.

## Optimizing Data Distribution

When you create a table in Greenplum Database, you must declare a distribution key that allows for even data distribution across all segments in the system. Because the segments work on a query in parallel, Greenplum Database will always be as fast as the slowest segment. If the data is unbalanced, the segments that have more data will return their results slower and therefore slow down the entire system.

## Optimizing Your Database Design

Many performance issues can be improved by database design. Examine your database design and consider the following:

- Does the schema reflect the way the data is accessed?
- Can larger tables be broken down into partitions?
- Are you using the smallest data type possible to store column values?
- Are columns used to join tables of the same datatype?
- Are your indexes being used?

## Greenplum Database Maximum Limits

To help optimize database design, review the maximum limits that Greenplum Database supports:

| Dimension                         | Limit                                       |
|-----------------------------------|---|
| Database Size                     | Unlimited                                   |
| Table Size                        | Unlimited, 128 TB per partition per segment |
| Row Size                          | 1.6 TB (1600 columns * 1 GB)                |
| Field Size                        | 1 GB  |
| Rows per Table                    | 281474976710656 (2 <sup>48</sup> )          |
| Columns per Table/View            | 1600  |
| Indexes per Table                 | Unlimited                                   |
| Columns per Index                 | 32  |
| Table-level Constraints per Table | Unlimited                                   |
| Table Name Length                 | 63 Bytes (Limited by <i>name</i> data type) |

Dimensions listed as unlimited are not intrinsically limited by Greenplum Database. However, they are limited in practice to available disk space and memory/swap space. Performance may degrade when these values are unusually large.

### Note:

There is a maximum limit on the number of objects (tables, indexes, and views, but not rows) that may exist at one time. This limit is 4294967296 (2<sup>32</sup>).

## Greenplum Database Memory Overview

Memory is a key resource for a Greenplum Database system and, when used efficiently, can ensure high performance and throughput. This topic describes how segment host memory is allocated between segments and the options available to administrators to configure memory.

A Greenplum Database segment host runs multiple PostgreSQL instances, all sharing the host's memory. The segments have an identical configuration and they consume similar amounts of memory, CPU, and disk IO simultaneously, while working on queries in parallel.

For best query throughput, the memory configuration should be managed carefully. There are memory configuration options at every level in Greenplum Database, from operating system parameters, to managing resources with resource queues and resource groups, to setting the amount of memory allocated to an individual query.

## Segment Host Memory

On a Greenplum Database segment host, the available host memory is shared among all the processes running on the computer, including the operating system, Greenplum Database segment instances, and other application processes. Administrators must determine what Greenplum Database and non-Greenplum Database processes share the hosts' memory and configure the system to use the memory efficiently. It is equally important to monitor memory usage regularly to detect any changes in the way host memory is consumed by Greenplum Database or other processes.

The following figure illustrates how memory is consumed on a Greenplum Database segment host when resource queue-based resource management is active.

Beginning at the bottom of the illustration, the line labeled *A* represents the total host memory. The line directly above line *A* shows that the total host memory comprises both physical RAM and swap space.

The line labelled *B* shows that the total memory available must be shared by Greenplum Database and all other processes on the host. Non-Greenplum Database processes include the operating system and any other applications, for example system monitoring agents. Some applications may use a significant portion of memory and, as a result, you may have to adjust the number of segments per Greenplum Database host or the amount of memory per segment.

The segments (*C*) each get an equal share of the Greenplum Database Memory (*B*).

Within a segment, the currently active resource management scheme, *Resource Queues* or *Resource Groups*, governs how memory is allocated to run a SQL statement. These constructs allow you to translate business requirements into execution policies in your Greenplum Database system and to guard against queries that could degrade performance. For an overview of resource groups and resource queues, refer to [Managing Resources](#).

## Options for Configuring Segment Host Memory

Host memory is the total memory shared by all applications on the segment host. You can configure the amount of host memory using any of the following methods:

- Add more RAM to the nodes to increase the physical memory.
- Allocate swap space to increase the size of virtual memory.
- Set the kernel parameters `vm.overcommit_memory` and `vm.overcommit_ratio` to configure how the operating system handles large memory allocation requests.

The physical RAM and OS configuration are usually managed by the platform team and system administrators. See the [Greenplum Database Installation Guide](#) for the recommended kernel parameters and for how to set the `/etc/sysctl.conf` file parameters.

The amount of memory to reserve for the operating system and other processes is workload dependent. The minimum recommendation for operating system memory is 32GB, but if there is much concurrency in Greenplum Database, increasing to 64GB of reserved memory may be required. The largest user of operating system memory is SLAB, which increases as Greenplum Database concurrency and the number of sockets used increases.

The `vm.overcommit_memory` kernel parameter should always be set to 2, the only safe value for Greenplum Database.

The `vm.overcommit_ratio` kernel parameter sets the percentage of RAM that is used for application processes, the remainder reserved for the operating system. The default for Red Hat is 50 (50%). Setting this parameter too high may result in insufficient memory reserved for the operating system, which can cause segment host failure or database failure. Leaving the setting at the default of 50 is generally safe, but conservative. Setting the value too low reduces the amount of concurrency and the complexity of queries you can run at the same time by reducing the amount of memory available to Greenplum Database. When increasing `vm.overcommit_ratio`, it is important to remember to always reserve some memory for operating system activities.

### Configuring `vm.overcommit_ratio` when Resource Group-Based Resource Management is Active

When resource group-based resource management is active, tune the operating system `vm.overcommit_ratio` as necessary. If your memory utilization is too low, increase the value; if your memory or swap usage is too high, decrease the setting.

### Configuring `vm.overcommit_ratio` when Resource Queue-Based Resource Management is Active

To calculate a safe value for `vm.overcommit_ratio` when resource queue-based resource management is active, first determine the total memory available to Greenplum Database processes, `gp_vmem_rq`.

- If the total system memory is less than 256 GB, use this formula:

$$gp\_vmem\_rq = ((SWAP + RAM) - (7.5GB + 0.05 * RAM)) / 1.7$$

- If the total system memory is equal to or greater than 256 GB, use this formula:

$$gp\_vmem\_rq = ((SWAP + RAM) - (7.5GB + 0.05 * RAM)) / 1.17$$

where `SWAP` is the swap space on the host in GB, and `RAM` is the number of GB of RAM installed on the host.

When resource queue-based resource management is active, use `gp_vmem_rq` to calculate the `vm.overcommit_ratio` value with this formula:

```
vm.overcommit_ratio = (RAM - 0.026 * gp_vmem_rq) / RAM
```

## Configuring Greenplum Database Memory

Greenplum Database Memory is the amount of memory available to all Greenplum Database segment instances.

When you set up the Greenplum Database cluster, you determine the number of primary segments to run per host and the amount of memory to allocate for each segment. Depending on the CPU cores, amount of physical RAM, and workload characteristics, the number of segments is usually a value between 4 and 8. With segment mirroring enabled, it is important to allocate memory for the maximum number of primary segments running on a host during a failure. For example, if you use the default grouping mirror configuration, a segment host failure doubles the number of acting primaries on the host that has the failed host's mirrors. Mirror configurations that spread each host's mirrors over multiple other hosts can lower the maximum, allowing more memory to be allocated for each segment. For example, if you use a block mirroring configuration with 4 hosts per block and 8 primary segments per host, a single host failure would cause other hosts in the block to have a maximum of 11 active primaries, compared to 16 for the default grouping mirror configuration.

### Configuring Segment Memory when Resource Group-Based Resource Management is Active

When resource group-based resource management is active, the amount of memory allocated to each segment on a segment host is the memory available to Greenplum Database multiplied by the `gp_resource_group_memory_limit` server configuration parameter and divided by the number of active primary segments on the host. Use the following formula to calculate segment memory when using resource groups for resource management.

```
rg_perseg_mem = ((RAM * (vm.overcommit_ratio / 100) + SWAP) * gp_resource_group_memory_limit) / num_active_primary_segments
```

Resource groups expose additional configuration parameters that enable you to further control and refine the amount of memory allocated for queries.

### Configuring Segment Memory when Resource Queue-Based Resource Management is Active

When resource queue-based resource management is active, the `gp_vmem_protect_limit` server configuration parameter value identifies the amount of memory to allocate to each segment. This value is estimated by calculating the memory available for all Greenplum Database processes and dividing by the maximum number of primary segments during a failure. If `gp_vmem_protect_limit` is set too high, queries can fail. Use the following formula to calculate a safe value for `gp_vmem_protect_limit`; provide the `gp_vmem_rq` value that you calculated earlier.

```
gp_vmem_protect_limit = gp_vmem_rq / max_acting_primary_segments
```

where `max_acting_primary_segments` is the maximum number of primary segments that could be running on a host when mirror segments are activated due to a host or segment failure.

**Note:** The `gp_vmem_protect_limit` setting is enforced only when resource queue-based resource management is active in Greenplum Database. Greenplum ignores this configuration parameter when resource group-based resource management is active.

Resource queues expose additional configuration parameters that enable you to further control and refine the amount of memory allocated for queries.

## Example Memory Configuration Calculations

This section provides example memory calculations for resource queues and resource groups for a Greenplum Database system with the following specifications:

- Total RAM = 256GB
- Swap = 64GB
- 8 primary segments and 8 mirror segments per host, in blocks of 4 hosts
- Maximum number of primaries per host during failure is 11

### Resource Group Example

When resource group-based resource management is active in Greenplum Database, the usable memory available on a host is a function of the amount of RAM and swap space configured for the system, as well as the `vm.overcommit_ratio` system parameter setting:

```
total_node_usable_memory = RAM * (vm.overcommit_ratio / 100) + Swap
                        = 256GB * (50/100) + 64GB
                        = 192GB
```

Assuming the default `gp_resource_group_memory_limit` value (.7), the memory allocated to a Greenplum Database host with the example configuration is:

```
total_gp_memory = total_node_usable_memory * gp_resource_group_memory_limit
                = 192GB * .7
                = 134.4GB
```

The memory available to a Greenplum Database segment on a segment host is a function of the memory reserved for Greenplum on the host and the number of active primary segments on the host. On cluster startup:

```
gp_seg_memory = total_gp_memory / number_of_active_primary_segments
               = 134.4GB / 8
               = 16.8GB
```

Note that when 3 mirror segments switch to primary segments, the per-segment memory is still 16.8GB. Total memory usage on the segment host may approach:

```
total_gp_memory_with primaries = 16.8GB * 11 = 184.8GB
```

### Resource Queue Example

The `vm.overcommit_ratio` calculation for the example system when resource queue-based resource management is active in Greenplum Database follows:

```
gp_vmem_rq = ((SWAP + RAM) - (7.5GB + 0.05 * RAM)) / 1.7
            = ((64 + 256) - (7.5 + 0.05 * 256)) / 1.7
            = 176

vm.overcommit_ratio = (RAM - (0.026 * gp_vmem_rq)) / RAM
                    = (256 - (0.026 * 176)) / 256
                    = .982
```

You would set `vm.overcommit_ratio` of the example system to 98.

The `gp_vmem_protect_limit` calculation when resource queue-based resource management is active in Greenplum Database:

```
gp_vmem_protect_limit = gp_vmem_rq / maximum_acting_primary_segments
                       = 176 / 11
                       = 16GB
                       = 16384MB
```

You would set the `gp_vmem_protect_limit` server configuration parameter on the example system to 16384.

## Managing Resources

Greenplum Database provides features to help you prioritize and allocate resources to queries according to business requirements and to prevent queries from starting when resources are unavailable.

You can use resource management features to limit the number of concurrent queries, the amount of memory used to run a query, and the relative amount of CPU devoted to processing a query. Greenplum Database provides two schemes to manage resources - Resource Queues and Resource Groups.

**Important:** Significant Greenplum Database performance degradation has been observed when enabling resource group-based workload management on RedHat 6.x and CentOS 6.x. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x/8.x systems.

If you use RedHat 6 and the performance with resource groups is acceptable for your use case, upgrade your kernel to version 2.6.32-696 or higher to benefit from other fixes to the cgroups implementation.

Either the resource queue or the resource group management scheme can be active in Greenplum Database; both schemes cannot be active at the same time.

Resource queues are enabled by default when you install your Greenplum Database cluster. While you can create and assign resource groups when resource queues are active, you must explicitly enable resource groups to start using that management scheme.

The following table summarizes some of the differences between Resource Queues and Resource Groups.

| Metric              | Resource Queues  | Resource Groups   |
|---------------------|--|---|
| Concurrency         | Managed at the query level   | Managed at the transaction level  |
| CPU                 | Specify query priority   | Specify percentage of CPU resources; uses Linux Control Groups  |
| Memory              | Managed at the queue and operator level; users can over-subscribe                            | Managed at the transaction level, with enhanced allocation and tracking; users cannot over-subscribe  |
| Memory Isolation    | None   | Memory is isolated between resource groups and between transactions within the same resource group  |
| Users               | Limits are applied only to non-admin users   | Limits are applied to <code>SUPERUSER</code> and non-admin users alike  |
| Queueing            | Queue only when no slot available  | Queue when no slot is available or not enough available memory  |
| Query Failure       | Query may fail immediately if not enough memory  | Query may fail after reaching transaction fixed memory limit when no shared resource group memory exists and the transaction requests more memory |
| Limit Bypass        | Limits are not enforced for <code>SUPERUSER</code> roles and certain operators and functions | Limits are not enforced on <code>SET</code> , <code>RESET</code> , and <code>SHOW</code> commands   |
| External Components | None   | Manage PL/Container CPU and memory resources  |

- [Using Resource Queues](#)

Parent topic: [Managing Performance](#)

## Using Resource Groups

You use resource groups to set and enforce CPU, memory, and concurrent transaction limits in Greenplum Database. After you define a resource group, you can then assign the group to one or more Greenplum Database roles, or to an external component such as PL/Container, in order to control the resources used by those roles or components.

When you assign a resource group to a role (a role-based resource group), the resource limits that you define for the group apply to all of the roles to which you assign the group. For example, the memory limit for a resource group identifies the maximum memory usage for all running transactions submitted by Greenplum Database users in all roles to which you assign the group.

Similarly, when you assign a resource group to an external component, the group limits apply to all running instances of the component. For example, if you create a resource group for a PL/Container external component, the memory limit that you define for the group specifies the maximum memory usage for all running instances of each PL/Container runtime to which you assign the group.

## Understanding Role and Component Resource Groups

Greenplum Database supports two types of resource groups: groups that manage resources for roles, and groups that manage resources for external components such as PL/Container.

The most common application for resource groups is to manage the number of active queries that different roles may run concurrently in your Greenplum Database cluster. You can also manage the amount of CPU and memory resources that Greenplum allocates to each query.

Resource groups for roles use Linux control groups (cgroups) for CPU resource management. Greenplum Database tracks virtual memory internally for these resource groups using a memory auditor referred to as `vmtracker`.

When the user runs a query, Greenplum Database evaluates the query against a set of limits defined for the resource group. Greenplum Database runs the query immediately if the group's resource limits have not yet been reached and the query does not cause the group to exceed the concurrent transaction limit. If these conditions are not met, Greenplum Database queues the query. For example, if the maximum number of concurrent transactions for the resource group has already been reached, a subsequent query is queued and must wait until other queries complete

before it runs. Greenplum Database may also run a pending query when the resource group's concurrency and memory limits are altered to large enough values.

Within a resource group for roles, transactions are evaluated on a first in, first out basis. Greenplum Database periodically assesses the active workload of the system, reallocating resources and starting/queuing jobs as necessary.

You can also use resource groups to manage the CPU and memory resources of external components such as PL/Container. Resource groups for external components use Linux cgroups to manage both the total CPU and total memory resources for the component.

**Note:** Containerized deployments of Greenplum Database might create a hierarchical set of nested cgroups to manage host system resources. The nesting of cgroups affects the Greenplum Database resource group limits for CPU percentage, CPU cores, and memory (except for Greenplum Database external components). The Greenplum Database resource group system resource limit is based on the quota for the parent group.

For example, Greenplum Database is running in a cgroup demo, and the Greenplum Database cgroup is nested in the cgroup demo. If the cgroup demo is configured with a CPU limit of 60% of system CPU resources and the Greenplum Database resource group CPU limit is set 90%, the Greenplum Database limit of host system CPU resources is 54% (0.6 x 0.9).

Nested cgroups do not affect memory limits for Greenplum Database external components such as PL/Container. Memory limits for external components can only be managed if the cgroup that is used to manage Greenplum Database resources is not nested, the cgroup is configured as a top-level cgroup.

For information about configuring cgroups for use by resource groups, see [Configuring and Using Resource Groups](#).

## Resource Group Attributes and Limits

When you create a resource group, you:

- Specify the type of resource group by identifying how memory for the group is audited.
- Provide a set of limits that determine the amount of CPU and memory resources available to the group.

Resource group attributes and limits:

| Limit Type     | Description  |
|----------------|--|
| MEMORY_AUDITOR | The memory auditor in use for the resource group. <code>vmtracker</code> (the default) is required if you want to assign the resource group to roles. Specify <code>cgroup</code> to assign the resource group to an external component. |
| CONCURRENCY    | The maximum number of concurrent transactions, including active and idle transactions, that are permitted in the resource group.   |
| CPU_RATE_LIMIT | The percentage of CPU resources available to this resource group.  |
| CPUSET         | The CPU cores to reserve for this resource group.  |
| MEMORY_LIMIT   | The percentage of reserved memory resources available to this resource group.  |

| Limit Type              | Description   |
|-------------------------|---|
| MEMORY_SHA<br>RED_QUOTA | The percentage of reserved memory to share across transactions submitted in this resource group.                            |
| MEMORY_SPILL_RATIO      | The memory usage threshold for memory-intensive transactions. When a transaction reaches this threshold, it spills to disk. |

**Note:** Resource limits are not enforced on `SET`, `RESET`, and `SHOW` commands.

## Memory Auditor

The `MEMORY_AUDITOR` attribute specifies the type of resource group by identifying the memory auditor for the group. A resource group that specifies the `vmtracker` `MEMORY_AUDITOR` identifies a resource group for roles. A resource group specifying the `cgroup` `MEMORY_AUDITOR` identifies a resource group for external components.

The default `MEMORY_AUDITOR` is `vmtracker`.

The `MEMORY_AUDITOR` that you specify for a resource group determines if and how Greenplum Database uses the limit attributes to manage CPU and memory resources:

| Limit Type          | Resource Group for Roles | Resource Group for External Components |
|---------------------|--------------------------|--|
| CONCURRENCY         | Yes                      | No; must be zero (0)                   |
| CPU_RATE_LIMIT      | Yes                      | Yes                                    |
| CPUSET              | Yes                      | Yes                                    |
| MEMORY_LIMIT        | Yes                      | Yes                                    |
| MEMORY_SHARED_QUOTA | Yes                      | Component-specific                     |
| MEMORY_SPILL_RATIO  | Yes                      | Component-specific                     |

**Note:** For queries managed by resource groups that are configured to use the `vmtracker` memory auditor, Greenplum Database supports the automatic termination of queries based on the amount of memory the queries are using. See the server configuration parameter [runaway\\_detector\\_activation\\_percent](#).

## Transaction Concurrency Limit

The `CONCURRENCY` limit controls the maximum number of concurrent transactions permitted for a resource group for roles.

**Note:** The `CONCURRENCY` limit is not applicable to resource groups for external components and must be set to zero (0) for such groups.

Each resource group for roles is logically divided into a fixed number of slots equal to the `CONCURRENCY` limit. Greenplum Database allocates these slots an equal, fixed percentage of memory resources.

The default `CONCURRENCY` limit value for a resource group for roles is 20.

Greenplum Database queues any transactions submitted after the resource group reaches its `CONCURRENCY` limit. When a running transaction completes, Greenplum Database un-queues and runs the earliest queued transaction if sufficient memory resources exist.

You can set the server configuration parameter `gp_resource_group_bypass` to bypass a resource group concurrency limit.

You can set the server configuration parameter `gp_resource_group_queuing_timeout` to specify the amount of time a transaction remains in the queue before Greenplum Database cancels the transaction. The default timeout is zero, Greenplum queues transactions indefinitely.

## CPU Limits

You configure the share of CPU resources to reserve for a resource group on a segment host by assigning specific CPU core(s) to the group, or by identifying the percentage of segment CPU resources to allocate to the group. Greenplum Database uses the `CPUSET` and `CPU_RATE_LIMIT` resource group limits to identify the CPU resource allocation mode. You must specify only one of these limits when you configure a resource group.

You may employ both modes of CPU resource allocation simultaneously in your Greenplum Database cluster. You may also change the CPU resource allocation mode for a resource group at runtime.

The `gp_resource_group_cpu_limit` server configuration parameter identifies the maximum percentage of system CPU resources to allocate to resource groups on each Greenplum Database segment host. This limit governs the maximum CPU usage of all resource groups on a segment host regardless of the CPU allocation mode configured for the group. The remaining unreserved CPU resources are used for the OS kernel and the Greenplum Database auxiliary daemon processes. The default `gp_resource_group_cpu_limit` value is .9 (90%).

**Note:** The default `gp_resource_group_cpu_limit` value may not leave sufficient CPU resources if you are running other workloads on your Greenplum Database cluster nodes, so be sure to adjust this server configuration parameter accordingly.

**Warning:** Avoid setting `gp_resource_group_cpu_limit` to a value higher than .9. Doing so may result in high workload queries taking near all CPU resources, potentially starving Greenplum Database auxiliary processes.

## Assigning CPU Resources by Core

You identify the CPU cores that you want to reserve for a resource group with the `CPUSET` property. The CPU cores that you specify must be available in the system and cannot overlap with any CPU cores that you reserved for other resource groups. (Although Greenplum Database uses the cores that you assign to a resource group exclusively for that group, note that those CPU cores may also be used by non-Greenplum processes in the system.)

Specify a comma-separated list of single core numbers or number intervals when you configure `CPUSET`. You must enclose the core numbers/intervals in single quotes, for example, '1,3-4'.

When you assign CPU cores to `CPUSET` groups, consider the following:

- A resource group that you create with `CPUSET` uses the specified cores exclusively. If there are no running queries in the group, the reserved cores are idle and cannot be used by

queries in other resource groups. Consider minimizing the number of `CPUSET` groups to avoid wasting system CPU resources.

- Consider keeping CPU core 0 unassigned. CPU core 0 is used as a fallback mechanism in the following cases:
  - `admin_group` and `default_group` require at least one CPU core. When all CPU cores are reserved, Greenplum Database assigns CPU core 0 to these default groups. In this situation, the resource group to which you assigned CPU core 0 shares the core with `admin_group` and `default_group`.
  - If you restart your Greenplum Database cluster with one node replacement and the node does not have enough cores to service all `CPUSET` resource groups, the groups are automatically assigned CPU core 0 to avoid system start failure.
- Use the lowest possible core numbers when you assign cores to resource groups. If you replace a Greenplum Database node and the new node has fewer CPU cores than the original, or if you back up the database and want to restore it on a cluster with nodes with fewer CPU cores, the operation may fail. For example, if your Greenplum Database cluster has 16 cores, assigning cores 1-7 is optimal. If you create a resource group and assign CPU core 9 to this group, database restore to an 8 core node will fail.

Resource groups that you configure with `CPUSET` have a higher priority on CPU resources. The maximum CPU resource usage percentage for all resource groups configured with `CPUSET` on a segment host is the number of CPU cores reserved divided by the number of all CPU cores, multiplied by 100.

When you configure `CPUSET` for a resource group, Greenplum Database deactivates `CPU_RATE_LIMIT` for the group and sets the value to -1.

**Note:** You must configure `CPUSET` for a resource group *after* you have enabled resource group-based resource management for your Greenplum Database cluster.

## Assigning CPU Resources by Percentage

The Greenplum Database node CPU percentage is divided equally among each segment on the Greenplum node. Each resource group that you configure with a `CPU_RATE_LIMIT` reserves the specified percentage of the segment CPU for resource management.

The minimum `CPU_RATE_LIMIT` percentage you can specify for a resource group is 1, the maximum is 100.

The sum of `CPU_RATE_LIMITS` specified for all resource groups that you define in your Greenplum Database cluster must not exceed 100.

The maximum CPU resource usage for all resource groups configured with a `CPU_RATE_LIMIT` on a segment host is the minimum of:

- The number of non-reserved CPU cores divided by the number of all CPU cores, multiplied by 100, and
- The `gp_resource_group_cpu_limit` value.

When you configure `CPU_RATE_LIMIT` for a resource group, Greenplum Database deactivates `CPUSET` for the group and sets the value to -1.

There are two different ways of assigning CPU resources by percentage, determined by the value of the configuration parameter `gp_resource_group_cpu_ceiling_enforcement`:

### Elastic mode

This mode is active when `gp_resource_group_cpu_ceiling_enforcement` is set to `false` (default). It is elastic in that Greenplum Database may allocate the CPU resources of an idle resource group to a busier one(s). In such situations, CPU resources are re-allocated to the previously idle resource group when that resource group next becomes active. If multiple resource groups are busy, they are allocated the CPU resources of any idle resource groups based on the ratio of their `CPU_RATE_LIMITS`. For example, a resource group created with a `CPU_RATE_LIMIT` of 40 will be allocated twice as much extra CPU resource as a resource group that you create with a `CPU_RATE_LIMIT` of 20.

### Ceiling Enforcement mode

This mode is active when `gp_resource_group_cpu_ceiling_enforcement` is set to `true`. The resource group is enforced to not use more CPU resources than the defined value `CPU_RATE_LIMIT`, avoiding the use of the CPU burst feature.

## Memory Limits

When resource groups are enabled, memory usage is managed at the Greenplum Database node, segment, and resource group levels. You can also manage memory at the transaction level with a resource group for roles.

The `gp_resource_group_memory_limit` server configuration parameter identifies the maximum percentage of system memory resources to allocate to resource groups on each Greenplum Database segment host. The default `gp_resource_group_memory_limit` value is .7 (70%).

The memory resource available on a Greenplum Database node is further divided equally among each segment on the node. When resource group-based resource management is active, the amount of memory allocated to each segment on a segment host is the memory available to Greenplum Database multiplied by the `gp_resource_group_memory_limit` server configuration parameter and divided by the number of active primary segments on the host:

```
rg_perseg_mem = ((RAM * (vm.overcommit_ratio / 100) + SWAP) * gp_resource_group_memory_limit) / num_active_primary_segments
```

Each resource group may reserve a percentage of the segment memory for resource management. You identify this percentage via the `MEMORY_LIMIT` value that you specify when you create the resource group. The minimum `MEMORY_LIMIT` percentage you can specify for a resource group is 0, the maximum is 100. When `MEMORY_LIMIT` is 0, Greenplum Database reserves no memory for the resource group, but uses resource group global shared memory to fulfill all memory requests in the group. Refer to [Global Shared Memory](#) for more information about resource group global shared memory.

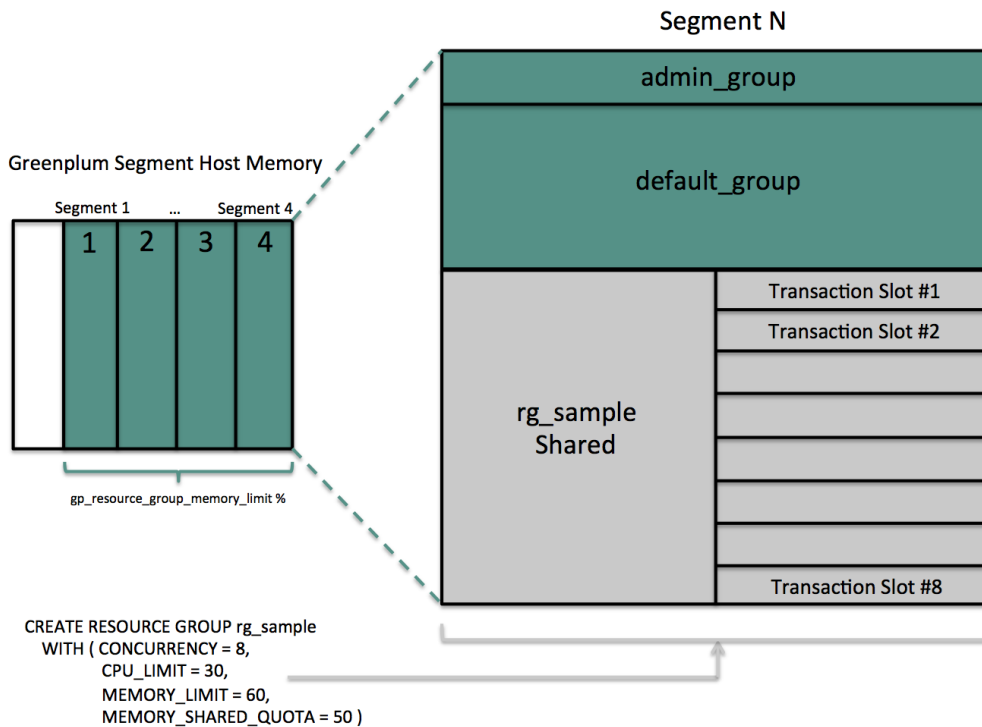

The sum of `MEMORY_LIMITS` specified for all resource groups that you define in your Greenplum Database cluster must not exceed 100.

## Additional Memory Limits for Role-based Resource Groups

If resource group memory is reserved for roles (non-zero `MEMORY_LIMIT`), the memory is further divided into fixed and shared components. The `MEMORY_SHARED_QUOTA` value that you specify when you create the resource group identifies the percentage of reserved resource group memory that may be shared among the currently running transactions. This memory is allotted on a first-come, first-served basis. A running transaction may use none, some, or all of the `MEMORY_SHARED_QUOTA`.

The minimum `MEMORY_SHARED_QUOTA` that you can specify is 0, the maximum is 100. The default `MEMORY_SHARED_QUOTA` is 80.

As mentioned previously, `CONCURRENCY` identifies the maximum number of concurrently running transactions permitted in a resource group for roles. If fixed memory is reserved by a resource group (non-zero `MEMORY_LIMIT`), it is divided into `CONCURRENCY` number of transaction slots. Each slot is allocated a fixed, equal amount of the resource group memory. Greenplum Database guarantees this fixed memory to each transaction.

When a query's memory usage exceeds the fixed per-transaction memory usage amount, Greenplum Database allocates available resource group shared memory to the query. The maximum amount of resource group memory available to a specific transaction slot is the sum of the transaction's fixed memory and the full resource group shared memory allotment.

### Global Shared Memory

The sum of the `MEMORY_LIMITS` configured for all resource groups (including the default `admin_group` and `default_group` groups) identifies the percentage of reserved resource group memory. If this sum is less than 100, Greenplum Database allocates any unreserved memory to a resource group global shared memory pool.

Resource group global shared memory is available only to resource groups that you configure with the `vmtracker` memory auditor.

When available, Greenplum Database allocates global shared memory to a transaction after first allocating slot and resource group shared memory (if applicable). Greenplum Database allocates resource group global shared memory to transactions on a first-come first-served basis.

**Note:** Greenplum Database tracks, but does not actively monitor, transaction memory usage in resource groups. If the memory usage for a resource group exceeds its fixed memory allotment, a transaction in the resource group fails when *all* of these conditions are met:

- No available resource group shared memory exists.
- No available global shared memory exists.
- The transaction requests additional memory.

Greenplum Database uses resource group memory more efficiently when you leave some memory (for example, 10-20%) unallocated for the global shared memory pool. The availability of global shared memory also helps to mitigate the failure of memory-consuming or unpredicted queries.

### Query Operator Memory

Most query operators are non-memory-intensive; that is, during processing, Greenplum Database can hold their data in allocated memory. When memory-intensive query operators such as join and sort process more data than can be held in memory, data is spilled to disk.

The `gp_resgroup_memory_policy` server configuration parameter governs the memory allocation and distribution algorithm for all query operators. Greenplum Database supports `eager-free` (the default) and `auto` memory policies for resource groups. When you specify the `auto` policy, Greenplum Database uses resource group memory limits to distribute memory across query operators, allocating a fixed size of memory to non-memory-intensive operators and the rest to memory-intensive operators. When the `eager_free` policy is in place, Greenplum Database distributes memory among operators more optimally by re-allocating memory released by operators that have completed their processing to operators in a later query stage.

`MEMORY_SPILL_RATIO` identifies the memory usage threshold for memory-intensive operators in a transaction. When this threshold is reached, a transaction spills to disk. Greenplum Database uses the `MEMORY_SPILL_RATIO` to determine the initial memory to allocate to a transaction.

You can specify an integer percentage value from 0 to 100 inclusive for `MEMORY_SPILL_RATIO`. The default `MEMORY_SPILL_RATIO` is 0.

When `MEMORY_SPILL_RATIO` is 0, Greenplum Database uses the `statement_mem` server configuration parameter value to control initial query operator memory.

**Note:** When you set `MEMORY_LIMIT` to 0, `MEMORY_SPILL_RATIO` must also be set to 0.

You can selectively set the `MEMORY_SPILL_RATIO` on a per-query basis at the session level with the `memory_spill_ratio` server configuration parameter.

## About How Greenplum Database Allocates Transaction Memory

The query planner pre-computes the maximum amount of memory that each node in the plan tree can use. When resource group-based resource management is active and the `MEMORY_SPILL_RATIO` for the resource group is non-zero, the following formula roughly specifies the maximum amount of memory that Greenplum Database allocates to a transaction:

```
query_mem = (rg_perseg_mem * memory_limit) * memory_spill_ratio / concurrency
```

Where `memory_limit`, `memory_spill_ratio`, and `concurrency` are specified by the resource group under which the transaction runs.

By default, Greenplum Database calculates the maximum amount of segment host memory allocated to a transaction based on the `rg_perseg_mem` and the number of primary segments configured on the *master host*.

**Note:** If the memory configuration on your Greenplum Database master and segment hosts differ, you may encounter out-of-memory conditions or underutilization of resources with the default configuration.

If the hardware configuration of your master and segment hosts differ, set the `gp_resource_group_enable_recalculate_query_mem` server configuration parameter to `true`; this prompts Greenplum Database to recalculate the maximum per-query memory allotment on each segment host based on the `rg_perseg_mem` and the number of primary segments configured on *that segment host*.

### `memory_spill_ratio` and Low Memory Queries

A low `statement_mem` setting (for example, in the 10MB range) has been shown to increase the performance of queries with low memory requirements. Use the `memory_spill_ratio` and `statement_mem` server configuration parameters to override the setting on a per-query basis. For example:

```
SET memory_spill_ratio=0;
SET statement_mem='10 MB';
```

## About Using Reserved Resource Group Memory vs. Using Resource Group Global Shared Memory

When you do not reserve memory for a resource group (`MEMORY_LIMIT` and `MEMORY_SPILL_RATIO` are set to 0):

- It increases the size of the resource group global shared memory pool.
- The resource group functions similarly to a resource queue, using the `statement_mem` server configuration parameter value to control initial query operator memory.
- Any query submitted in the resource group competes for resource group global shared memory on a first-come, first-served basis with queries running in other groups.
- There is no guarantee that Greenplum Database will be able to allocate memory for a query running in the resource group. The risk of a query in the group encountering an out of

memory (OOM) condition increases when there are many concurrent queries consuming memory from the resource group global shared memory pool at the same time.

To reduce the risk of OOM for a query running in an important resource group, consider reserving some fixed memory for the group. While reserving fixed memory for a group reduces the size of the resource group global shared memory pool, this may be a fair tradeoff to reduce the risk of encountering an OOM condition in a query running in a critical resource group.

## Other Memory Considerations

Resource groups for roles track all Greenplum Database memory allocated via the `palloc()` function. Memory that you allocate using the Linux `malloc()` function is not managed by these resource groups. To ensure that resource groups for roles are accurately tracking memory usage, avoid using `malloc()` to allocate large amounts of memory in custom Greenplum Database user-defined functions.

## Using VMware Tanzu Greenplum Command Center to Manage Resource Groups

Using Tanzu Greenplum Command Center, an administrator can create and manage resource groups, change roles' resource groups, and create workload management rules.

Workload management assignment rules assign transactions to different resource groups based on user-defined criteria. If no assignment rule is matched, Greenplum Database assigns the transaction to the role's default resource group.

Refer to the [Greenplum Command Center documentation](#) for more information about creating and managing resource groups and workload management rules.

## Configuring and Using Resource Groups

**Important:** Significant Greenplum Database performance degradation has been observed when enabling resource group-based workload management on RedHat 6.x and CentOS 6.x systems. This issue is caused by a Linux cgroup kernel bug. This kernel bug has been fixed in CentOS 7.x and Red Hat 7.x/8.x systems.

If you use RedHat 6 and the performance with resource groups is acceptable for your use case, upgrade your kernel to version 2.6.32-696 or higher to benefit from other fixes to the cgroups implementation.

### Prerequisite

Greenplum Database resource groups use Linux Control Groups (cgroups) to manage CPU resources. Greenplum Database also uses cgroups to manage memory for resource groups for external components. With cgroups, Greenplum isolates the CPU and external component memory usage of your Greenplum processes from other processes on the node. This allows Greenplum to support CPU and external component memory usage restrictions on a per-resource-group basis.

For detailed information about cgroups, refer to the Control Groups documentation for your Linux distribution.

Complete the following tasks on each node in your Greenplum Database cluster to set up cgroups for use with resource groups:

1. If not already installed, install the Control Groups operating system package on each Greenplum Database node. The command that you run to perform this task will differ based on the operating system installed on the node. You must be the superuser or have `sudo` access to run the command:

- o Redhat/CentOS 7.x/8.x systems:

```
sudo yum install libcgroup-tools
```

- o Redhat/CentOS 6.x systems:

```
sudo yum install libcgroup
```

2. Locate the cgroups configuration file `/etc/cgconfig.conf`. You must be the superuser or have `sudo` access to edit this file:

```
sudo vi /etc/cgconfig.conf
```

3. Add the following configuration information to the file:

```
group gpdb {
    perm {
        task {
            uid = gpadmin;
            gid = gpadmin;
        }
        admin {
            uid = gpadmin;
            gid = gpadmin;
        }
    }
    cpu {
    }
    cpuacct {
    }
    cpuset {
    }
    memory {
    }
}
```

This content configures CPU, CPU accounting, CPU core set, and memory control groups managed by the `gpadmin` user. Greenplum Database uses the memory control group only for those resource groups created with the `cgroup MEMORY_AUDITOR`.

4. Start the cgroups service on each Greenplum Database node. The command that you run to perform this task will differ based on the operating system installed on the node. You must be the superuser or have `sudo` access to run the command:

- o Redhat/CentOS 7.x/8.x systems:

```
sudo cgconfigparser -l /etc/cgconfig.conf
```

- o Redhat/CentOS 6.x systems:

```
sudo service cgconfig start
```

5. Identify the `cgroup` directory mount point for the node:

```
grep cgroup /proc/mounts
```

The first line of output identifies the `cgroup` mount point.

6. Verify that you set up the Greenplum Database cgroups configuration correctly by running the following commands. Replace `<cgroup_mount_point>` with the mount point that you identified in the previous step:

```
ls -l <cgroup_mount_point>/cpu/gpdb
ls -l <cgroup_mount_point>/cpuacct/gpdb
ls -l <cgroup_mount_point>/cpuset/gpdb
ls -l <cgroup_mount_point>/memory/gpdb
```

If these directories exist and are owned by `gpadmin:gpadmin`, you have successfully configured cgroups for Greenplum Database CPU resource management.

7. To automatically recreate Greenplum Database required cgroup hierarchies and parameters when your system is restarted, configure your system to enable the Linux cgroup service daemon `cgconfig.service` (Redhat/CentOS 7.x/8.x) or `cgconfig` (Redhat/CentOS 6.x) at node start-up. For example, configure one of the following cgroup service commands in your preferred service auto-start tool:

- o Redhat/CentOS 7.x/8.x systems:

```
sudo systemctl enable cgconfig.service
```

To start the service immediately (without having to reboot) enter:

```
sudo systemctl start cgconfig.service
```

- o Redhat/CentOS 6.x systems:

```
sudo chkconfig cgconfig on
```

You may choose a different method to recreate the Greenplum Database resource group cgroup hierarchies.

## Procedure

To use resource groups in your Greenplum Database cluster, you:

1. [Enable resource groups for your Greenplum Database cluster.](#)
2. [Create resource groups.](#)
3. [Assign the resource groups to one or more roles.](#)
4. [Use resource management system views to monitor and manage the resource groups.](#)

## Enabling Resource Groups

When you install Greenplum Database, resource queues are enabled by default. To use resource groups instead of resource queues, you must set the `gp_resource_manager` server configuration parameter.

1. Set the `gp_resource_manager` server configuration parameter to the value "group":

```
gpconfig -s gp_resource_manager
gpconfig -c gp_resource_manager -v "group"
```

2. Restart Greenplum Database:

```
gpstop
gpstart
```

Once enabled, any transaction submitted by a role is directed to the resource group assigned to the role, and is governed by that resource group's concurrency, memory, and CPU limits. Similarly, CPU and memory usage by an external component is governed by the CPU and memory limits configured for the resource group assigned to the component.

Greenplum Database creates two default resource groups for roles named `admin_group` and `default_group`. When you enable resources groups, any role that was not explicitly assigned a resource group is assigned the default group for the role's capability. `SUPERUSER` roles are assigned the `admin_group`, non-admin roles are assigned the group named `default_group`.

The default resource groups `admin_group` and `default_group` are created with the following resource limits:

| Limit Type          | admin_group | default_group |
|---------------------|-------------|---------------|
| CONCURRENCY         | 10          | 20            |
| CPU_RATE_LIMIT      | 10          | 30            |
| CPUSET              | -1          | -1            |
| MEMORY_LIMIT        | 10          | 0             |
| MEMORY_SHARED_QUOTA | 80          | 80            |
| MEMORY_SPILL_RATIO  | 0           | 0             |
| MEMORY_AUDITOR      | vmtracker   | vmtracker     |

Keep in mind that the `CPU_RATE_LIMIT` and `MEMORY_LIMIT` values for the default resource groups `admin_group` and `default_group` contribute to the total percentages on a segment host. You may find that you need to adjust these limits for `admin_group` and/or `default_group` as you create and add new resource groups to your Greenplum Database deployment.

## Creating Resource Groups

When you create a resource group for a role, you provide a name and a CPU resource allocation mode. You can optionally provide a concurrent transaction limit and memory limit, shared quota, and spill ratio values. Use the [CREATE RESOURCE GROUP](#) command to create a new resource group.

When you create a resource group for a role, you must provide a `CPU_RATE_LIMIT` or `CPUSET` limit value. These limits identify the percentage of Greenplum Database CPU resources to allocate to this resource group. You may specify a `MEMORY_LIMIT` to reserve a fixed amount of memory for the resource group. If you specify a `MEMORY_LIMIT` of 0, Greenplum Database uses global shared memory to fulfill all memory requirements for the resource group.

For example, to create a resource group named `rgroup1` with a CPU limit of 20, a memory limit of 25, and a memory spill ratio of 20:

```
=# CREATE RESOURCE GROUP rgroup1 WITH (CPU_RATE_LIMIT=20, MEMORY_LIMIT=25, MEMORY_SPILL_RATIO=20);
```

The CPU limit of 20 is shared by every role to which `rgroup1` is assigned. Similarly, the memory limit of 25 is shared by every role to which `rgroup1` is assigned. `rgroup1` utilizes the default `MEMORY_AUDITOR` `vmtracker` and the default `CONCURRENCY` setting of 20.

When you create a resource group for an external component, you must provide `CPU_RATE_LIMIT` or `CPUSET` and `MEMORY_LIMIT` limit values. You must also provide the `MEMORY_AUDITOR` and explicitly set `CONCURRENCY` to zero (0). For example, to create a resource group named `rgroup_extcomp` for which you reserve CPU core 1 and assign a memory limit of 15:

```
=# CREATE RESOURCE GROUP rgroup_extcomp WITH (MEMORY_AUDITOR=cgroup, CONCURRENCY=0, CPUSET='1', MEMORY_LIMIT=15);
```

The [ALTER RESOURCE GROUP](#) command updates the limits of a resource group. To change the limits of a resource group, specify the new values that you want for the group. For example:

```
=# ALTER RESOURCE GROUP rg_role_light SET CONCURRENCY 7;
=# ALTER RESOURCE GROUP exec SET MEMORY_SPILL_RATIO 25;
=# ALTER RESOURCE GROUP rgroup1 SET CPUSET '2,4';
```

**Note:** You cannot set or alter the `CONCURRENCY` value for the `admin_group` to zero (0).

The [DROP RESOURCE GROUP](#) command drops a resource group. To drop a resource group for a role, the group cannot be assigned to any role, nor can there be any transactions active or waiting in the resource group. Dropping a resource group for an external component in which there are running instances terminates the running instances.

To drop a resource group:

```
=# DROP RESOURCE GROUP exec;
```

## Configuring Automatic Query Termination Based on Memory Usage

When resource groups have a global shared memory pool, the server configuration parameter `runaway_detector_activation_percent` sets the percent of utilized global shared memory that triggers the termination of queries that are managed by resource groups that are configured to use the `vmtracker` memory auditor, such as `admin_group` and `default_group`.

Resource groups have a global shared memory pool when the sum of the `MEMORY_LIMIT` attribute values configured for all resource groups is less than 100. For example, if you have 3 resource groups configured with `MEMORY_LIMIT` values of 10 , 20, and 30, then global shared memory is 40% = 100% - (10% + 20% + 30%).

For information about global shared memory, see [Global Shared Memory](#).

## Assigning a Resource Group to a Role

When you create a resource group with the default `MEMORY_AUDITOR vmtracker`, the group is available for assignment to one or more roles (users). You assign a resource group to a database role using the `RESOURCE GROUP` clause of the `CREATE ROLE` or `ALTER ROLE` commands. If you do not specify a resource group for a role, the role is assigned the default group for the role's capability. `SUPERUSER` roles are assigned the `admin_group`, non-admin roles are assigned the group named `default_group`.

Use the `ALTER ROLE` or `CREATE ROLE` commands to assign a resource group to a role. For example:

```
=# ALTER ROLE bill RESOURCE GROUP rg_light;
=# CREATE ROLE mary RESOURCE GROUP exec;
```

You can assign a resource group to one or more roles. If you have defined a role hierarchy, assigning a resource group to a parent role does not propagate down to the members of that role group.

**Note:** You cannot assign a resource group that you create for an external component to a role.

If you wish to remove a resource group assignment from a role and assign the role the default group, change the role's group name assignment to `NONE`. For example:

```
=# ALTER ROLE mary RESOURCE GROUP NONE;
```

## Monitoring Resource Group Status

Monitoring the status of your resource groups and queries may involve the following tasks:

- [Viewing Resource Group Limits](#)
- [Viewing Resource Group Query Status and CPU/Memory Usage](#)
- [Viewing the Resource Group Assigned to a Role](#)
- [Viewing a Resource Group's Running and Pending Queries](#)
- [Cancelling a Running or Queued Transaction in a Resource Group](#)

### Viewing Resource Group Limits

The `gp_resgroup_config gp_toolkit` system view displays the current limits for a resource group. To view the limits of all resource groups:

```
=# SELECT * FROM gp_toolkit.gp_resgroup_config;
```

## Viewing Resource Group Query Status and CPU/Memory Usage

The `gp_resgroup_status gp_toolkit` system view enables you to view the status and activity of a resource group. The view displays the number of running and queued transactions. It also displays the real-time CPU and memory usage of the resource group. To view this information:

```
=# SELECT * FROM gp_toolkit.gp_resgroup_status;
```

### Viewing Resource Group CPU/Memory Usage Per Host

The `gp_resgroup_status_per_host gp_toolkit` system view enables you to view the real-time CPU and memory usage of a resource group on a per-host basis. To view this information:

```
=# SELECT * FROM gp_toolkit.gp_resgroup_status_per_host;
```

### Viewing Resource Group CPU/Memory Usage Per Segment

The `gp_resgroup_status_per_segment gp_toolkit` system view enables you to view the real-time CPU and memory usage of a resource group on a per-segment, per-host basis. To view this information:

```
=# SELECT * FROM gp_toolkit.gp_resgroup_status_per_segment;
```

## Viewing the Resource Group Assigned to a Role

To view the resource group-to-role assignments, perform the following query on the `pg_roles` and `pg_resgroup` system catalog tables:

```
=# SELECT rolname, rsgname FROM pg_roles, pg_resgroup
   WHERE pg_roles.rolresgroup=pg_resgroup.oid;
```

## Viewing a Resource Group's Running and Pending Queries

To view a resource group's running queries, pending queries, and how long the pending queries have been queued, examine the `pg_stat_activity` system catalog table:

```
=# SELECT query, waiting, rsgname, rsgqueueduration
   FROM pg_stat_activity;
```

`pg_stat_activity` displays information about the user/role that initiated a query. A query that uses an external component such as PL/Container is composed of two parts: the query operator that runs in Greenplum Database and the UDF that runs in a PL/Container instance. Greenplum Database processes the query operators under the resource group assigned to the role that initiated the query. A UDF running in a PL/Container instance runs under the resource group assigned to the PL/Container runtime. The latter is not represented in the `pg_stat_activity` view; Greenplum Database does not have any insight into how external components such as PL/Container manage memory in running instances.

## Cancelling a Running or Queued Transaction in a Resource Group

There may be cases when you want to cancel a running or queued transaction in a resource group. For example, you may want to remove a query that is waiting in the resource group queue but has not yet been run. Or, you may want to stop a running query that is taking too long to run, or one that is sitting idle in a transaction and taking up resource group transaction slots that are needed by other users.

By default, transactions can remain queued in a resource group indefinitely. If you want Greenplum Database to cancel a queued transaction after a specific amount of time, set the server configuration parameter `gp_resource_group_queuing_timeout`. When this parameter is set to a value (milliseconds) greater than 0, Greenplum cancels any queued transaction when it has waited longer than the configured timeout.

To manually cancel a running or queued transaction, you must first determine the process id (pid) associated with the transaction. Once you have obtained the process id, you can invoke `pg_cancel_backend()` to end that process, as shown below.

For example, to view the process information associated with all statements currently active or waiting in all resource groups, run the following query. If the query returns no results, then there are no running or queued transactions in any resource group.

```
=# SELECT rolname, g.rsgname, pid, waiting, state, query, datname
   FROM pg_roles, gp_toolkit.gp_resgroup_status g, pg_stat_activity
  WHERE pg_roles.rolresgroup=g.groupid
        AND pg_stat_activity.username=pg_roles.rolname;
```

Sample partial query output:

| rolname | rsgname  | pid   | waiting | state  | query                    | datname |
|---------|----------|-------|---------|--------|--------------------------|---------|
| sammy   | rg_light | 31861 | f       | idle   | SELECT * FROM mytesttbl; | testdb  |
| billy   | rg_light | 31905 | t       | active | SELECT * FROM topten;    | testdb  |

Use this output to identify the process id (pid) of the transaction you want to cancel, and then cancel the process. For example, to cancel the pending query identified in the sample output above:

```
=# SELECT pg_cancel_backend(31905);
```

You can provide an optional message in a second argument to `pg_cancel_backend()` to indicate to the user why the process was cancelled.

**Note:**

Do not use an operating system `KILL` command to cancel any Greenplum Database process.

## Moving a Query to a Different Resource Group

A user with Greenplum Database superuser privileges can run the `gp_toolkit.pg_resgroup_move_query()` function to move a running query from one resource group to another, without stopping the query. Use this function to expedite a long-running query by moving it to a resource group with a higher resource allotment or availability.

**Note:** You can move only an active or running query to a new resource group. You cannot move a queued or pending query that is in an idle state due to concurrency or memory limits.

`pg_resgroup_move_query()` requires the process id (pid) of the running query, as well as the name of the resource group to which you want to move the query. The signature of the function follows:

```
pg_resgroup_move_query( pid int4, group_name text );
```

You can obtain the pid of a running query from the `pg_stat_activity` system view as described in [Cancelling a Running or Queued Transaction in a Resource Group](#). Use the `gp_toolkit.gp_resgroup_status` view to list the name, id, and status of each resource group.

When you invoke `pg_resgroup_move_query()`, the query is subject to the limits configured for the destination resource group:

- If the group has already reached its concurrent task limit, Greenplum Database queues the query until a slot opens.
- If the destination resource group does not have enough memory available to service the query's current memory requirements, Greenplum Database returns the error: `group <group_name> doesn't have enough memory ....` In this situation, you may choose to increase the group shared memory allotted to the destination resource group, or perhaps wait a period of time for running queries to complete and then invoke the function again.

After Greenplum moves the query, there is no way to guarantee that a query currently running in the destination resource group does not exceed the group memory quota. In this situation, one or more running queries in the destination group may fail, including the moved query. Reserve enough resource group global shared memory to minimize the potential for this scenario to occur.

`pg_resgroup_move_query()` moves only the specified query to the destination resource group. Greenplum Database assigns subsequent queries that you submit in the session to the original resource group.

**Note:** Greenplum Database version 6.8 introduced support for moving a query to a different resource group.

- If you upgraded from a previous Greenplum 6.x installation, you must manually register the supporting functions for this feature, and grant access to the functions as follows:

```
CREATE FUNCTION gp_toolkit.pg_resgroup_check_move_query(IN session_id int, IN g
roupid oid, OUT session_mem int, OUT available_mem int)
RETURNS SETOF record
AS 'gp_resource_group', 'pg_resgroup_check_move_query'
VOLATILE LANGUAGE C;
```

```
GRANT EXECUTE ON FUNCTION gp_toolkit.pg_resgroup_check_move_query(int, oid, OUT
int, OUT int) TO public;

CREATE FUNCTION gp_toolkit.pg_resgroup_move_query(session_id int4, groupid tex
t)
RETURNS bool
AS 'gp_resource_group', 'pg_resgroup_move_query'
VOLATILE LANGUAGE C;
GRANT EXECUTE ON FUNCTION gp_toolkit.pg_resgroup_move_query(int4, text) TO publ
ic;
```

- If you register the supporting functions and then you downgrade your Greenplum Database installation to version 6.7.x or older, manually drop these functions as follows:

```
DROP FUNCTION gp_toolkit.pg_resgroup_check_move_query(IN int, IN oid, OUT int,
OUT int);
DROP FUNCTION gp_toolkit.pg_resgroup_move_query(int4, text);
```

## Resource Group Frequently Asked Questions

### CPU

- **Why is CPU usage lower than the `CPU_RATE_LIMIT` configured for the resource group?**

You may run into this situation when a low number of queries and slices are running in the resource group, and these processes are not utilizing all of the cores on the system.

- **Why is CPU usage for the resource group higher than the configured `CPU_RATE_LIMIT`?**

This situation can occur in the following circumstances:

- A resource group may utilize more CPU than its `CPU_RATE_LIMIT` when other resource groups are idle. In this situation, Greenplum Database allocates the CPU resource of an idle resource group to a busier one. This resource group feature is called CPU burst.
- The operating system CPU scheduler may cause CPU usage to spike, then drop down. If you believe this might be occurring, calculate the average CPU usage within a given period of time (for example, 5 seconds) and use that average to determine if CPU usage is higher than the configured limit.

### Memory

- **Why did my query return an "out of memory" error?**

A transaction submitted in a resource group fails and exits when memory usage exceeds its fixed memory allotment, no available resource group shared memory exists, and the transaction requests more memory.

- **Why did my query return a "memory limit reached" error?**

Greenplum Database automatically adjusts transaction and group memory to the new settings when you use `ALTER RESOURCE GROUP` to change a resource group's memory and/or concurrency limits. An "out of memory" error may occur if you recently altered resource

group attributes and there is no longer a sufficient amount of memory available for a currently running query.

- **Why does the actual memory usage of my resource group exceed the amount configured for the group?**

The actual memory usage of a resource group may exceed the configured amount when one or more queries running in the group is allocated memory from the global shared memory pool. (If no global shared memory is available, queries fail and do not impact the memory resources of other resource groups.)

When global shared memory is available, memory usage may also exceed the configured amount when a transaction spills to disk. Greenplum Database statements continue to request memory when they start to spill to disk because:

- Spilling to disk requires extra memory to work.
- Other operators may continue to request memory.  
Memory usage grows in spill situations; when global shared memory is available, the resource group may eventually use up to 200-300% of its configured group memory limit.

## Concurrency

- **Why is the number of running transactions lower than the `CONCURRENCY` limit configured for the resource group?**

Greenplum Database considers memory availability before running a transaction, and will queue the transaction if there is not enough memory available to serve it. If you use `ALTER RESOURCE GROUP` to increase the `CONCURRENCY` limit for a resource group but do not also adjust memory limits, currently running transactions may be consuming all allotted memory resources for the group. When in this state, Greenplum Database queues subsequent transactions in the resource group.

- **Why is the number of running transactions in the resource group higher than the configured `CONCURRENCY` limit?**

The resource group may be running `SET` and `SHOW` commands, which bypass resource group transaction checks.

## Using Resource Queues

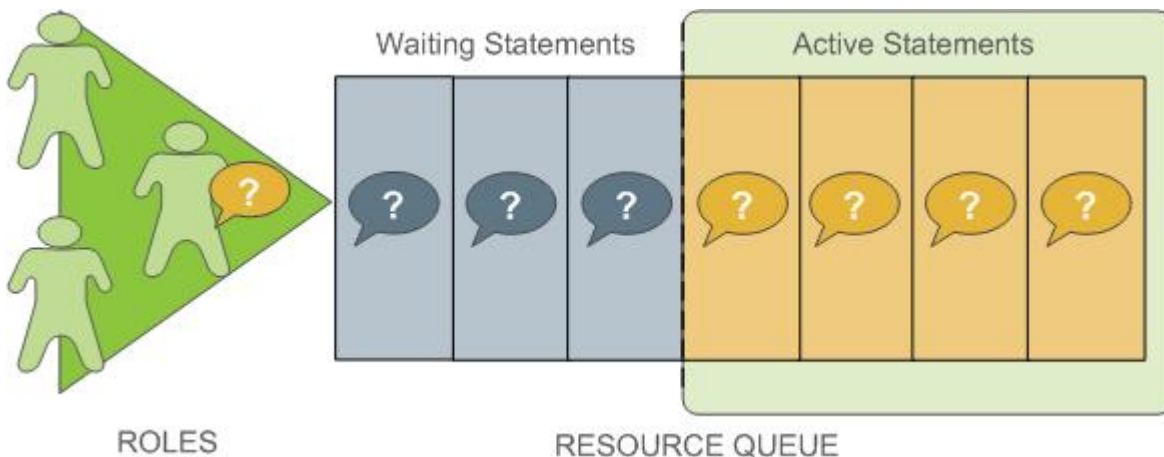

Use Greenplum Database resource queues to prioritize and allocate resources to queries according to business requirements and to prevent queries from starting when resources are unavailable.

Resource queues are one tool to manage the degree of concurrency in a Greenplum Database system. Resource queues are database objects that you create with the `CREATE RESOURCE QUEUE` SQL statement. You can use them to manage the number of active queries that may run concurrently, the amount of memory each type of query is allocated, and the relative priority of queries. Resource queues can also guard against queries that would consume too many resources and degrade overall system performance.

Each database role is associated with a single resource queue; multiple roles can share the same resource queue. Roles are assigned to resource queues using the `RESOURCE QUEUE` phrase of the

`CREATE ROLE` or `ALTER ROLE` statements. If a resource queue is not specified, the role is associated with the default resource queue, `pg_default`.

When the user submits a query for execution, the query is evaluated against the resource queue's limits. If the query does not cause the queue to exceed its resource limits, then that query will run immediately. If the query causes the queue to exceed its limits (for example, if the maximum number of active statement slots are currently in use), then the query must wait until queue resources are free before it can run. Queries are evaluated on a first in, first out basis. If query prioritization is enabled, the active workload on the system is periodically assessed and processing resources are reallocated according to query priority (see [How Priorities Work](#)). Roles with the `SUPERUSER` attribute are exempt from resource queue limits. Superuser queries always run immediately regardless of limits imposed by their assigned resource queue.

Resource queues define classes of queries with similar resource requirements. Administrators should create resource queues for the various types of workloads in their organization. For example, you could create resource queues for the following classes of queries, corresponding to different service level agreements:

- ETL queries
- Reporting queries
- Executive queries

A resource queue has the following characteristics:

#### `MEMORY_LIMIT`

The amount of memory used by all the queries in the queue (per segment). For example, setting `MEMORY_LIMIT` to 2GB on the ETL queue allows ETL queries to use up to 2GB of memory in each segment.

#### `ACTIVE_STATEMENTS`

The number of *slots* for a queue; the maximum concurrency level for a queue. When all slots are used, new queries must wait. Each query uses an equal amount of memory by default.

For example, the `pg_default` resource queue has `ACTIVE_STATEMENTS = 20`.

#### `PRIORITY`

The relative CPU usage for queries. This may be one of the following levels: `LOW`, `MEDIUM`, `HIGH`, `MAX`. The default level is `MEDIUM`. The query prioritization mechanism monitors the CPU usage of all the queries running in the system, and adjusts the CPU usage for each to

conform to its priority level. For example, you could set `MAX` priority to the `executive` resource queue and `MEDIUM` to other queues to ensure that executive queries receive a greater share of CPU.

#### `MAX_COST`

Query plan cost limit.

The Greenplum Database optimizer assigns a numeric cost to each query. If the cost exceeds the `MAX_COST` value set for the resource queue, the query is rejected as too expensive.

**Note:** GPORCA and the Postgres Planner utilize different query costing models and may compute different costs for the same query. The Greenplum Database resource queue resource management scheme neither differentiates nor aligns costs between GPORCA and the Postgres Planner; it uses the literal cost value returned from the optimizer to throttle queries.

When resource queue-based resource management is active, use the `MEMORY_LIMIT` and `ACTIVE_STATEMENTS` limits for resource queues rather than configuring cost-based limits. Even when using GPORCA, Greenplum Database may fall back to using the Postgres Planner for certain queries, so using cost-based limits can lead to unexpected results.

The default configuration for a Greenplum Database system has a single default resource queue named `pg_default`. The `pg_default` resource queue has an `ACTIVE_STATEMENTS` setting of 20, no `MEMORY_LIMIT`, medium `PRIORITY`, and no set `MAX_COST`. This means that all queries are accepted and run immediately, at the same priority and with no memory limitations; however, only twenty queries may run concurrently.

The number of concurrent queries a resource queue allows depends on whether the `MEMORY_LIMIT` parameter is set:

- If no `MEMORY_LIMIT` is set for a resource queue, the amount of memory allocated per query is the value of the `statement_mem` server configuration parameter. The maximum memory the resource queue can use is the product of `statement_mem` and `ACTIVE_STATEMENTS`.
- When a `MEMORY_LIMIT` is set on a resource queue, the number of queries that the queue can run concurrently is limited by the queue's available memory.

A query admitted to the system is allocated an amount of memory and a query plan tree is generated for it. Each node of the tree is an operator, such as a sort or hash join. Each operator is a separate execution thread and is allocated a fraction of the overall statement memory, at minimum 100KB. If the plan has a large number of operators, the minimum memory required for operators can exceed the available memory and the query will be rejected with an insufficient memory error. Operators determine if they can complete their tasks in the memory allocated, or if they must spill data to disk, in work files. The mechanism that allocates and controls the amount of memory used by each operator is called *memory quota*.

Not all SQL statements submitted through a resource queue are evaluated against the queue limits. By default only `SELECT`, `SELECT INTO`, `CREATE TABLE AS SELECT`, and `DECLARE CURSOR` statements are evaluated. If the server configuration parameter `resource_select_only` is set to `off`, then `INSERT`, `UPDATE`, and `DELETE` statements will be evaluated as well.

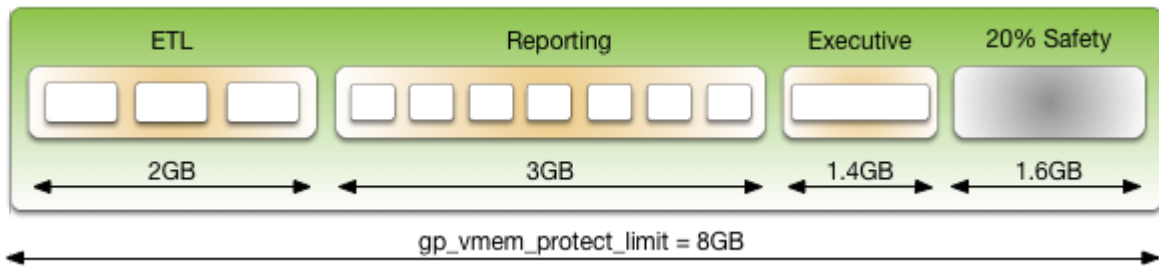

Also, an SQL statement that is run during the execution of an `EXPLAIN ANALYZE` command is excluded from resource queues.

**Parent topic:** [Managing Resources](#)

## Resource Queue Example

The default resource queue, `pg_default`, allows a maximum of 20 active queries and allocates the same amount of memory to each. This is generally not adequate resource control for production systems. To ensure that the system meets performance expectations, you can define classes of queries and assign them to resource queues configured to run them with the concurrency, memory, and CPU resources best suited for that class of query.

The following illustration shows an example resource queue configuration for a Greenplum Database system with `gp_vmem_protect_limit` set to 8GB:

This example has three classes of queries with different characteristics and service level agreements (SLAs). Three resource queues are configured for them. A portion of the segment memory is reserved as a safety margin.

| Resource Queue Name | Active Statements | Memory Limit | Memory per Query |
|---------------------|-------------------|--------------|------------------|
| ETL                 | 3                 | 2GB          | 667MB            |
| Reporting           | 7                 | 3GB          | 429MB            |
| Executive           | 1                 | 1.4GB        | 1.4GB            |

The total memory allocated to the queues is 6.4GB, or 80% of the total segment memory defined by the `gp_vmem_protect_limit` server configuration parameter. Allowing a safety margin of 20% accommodates some operators and queries that are known to use more memory than they are allocated by the resource queue.

See the `CREATE RESOURCE QUEUE` and `CREATE/ALTER ROLE` statements in the *Greenplum Database Reference Guide* for help with command syntax and detailed reference information.

## How Memory Limits Work

Setting `MEMORY_LIMIT` on a resource queue sets the maximum amount of memory that all active queries submitted through the queue can consume for a segment instance. The amount of memory allotted to a query is the queue memory limit divided by the active statement limit. (Use the memory limits in conjunction with statement-based queues rather than cost-based queues.) For example, if a queue has a memory limit of 2000MB and an active statement limit of 10, each query submitted through the queue is allotted 200MB of memory by default. The default memory allotment can be overridden on a per-query basis using the `statement_mem` server configuration parameter (up to the queue memory limit). Once a query has started running, it holds its allotted memory in the queue until it completes, even if during execution it actually consumes less than its allotted amount of memory.

You can use the `statement_mem` server configuration parameter to override memory limits set by the current resource queue. At the session level, you can increase `statement_mem` up to the resource queue's `MEMORY_LIMIT`. This will allow an individual query to use all of the memory allocated for the entire queue without affecting other resource queues.

The value of `statement_mem` is capped using the `max_statement_mem` configuration parameter (a superuser parameter). For a query in a resource queue with `MEMORY_LIMIT` set, the maximum value for `statement_mem` is `min(MEMORY_LIMIT, max_statement_mem)`. When a query is admitted, the memory allocated to it is subtracted from `MEMORY_LIMIT`. If `MEMORY_LIMIT` is exhausted, new queries in the same resource queue must wait. This happens even if `ACTIVE_STATEMENTS` has not yet been reached. Note that this can happen only when `statement_mem` is used to override the memory allocated by the resource queue.

For example, consider a resource queue named `adhoc` with the following settings:

- `MEMORY_LIMIT` is 1.5GB
- `ACTIVE_STATEMENTS` is 3

By default each statement submitted to the queue is allocated 500MB of memory. Now consider the following series of events:

1. User `ADHOC_1` submits query `Q1`, overriding `STATEMENT_MEM` to 800MB. The `Q1` statement is admitted into the system.
2. User `ADHOC_2` submits query `Q2`, using the default 500MB.
3. With `Q1` and `Q2` still running, user `ADHOC3` submits query `Q3`, using the default 500MB.

Queries `Q1` and `Q2` have used 1300MB of the queue's 1500MB. Therefore, `Q3` must wait for `Q1` or `Q2` to complete before it can run.

If `MEMORY_LIMIT` is not set on a queue, queries are admitted until all of the `ACTIVE_STATEMENTS` slots are in use, and each query can set an arbitrarily high `statement_mem`. This could lead to a resource queue using unbounded amounts of memory.

For more information on configuring memory limits on a resource queue, and other memory utilization controls, see [Creating Queues with Memory Limits](#).

## statement\_mem and Low Memory Queries

A low `statement_mem` setting (for example, in the 1-3MB range) has been shown to increase the performance of queries with low memory requirements. Use the `statement_mem` server configuration parameter to override the setting on a per-query basis. For example:

```
SET statement_mem='2MB';
```

## How Priorities Work

The `PRIORITY` setting for a resource queue differs from the `MEMORY_LIMIT` and `ACTIVE_STATEMENTS` settings, which determine whether a query will be admitted to the queue and eventually run. The `PRIORITY` setting applies to queries after they become active. Active queries share available CPU resources as determined by the priority settings for its resource queue. When a statement from a high-priority queue enters the group of actively running statements, it may claim a greater share of

the available CPU, reducing the share allocated to already-running statements in queues with a lesser priority setting.

The comparative size or complexity of the queries does not affect the allotment of CPU. If a simple, low-cost query is running simultaneously with a large, complex query, and their priority settings are the same, they will be allocated the same share of available CPU resources. When a new query becomes active, the CPU shares will be recalculated, but queries of equal priority will still have equal amounts of CPU.

For example, an administrator creates three resource queues: *adhoc* for ongoing queries submitted by business analysts, *reporting* for scheduled reporting jobs, and *executive* for queries submitted by executive user roles. The administrator wants to ensure that scheduled reporting jobs are not heavily affected by unpredictable resource demands from ad-hoc analyst queries. Also, the administrator wants to make sure that queries submitted by executive roles are allotted a significant share of CPU. Accordingly, the resource queue priorities are set as shown:

- *adhoc* — Low priority
- *reporting* — High priority
- *executive* — Maximum priority

At runtime, the CPU share of active statements is determined by these priority settings. If queries 1 and 2 from the reporting queue are running simultaneously, they have equal shares of CPU. When an ad-hoc query becomes active, it claims a smaller share of CPU. The exact share used by the reporting queries is adjusted, but remains equal due to their equal priority setting:

**Note:**

The percentages shown in these illustrations are approximate. CPU usage between high, low and maximum priority queues is not always calculated in precisely these proportions.

When an executive query enters the group of running statements, CPU usage is adjusted to account for its maximum priority setting. It may be a simple query compared to the analyst and reporting queries, but until it is completed, it will claim the largest share of CPU.

Query 1 from reporting (High Priority)

Query 2 from *reporting* (High Priority)

Query 3 from *adhoc* (Low Priority)

Query 4 from *executive* (Max. Priority)

For more information about commands to set priorities, see [Setting Priority Levels](#).

## Steps to Enable Resource Management

Enabling and using resource management in Greenplum Database involves the following high-level tasks:

1. Configure resource management. See [Configuring Resource Management](#).
2. Create the resource queues and set limits on them. See [Creating Resource Queues and Modifying Resource Queues](#).
3. Assign a queue to one or more user roles. See [Assigning Roles \(Users\) to a Resource Queue](#).
4. Use the resource management system views to monitor and manage the resource queues. See [Checking Resource Queue Status](#).

## Configuring Resource Management

Resource scheduling is enabled by default when you install Greenplum Database, and is required for all roles. The default resource queue, `pg_default`, has an active statement limit of 20, no memory limit, and a medium priority setting. Create resource queues for the various types of workloads.

## To configure resource management

- The following parameters are for the general configuration of resource queues:
  - `max_resource_queues` - Sets the maximum number of resource queues.
  - `max_resource_portals_per_transaction` - Sets the maximum number of simultaneously open cursors allowed per transaction. Note that an open cursor will hold an active query slot in a resource queue.
  - `resource_select_only` - If set to *on*, then `SELECT`, `SELECT INTO`, `CREATE TABLE AS`SELECT`, and `DECLARE CURSOR` commands are evaluated. If set to *off* `INSERT`, `UPDATE`, and `DELETE` commands will be evaluated as well.
  - `resource_cleanup_gangs_on_wait` - Cleans up idle segment worker processes before taking a slot in the resource queue.
  - `stats_queue_level` - Enables statistics collection on resource queue usage, which can then be viewed by querying the `pg_stat_resqueues` system view.
- The following parameters are related to memory utilization:
  - `gp_resqueue_memory_policy` - Enables Greenplum Database memory management features.
 

In Greenplum Database 4.2 and later, the distribution algorithm `eager_free` takes advantage of the fact that not all operators run at the same time. The query plan is divided into stages and Greenplum Database eagerly frees memory allocated to a previous stage at the end of that stage's execution, then allocates the eagerly freed memory to the new stage.

When set to *none*, memory management is the same as in Greenplum Database releases prior to 4.1. When set to *auto*, query memory usage is controlled by `statement_mem` and resource queue memory limits.
  - `statement_mem` and `max_statement_mem` - Used to allocate memory to a particular query at runtime (override the default allocation assigned by the resource queue). `max_statement_mem` is set by database superusers to prevent regular database users from over-allocation.
  - `gp_vmem_protect_limit` - Sets the upper boundary that all query processes can consume and should not exceed the amount of physical memory of a segment host. When a segment host reaches this limit during query execution, the queries that cause the limit to be exceeded will be cancelled.
  - `gp_vmem_idle_resource_timeout` and `gp_vmem_protect_segworker_cache_limit` - used to free memory on segment hosts held by idle database processes. Administrators may want to adjust these settings on systems with lots of concurrency.

- `shared_buffers` - Sets the amount of memory a Greenplum server instance uses for shared memory buffers. This setting must be at least 128 kilobytes and at least 16 kilobytes times `max_connections`. The value must not exceed the operating system shared memory maximum allocation request size, `shmmax` on Linux. See the *Greenplum Database Installation Guide* for recommended OS memory settings for your platform.
3. The following parameters are related to query prioritization. Note that the following parameters are all *local* parameters, meaning they must be set in the `postgresql.conf` files of the master and all segments:
- `gp_resqueue_priority` - The query prioritization feature is enabled by default.
  - `gp_resqueue_priority_sweeper_interval` - Sets the interval at which CPU usage is recalculated for all active statements. The default value for this parameter should be sufficient for typical database operations.
  - `gp_resqueue_priority_cpucores_per_segment` - Specifies the number of CPU cores allocated per segment instance on a segment host. If the segment is configured with primary-mirror segment instance pairs, use the number of primary segment instances on the host in the calculation. The default value is 4 for the master and segment hosts.

Each Greenplum host checks its own `postgresql.conf` file for the value of this parameter. This parameter also affects the master host, where it should be set to a value reflecting the higher ratio of CPU cores. For example, on a cluster that has 10 CPU cores per segment host and 4 primary segments per host, you would specify the following values for `gp_resqueue_priority_cpucores_per_segment`:

- 10 on the master and standby master hosts. Typically, only a single master segment instance runs on the master host.
- 2.5 on each segment host (10 cores divided by 4 primary segments).  
If the parameter value is not set correctly, either the CPU might not be fully utilized, or query prioritization might not work as expected. For example, if the Greenplum Database cluster has fewer than one segment instance per CPU core on your segment hosts, make sure that you adjust this value accordingly.

Actual CPU core utilization is based on the ability of Greenplum Database to parallelize a query and the resources required to run the query.

**Note:** Include any CPU core that is available to the operating system in the number of CPU cores, including virtual CPU cores.

4. If you wish to view or change any of the resource management parameter values, you can use the `gpconfig` utility.
5. For example, to see the setting of a particular parameter:

```
$ gpconfig --show gp_vmem_protect_limit
```

6. For example, to set one value on all segment instances and a different value on the master:

```
$ gpconfig -c gp_resqueue_priority_cpucores_per_segment -v 2 -m 8
```

- Restart Greenplum Database to make the configuration changes effective:

```
$ gpstop -r
```

## Creating Resource Queues

Creating a resource queue involves giving it a name, setting an active query limit, and optionally a query priority on the resource queue. Use the `CREATE RESOURCE QUEUE` command to create new resource queues.

### Creating Queues with an Active Query Limit

Resource queues with an `ACTIVE_STATEMENTS` setting limit the number of queries that can be run by roles assigned to that queue. For example, to create a resource queue named `adhoc` with an active query limit of three:

```
=# CREATE RESOURCE QUEUE adhoc WITH (ACTIVE_STATEMENTS=3);
```

This means that for all roles assigned to the `adhoc` resource queue, only three active queries can be running on the system at any given time. If this queue has three queries running, and a fourth query is submitted by a role in that queue, that query must wait until a slot is free before it can run.

### Creating Queues with Memory Limits

Resource queues with a `MEMORY_LIMIT` setting control the amount of memory for all the queries submitted through the queue. The total memory should not exceed the physical memory available per-segment. Set `MEMORY_LIMIT` to 90% of memory available on a per-segment basis. For example, if a host has 48 GB of physical memory and 6 segment instances, then the memory available per segment instance is 8 GB. You can calculate the recommended `MEMORY_LIMIT` for a single queue as  $0.90 * 8 = 7.2$  GB. If there are multiple queues created on the system, their total memory limits must also add up to 7.2 GB.

When used in conjunction with `ACTIVE_STATEMENTS`, the default amount of memory allotted per query is: `MEMORY_LIMIT` `/ `ACTIVE_STATEMENTS`. When used in conjunction with `MAX_COST`, the default amount of memory allotted per query is: `MEMORY_LIMIT * (query_cost / MAX_COST)`. Use `MEMORY_LIMIT` in conjunction with `ACTIVE_STATEMENTS` rather than with `MAX_COST`.

For example, to create a resource queue with an active query limit of 10 and a total memory limit of 2000MB (each query will be allocated 200MB of segment host memory at execution time):

```
=# CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20,
MEMORY_LIMIT='2000MB');
```

The default memory allotment can be overridden on a per-query basis using the `statement_mem` server configuration parameter, provided that `MEMORY_LIMIT` or `max_statement_mem` is not exceeded.

For example, to allocate more memory to a particular query:

```
=> SET statement_mem='2GB';
=> SELECT * FROM my_big_table WHERE column='value' ORDER BY id;
=> RESET statement_mem;
```

As a general guideline, `MEMORY_LIMIT` for all of your resource queues should not exceed the amount of physical memory of a segment host. If workloads are staggered over multiple queues, it may be OK to oversubscribe memory allocations, keeping in mind that queries may be cancelled during execution if the segment host memory limit (`gp_vmem_protect_limit`) is exceeded.

## Setting Priority Levels

To control a resource queue's consumption of available CPU resources, an administrator can assign an appropriate priority level. When high concurrency causes contention for CPU resources, queries and statements associated with a high-priority resource queue will claim a larger share of available CPU than lower priority queries and statements.

Priority settings are created or altered using the `WITH` parameter of the commands `CREATE RESOURCE QUEUE` and `ALTER RESOURCE QUEUE`. For example, to specify priority settings for the `adhoc` and `reporting` queues, an administrator would use the following commands:

```
=# ALTER RESOURCE QUEUE adhoc WITH (PRIORITY=LOW);
=# ALTER RESOURCE QUEUE reporting WITH (PRIORITY=HIGH);
```

To create the `executive` queue with maximum priority, an administrator would use the following command:

```
=# CREATE RESOURCE QUEUE executive WITH (ACTIVE_STATEMENTS=3, PRIORITY=MAX);
```

When the query prioritization feature is enabled, resource queues are given a `MEDIUM` priority by default if not explicitly assigned. For more information on how priority settings are evaluated at runtime, see [How Priorities Work](#).

**Important:** In order for resource queue priority levels to be enforced on the active query workload, you must enable the query prioritization feature by setting the associated server configuration parameters. See [Configuring Resource Management](#).

## Assigning Roles (Users) to a Resource Queue

Once a resource queue is created, you must assign roles (users) to their appropriate resource queue. If roles are not explicitly assigned to a resource queue, they will go to the default resource queue, `pg_default`. The default resource queue has an active statement limit of 20, no cost limit, and a medium priority setting.

Use the `ALTER ROLE` or `CREATE ROLE` commands to assign a role to a resource queue. For example:

```
=# ALTER ROLE `name` RESOURCE QUEUE `queue_name`;
=# CREATE ROLE `name` WITH LOGIN RESOURCE QUEUE `queue_name`;
```

A role can only be assigned to one resource queue at any given time, so you can use the `ALTER ROLE` command to initially assign or change a role's resource queue.

Resource queues must be assigned on a user-by-user basis. If you have a role hierarchy (for example, a group-level role) then assigning a resource queue to the group does not propagate down to the users in that group.

Superusers are always exempt from resource queue limits. Superuser queries will always run regardless of the limits set on their assigned queue.

## Removing a Role from a Resource Queue

All users *must* be assigned to a resource queue. If not explicitly assigned to a particular queue, users will go into the default resource queue, `pg_default`. If you wish to remove a role from a resource queue and put them in the default queue, change the role's queue assignment to `none`. For example:

```
=# ALTER ROLE `role_name` RESOURCE QUEUE none;
```

## Modifying Resource Queues

After a resource queue has been created, you can change or reset the queue limits using the `ALTER RESOURCE QUEUE` command. You can remove a resource queue using the `DROP RESOURCE QUEUE` command. To change the roles (users) assigned to a resource queue, [Assigning Roles \(Users\) to a Resource Queue](#).

### Altering a Resource Queue

The `ALTER RESOURCE QUEUE` command changes the limits of a resource queue. To change the limits of a resource queue, specify the new values you want for the queue. For example:

```
=# ALTER RESOURCE QUEUE <adhoc> WITH (ACTIVE_STATEMENTS=5);
=# ALTER RESOURCE QUEUE <exec> WITH (PRIORITY=MAX);
```

To reset active statements or memory limit to no limit, enter a value of `-1`. To reset the maximum query cost to no limit, enter a value of `-1.0`. For example:

```
=# ALTER RESOURCE QUEUE <adhoc> WITH (MAX_COST=-1.0, MEMORY_LIMIT='2GB');
```

You can use the `ALTER RESOURCE QUEUE` command to change the priority of queries associated with a resource queue. For example, to set a queue to the minimum priority level:

```
ALTER RESOURCE QUEUE <webuser> WITH (PRIORITY=MIN);
```

## Dropping a Resource Queue

The `DROP RESOURCE QUEUE` command drops a resource queue. To drop a resource queue, the queue cannot have any roles assigned to it, nor can it have any statements waiting in the queue. See [Removing a Role from a Resource Queue](#) and [Clearing a Waiting Statement From a Resource Queue](#) for instructions on emptying a resource queue. To drop a resource queue:

```
=# DROP RESOURCE QUEUE <name>;
```

## Checking Resource Queue Status

Checking resource queue status involves the following tasks:

- [Viewing Queued Statements and Resource Queue Status](#)
- [Viewing Resource Queue Statistics](#)
- [Viewing the Roles Assigned to a Resource Queue](#)
- [Viewing the Waiting Queries for a Resource Queue](#)
- [Clearing a Waiting Statement From a Resource Queue](#)
- [Viewing the Priority of Active Statements](#)
- [Resetting the Priority of an Active Statement](#)

## Viewing Queued Statements and Resource Queue Status

The `gp_toolkit.gp_resqueue_status` view allows administrators to see status and activity for a resource queue. It shows how many queries are waiting to run and how many queries are currently active in the system from a particular resource queue. To see the resource queues created in the system, their limit attributes, and their current status:

```
=# SELECT * FROM gp_toolkit.gp_resqueue_status;
```

## Viewing Resource Queue Statistics

If you want to track statistics and performance of resource queues over time, you can enable statistics collecting for resource queues. This is done by setting the following server configuration parameter in your master `postgresql.conf` file:

```
stats_queue_level = on
```

Once this is enabled, you can use the `pg_stat_resqueues` system view to see the statistics collected on resource queue usage. Note that enabling this feature does incur slight performance overhead, as each query submitted through a resource queue must be tracked. It may be useful to enable statistics collecting on resource queues for initial diagnostics and administrative planning, and then deactivate the feature for continued use.

See the Statistics Collector section in the PostgreSQL documentation for more information about collecting statistics in Greenplum Database.

## Viewing the Roles Assigned to a Resource Queue

To see the roles assigned to a resource queue, perform the following query of the `pg_roles` and `gp_toolkit.gp_resqueue_status` system catalog tables:

```
=# SELECT rolname, rsqname FROM pg_roles,
       gp_toolkit.gp_resqueue_status
       WHERE pg_roles.rolresqueue=gp_toolkit.gp_resqueue_status.queueid;
```

You may want to create a view of this query to simplify future inquiries. For example:

```
=# CREATE VIEW role2queue AS
  SELECT rolname, rsqname FROM pg_roles, gp_resqueue
  WHERE pg_roles.rolresqueue=gp_toolkit.gp_resqueue_status.queueid;
```

Then you can just query the view:

```
=# SELECT * FROM role2queue;
```

## Viewing the Waiting Queries for a Resource Queue

When a slot is in use for a resource queue, it is recorded in the `pg_locks` system catalog table. This is where you can see all of the currently active and waiting queries for all resource queues. To check that statements are being queued (even statements that are not waiting), you can also use the `gp_toolkit.gp_locks_on_resqueue` view. For example:

```
=# SELECT * FROM gp_toolkit.gp_locks_on_resqueue WHERE lorwaiting='true';
```

If this query returns no results, then that means there are currently no statements waiting in a resource queue.

## Clearing a Waiting Statement From a Resource Queue

In some cases, you may want to clear a waiting statement from a resource queue. For example, you may want to remove a query that is waiting in the queue but has not been run yet. You may also want to stop a query that has been started if it is taking too long to run, or if it is sitting idle in a transaction and taking up resource queue slots that are needed by other users. To do this, you must first identify the statement you want to clear, determine its process id (pid), and then, use `pg_cancel_backend` with the process id to end that process, as shown below. An optional message to the process can be passed as the second parameter, to indicate to the user why the process was cancelled.

For example, to see process information about all statements currently active or waiting in all resource queues, run the following query:

```
=# SELECT rolname, rsqname, pg_locks.pid as pid, granted, state,
       query, datname
       FROM pg_roles, gp_toolkit.gp_resqueue_status, pg_locks,
```

```

pg_stat_activity
WHERE pg_roles.rolresqueue=pg_locks.objid
AND pg_locks.objid=gp_toolkit.gp_resqueue_status.queueid
AND pg_stat_activity.pid=pg_locks.pid
AND pg_stat_activity.username=pg_roles.rolname;

```

If this query returns no results, then that means there are currently no statements in a resource queue. A sample of a resource queue with two statements in it looks something like this:

| rolname | rsqname | pid   | granted | state  | query                  | datname |
|---------|---------|-------|---------|--------|------------------------|---------|
| sammy   | webuser | 31861 | t       | idle   | SELECT * FROM testtbl; | namesdb |
| daria   | webuser | 31905 | f       | active | SELECT * FROM topten;  | namesdb |

Use this output to identify the process id (pid) of the statement you want to clear from the resource queue. To clear the statement, you would then open a terminal window (as the `gpadmin` database superuser or as root) on the master host and cancel the corresponding process. For example:

```
=# pg_cancel_backend(31905)
```

**Important:** Do not use the operating system `KILL` command.

## Viewing the Priority of Active Statements

The `gp_toolkit` administrative schema has a view called `gp_resq_priority_statement`, which lists all statements currently being run and provides the priority, session ID, and other information.

This view is only available through the `gp_toolkit` administrative schema. See the *Greenplum Database Reference Guide* for more information.

## Resetting the Priority of an Active Statement

Superusers can adjust the priority of a statement currently being run using the built-in function `gp_adjust_priority(session_id, statement_count, priority)`. Using this function, superusers can raise or lower the priority of any query. For example:

```
=# SELECT gp_adjust_priority(752, 24905, 'HIGH')
```

To obtain the session ID and statement count parameters required by this function, superusers can use the `gp_toolkit` administrative schema view, `gp_resq_priority_statement`. From the view, use these values for the function parameters.

- The value of the `rqpsession` column for the `session_id` parameter
- The value of the `rqpcmd` column for the `statement_count` parameter
- The value of `rqppriority` column is the current priority. You can specify a string value of `MAX`, `HIGH`, `MEDIUM`, or `LOW` as the `priority`.

**Note:** The `gp_adjust_priority()` function affects only the specified statement. Subsequent statements in the same resource queue are run using the queue's normally assigned priority.

## Investigating a Performance Problem

This section provides guidelines for identifying and troubleshooting performance problems in a Greenplum Database system.

This topic lists steps you can take to help identify the cause of a performance problem. If the problem affects a particular workload or query, you can focus on tuning that particular workload. If the performance problem is system-wide, then hardware problems, system failures, or resource contention may be the cause.

**Parent topic:** [Managing Performance](#)

## Checking System State

Use the `gpstate` utility to identify failed segments. A Greenplum Database system will incur performance degradation when segment instances are down because other hosts must pick up the processing responsibilities of the down segments.

Failed segments can indicate a hardware failure, such as a failed disk drive or network card. Greenplum Database provides the hardware verification tool `gpcheckperf` to help identify the segment hosts with hardware issues.

## Checking Database Activity

- [Checking for Active Sessions \(Workload\)](#)
- [Checking for Locks \(Contention\)](#)
- [Checking Query Status and System Utilization](#)

### Checking for Active Sessions (Workload)

The `pg_stat_activity` system catalog view shows one row per server process; it shows the database OID, database name, process ID, user OID, user name, current query, time at which the current query began execution, time at which the process was started, client address, and port number. To obtain the most information about the current system workload, query this view as the database superuser. For example:

```
SELECT * FROM pg_stat_activity;
```

Note that the information does not update instantaneously.

### Checking for Locks (Contention)

The `pg_locks` system catalog view allows you to see information about outstanding locks. If a transaction is holding a lock on an object, any other queries must wait for that lock to be released before they can continue. This may appear to the user as if a query is hanging.

Examine `pg_locks` for ungranted locks to help identify contention between database client sessions. `pg_locks` provides a global view of all locks in the database system, not only those relevant to the current database. You can join its relation column against `pg_class.oid` to identify locked relations (such as tables), but this works correctly only for relations in the current database.

You can join the `pid` column to the `pg_stat_activity.pid` to see more information about the session holding or waiting to hold a lock. For example:

```
SELECT locktype, database, c.relname, l.relation,
       l.transactionid, l.pid, l.mode, l.granted,
       a.query
       FROM pg_locks l, pg_class c, pg_stat_activity a
       WHERE l.relation=c.oid AND l.pid=a.pid
       ORDER BY c.relname;
```

If you use resource groups, queries that are waiting will also show in `pg_locks`. To see how many queries are waiting to run in a resource group, use the `gp_resgroup_status` system catalog view. For example:

```
SELECT * FROM gp_toolkit.gp_resgroup_status;
```

Similarly, if you use resource queues, queries that are waiting in a queue also show in `pg_locks`. To see how many queries are waiting to run from a resource queue, use the `gp_resqueue_status` system catalog view. For example:

```
SELECT * FROM gp_toolkit.gp_resqueue_status;
```

## Checking Query Status and System Utilization

You can use system monitoring utilities such as `ps`, `top`, `iostat`, `vmstat`, `netstat` and so on to monitor database activity on the hosts in your Greenplum Database array. These tools can help identify Greenplum Database processes (`postgres` processes) currently running on the system and the most resource intensive tasks with regards to CPU, memory, disk I/O, or network activity. Look at these system statistics to identify queries that degrade database performance by overloading the system and consuming excessive resources. Greenplum Database's management tool `gpssh` allows you to run these system monitoring commands on several hosts simultaneously.

You can create and use the Greenplum Database `session_level_memory_consumption` view that provides information about the current memory utilization and idle time for sessions that are running queries on Greenplum Database. For information about the view, see [Viewing Session Memory Usage Information](#).

You can enable a dedicated database, `gpperfmon`, in which data collection agents running on each segment host save query and system utilization metrics. Refer to the `gpperfmon_install` management utility reference in the *Greenplum Database Management Utility Reference Guide* for help creating the `gpperfmon` database and managing the agents. See documentation for the tables and views in the `gpperfmon` database in the *Greenplum Database Reference Guide*.

The optional VMware Tanzu Greenplum Command Center web-based user interface graphically displays query and system utilization metrics. See the [Greenplum Command Center Documentation](#) web site for procedures to enable Greenplum Command Center.

## Troubleshooting Problem Queries

If a query performs poorly, look at its query plan to help identify problems. The `EXPLAIN` command shows the query plan for a given query. See [Query Profiling](#) for more information about reading query plans and identifying problems.

When an out of memory event occurs during query execution, the Greenplum Database memory accounting framework reports detailed memory consumption of every query running at the time of the event. The information is written to the Greenplum Database segment logs.

## Investigating Error Messages

Greenplum Database log messages are written to files in the `log` directory within the master's or segment's data directory. Because the master log file contains the most information, you should always check it first. Log files roll over daily and use the naming convention: `gpdb-YYYY-MM-DD_hhmmss.csv`. To locate the log files on the master host:

```
$ cd $MASTER_DATA_DIRECTORY/log
```

Log lines have the format of:

```
<timestamp> | <user> | <database> | <statement_id> | <con#><cmd#>
|:-<LOG_LEVEL>: <log_message>
```

You may want to focus your search for `WARNING`, `ERROR`, `FATAL` or `PANIC` log level messages. You can use the Greenplum utility `gplogfilter` to search through Greenplum Database log files. For example, when you run the following command on the master host, it checks for problem log messages in the standard logging locations:

```
$ gplogfilter -t
```

To search for related log entries in the segment log files, you can run `gplogfilter` on the segment hosts using `gpssh`. You can identify corresponding log entries by the `statement_id` or `con#` (session identifier). For example, to search for log messages in the segment log files containing the string `con6` and save output to a file:

```
gpssh -f seg_hosts_file -e 'source
/usr/local/greenplum-db/greenplum_path.sh ; gplogfilter -f
con6 /gpdata/*/log/gpdb*.csv' > seglog.out
```

## Gathering Information for VMware Customer Support

The Greenplum Magic Tool (GPMT) can run diagnostics and collect information from a Greenplum Database system. You can then send the information to VMware Customer Support to aid in the diagnosis of Greenplum Database errors or system failures.

The `gpmnt` utility command is available in the `bin` directory of your Greenplum Database installation. See [gpmnt](#) for usage information.

# Greenplum Database Best Practices

A best practice is a method or technique that has consistently shown results superior to those achieved with other means. Best practices are found through experience and are proven to reliably lead to a desired result. Best practices are a commitment to use any product correctly and optimally, by leveraging all the knowledge and expertise available to ensure success.

This document does not teach you how to use Greenplum Database features. Links are provided to other relevant parts of the Greenplum Database documentation for information on how to use and implement specific Greenplum Database features. This document addresses the most important best practices to follow when designing, implementing, and using Greenplum Database.

It is not the intent of this document to cover the entire product or compendium of features, but rather to provide a summary of *what matters most* in Greenplum Database. This document does not address *edge* use cases. While edge use cases can further leverage and benefit from Greenplum Database features, they require a proficient knowledge and expertise with these features, as well as a deep understanding of your environment, including SQL access, query execution, concurrency, workload, and other factors.

By mastering these best practices, you will increase the success of your Greenplum Database clusters in the areas of maintenance, support, performance, and scalability.

- **Best Practices Summary**  
A summary of best practices for Greenplum Database.
- **System Configuration**  
Requirements and best practices for system administrators who are configuring Greenplum Database cluster hosts.
- **Schema Design**  
Best practices for designing Greenplum Database schemas.
- **Memory and Resource Management with Resource Groups**  
Managing Greenplum Database resources with resource groups.
- **Memory and Resource Management with Resource Queues**  
Avoid memory errors and manage Greenplum Database resources.
- **System Monitoring and Maintenance**  
Best practices for regular maintenance that will ensure Greenplum Database high availability and optimal performance.
- **Loading Data**  
Description of the different ways to add data to Greenplum Database.
- **Security**  
Best practices to ensure the highest level of system security.

- **Encrypting Data and Database Connections**  
Best practices for implementing encryption and managing keys.
- **Tuning SQL Queries**  
The Greenplum Database cost-based optimizer evaluates many strategies for running a query and chooses the least costly method.
- **High Availability**  
Greenplum Database supports highly available, fault-tolerant database services when you enable and properly configure Greenplum high availability features. To guarantee a required level of service, each component must have a standby ready to take its place if it should fail.

## Best Practices Summary

A summary of best practices for Greenplum Database.

### Data Model

Greenplum Database is an analytical MPP shared-nothing database. This model is significantly different from a highly normalized/transactional SMP database. Because of this, the following best practices are recommended.

- Greenplum Database performs best with a denormalized schema design suited for MPP analytical processing for example, Star or Snowflake schema, with large fact tables and smaller dimension tables.
- Use the same data types for columns used in joins between tables.

See [Schema Design](#).

### Heap vs. Append-Optimized Storage

- Use heap storage for tables and partitions that will receive iterative batch and singleton `UPDATE`, `DELETE`, and `INSERT` operations.
- Use heap storage for tables and partitions that will receive concurrent `UPDATE`, `DELETE`, and `INSERT` operations.
- Use append-optimized storage for tables and partitions that are updated infrequently after the initial load and have subsequent inserts only performed in large batch operations.
- Avoid performing singleton `INSERT`, `UPDATE`, or `DELETE` operations on append-optimized tables.
- Avoid performing concurrent batch `UPDATE` or `DELETE` operations on append-optimized tables. Concurrent batch `INSERT` operations are acceptable.

See [Heap Storage](#) or [Append-Optimized Storage](#).

### Row vs. Column Oriented Storage

- Use row-oriented storage for workloads with iterative transactions where updates are required and frequent inserts are performed.

- Use row-oriented storage when selects against the table are wide.
- Use row-oriented storage for general purpose or mixed workloads.
- Use column-oriented storage where selects are narrow and aggregations of data are computed over a small number of columns.
- Use column-oriented storage for tables that have single columns that are regularly updated without modifying other columns in the row.

See [Row or Column Orientation](#).

## Compression

- Use compression on large append-optimized and partitioned tables to improve I/O across the system.
- Set the column compression settings at the level where the data resides.
- Balance higher levels of compression with the time and CPU cycles needed to compress and uncompress data.

See [Compression](#).

## Distributions

- Explicitly define a column or random distribution for all tables. Do not use the default.
- Use a single column that will distribute data across all segments evenly.
- Do not distribute on columns that will be used in the `WHERE` clause of a query.
- Do not distribute on dates or timestamps.
- Never distribute and partition tables on the same column.
- Achieve local joins to significantly improve performance by distributing on the same column for large tables commonly joined together.
- To ensure there is no data skew, validate that data is evenly distributed after the initial load and after incremental loads.

See [Distributions](#).

## Resource Queue Memory Management

- Set `vm.overcommit_memory` to 2.
- Do not configure the OS to use huge pages.
- Use `gp_vmem_protect_limit` to set the maximum memory that the instance can allocate for *all* work being done in each segment database.
- You can use `gp_vmem_protect_limit` by calculating:
  - `gp_vmem` – the total memory available to Greenplum Database
    - If the total system memory is less than 256 GB, use this formula:

$$\text{gp\_vmem} = ((\text{SWAP} + \text{RAM}) - (7.5\text{GB} + 0.05 * \text{RAM})) / 1.7$$

- If the total system memory is equal to or greater than 256 GB, use this formula:

$$\text{gp\_vmem} = ((\text{SWAP} + \text{RAM}) - (7.5\text{GB} + 0.05 * \text{RAM})) / 1.17$$

where `SWAP` is the host's swap space in GB, and `RAM` is the host's RAM in GB.

- `max_acting_primary_segments` – the maximum number of primary segments that could be running on a host when mirror segments are activated due to a host or segment failure.
- `gp_vmem_protect_limit`

$$\text{gp\_vmem\_protect\_limit} = \text{gp\_vmem} / \text{acting\_primary\_segments}$$

Convert to MB to set the value of the configuration parameter.

- In a scenario where a large number of workfiles are generated calculate the `gp_vmem` factor with this formula to account for the workfiles.
  - If the total system memory is less than 256 GB:

$$\text{gp\_vmem} = ((\text{SWAP} + \text{RAM}) - (7.5\text{GB} + 0.05 * \text{RAM} - (300\text{KB} * \text{total\_}\_\_\text{workfiles}))) / 1.7$$

- If the total system memory is equal to or greater than 256 GB:

$$\text{gp\_vmem} = ((\text{SWAP} + \text{RAM}) - (7.5\text{GB} + 0.05 * \text{RAM} - (300\text{KB} * \text{total\_}\_\_\text{workfiles}))) / 1.17$$

- Never set `gp_vmem_protect_limit` too high or larger than the physical RAM on the system.
- Use the calculated `gp_vmem` value to calculate the setting for the `vm.overcommit_ratio` operating system parameter:

$$\text{vm.overcommit\_ratio} = (\text{RAM} - 0.026 * \text{gp\_vmem}) / \text{RAM}$$

- Use `statement_mem` to allocate memory used for a query per segment db.
- Use resource queues to set both the numbers of active queries (`ACTIVE_STATEMENTS`) and the amount of memory (`MEMORY_LIMIT`) that can be utilized by queries in the queue.
- Associate all users with a resource queue. Do not use the default queue.
- Set `PRIORITY` to match the real needs of the queue for the workload and time of day. Avoid using MAX priority.
- Ensure that resource queue memory allocations do not exceed the setting for `gp_vmem_protect_limit`.
- Dynamically update resource queue settings to match daily operations flow.

See [Setting the Greenplum Recommended OS Parameters and Memory and Resource Management with Resource Queues](#).

## Partitioning

- Partition large tables only. Do not partition small tables.
- Use partitioning only if partition elimination (partition pruning) can be achieved based on the query criteria.
- Choose range partitioning over list partitioning.
- Partition the table based on a commonly-used column, such as a date column.
- Never partition and distribute tables on the same column.
- Do not use default partitions.
- Do not use multi-level partitioning; create fewer partitions with more data in each partition.
- Validate that queries are selectively scanning partitioned tables (partitions are being eliminated) by examining the query `EXPLAIN` plan.
- Do not create too many partitions with column-oriented storage because of the total number of physical files on every segment: `physical files = segments x columns x partitions`

See [Partitioning](#).

## Indexes

- In general indexes are not needed in Greenplum Database.
- Create an index on a single column of a columnar table for drill-through purposes for high cardinality tables that require queries with high selectivity.
- Do not index columns that are frequently updated.
- Consider dropping indexes before loading data into a table. After the load, re-create the indexes for the table.
- Create selective B-tree indexes.
- Do not create bitmap indexes on columns that are updated.
- Avoid using bitmap indexes for unique columns, very high or very low cardinality data. Bitmap indexes perform best when the column has a low cardinality—100 to 100,000 distinct values.
- Do not use bitmap indexes for transactional workloads.
- In general do not index partitioned tables. If indexes are needed, the index columns must be different than the partition columns.

See [Indexes](#).

## Resource Queues

- Use resource queues to manage the workload on the cluster.
- Associate all roles with a user-defined resource queue.

- Use the `ACTIVE_STATEMENTS` parameter to limit the number of active queries that members of the particular queue can run concurrently.
- Use the `MEMORY_LIMIT` parameter to control the total amount of memory that queries running through the queue can utilize.
- Alter resource queues dynamically to match the workload and time of day.

See [Configuring Resource Queues](#).

## Monitoring and Maintenance

- Implement the "Recommended Monitoring and Maintenance Tasks" in the *Greenplum Database Administrator Guide*.
- Run `gpcheckperf` at install time and periodically thereafter, saving the output to compare system performance over time.
- Use all the tools at your disposal to understand how your system behaves under different loads.
- Examine any unusual event to determine the cause.
- Monitor query activity on the system by running explain plans periodically to ensure the queries are running optimally.
- Review plans to determine whether index are being used and partition elimination is occurring as expected.
- Know the location and content of system log files and monitor them on a regular basis, not just when problems arise.

See [System Monitoring and Maintenance](#), [Query Profiling](#) and [Monitoring Greenplum Database Log Files](#).

## ANALYZE

- Determine if analyzing the database is actually needed. Analyzing is not needed if `gp_autostats_mode` is set to `on_no_stats` (the default) and the table is not partitioned.
- Use `analyzedb` in preference to `ANALYZE` when dealing with large sets of tables, as it does not require analyzing the entire database. The `analyzedb` utility updates statistics data for the specified tables incrementally and concurrently. For append optimized tables, `analyzedb` updates statistics incrementally only if the statistics are not current. For heap tables, statistics are always updated. `ANALYZE` does not update the table metadata that the `analyzedb` utility uses to determine whether table statistics are up to date.
- Selectively run `ANALYZE` at the table level when needed.
- Always run `ANALYZE` after `INSERT`, `UPDATE`, and `DELETE` operations that significantly changes the underlying data.
- Always run `ANALYZE` after `CREATE INDEX` operations.
- If `ANALYZE` on very large tables takes too long, run `ANALYZE` only on the columns used in a join condition, `WHERE` clause, `SORT`, `GROUP BY`, or `HAVING` clause.

- When dealing with large sets of tables, use `analyzedb` instead of `ANALYZE`.
- Run `analyzedb` on the root partition any time that you add a new partition(s) to a partitioned table. This operation both analyzes the child leaf partitions in parallel and merges any updated statistics into the root partition.

See [Updating Statistics with ANALYZE](#).

## Vacuum

- Run `VACUUM` after large `UPDATE` and `DELETE` operations.
- Do not run `VACUUM FULL`. Instead run a `CREATE TABLE...AS` operation, then rename and drop the original table.
- Frequently run `VACUUM` on the system catalogs to avoid catalog bloat and the need to run `VACUUM FULL` on catalog tables.
- Never issue a `kill` command against `VACUUM` on catalog tables.

See [Managing Bloat in a Database](#).

## Loading

- Maximize the parallelism as the number of segments increase.
- Spread the data evenly across as many ETL nodes as possible.
  - Split very large data files into equal parts and spread the data across as many file systems as possible.
  - Run two `gpfdist` instances per file system.
  - Run `gpfdist` on as many interfaces as possible.
  - Use `gp_external_max_segs` to control the number of segments that will request data from the `gpfdist` process.
  - Always keep `gp_external_max_segs` and the number of `gpfdist` processes an even factor.
- Always drop indexes before loading into existing tables and re-create the index after loading.
- Run `VACUUM` after load errors to recover space.

See [Loading Data](#).

## Security

- Secure the `gpadmin` user id and only allow essential system administrators access to it.
- Administrators should only log in to Greenplum as `gpadmin` when performing certain system maintenance tasks (such as upgrade or expansion).
- Limit users who have the `SUPERUSER` role attribute. Roles that are superusers bypass all access privilege checks in Greenplum Database, as well as resource queuing. Only system

administrators should be given superuser rights. See "Altering Role Attributes" in the *Greenplum Database Administrator Guide*.

- Database users should never log on as `gpadmin`, and ETL or production workloads should never run as `gpadmin`.
- Assign a distinct Greenplum Database role to each user, application, or service that logs in.
- For applications or web services, consider creating a distinct role for each application or service.
- Use groups to manage access privileges.
- Protect the root password.
- Enforce a strong password policy for operating system passwords.
- Ensure that important operating system files are protected.

See [Security](#).

## Encryption

- Encrypting and decrypting data has a performance cost; only encrypt data that requires encryption.
- Do performance testing before implementing any encryption solution in a production system.
- Server certificates in a production Greenplum Database system should be signed by a certificate authority (CA) so that clients can authenticate the server. The CA may be local if all clients are local to the organization.
- Client connections to Greenplum Database should use SSL encryption whenever the connection goes through an insecure link.
- A symmetric encryption scheme, where the same key is used to both encrypt and decrypt, has better performance than an asymmetric scheme and should be used when the key can be shared safely.
- Use cryptographic functions to encrypt data on disk. The data is encrypted and decrypted in the database process, so it is important to secure the client connection with SSL to avoid transmitting unencrypted data.
- Use the `gpfdists` protocol to secure ETL data as it is loaded into or unloaded from the database.

See [Encrypting Data and Database Connections](#)

## High Availability

**Note:** The following guidelines apply to actual hardware deployments, but not to public cloud-based infrastructure, where high availability solutions may already exist.

- Use a hardware RAID storage solution with 8 to 24 disks.
- Use RAID 1, 5, or 6 so that the disk array can tolerate a failed disk.

- Configure a hot spare in the disk array to allow rebuild to begin automatically when disk failure is detected.
- Protect against failure of the entire disk array and degradation during rebuilds by mirroring the RAID volume.
- Monitor disk utilization regularly and add additional space when needed.
- Monitor segment skew to ensure that data is distributed evenly and storage is consumed evenly at all segments.
- Set up a standby master instance to take over if the primary master fails.
- Plan how to switch clients to the new master instance when a failure occurs, for example, by updating the master address in DNS.
- Set up monitoring to send notifications in a system monitoring application or by email when the primary fails.
- Set up mirrors for all segments.
- Locate primary segments and their mirrors on different hosts to protect against host failure.
- Recover failed segments promptly, using the `gprecoverseg` utility, to restore redundancy and return the system to optimal balance.
- Consider a Dual Cluster configuration to provide an additional level of redundancy and additional query processing throughput.
- Backup Greenplum databases regularly unless the data is easily restored from sources.
- If backups are saved to local cluster storage, move the files to a safe, off-cluster location when the backup is complete.
- If backups are saved to NFS mounts, use a scale-out NFS solution such as Dell EMC Isilon to prevent IO bottlenecks.
- Consider using Greenplum integration to stream backups to the Dell EMC Data Domain enterprise backup platform.

See [High Availability](#).

**Parent topic:** [Greenplum Database Best Practices](#)

## System Configuration

Requirements and best practices for system administrators who are configuring Greenplum Database cluster hosts.

Configuration of the Greenplum Database cluster is usually performed as root.

## Configuring the Timezone

Greenplum Database selects a timezone to use from a set of internally stored PostgreSQL timezones. The available PostgreSQL timezones are taken from the Internet Assigned Numbers Authority (IANA) Time Zone Database, and Greenplum Database updates its list of available timezones as necessary when the IANA database changes for PostgreSQL.

Greenplum selects the timezone by matching a PostgreSQL timezone with the user specified time zone, or the host system time zone if no time zone is configured. For example, when selecting a default timezone, Greenplum uses an algorithm to select a PostgreSQL timezone based on the host system timezone files. If the system timezone includes leap second information, Greenplum Database cannot match the system timezone with a PostgreSQL timezone. In this case, Greenplum Database calculates a "best match" with a PostgreSQL timezone based on information from the host system.

As a best practice, configure Greenplum Database and the host systems to use a known, supported timezone. This sets the timezone for the Greenplum Database master and segment instances, and prevents Greenplum Database from recalculating a "best match" timezone each time the cluster is restarted, using the current system timezone and Greenplum timezone files (which may have been updated from the IANA database since the last restart). Use the `gpconfig` utility to show and set the Greenplum Database timezone. For example, these commands show the Greenplum Database timezone and set the timezone to `US/Pacific`.

```
# gpconfig -s TimeZone
# gpconfig -c TimeZone -v 'US/Pacific'
```

You must restart Greenplum Database after changing the timezone. The command `gpstop -ra` restarts Greenplum Database. The catalog view `pg_timezone_names` provides Greenplum Database timezone information.

## File System

XFS is the file system used for Greenplum Database data directories. Use the mount options described in [Configuring Your Systems](#).

## Port Configuration

See the [recommended OS parameter settings](#) in the *Greenplum Database Installation Guide* for further details.

Set up `ip_local_port_range` so it does not conflict with the Greenplum Database port ranges. For example, setting this range in `/etc/sysctl.conf`:

```
net.ipv4.ip_local_port_range = 10000 65535
```

you could set the Greenplum Database base port numbers to these values.

```
PORT_BASE = 6000
MIRROR_PORT_BASE = 7000
```

See the [Recommended OS Parameters Settings](#) in the *Greenplum Database Installation Guide* for further details.

## I/O Configuration

Set the blockdev read-ahead size to 16384 on the devices that contain data directories. This command sets the read-ahead size for `/dev/sdb`.

```
# /sbin/blockdev --setra 16384 /dev/sdb
```

This command returns the read-ahead size for `/dev/sdb`.

```
# /sbin/blockdev --getra /dev/sdb
16384
```

See the [Recommended OS Parameters Settings](#) in the *Greenplum Database Installation Guide* for further details.

The deadline IO scheduler should be set for all data directory devices.

```
# cat /sys/block/sdb/queue/scheduler
noop anticipatory [deadline] cfq
```

The maximum number of OS files and processes should be increased in the `/etc/security/limits.conf` file.

```
* soft nofile 524288
* hard nofile 524288
* soft nproc 131072
* hard nproc 131072
```

## OS Memory Configuration

The Linux `sysctl` `vm.overcommit_memory` and `vm.overcommit_ratio` variables affect how the operating system manages memory allocation. See the `/etc/sysctl.conf` file parameters guidelines in the *Greenplum Database Installation Guide* for further details.

`vm.overcommit_memory` determines the method the OS uses for determining how much memory can be allocated to processes. This should be always set to 2, which is the only safe setting for the database.

**Note:** For information on configuration of overcommit memory, refer to:

- [https://en.wikipedia.org/wiki/Memory\\_overcommitment](https://en.wikipedia.org/wiki/Memory_overcommitment)
- <https://www.kernel.org/doc/Documentation/vm/overcommit-accounting>

`vm.overcommit_ratio` is the percent of RAM that is used for application processes. The default is 50 on Red Hat Enterprise Linux. See [Resource Queue Segment Memory Configuration](#) for a formula to calculate an optimal value.

Do not enable huge pages in the operating system.

See also [Memory and Resource Management with Resource Queues](#).

## Shared Memory Settings

Greenplum Database uses shared memory to communicate between `postgres` processes that are part of the same `postgres` instance. The following shared memory settings should be set in `sysctl` and are rarely modified. See the `sysctl.conf` file parameters in the *Greenplum Database Installation Guide* for further details.

```
kernel.shmmax = 810810728448
kernel.shmmni = 4096
kernel.shmall = 197951838
```

See [Setting the Greenplum Recommended OS Parameters](#) for more details.

## Number of Segments per Host

Determining the number of segments to run on each segment host has immense impact on overall system performance. The segments share the host's CPU cores, memory, and NICs with each other and with other processes running on the host. Over-estimating the number of segments a server can accommodate is a common cause of suboptimal performance.

The factors that must be considered when choosing how many segments to run per host include the following:

- Number of cores
- Amount of physical RAM installed in the server
- Number of NICs
- Amount of storage attached to server
- Mixture of primary and mirror segments
- ETL processes that will run on the hosts
- Non-Greenplum processes running on the hosts

## Resource Queue Segment Memory Configuration

The `gp_vmem_protect_limit` server configuration parameter specifies the amount of memory that all active postgres processes for a single segment can consume at any given time. Queries that exceed this amount will fail. Use the following calculations to estimate a safe value for `gp_vmem_protect_limit`.

1. Calculate `gp_vmem`, the host memory available to Greenplum Database.
  - If the total system memory is less than 256 GB, use this formula:

$$gp\_vmem = ((SWAP + RAM) - (7.5GB + 0.05 * RAM)) / 1.7$$

- If the total system memory is equal to or greater than 256 GB, use this formula:

$$gp\_vmem = ((SWAP + RAM) - (7.5GB + 0.05 * RAM)) / 1.17$$

where `SWAP` is the host's swap space in GB and `RAM` is the RAM installed on the host in GB.

2. Calculate `max_acting_primary_segments`. This is the maximum number of primary segments that can be running on a host when mirror segments are activated due to a segment or host failure on another host in the cluster. With mirrors arranged in a 4-host block with 8 primary segments per host, for example, a single segment host failure would activate two or three mirror segments on each remaining host in the failed host's block. The

`max_acting_primary_segments` value for this configuration is 11 (8 primary segments plus 3 mirrors activated on failure).

3. Calculate `gp_vmem_protect_limit` by dividing the total Greenplum Database memory by the maximum number of acting primaries:

```
gp_vmem_protect_limit = gp_vmem / max_acting_primary_segments
```

Convert to megabytes to find the value to set for the `gp_vmem_protect_limit` system configuration parameter.

For scenarios where a large number of workfiles are generated, adjust the calculation for `gp_vmem` to account for the workfiles.

- If the total system memory is less than 256 GB:

```
gp_vmem = ((SWAP + RAM) - (7.5GB + 0.05 * RAM - (300KB * total_#_workfiles))) / 1.7
```

- If the total system memory is equal to or greater than 256 GB:

```
gp_vmem = ((SWAP + RAM) - (7.5GB + 0.05 * RAM - (300KB * total_#_workfiles))) / 1.17
```

For information about monitoring and managing workfile usage, see the *Greenplum Database Administrator Guide*.

You can calculate the value of the `vm.overcommit_ratio` operating system parameter from the value of `gp_vmem`:

```
vm.overcommit_ratio = (RAM - 0.026 * gp_vmem) / RAM
```

See [OS Memory Configuration](#) for more about about `vm.overcommit_ratio`.

See also [Memory and Resource Management with Resource Queues](#).

## Resource Queue Statement Memory Configuration

The `statement_mem` server configuration parameter is the amount of memory to be allocated to any single query in a segment database. If a statement requires additional memory it will spill to disk. Calculate the value for `statement_mem` with the following formula:

$$(\text{gp\_vmem\_protect\_limit} * .9) / \text{max\_expected\_concurrent\_queries}$$

For example, for 40 concurrent queries with `gp_vmem_protect_limit` set to 8GB (8192MB), the calculation for `statement_mem` would be:

$$(8192\text{MB} * .9) / 40 = 184\text{MB}$$

Each query would be allowed 184MB of memory before it must spill to disk.

To increase `statement_mem` safely you must either increase `gp_vmem_protect_limit` or reduce the number of concurrent queries. To increase `gp_vmem_protect_limit`, you must add physical RAM and/or swap space, or reduce the number of segments per host.

Note that adding segment hosts to the cluster cannot help out-of-memory errors unless you use the additional hosts to decrease the number of segments per host.

Spill files are created when there is not enough memory to fit all the mapper output, usually when 80% of the buffer space is occupied.

Also, see [Resource Management](#) for best practices for managing query memory using resource queues.

## Resource Queue Spill File Configuration

Greenplum Database creates *spill files* (also called *workfiles*) on disk if a query is allocated insufficient memory to run in memory. A single query can create no more than 100,000 spill files, by default, which is sufficient for the majority of queries.

You can control the maximum number of spill files created per query and per segment with the configuration parameter `gp_workfile_limit_files_per_query`. Set the parameter to 0 to allow queries to create an unlimited number of spill files. Limiting the number of spill files permitted prevents run-away queries from disrupting the system.

A query could generate a large number of spill files if not enough memory is allocated to it or if data skew is present in the queried data. If a query creates more than the specified number of spill files, Greenplum Database returns this error:

```
ERROR: number of workfiles per query limit exceeded
```

Before raising the `gp_workfile_limit_files_per_query`, try reducing the number of spill files by changing the query, changing the data distribution, or changing the memory configuration.

The `gp_toolkit` schema includes views that allow you to see information about all the queries that are currently using spill files. This information can be used for troubleshooting and for tuning queries:

- The `gp_workfile_entries` view contains one row for each operator using disk space for workfiles on a segment at the current time. See [How to Read Explain Plans](#) for information about operators.
- The `gp_workfile_usage_per_query` view contains one row for each query using disk space for workfiles on a segment at the current time.
- The `gp_workfile_usage_per_segment` view contains one row for each segment. Each row displays the total amount of disk space used for workfiles on the segment at the current time.

See the *Greenplum Database Reference Guide* for descriptions of the columns in these views.

The `gp_workfile_compression` configuration parameter specifies whether the spill files are compressed. It is `off` by default. Enabling compression can improve performance when spill files are used.

**Parent topic:** [Greenplum Database Best Practices](#)

## Schema Design

Best practices for designing Greenplum Database schemas.

Greenplum Database is an analytical, shared-nothing database, which is much different than a highly normalized, transactional SMP database. Greenplum Database performs best with a denormalized schema design suited for MPP analytical processing, a star or snowflake schema, with large centralized fact tables connected to multiple smaller dimension tables.

**Parent topic:** [Greenplum Database Best Practices](#)

## Data Types

### Use Types Consistently

Use the same data types for columns used in joins between tables. If the data types differ, Greenplum Database must dynamically convert the data type of one of the columns so the data values can be compared correctly. With this in mind, you may need to increase the data type size to facilitate joins to other common objects.

### Choose Data Types that Use the Least Space

You can increase database capacity and improve query execution by choosing the most efficient data types to store your data.

Use `TEXT` or `VARCHAR` rather than `CHAR`. There are no performance differences among the character data types, but using `TEXT` or `VARCHAR` can decrease the storage space used.

Use the smallest numeric data type that will accommodate your data. Using `BIGINT` for data that fits in `INT` or `SMALLINT` wastes storage space.

## Storage Model

Greenplum Database provides an array of storage options when creating tables. It is very important to know when to use heap storage versus append-optimized (AO) storage, and when to use row-oriented storage versus column-oriented storage. The correct selection of heap versus AO and row versus column is extremely important for large fact tables, but less important for small dimension tables.

The best practices for determining the storage model are:

1. Design and build an insert-only model, truncating a daily partition before load.
2. For large partitioned fact tables, evaluate and use optimal storage options for different partitions. One storage option is not always right for the entire partitioned table. For example, some partitions can be row-oriented while others are column-oriented.
3. When using column-oriented storage, every column is a separate file on *every* Greenplum Database segment. For tables with a large number of columns consider columnar storage for data often accessed (hot) and row-oriented storage for data not often accessed (cold).
4. Storage options should be set at the partition level.
5. Compress large tables to improve I/O performance and to make space in the cluster.

### Heap Storage or Append-Optimized Storage

Heap storage is the default model, and is the model PostgreSQL uses for all database tables. Use heap storage for tables and partitions that will receive iterative `UPDATE`, `DELETE`, and singleton `INSERT` operations. Use heap storage for tables and partitions that will receive concurrent `UPDATE`, `DELETE`, and `INSERT` operations.

Use append-optimized storage for tables and partitions that are updated infrequently after the initial load and have subsequent inserts performed only in batch operations. Avoid performing singleton `INSERT`, `UPDATE`, or `DELETE` operations on append-optimized tables. Concurrent batch `INSERT` operations are acceptable, but *never* perform concurrent batch `UPDATE` or `DELETE` operations.

The append-optimized storage model is inappropriate for frequently updated tables, because space occupied by rows that are updated and deleted in append-optimized tables is not recovered and reused as efficiently as with heap tables. Append-optimized storage is intended for large tables that are loaded once, updated infrequently, and queried frequently for analytical query processing.

## Row or Column Orientation

Row orientation is the traditional way to store database tuples. The columns that comprise a row are stored on disk contiguously, so that an entire row can be read from disk in a single I/O.

Column orientation stores column values together on disk. A separate file is created for each column. If the table is partitioned, a separate file is created for each column and partition. When a query accesses only a small number of columns in a column-oriented table with many columns, the cost of I/O is substantially reduced compared to a row-oriented table; any columns not referenced do not have to be retrieved from disk.

Row-oriented storage is recommended for transactional type workloads with iterative transactions where updates are required and frequent inserts are performed. Use row-oriented storage when selects against the table are wide, where many columns of a single row are needed in a query. If the majority of columns in the `SELECT` list or `WHERE` clause is selected in queries, use row-oriented storage. Use row-oriented storage for general purpose or mixed workloads, as it offers the best combination of flexibility and performance.

Column-oriented storage is optimized for read operations but it is not optimized for write operations; column values for a row must be written to different places on disk. Column-oriented tables can offer optimal query performance on large tables with many columns where only a small subset of columns are accessed by the queries.

Another benefit of column orientation is that a collection of values of the same data type can be stored together in less space than a collection of mixed type values, so column-oriented tables use less disk space (and consequently less disk I/O) than row-oriented tables. Column-oriented tables also compress better than row-oriented tables.

Use column-oriented storage for data warehouse analytic workloads where selects are narrow or aggregations of data are computed over a small number of columns. Use column-oriented storage for tables that have single columns that are regularly updated without modifying other columns in the row. Reading a complete row in a wide columnar table requires more time than reading the same row from a row-oriented table. It is important to understand that each column is a separate physical file on *every* segment in Greenplum Database.

## Compression

Greenplum Database offers a variety of options to compress append-optimized tables and partitions. Use compression to improve I/O across the system by allowing more data to be read with each disk read operation. The best practice is to set the column compression settings at the partition level.

Note that new partitions added to a partitioned table do not automatically inherit compression defined at the table level; you must *specifically* define compression when you add new partitions.

Run-length encoding (RLE) compression provides the best levels of compression. Higher levels of compression usually result in more compact storage on disk, but require additional time and CPU cycles when compressing data on writes and uncompressing on reads. Sorting data, in combination with the various compression options, can achieve the highest level of compression.

Data compression should never be used for data that is stored on a compressed file system.

Test different compression types and ordering methods to determine the best compression for your specific data. For example, you might start zstd compression at level 8 or 9 and adjust for best results. RLE compression works best with files that contain repetitive data.

## Distributions

An optimal distribution that results in evenly distributed data is the most important factor in Greenplum Database. In an MPP shared nothing environment overall response time for a query is measured by the completion time for all segments. The system is only as fast as the slowest segment. If the data is skewed, segments with more data will take more time to complete, so every segment must have an approximately equal number of rows and perform approximately the same amount of processing. Poor performance and out of memory conditions may result if one segment has significantly more data to process than other segments.

Consider the following best practices when deciding on a distribution strategy:

- Explicitly define a column or random distribution for all tables. Do not use the default.
- Ideally, use a single column that will distribute data across all segments evenly.
- Do not distribute on columns that will be used in the `WHERE` clause of a query.
- Do not distribute on dates or timestamps.
- The distribution key column data should contain unique values or very high cardinality.
- If a single column cannot achieve an even distribution, use a multi-column distribution key with a maximum of two columns. Additional column values do not typically yield a more even distribution and they require additional time in the hashing process.
- If a two-column distribution key cannot achieve an even distribution of data, use a random distribution. Multi-column distribution keys in most cases require motion operations to join tables, so they offer no advantages over a random distribution.

Greenplum Database random distribution is not round-robin, so there is no guarantee of an equal number of records on each segment. Random distributions typically fall within a target range of less than ten percent variation.

Optimal distributions are critical when joining large tables together. To perform a join, matching rows must be located together on the same segment. If data is not distributed on the same join column, the rows needed from one of the tables are dynamically redistributed to the other

segments. In some cases a broadcast motion, in which each segment sends its individual rows to all other segments, is performed rather than a redistribution motion, where each segment rehashes the data and sends the rows to the appropriate segments according to the hash key.

## Local (Co-located) Joins

Using a hash distribution that evenly distributes table rows across all segments and results in local joins can provide substantial performance gains. When joined rows are on the same segment, much of the processing can be accomplished within the segment instance. These are called *local* or *co-located* joins. Local joins minimize data movement; each segment operates independently of the other segments, without network traffic or communications between segments.

To achieve local joins for large tables commonly joined together, distribute the tables on the same column. Local joins require that both sides of a join be distributed on the same columns (and in the same order) *and* that all columns in the distribution clause are used when joining tables. The distribution columns must also be the same data type—although some values with different data types may appear to have the same representation, they are stored differently and hash to different values, so they are stored on different segments.

## Data Skew

Data skew is often the root cause of poor query performance and out of memory conditions. Skewed data affects scan (read) performance, but it also affects all other query execution operations, for instance, joins and group by operations.

It is very important to *validate* distributions to *ensure* that data is evenly distributed after the initial load. It is equally important to *continue* to validate distributions after incremental loads.

The following query shows the number of rows per segment as well as the variance from the minimum and maximum numbers of rows:

```
SELECT 'Example Table' AS "Table Name",
       max(c) AS "Max Seg Rows", min(c) AS "Min Seg Rows",
       (max(c)-min(c))*100.0/max(c) AS "Percentage Difference Between Max & Min"
FROM (SELECT count(*) c, gp_segment_id FROM facts GROUP BY 2) AS a;
```

The `gp_toolkit` schema has two views that you can use to check for skew.

- The `gp_toolkit.gp_skew_coefficients` view shows data distribution skew by calculating the coefficient of variation (CV) for the data stored on each segment. The `skccoeff` column shows the coefficient of variation (CV), which is calculated as the standard deviation divided by the average. It takes into account both the average and variability around the average of a data series. The lower the value, the better. Higher values indicate greater data skew.
- The `gp_toolkit.gp_skew_idle_fractions` view shows data distribution skew by calculating the percentage of the system that is idle during a table scan, which is an indicator of computational skew. The `siffraction` column shows the percentage of the system that is idle during a table scan. This is an indicator of uneven data distribution or query processing skew. For example, a value of 0.1 indicates 10% skew, a value of 0.5 indicates 50% skew, and so on. Tables that have more than 10% skew should have their distribution policies evaluated.

## Processing Skew

Processing skew results when a disproportionate amount of data flows to, and is processed by, one or a few segments. It is often the culprit behind Greenplum Database performance and stability issues. It can happen with operations such as join, sort, aggregation, and various OLAP operations. Processing skew happens in flight while a query is running and is not as easy to detect as data skew, which is caused by uneven data distribution due to the wrong choice of distribution keys. Data skew is present at the table level, so it can be easily detected and avoided by choosing optimal distribution keys.

If single segments are failing, that is, not all segments on a host, it may be a processing skew issue. Identifying processing skew is currently a manual process. First look for spill files. If there is skew, but not enough to cause spill, it will not become a performance issue. If you determine skew exists, then find the query responsible for the skew.

The remedy for processing skew in almost all cases is to rewrite the query. Creating temporary tables can eliminate skew. Temporary tables can be randomly distributed to force a two-stage aggregation.

## Partitioning

A good partitioning strategy reduces the amount of data to be scanned by reading only the partitions needed to satisfy a query.

Each partition is a separate physical file or set of files (in the case of column-oriented tables) on *every* segment. Just as reading a complete row in a wide columnar table requires more time than reading the same row from a heap table, *reading all partitions in a partitioned table requires more time than reading the same data from a non-partitioned table.*

Following are partitioning best practices:

- Partition large tables only, do not partition small tables.
- Use partitioning on large tables *only* when partition elimination (partition pruning) can be achieved based on query criteria and is accomplished by partitioning the table based on the query predicate. Whenever possible, use range partitioning instead of list partitioning.
- The query planner can selectively scan partitioned tables only when the query contains a direct and simple restriction of the table using immutable operators, such as `=`, `<`, `<=`, `>`, `>=`, and `<>`.
- Selective scanning recognizes `STABLE` and `IMMUTABLE` functions, but does not recognize `VOLATILE` functions within a query. For example, `WHERE` clauses such as

```
date > CURRENT_DATE
```

cause the query planner to selectively scan partitioned tables, but a `WHERE` clause such as

```
time > TIMEOFDAY
```

does not. It is important to validate that queries are selectively scanning partitioned tables (partitions are being eliminated) by examining the query `EXPLAIN` plan.

- Do not use default partitions. The default partition is always scanned but, more importantly, in many environments they tend to overfill resulting in poor performance.
- *Never* partition and distribute tables on the same column.
- Do not use multi-level partitioning. While sub-partitioning is supported, it is not recommended because typically subpartitions contain little or no data. It is a myth that performance increases as the number of partitions or subpartitions increases; the administrative overhead of maintaining many partitions and subpartitions will outweigh any performance benefits. For performance, scalability and manageability, balance partition scan performance with the number of overall partitions.
- Beware of using too many partitions with column-oriented storage.
- Consider workload concurrency and the average number of partitions opened and scanned for all concurrent queries.

## Number of Partition and Columnar Storage Files

The only hard limit for the number of files Greenplum Database supports is the operating system's open file limit. It is important, however, to consider the total number of files in the cluster, the number of files on every segment, and the total number of files on a host. In an MPP shared nothing environment, every node operates independently of other nodes. Each node is constrained by its disk, CPU, and memory. CPU and I/O constraints are not common with Greenplum Database, but memory is often a limiting factor because the query execution model optimizes query performance in memory.

The optimal number of files per segment also varies based on the number of segments on the node, the size of the cluster, SQL access, concurrency, workload, and skew. There are generally six to eight segments per host, but large clusters should have fewer segments per host. When using partitioning and columnar storage it is important to balance the total number of files in the cluster, but it is *more* important to consider the number of files per segment and the total number of files on a node.

Example with 64GB Memory per Node

- Number of nodes: 16
- Number of segments per node: 8
- Average number of files per segment: 10,000

The total number of files per node is  $8 * 10,000 = 80,000$  and the total number of files for the cluster is  $8 * 16 * 10,000 = 1,280,000$ . The number of files increases quickly as the number of partitions and the number of columns increase.

As a general best practice, limit the total number of files per node to under 100,000. As the previous example shows, the optimal number of files per segment and total number of files per node depends on the hardware configuration for the nodes (primarily memory), size of the cluster, SQL access, concurrency, workload and skew.

## Indexes

Indexes are not generally needed in Greenplum Database. Most analytical queries operate on large volumes of data, while indexes are intended for locating single rows or small numbers of rows of data. In Greenplum Database, a sequential scan is an efficient method to read data as each segment contains an equal portion of the data and all segments work in parallel to read the data.

If adding an index does not produce performance gains, drop it. Verify that every index you create is used by the optimizer.

For queries with high selectivity, indexes may improve query performance. Create an index on a single column of a columnar table for drill through purposes for high cardinality columns that are required for highly selective queries.

Do not index columns that are frequently updated. Creating an index on a column that is frequently updated increases the number of writes required on updates.

Indexes on expressions should be used only if the expression is used frequently in queries.

An index with a predicate creates a partial index that can be used to select a small number of rows from large tables.

Avoid overlapping indexes. Indexes that have the same leading column are redundant.

Indexes can improve performance on compressed append-optimized tables for queries that return a targeted set of rows. For compressed data, an index access method means only the necessary pages are uncompressed.

Create selective B-tree indexes. Index selectivity is a ratio of the number of distinct values a column has divided by the number of rows in a table. For example, if a table has 1000 rows and a column has 800 distinct values, the selectivity of the index is 0.8, which is considered good.

As a general rule, drop indexes before loading data into a table. The load will run an order of magnitude faster than loading data into a table with indexes. After the load, re-create the indexes.

Bitmap indexes are suited for querying and not updating. Bitmap indexes perform best when the column has a low cardinality—100 to 100,000 distinct values. Do not use bitmap indexes for unique columns, very high, or very low cardinality data. Do not use bitmap indexes for transactional workloads.

If indexes are needed on partitioned tables, the index columns must be different than the partition columns. A benefit of indexing partitioned tables is that because the b-tree performance degrades exponentially as the size of the b-tree grows, creating indexes on partitioned tables creates smaller b-trees that perform better than with non-partitioned tables.

## Column Sequence and Byte Alignment

For optimum performance lay out the columns of a table to achieve data type byte alignment. Lay out the columns in heap tables in the following order:

1. Distribution and partition columns
2. Fixed numeric types
3. Variable data types

Lay out the data types from largest to smallest, so that `BIGINT` and `TIMESTAMP` come before `INT` and `DATE`, and all of these types come before `TEXT`, `VARCHAR`, or `NUMERIC(x, y)`. For example, 8-byte

types first (`BIGINT`, `TIMESTAMP`), 4-byte types next (`INT`, `DATE`), 2-byte types next (`SMALLINT`), and variable data type last (`VARCHAR`).

Instead of defining columns in this sequence:

```
Int, Bigint, Timestamp, Bigint, Timestamp, Int (distribution key), Date (partition key), Bigint, Smallint
```

define the columns in this sequence:

```
Int (distribution key), Date (partition key), Bigint, Bigint, Timestamp, Bigint, Timestamp, Int, Smallint
```

## Memory and Resource Management with Resource Groups

Managing Greenplum Database resources with resource groups.

Memory, CPU, and concurrent transaction management have a significant impact on performance in a Greenplum Database cluster. Resource groups are a newer resource management scheme that enforce memory, CPU, and concurrent transaction limits in Greenplum Database.

- [Configuring Memory for Greenplum Database](#)
- [Memory Considerations when using Resource Groups](#)
- [Configuring Resource Groups](#)
- [Low Memory Queries](#)
- [Administrative Utilities and admin\\_group Concurrency](#)

## Configuring Memory for Greenplum Database

While it is not always possible to increase system memory, you can avoid many out-of-memory conditions by configuring resource groups to manage expected workloads.

The following operating system and Greenplum Database memory settings are significant when you manage Greenplum Database resources with resource groups:

- **vm.overcommit\_memory**

This Linux kernel parameter, set in `/etc/sysctl.conf`, identifies the method that the operating system uses to determine how much memory can be allocated to processes. `vm.overcommit_memory` must always be set to 2 for Greenplum Database systems.

- **vm.overcommit\_ratio**

This Linux kernel parameter, set in `/etc/sysctl.conf`, identifies the percentage of RAM that is used for application processes; the remainder is reserved for the operating system. Tune the setting as necessary. If your memory utilization is too low, increase the value; if your memory or swap usage is too high, decrease the setting.

- **gp\_resource\_group\_memory\_limit**

The percentage of system memory to allocate to Greenplum Database. The default value is `.7` (70%).

- **gp\_resource\_group\_enable\_recalculate\_query\_mem**

By default, Greenplum Database calculates the maximum per-query memory allotment for all hosts using the memory configuration of, and the number of primary segments configured on, the master host.

**Note:** The default behavior may lead to out of memory issues and underutilization of resources when the hardware configuration of the master and segment hosts differ.

If the hardware configuration of your master and segment hosts differ, set the `gp_resource_group_enable_recalculate_query_mem` server configuration parameter to `true`; this prompts Greenplum Database to recalculate the maximum per-query memory allotment on each segment host based on the memory and the number of primary segments configured on that segment host.

- **gp\_workfile\_limit\_files\_per\_query**

Set `gp_workfile_limit_files_per_query` to limit the maximum number of temporary spill files (workfiles) allowed per query. Spill files are created when a query requires more memory than it is allocated. When the limit is exceeded the query is terminated. The default is zero, which allows an unlimited number of spill files and may fill up the file system.

- **gp\_workfile\_compression**

If there are numerous spill files then set `gp_workfile_compression` to compress the spill files. Compressing spill files may help to avoid overloading the disk subsystem with IO operations.

- **memory\_spill\_ratio**

Set `memory_spill_ratio` to increase or decrease the amount of query operator memory Greenplum Database allots to a query. When `memory_spill_ratio` is larger than 0, it represents the percentage of resource group memory to allot to query operators. If concurrency is high, this memory amount may be small even when `memory_spill_ratio` is set to the max value of 100. When you set `memory_spill_ratio` to 0, Greenplum Database uses the `statement_mem` setting to determine the initial amount of query operator memory to allot.

- **statement\_mem**

When `memory_spill_ratio` is 0, Greenplum Database uses the `statement_mem` setting to determine the amount of memory to allocate to a query.

Other considerations:

- Do not configure the operating system to use huge pages. See the [Recommended OS Parameters Settings](#) in the *Greenplum Installation Guide*.
- When you configure resource group memory, consider memory requirements for mirror segments that become primary segments during a failure to ensure that database operations can continue when primary segments or segment hosts fail.

## Memory Considerations when using Resource Groups

Available memory for resource groups may be limited on systems that use low or no swap space, and that use the default `vm.overcommit_ratio` and `gp_resource_group_memory_limit` settings. To

ensure that Greenplum Database has a reasonable per-segment-host memory limit, you may be required to increase one or more of the following configuration settings:

1. The swap size on the system.
2. The system's `vm.overcommit_ratio` setting.
3. The resource group `gp_resource_group_memory_limit` setting.

## Configuring Resource Groups

Greenplum Database resource groups provide a powerful mechanism for managing the workload of the cluster. Consider these general guidelines when you configure resource groups for your system:

- A transaction submitted by any Greenplum Database role with `SUPERUSER` privileges runs under the default resource group named `admin_group`. Keep this in mind when scheduling and running Greenplum administration utilities.
- Ensure that you assign each non-admin role a resource group. If you do not assign a resource group to a role, queries submitted by the role are handled by the default resource group named `default_group`.
- Use the `CONCURRENCY` resource group parameter to limit the number of active queries that members of a particular resource group can run concurrently.
- Use the `MEMORY_LIMIT` and `MEMORY_SPILL_RATIO` parameters to control the maximum amount of memory that queries running in the resource group can consume.
- Greenplum Database assigns unreserved memory ( $100 - (\text{sum of all resource group } \text{MEMORY\_LIMITS})$ ) to a global shared memory pool. This memory is available to all queries on a first-come, first-served basis.
- Alter resource groups dynamically to match the real requirements of the group for the workload and the time of day.
- Use the `gp_toolkit` views to examine resource group resource usage and to monitor how the groups are working.
- Consider using Tanzu Greenplum Command Center to create and manage resource groups, and to define the criteria under which Command Center dynamically assigns a transaction to a resource group.

## Low Memory Queries

A low `statement_mem` setting (for example, in the 10MB range) has been shown to increase the performance of queries with low memory requirements. Use the `memory_spill_ratio` and `statement_mem` server configuration parameters to override the setting on a per-query basis. For example:

```
SET memory_spill_ratio=0;
SET statement_mem='10 MB';
```

## Administrative Utilities and `admin_group` Concurrency

The default resource group for database transactions initiated by Greenplum Database `SUPERUSERS` is the group named `admin_group`. The default `CONCURRENCY` value for the `admin_group` resource group is 10.

Certain Greenplum Database administrative utilities may use more than one `CONCURRENCY` slot at runtime, such as `gpbackup` that you invoke with the `--jobs` option. If the utility(s) you run require more concurrent transactions than that configured for `admin_group`, consider temporarily increasing the group's `MEMORY_LIMIT` and `CONCURRENCY` values to meet the utility's requirement, making sure to return these parameters back to their original settings when the utility completes.

**Note:** Memory allocation changes that you initiate with `ALTER RESOURCE GROUP` may not take effect immediately due to resource consumption by currently running queries. Be sure to alter resource group parameters in advance of your maintenance window.

**Parent topic:** [Greenplum Database Best Practices](#)

## Memory and Resource Management with Resource Queues

Avoid memory errors and manage Greenplum Database resources.

**Note:** Resource groups are a newer resource management scheme that enforces memory, CPU, and concurrent transaction limits in Greenplum Database. The [Managing Resources](#) topic provides a comparison of the resource queue and the resource group management schemes. Refer to [Using Resource Groups](#) for configuration and usage information for this resource management scheme.

Memory management has a significant impact on performance in a Greenplum Database cluster. The default settings are suitable for most environments. Do not change the default settings until you understand the memory characteristics and usage on your system.

- [Resolving Out of Memory Errors](#)
- [Low Memory Queries](#)
- [Configuring Memory for Greenplum Database](#)
- [Configuring Resource Queues](#)

## Resolving Out of Memory Errors

An out of memory error message identifies the Greenplum segment, host, and process that experienced the out of memory error. For example:

```
Out of memory (seg27 host.example.com pid=47093)
VM Protect failed to allocate 4096 bytes, 0 MB available
```

Some common causes of out-of-memory conditions in Greenplum Database are:

- Insufficient system memory (RAM) available on the cluster
- Improperly configured memory parameters
- Data skew at the segment level
- Operational skew at the query level

Following are possible solutions to out of memory conditions:

- Tune the query to require less memory
- Reduce query concurrency using a resource queue
- Validate the `gp_vmem_protect_limit` configuration parameter at the database level. See calculations for the maximum safe setting in [Configuring Memory for Greenplum Database](#).
- Set the memory quota on a resource queue to limit the memory used by queries run within the resource queue
- Use a session setting to reduce the `statement_mem` used by specific queries
- Decrease `statement_mem` at the database level
- Decrease the number of segments per host in the Greenplum Database cluster. This solution requires a re-initializing Greenplum Database and reloading your data.
- Increase memory on the host, if possible. (Additional hardware may be required.)

Adding segment hosts to the cluster will not in itself alleviate out of memory problems. The memory used by each query is determined by the `statement_mem` parameter and it is set when the query is invoked. However, if adding more hosts allows decreasing the number of segments per host, then the amount of memory allocated in `gp_vmem_protect_limit` can be raised.

## Low Memory Queries

A low `statement_mem` setting (for example, in the 1-3MB range) has been shown to increase the performance of queries with low memory requirements. Use the `statement_mem` server configuration parameter to override the setting on a per-query basis. For example:

```
SET statement_mem='2MB';
```

## Configuring Memory for Greenplum Database

Most out of memory conditions can be avoided if memory is thoughtfully managed.

It is not always possible to increase system memory, but you can prevent out-of-memory conditions by configuring memory use correctly and setting up resource queues to manage expected workloads.

It is important to include memory requirements for mirror segments that become primary segments during a failure to ensure that the cluster can continue when primary segments or segment hosts fail.

The following are recommended operating system and Greenplum Database memory settings:

- Do not configure the OS to use huge pages.
- **vm.overcommit\_memory**

This is a Linux kernel parameter, set in `/etc/sysctl.conf` and it should always be set to 2. It determines the method the OS uses for determining how much memory can be allocated to processes and 2 is the only safe setting for Greenplum Database. Please review the `sysctl` parameters in the [Greenplum Database Installation Guide](#).

- **vm.overcommit\_ratio**

This is a Linux kernel parameter, set in `/etc/sysctl.conf`. It is the percentage of RAM that is used for application processes. The remainder is reserved for the operating system. The default on Red Hat is 50.

Setting `vm.overcommit_ratio` too high may result in not enough memory being reserved for the operating system, which can result in segment host failure or database failure. Setting the value too low reduces the amount of concurrency and query complexity that can be run by reducing the amount of memory available to Greenplum Database. When increasing the setting it is important to remember to always reserve some memory for operating system activities.

See [Greenplum Database Memory Overview](#) for instructions to calculate a value for `vm.overcommit_ratio`.

- **gp\_vmem\_protect\_limit**

Use `gp_vmem_protect_limit` to set the maximum memory that the instance can allocate for *all* work being done in each segment database. Never set this value larger than the physical RAM on the system. If `gp_vmem_protect_limit` is too high, it is possible for memory to become exhausted on the system and normal operations may fail, causing segment failures. If `gp_vmem_protect_limit` is set to a safe lower value, true memory exhaustion on the system is prevented; queries may fail for hitting the limit, but system disruption and segment failures are avoided, which is the desired behavior.

See [Resource Queue Segment Memory Configuration](#) for instructions to calculate a safe value for `gp_vmem_protect_limit`.

- **runaway\_detector\_activation\_percent**

Runaway Query Termination, introduced in Greenplum Database 4.3.4, prevents out of memory conditions. The `runaway_detector_activation_percent` system parameter controls the percentage of `gp_vmem_protect_limit` memory utilized that triggers termination of queries. It is set on by default at 90%. If the percentage of `gp_vmem_protect_limit` memory that is utilized for a segment exceeds the specified value, Greenplum Database terminates queries based on memory usage, beginning with the query consuming the largest amount of memory. Queries are terminated until the utilized percentage of `gp_vmem_protect_limit` is below the specified percentage.

- **statement\_mem**

Use `statement_mem` to allocate memory used for a query per segment database. If additional memory is required it will spill to disk. Set the optimal value for `statement_mem` as follows:

```
(vmprotect * .9) / max_expected_concurrent_queries
```

The default value of `statement_mem` is 125MB. For example, on a system that is configured with 8 segments per host, a query uses 1GB of memory on each segment server (8 segments \* 125MB) with the default `statement_mem` setting. Set `statement_mem` at the session level for specific queries that require additional memory to complete. This setting works well to manage query memory on clusters with low concurrency. For clusters with high concurrency also use resource queues to provide additional control on what and how much is running on the system.

- **gp\_workfile\_limit\_files\_per\_query**

Set `gp_workfile_limit_files_per_query` to limit the maximum number of temporary spill files (workfiles) allowed per query. Spill files are created when a query requires more memory than it is allocated. When the limit is exceeded the query is terminated. The default is zero, which allows an unlimited number of spill files and may fill up the file system.

- **gp\_workfile\_compression**

If there are numerous spill files then set `gp_workfile_compression` to compress the spill files. Compressing spill files may help to avoid overloading the disk subsystem with IO operations.

## Configuring Resource Queues

Greenplum Database resource queues provide a powerful mechanism for managing the workload of the cluster. Queues can be used to limit both the numbers of active queries and the amount of memory that can be used by queries in the queue. When a query is submitted to Greenplum Database, it is added to a resource queue, which determines if the query should be accepted and when the resources are available to run it.

- Associate all roles with an administrator-defined resource queue.

Each login user (role) is associated with a single resource queue; any query the user submits is handled by the associated resource queue. If a queue is not explicitly assigned the user's queries are handed by the default queue, `pg_default`.

- Do not run queries with the `gpadmin` role or other superuser roles.

Superusers are exempt from resource queue limits, therefore superuser queries always run regardless of the limits set on their assigned queue.

- Use the `ACTIVE_STATEMENTS` resource queue parameter to limit the number of active queries that members of a particular queue can run concurrently.
- Use the `MEMORY_LIMIT` parameter to control the total amount of memory that queries running through the queue can utilize. By combining the `ACTIVE_STATEMENTS` and `MEMORY_LIMIT` attributes an administrator can fully control the activity emitted from a given resource queue.

The allocation works as follows: Suppose a resource queue, `sample_queue`, has `ACTIVE_STATEMENTS` set to 10 and `MEMORY_LIMIT` set to 2000MB. This limits the queue to approximately 2 gigabytes of memory per segment. For a cluster with 8 segments per server, the total usage per server is 16 GB for `sample_queue` (2GB \* 8 segments/server). If a segment server has 64GB of RAM, there could be no more than four of this type of resource queue on the system before there is a chance of running out of memory (4 queues \* 16GB per queue).

Note that by using `STATEMENT_MEM`, individual queries running in the queue can allocate more than their "share" of memory, thus reducing the memory available for other queries in the queue.

- Resource queue priorities can be used to align workloads with desired outcomes. Queues with `MAX` priority throttle activity in all other queues until the `MAX` queue completes running

all queries.

- Alter resource queues dynamically to match the real requirements of the queue for the workload and time of day. You can script an operational flow that changes based on the time of day and type of usage of the system and add `crontab` entries to run the scripts.
- Use `gptoolkit` to view resource queue usage and to understand how the queues are working.

## System Monitoring and Maintenance

Best practices for regular maintenance that will ensure Greenplum Database high availability and optimal performance.

- [Updating Statistics with ANALYZE](#)
- [Managing Bloat in a Database](#)
- [Monitoring Greenplum Database Log Files](#)

Parent topic: [Greenplum Database Best Practices](#)

## Monitoring

Greenplum Database includes utilities that are useful for monitoring the system.

The `gp_toolkit` schema contains several views that can be accessed using SQL commands to query system catalogs, log files, and operating environment for system status information.

The `gp_stats_missing` view shows tables that do not have statistics and require `ANALYZE` to be run.

For additional information on `gpstate` and `gpcheckperf` refer to the *Greenplum Database Utility Guide*. For information about the `gp_toolkit` schema, see the *Greenplum Database Reference Guide*.

### gpstate

The `gpstate` utility program displays the status of the Greenplum system, including which segments are down, master and segment configuration information (hosts, data directories, etc.), the ports used by the system, and mapping of primary segments to their corresponding mirror segments.

Run `gpstate -Q` to get a list of segments that are marked "down" in the master system catalog.

To get detailed status information for the Greenplum system, run `gpstate -s`.

### gpcheckperf

The `gpcheckperf` utility tests baseline hardware performance for a list of hosts. The results can help identify hardware issues. It performs the following checks:

- disk I/O test – measures I/O performance by writing and reading a large file using the `dd` operating system command. It reports read and write rates in megabytes per second.
- memory bandwidth test – measures sustainable memory bandwidth in megabytes per second using the STREAM benchmark.

- network performance test – runs the `gpnetbench` network benchmark program (optionally `netperf`) to test network performance. The test is run in one of three modes: parallel pair test (`-r N`), serial pair test (`-r n`), or full-matrix test (`-r M`). The minimum, maximum, average, and median transfer rates are reported in megabytes per second.

To obtain valid numbers from `gpcheckperf`, the database system must be stopped. The numbers from `gpcheckperf` can be inaccurate even if the system is up and running with no query activity.

`gpcheckperf` requires a trusted host setup between the hosts involved in the performance test. It calls `gpssh` and `gpscp`, so these utilities must also be in your `PATH`. Specify the hosts to check individually (`-h *host1* -h *host2* ...`) or with `-f *hosts_file*`, where `*hosts_file*` is a text file containing a list of the hosts to check. If you have more than one subnet, create a separate host file for each subnet so that you can test the subnets separately.

By default, `gpcheckperf` runs the disk I/O test, the memory test, and a serial pair network performance test. With the disk I/O test, you must use the `-d` option to specify the file systems you want to test. The following command tests disk I/O and memory bandwidth on hosts listed in the `subnet_1_hosts` file:

```
$ gpcheckperf -f subnet_1_hosts -d /data1 -d /data2 -r ds
```

The `-r` option selects the tests to run: disk I/O (`d`), memory bandwidth (`s`), network parallel pair (`N`), network serial pair test (`n`), network full-matrix test (`M`). Only one network mode can be selected per execution. See the *Greenplum Database Reference Guide* for the detailed `gpcheckperf` reference.

## Monitoring with Operating System Utilities

The following Linux/UNIX utilities can be used to assess host performance:

- `iostat` allows you to monitor disk activity on segment hosts.
- `top` displays a dynamic view of operating system processes.
- `vmstat` displays memory usage statistics.

You can use `gpssh` to run utilities on multiple hosts.

## Best Practices

- Implement the "Recommended Monitoring and Maintenance Tasks" in the *Greenplum Database Administrator Guide*.
- Run `gpcheckperf` at install time and periodically thereafter, saving the output to compare system performance over time.
- Use all the tools at your disposal to understand how your system behaves under different loads.
- Examine any unusual event to determine the cause.
- Monitor query activity on the system by running explain plans periodically to ensure the queries are running optimally.
- Review plans to determine whether index are being used and partition elimination is occurring as expected.

## Additional Information

- [gpcheckperf](#) reference in the *Greenplum Database Utility Guide*.
- "Recommended Monitoring and Maintenance Tasks" in the *Greenplum Database Administrator Guide*.
- [Sustainable Memory Bandwidth in Current High Performance Computers](#). John D. McCalpin. Oct 12, 1995.
- [www.netperf.org](http://www.netperf.org) to use [netperf](#), netperf must be installed on each host you test. See [gpcheckperf](#) reference for more information.

## Updating Statistics with ANALYZE

The most important prerequisite for good query performance is to begin with accurate statistics for the tables. Updating statistics with the [ANALYZE](#) statement enables the query planner to generate optimal query plans. When a table is analyzed, information about the data is stored in the system catalog tables. If the stored information is out of date, the planner can generate inefficient plans.

## Generating Statistics Selectively

Running [ANALYZE](#) with no arguments updates statistics for all tables in the database. This can be a very long-running process and it is not recommended. You should [ANALYZE](#) tables selectively when data has changed or use the [analyzedb](#) utility.

Running [ANALYZE](#) on a large table can take a long time. If it is not feasible to run [ANALYZE](#) on all columns of a very large table, you can generate statistics for selected columns only using [ANALYZE table\(column, ...\)](#). Be sure to include columns used in joins, [WHERE](#) clauses, [SORT](#) clauses, [GROUP BY](#) clauses, or [HAVING](#) clauses.

For a partitioned table, you can run [ANALYZE](#) on just partitions that have changed, for example, if you add a new partition. Note that for partitioned tables, you can run [ANALYZE](#) on the parent (main) table, or on the leaf nodes—the partition files where data and statistics are actually stored. The intermediate files for sub-partitioned tables store no data or statistics, so running [ANALYZE](#) on them does not work. You can find the names of the partition tables in the [pg\\_partitions](#) system catalog:

```
SELECT partitiontablename from pg_partitions WHERE tablename='parent_table';
```

## Improving Statistics Quality

There is a trade-off between the amount of time it takes to generate statistics and the quality, or accuracy, of the statistics.

To allow large tables to be analyzed in a reasonable amount of time, [ANALYZE](#) takes a random sample of the table contents, rather than examining every row. To increase the number of sample values for all table columns adjust the [default\\_statistics\\_target](#) configuration parameter. The target value ranges from 1 to 1000; the default target value is 100. The [default\\_statistics\\_target](#) variable applies to all columns by default, and specifies the number of values that are stored in the list of common values. A larger target may improve the quality of the query planner's estimates,

especially for columns with irregular data patterns. `default_statistics_target` can be set at the master/session level and requires a reload.

## When to Run ANALYZE

Run `ANALYZE`:

- after loading data,
- after `CREATE INDEX` operations,
- and after `INSERT`, `UPDATE`, and `DELETE` operations that significantly change the underlying data.

`ANALYZE` requires only a read lock on the table, so it may be run in parallel with other database activity, but do not run `ANALYZE` while performing loads, `INSERT`, `UPDATE`, `DELETE`, and `CREATE INDEX` operations.

## Configuring Automatic Statistics Collection

The `gp_autostats_mode` configuration parameter, together with the `gp_autostats_on_change_threshold` parameter, determines when an automatic analyze operation is triggered. When automatic statistics collection is triggered, the planner adds an `ANALYZE` step to the query.

By default, `gp_autostats_mode` is `on_no_stats`, which triggers statistics collection for `CREATE TABLE AS SELECT`, `INSERT`, or `COPY` operations invoked by the table owner on any table that has no existing statistics.

Setting `gp_autostats_mode` to `on_change` triggers statistics collection only when the number of rows affected exceeds the threshold defined by `gp_autostats_on_change_threshold`, which has a default value of 2147483647. The following operations invoked on a table by its owner can trigger automatic statistics collection with `on_change`: `CREATE TABLE AS SELECT`, `UPDATE`, `DELETE`, `INSERT`, and `COPY`.

Setting the `gp_autostats_allow_nonowner` server configuration parameter to `true` also instructs Greenplum Database to trigger automatic statistics collection on a table when:

- `gp_autostats_mode=on_change` and the table is modified by a non-owner.
- `gp_autostats_mode=on_no_stats` and the first user to `INSERT` or `COPY` into the table is a non-owner.

Setting `gp_autostats_mode` to `none` deactivates automatics statistics collection.

For partitioned tables, automatic statistics collection is not triggered if data is inserted from the top-level parent table of a partitioned table. But automatic statistics collection *is* triggered if data is inserted directly in a leaf table (where the data is stored) of the partitioned table.

**Parent topic:** [System Monitoring and Maintenance](#)

## Managing Bloat in a Database

Database bloat occurs in heap tables, append-optimized tables, indexes, and system catalogs and affects database performance and disk usage. You can detect database bloat and remove it from the database.

- [About Bloat](#)
- [Detecting Bloat](#)
- [Removing Bloat from Database Tables](#)
- [Removing Bloat from Append-Optimized Tables](#)
- [Removing Bloat from Indexes](#)
- [Removing Bloat from System Catalogs](#)

## About Bloat

Database bloat is disk space that was used by a table or index and is available for reuse by the database but has not been reclaimed. Bloat is created when updating tables or indexes.

Because Greenplum Database heap tables use the PostgreSQL Multiversion Concurrency Control (MVCC) storage implementation, a deleted or updated row is logically deleted from the database, but a non-visible image of the row remains in the table. These deleted rows, also called expired rows, are tracked in a free space map. Running `VACUUM` marks the expired rows as free space that is available for reuse by subsequent inserts.

It is normal for tables that have frequent updates to have a small or moderate amount of expired rows and free space that will be reused as new data is added. But when the table is allowed to grow so large that active data occupies just a small fraction of the space, the table has become significantly bloated. Bloated tables require more disk storage and additional I/O that can slow down query execution.

### Important:

It is very important to run `VACUUM` on individual tables after large `UPDATE` and `DELETE` operations to avoid the necessity of ever running `VACUUM FULL`.

Running the `VACUUM` command regularly on tables prevents them from growing too large. If the table does become significantly bloated, the `VACUUM FULL` command must be used to compact the table data.

If the free space map is not large enough to accommodate all of the expired rows, the `VACUUM` command is unable to reclaim space for expired rows that overflowed the free space map. The disk space may only be recovered by running `VACUUM FULL`, which locks the table, creates a new table, copies the table data to the new table, and then drops old table. This is an expensive operation that can take an exceptional amount of time to complete with a large table.

**Warning:** `VACUUM FULL` acquires an `ACCESS EXCLUSIVE` lock on tables. You should not run `VACUUM FULL`. If you run `VACUUM FULL` on tables, run it during a time when users and applications do not require access to the tables, such as during a time of low activity, or during a maintenance window.

## Detecting Bloat

The statistics collected by the `ANALYZE` statement can be used to calculate the expected number of disk pages required to store a table. The difference between the expected number of pages and the actual number of pages is a measure of bloat. The `gp_toolkit` schema provides the `gp_bloat_diag` view that identifies table bloat by comparing the ratio of expected to actual pages. To use it, make sure statistics are up to date for all of the tables in the database, then run the following SQL:

```
gpadmin=# SELECT * FROM gp_toolkit.gp_bloat_diag;
 bdirelid | bdinspname | bdirelname | bdirelpages | bdiexppages |          bddi
ag
-----+-----+-----+-----+-----+-----
          21488 | public      | t1         |          97 |             1 | significant amount o
f bloat suspected
(1 row)
```

The results include only tables with moderate or significant bloat. Moderate bloat is reported when the ratio of actual to expected pages is greater than four and less than ten. Significant bloat is reported when the ratio is greater than ten.

The `gp_toolkit.gp_bloat_expected_pages` view lists the actual number of used pages and expected number of used pages for each database object.

```
gpadmin=# SELECT * FROM gp_toolkit.gp_bloat_expected_pages LIMIT 5;
 btdrelid | btdrelpages | btdexppages
-----+-----+-----
    10789 |             1 |             1
    10794 |             1 |             1
    10799 |             1 |             1
     5004 |             1 |             1
     7175 |             1 |             1
(5 rows)
```

The `btdrelid` is the object ID of the table. The `btdrelpages` column reports the number of pages the table uses; the `btdexppages` column is the number of pages expected. Again, the numbers reported are based on the table statistics, so be sure to run `ANALYZE` on tables that have changed.

## Removing Bloat from Database Tables

The `VACUUM` command adds expired rows to the free space map so that the space can be reused. When `VACUUM` is run regularly on a table that is frequently updated, the space occupied by the expired rows can be promptly reused, preventing the table file from growing larger. It is also important to run `VACUUM` before the free space map is filled. For heavily updated tables, you may need to run `VACUUM` at least once a day to prevent the table from becoming bloated.

**Warning:** When a table is significantly bloated, it is better to run `VACUUM` before running `ANALYZE`. Analyzing a severely bloated table can generate poor statistics if the sample contains empty pages, so it is good practice to vacuum a bloated table before analyzing it.

When a table accumulates significant bloat, running the `VACUUM` command is insufficient. For small tables, running `VACUUM FULL <table_name>` can reclaim space used by rows that overflowed the free space map and reduce the size of the table file. However, a `VACUUM FULL` statement is an expensive operation that requires an `ACCESS EXCLUSIVE` lock and may take an exceptionally long and

unpredictable amount of time to finish for large tables. You should run `VACUUM FULL` on tables during a time when users and applications do not require access to the tables being vacuumed, such as during a time of low activity, or during a maintenance window.

## Removing Bloat from Append-Optimized Tables

Append-optimized tables are handled much differently than heap tables. Although append-optimized tables allow update, insert, and delete operations, these operations are not optimized and are not recommended with append-optimized tables. If you heed this advice and use append-optimized for *load-once/read-many* workloads, `VACUUM` on an append-optimized table runs almost instantaneously.

If you do run `UPDATE` or `DELETE` commands on an append-optimized table, expired rows are tracked in an auxiliary bitmap instead of the free space map. `VACUUM` is the only way to recover the space. Running `VACUUM` on an append-optimized table with expired rows compacts a table by rewriting the entire table without the expired rows. However, no action is performed if the percentage of expired rows in the table exceeds the value of the `gp_appendonly_compaction_threshold` configuration parameter, which is 10 (10%) by default. The threshold is checked on each segment, so it is possible that a `VACUUM` statement will compact an append-only table on some segments and not others. Compacting append-only tables can be deactivated by setting the `gp_appendonly_compaction` parameter to `no`.

## Removing Bloat from Indexes

The `VACUUM` command only recovers space from tables. To recover the space from indexes, recreate them using the `REINDEX` command.

To rebuild all indexes on a table run `REINDEX *table_name*`. To rebuild a particular index, run `REINDEX *index_name*`. `REINDEX` sets the `reltuples` and `relpages` to 0 (zero) for the index, To update those statistics, run `ANALYZE` on the table after reindexing.

## Removing Bloat from System Catalogs

Greenplum Database system catalog tables are heap tables and can become bloated over time. As database objects are created, altered, or dropped, expired rows are left in the system catalogs.

Using `gpload` to load data contributes to the bloat since `gpload` creates and drops external tables. (Rather than use `gpload`, it is recommended to use `gpfdist` to load data.)

Bloat in the system catalogs increases the time require to scan the tables, for example, when creating explain plans. System catalogs are scanned frequently and if they become bloated, overall system performance is degraded.

It is recommended to run `VACUUM` on system catalog tables nightly and at least weekly. At the same time, running `REINDEX SYSTEM` on system catalog tables removes bloat from the indexes.

Alternatively, you can reindex system tables using the `reindexdb` utility with the `-s (--system)` option. After removing catalog bloat, run `ANALYZE` to update catalog table statistics.

These are Greenplum Database system catalog maintenance steps.

1. Perform a `REINDEX` on the system catalog tables to rebuild the system catalog indexes. This removes bloat in the indexes and improves `VACUUM` performance.

**Note:** When performing `REINDEX` on the system catalog tables, locking will occur on the tables and might have an impact on currently running queries. You can schedule the `REINDEX` operation during a period of low activity to avoid disrupting ongoing business operations.

2. Perform a `VACUUM` on system catalog tables.
3. Perform an `ANALYZE` on the system catalog tables to update the table statistics.

If you are performing system catalog maintenance during a maintenance period and you need to stop a process due to time constraints, run the Greenplum Database function `pg_cancel_backend(<PID>)` to safely stop a Greenplum Database process.

The following script runs `REINDEX`, `VACUUM`, and `ANALYZE` on the system catalogs.

```
#!/bin/bash
DBNAME="<database_name>"
SYSTABLES="' pg_catalog.' || relname || ';' from pg_class a, pg_namespace b \
where a.relnamespace=b.oid and b.nspname='pg_catalog' and a.relkind='r'"

reindexdb -s -d $DBNAME
psql -tc "SELECT 'VACUUM' || $SYSTABLES" $DBNAME | psql -a $DBNAME
analyzedb -a -s pg_catalog -d $DBNAME
```

If the system catalogs become significantly bloated, you must run `VACUUM FULL` during a scheduled downtime period. During this period, stop all catalog activity on the system; `VACUUM FULL` takes `ACCESS EXCLUSIVE` locks against the system catalog. Running `VACUUM` regularly on system catalog tables can prevent the need for this more costly procedure.

These are steps for intensive system catalog maintenance.

1. Stop all catalog activity on the Greenplum Database system.
2. Perform a `VACUUM FULL` on the system catalog tables. See the following Note.
3. Perform an `ANALYZE` on the system catalog tables to update the catalog table statistics.

**Note:** The system catalog table `pg_attribute` is usually the largest catalog table. If the `pg_attribute` table is significantly bloated, a `VACUUM FULL` operation on the table might require a significant amount of time and might need to be performed separately. The presence of both of these conditions indicate a significantly bloated `pg_attribute` table that might require a long `VACUUM FULL` time:

- The `pg_attribute` table contains a large number of records.
- The diagnostic message for `pg_attribute` is `significant amount of bloat` in the `gp_toolkit.gp_bloat_diag` view.

**Parent topic:** [System Monitoring and Maintenance](#)

## Monitoring Greenplum Database Log Files

Know the location and content of system log files and monitor them on a regular basis and not just when problems arise.

The following table shows the locations of the various Greenplum Database log files. In file paths:

- `$GPADMIN_HOME` refers to the home directory of the `gpadmin` operating system user.
- `$MASTER_DATA_DIRECTORY` refers to the master data directory on the Greenplum Database master host.
- `$GPDATA_DIR` refers to a data directory on the Greenplum Database segment host.
- `host` identifies the Greenplum Database segment host name.
- `segprefix` identifies the segment prefix.
- `N` identifies the segment instance number.
- `date` is a date in the format `YYYYMMDD`.

| Path   | Description  |
|--|--|
| <code>\$GPADMIN_HOME/gpAdminLogs/*</code>  | Many different types of log files, directory on each server. <code>\$GPADMIN_HOME</code> is the default location for the <code>gpAdminLogs/</code> directory. You can specify a different location when you run an administrative utility command. |
| <code>\$GPADMIN_HOME/gpAdminLogs/gpinitsystem_date.log</code>  | system initialization log  |
| <code>\$GPADMIN_HOME/gpAdminLogs/gpsstart_date.log</code>  | start log  |
| <code>\$GPADMIN_HOME/gpAdminLogs/gpsstop_date.log</code>   | stop log   |
| <code>\$GPADMIN_HOME/gpAdminLogs/gpssegstart.py_host:gpadmin_date.log</code>                                   | segment host start log   |
| <code>\$GPADMIN_HOME/gpAdminLogs/gpssegstop.py_host:gpadmin_date.log</code>                                    | segment host stop log  |
| <code>\$MASTER_DATA_DIRECTORY/log/startup.log</code> ,<br><code>\$GPDATA_DIR/segprefixN/log/startup.log</code> | segment instance start log   |
| <code>\$MASTER_DATA_DIRECTORY/log/*.csv</code> ,<br><code>\$GPDATA_DIR/segprefixN/log/*.csv</code>             | master and segment database logs   |
| <code>\$GPDATA_DIR/mirror/segprefixN/log/*.csv</code>  | mirror segment database logs   |
| <code>\$GPDATA_DIR/primary/segprefixN/log/*.csv</code>   | primary segment database logs  |
| <code>/var/log/messages</code>   | Global Linux system messages   |

Use `gplogfilter -t (--trouble)` first to search the master log for messages beginning with `ERROR:`, `FATAL:`, or `PANIC:`. Messages beginning with `WARNING` may also provide useful information.

To search log files on the segment hosts, use the Greenplum `gplogfilter` utility with `gpssh` to connect to segment hosts from the master host. You can identify corresponding log entries in segment logs by the `statement_id`.

Greenplum Database can be configured to rotate database logs based on the size and/or age of the current log file. The `log_rotation_size` configuration parameter sets the size of an individual log file that triggers rotation. When the current log file size is equal to or greater than this size, the file is closed and a new log file is created. The `log_rotation_age` configuration parameter specifies the age of the current log file that triggers rotation. When the specified time has elapsed since the current log file was created, a new log file is created. The default `log_rotation_age`, 1d, creates a new log file 24 hours after the current log file was created.

**Parent topic:** [System Monitoring and Maintenance](#)

## Loading Data

Description of the different ways to add data to Greenplum Database.

**Parent topic:** [Greenplum Database Best Practices](#)

## INSERT Statement with Column Values

A singleton `INSERT` statement with values adds a single row to a table. The row flows through the master and is distributed to a segment. This is the slowest method and is not suitable for loading large amounts of data.

## COPY Statement

The PostgreSQL `COPY` statement copies data from an external file into a database table. It can insert multiple rows more efficiently than an `INSERT` statement, but the rows are still passed through the master. All of the data is copied in one command; it is not a parallel process.

Data input to the `COPY` command is from a file or the standard input. For example:

```
COPY table FROM '/data/mydata.csv' WITH CSV HEADER;
```

Use `COPY` to add relatively small sets of data, for example dimension tables with up to ten thousand rows, or one-time data loads.

Use `COPY` when scripting a process that loads small amounts of data, less than 10 thousand rows.

Since `COPY` is a single command, there is no need to deactivate autocommit when you use this method to populate a table.

You can run multiple concurrent `COPY` commands to improve performance.

## External Tables

External tables provide access to data in sources outside of Greenplum Database. They can be accessed with `SELECT` statements and are commonly used with the Extract, Load, Transform (ELT) pattern, a variant of the Extract, Transform, Load (ETL) pattern that takes advantage of Greenplum Database's fast parallel data loading capability.

With ETL, data is extracted from its source, transformed outside of the database using external transformation tools, such as Informatica or Datastage, and then loaded into the database.

With ELT, Greenplum external tables provide access to data in external sources, which could be read-only files (for example, text, CSV, or XML files), Web servers, Hadoop file systems, executable OS programs, or the Greenplum `gpfdist` file server, described in the next section. External tables support SQL operations such as select, sort, and join so the data can be loaded and transformed simultaneously, or loaded into a *load table* and transformed in the database into target tables.

The external table is defined with a `CREATE EXTERNAL TABLE` statement, which has a `LOCATION` clause to define the location of the data and a `FORMAT` clause to define the formatting of the source data so that the system can parse the input data. Files use the `file://` protocol, and must reside on a segment host in a location accessible by the Greenplum superuser. The data can be spread out among the segment hosts with no more than one file per primary segment on each host. The number of files listed in the `LOCATION` clause is the number of segments that will read the external table in parallel.

## External Tables with Gpfdist

The fastest way to load large fact tables is to use external tables with `gpfdist`. `gpfdist` is a file server program using an HTTP protocol that serves external data files to Greenplum Database segments in parallel. A `gpfdist` instance can serve 200 MB/second and many `gpfdist` processes can run simultaneously, each serving up a portion of the data to be loaded. When you begin the load using a statement such as `INSERT INTO <table> SELECT * FROM <external_table>`, the `INSERT` statement is parsed by the master and distributed to the primary segments. The segments connect to the `gpfdist` servers and retrieve the data in parallel, parse and validate the data, calculate a hash from the distribution key data and, based on the hash key, send the row to its destination segment. By default, each `gpfdist` instance will accept up to 64 connections from segments. With many segments and `gpfdist` servers participating in the load, data can be loaded at very high rates.

Primary segments access external files in parallel when using `gpfdist` up to the value of `gp_external_max_segs`. When optimizing `gpfdist` performance, maximize the parallelism as the number of segments increase. Spread the data evenly across as many ETL nodes as possible. Split very large data files into equal parts and spread the data across as many file systems as possible.

Run two `gpfdist` instances per file system. `gpfdist` tends to be CPU bound on the segment nodes when loading. But if, for example, there are eight racks of segment nodes, there is lot of available CPU on the segments to drive more `gpfdist` processes. Run `gpfdist` on as many interfaces as possible. Be aware of bonded NICs and be sure to start enough `gpfdist` instances to work them.

It is important to keep the work even across all these resources. The load is as fast as the slowest node. Skew in the load file layout will cause the overall load to bottleneck on that resource.

The `gp_external_max_segs` configuration parameter controls the number of segments each `gpfdist` process serves. The default is 64. You can set a different value in the `postgresql.conf` configuration file on the master. Always keep `gp_external_max_segs` and the number of `gpfdist` processes an even factor; that is, the `gp_external_max_segs` value should be a multiple of the number of `gpfdist` processes. For example, if there are 12 segments and 4 `gpfdist` processes, the planner round robins the segment connections as follows:

```
Segment 1 - gpfdist 1
Segment 2 - gpfdist 2
Segment 3 - gpfdist 3
Segment 4 - gpfdist 4
```

```
Segment 5 - gpfdist 1
Segment 6 - gpfdist 2
Segment 7 - gpfdist 3

```

Drop indexes before loading into existing tables and re-create the index after loading. Creating an index on pre-existing data is faster than updating it incrementally as each row is loaded.

Run `ANALYZE` on the table after loading. Deactivate automatic statistics collection during loading by setting `gp_autostats_mode` to `NONE`. Run `VACUUM` after load errors to recover space.

Performing small, high frequency data loads into heavily partitioned column-oriented tables can have a high impact on the system because of the number of physical files accessed per time interval.

## Gpload

`gpload` is a data loading utility that acts as an interface to the Greenplum external table parallel loading feature.

Beware of using `gpload` as it can cause catalog bloat by creating and dropping external tables. Use `gpfdist` instead, since it provides the best performance.

`gpload` runs a load using a specification defined in a YAML-formatted control file. It performs the following operations:

- Invokes `gpfdist` processes
- Creates a temporary external table definition based on the source data defined
- Runs an `INSERT`, `UPDATE`, or `MERGE` operation to load the source data into the target table in the database
- Drops the temporary external table
- Cleans up `gpfdist` processes

The load is accomplished in a single transaction.

## Best Practices

- Drop any indexes on an existing table before loading data and recreate the indexes after loading. Newly creating an index is faster than updating an index incrementally as each row is loaded.
- Deactivate automatic statistics collection during loading by setting the `gp_autostats_mode` configuration parameter to `NONE`.
- External tables are not intended for frequent or ad hoc access.
- When using `gpfdist`, maximize network bandwidth by running one `gpfdist` instance for each NIC on the ETL server. Divide the source data evenly between the `gpfdist` instances.

- When using `gpload`, run as many simultaneous `gpload` instances as resources allow. Take advantage of the CPU, memory, and networking resources available to increase the amount of data that can be transferred from ETL servers to the Greenplum Database.
- Use the `SEGMENT REJECT LIMIT` clause of the `COPY` statement to set a limit for the number or percentage of rows that can have errors before the `COPY FROM` command is cancelled. The reject limit is per segment; when any one segment exceeds the limit, the command is cancelled and no rows are added. Use the `LOG ERRORS` clause to save error rows. If a row has errors in the formatting—for example missing or extra values, or incorrect data types—Greenplum Database stores the error information and row internally. Use the `gp_read_error_log()` built-in SQL function to access this stored information.
- If the load has errors, run `VACUUM` on the table to recover space.
- After you load data into a table, run `VACUUM` on heap tables, including system catalogs, and `ANALYZE` on all tables. It is not necessary to run `VACUUM` on append-optimized tables. If the table is partitioned, you can vacuum and analyze just the partitions affected by the data load. These steps clean up any rows from prematurely ended loads, deletes, or updates and update statistics for the table.
- Recheck for segment skew in the table after loading a large amount of data. You can use a query like the following to check for skew:

```
SELECT gp_segment_id, count(*)
FROM schema.table
GROUP BY gp_segment_id ORDER BY 2;
```

- By default, `gpfdist` assumes a maximum record size of 32K. To load data records larger than 32K, you must increase the maximum row size parameter by specifying the `-m <*bytes*>` option on the `gpfdist` command line. If you use `gpload`, set the `MAX_LINE_LENGTH` parameter in the `gpload` control file.

**Note:** Integrations with Informatica Power Exchange are currently limited to the default 32K record length.

## Additional Information

See the *Greenplum Database Reference Guide* for detailed instructions for loading data using `gpfdist` and `gpload`.

# Identifying and Mitigating Heap Table Performance Issues

## Slow or Hanging Jobs

### Symptom:

The first scan of tuples after bulk data load, modification, or deletion jobs on heap tables are running slow or hanging.

### Potential Cause:

When a workload involves a bulk load, modification, or deletion of data in a heap table, the first scan post-operation may generate a large amount of WAL data when checksums are enabled

(`data_check_sums=true`) or hint bits are logged (`wal_log_hints=true`), leading to slow or hung jobs.

Affected workloads include: restoring from a backup, loading data with `gpccopy` or `COPY`, cluster expansion, `CTAS/INSERT/UPDATE/DELETE` operations, and `ALTER TABLE` operations that modify tuples.

### Explanation:

Greenplum Database uses hint bits to mark tuples as created and/or deleted by transactions. Hint bits, when set, can help in determining visibility of tuples without expensive `pg_clog` and `pg_subtrans` commit log lookups.

Hint bits are updated for every tuple on the first scan of the tuple after its creation or deletion. Because hint bits are checked and set on a per-tuple basis, even a read can result in heavy writes. When data checksums are enabled for heap tables (the default), hint bit updates are always WAL-logged.

### Solution:

If you have restored or loaded a complete database comprised primarily of heap tables, you may choose to run `VACUUM` against the entire database.

Alternatively, if you can identify the individual tables affected, you have two options:

1. Schedule and take a maintenance window and run `VACUUM` on the specific tables that have been loaded, updated, or deleted in bulk. This operation should scan all of the tuples and set and WAL-log the hint bits, taking the performance hit up-front.
2. Run `SELECT count(*) FROM <table-name>` on each table. This operation similarly scans all of the tuples and sets and WAL-logs the hint bits.

All subsequent scans as part of regular workloads on the tables should not be required to generate hints or their accompanying full page image WAL records.

## Security

Best practices to ensure the highest level of system security.

### Basic Security Best Practices

- Secure the `gpadmin` system user. Greenplum requires a UNIX user id to install and initialize the Greenplum Database system. This system user is referred to as `gpadmin` in the Greenplum documentation. The `gpadmin` user is the default database superuser in Greenplum Database, as well as the file system owner of the Greenplum installation and its underlying data files. The default administrator account is fundamental to the design of Greenplum Database. The system cannot run without it, and there is no way to limit the access of the `gpadmin` user id. This `gpadmin` user can bypass all security features of Greenplum Database. Anyone who logs on to a Greenplum host with this user id can read, alter, or delete any data, including system catalog data and database access rights. Therefore, it is very important to secure the `gpadmin` user id and only allow essential system administrators access to it. Administrators should only log in to Greenplum as `gpadmin` when performing certain system maintenance tasks (such as upgrade or expansion). Database users should never log on as `gpadmin`, and ETL or production workloads should never run as `gpadmin`.

- Assign a distinct role to each user who logs in. For logging and auditing purposes, each user who is allowed to log in to Greenplum Database should be given their own database role. For applications or web services, consider creating a distinct role for each application or service. See "Creating New Roles (Users)" in the *Greenplum Database Administrator Guide*.
- Use groups to manage access privileges. See "Creating Groups (Role Membership)" in the *Greenplum Database Administrator Guide*.
- Limit users who have the `SUPERUSER` role attribute. Roles that are superusers bypass all access privilege checks in Greenplum Database, as well as resource queuing. Only system administrators should be given superuser rights. See "Altering Role Attributes" in the *Greenplum Database Administrator Guide*.

## Password Strength Guidelines

To protect the network from intrusion, system administrators should verify the passwords used within an organization are strong ones. The following recommendations can strengthen a password:

- Minimum password length recommendation: At least 9 characters. MD5 passwords should be 15 characters or longer.
- Mix upper and lower case letters.
- Mix letters and numbers.
- Include non-alphanumeric characters.
- Pick a password you can remember.

The following are recommendations for password cracker software that you can use to determine the strength of a password.

- John The Ripper. A fast and flexible password cracking program. It allows the use of multiple word lists and is capable of brute-force password cracking. It is available online at <http://www.openwall.com/john/>.
- Crack. Perhaps the most well-known password cracking software, Crack is also very fast, though not as easy to use as John The Ripper. It can be found online at <http://www.crypticide.com/alecm/security/crack/c50-faq.html>.

The security of the entire system depends on the strength of the root password. This password should be at least 12 characters long and include a mix of capitalized letters, lowercase letters, special characters, and numbers. It should not be based on any dictionary word.

Password expiration parameters should be configured. The following commands must be run as `root` or using `sudo`.

Ensure the following line exists within the file `/etc/libuser.conf` under the `[import]` section.

```
login_defs = /etc/login.defs
```

Ensure no lines in the `[userdefaults]` section begin with the following text, as these words override settings from `/etc/login.defs`:

- `LU_SHADOWMAX`

- `LU_SHADOWMIN`
- `LU_SHADOWWARNING`

Ensure the following command produces no output. Any accounts listed by running this command should be locked.

```
grep "^+:" /etc/passwd /etc/shadow /etc/group
```

Note: We strongly recommend that customers change their passwords after initial setup.

```
cd /etc
chown root:root passwd shadow group gshadow
chmod 644 passwd group
chmod 400 shadow gshadow
```

Find all the files that are world-writable and that do not have their sticky bits set.

```
find / -xdev -type d \( -perm -0002 -a ! -perm -1000 \) -print
```

Set the sticky bit (`# chmod +t {dir}`) for all the directories that result from running the previous command.

Find all the files that are world-writable and fix each file listed.

```
find / -xdev -type f -perm -0002 -print
```

Set the right permissions (`# chmod o-w {file}`) for all the files generated by running the aforementioned command.

Find all the files that do not belong to a valid user or group and either assign an owner or remove the file, as appropriate.

```
find / -xdev \( -nouser -o -nogroup \) -print
```

Find all the directories that are world-writable and ensure they are owned by either root or a system account (assuming only system accounts have a User ID lower than 500). If the command generates any output, verify the assignment is correct or reassign it to root.

```
find / -xdev -type d -perm -0002 -uid +500 -print
```

Authentication settings such as password quality, password expiration policy, password reuse, password retry attempts, and more can be configured using the Pluggable Authentication Modules

(PAM) framework. PAM looks in the directory `/etc/pam.d` for application-specific configuration information. Running `authconfig` or `system-config-authentication` will re-write the PAM configuration files, destroying any manually made changes and replacing them with system defaults.

The default `pam_cracklib` PAM module provides strength checking for passwords. To configure `pam_cracklib` to require at least one uppercase character, lowercase character, digit, and special character, as recommended by the U.S. Department of Defense guidelines, edit the file `/etc/pam.d/system-auth` to include the following parameters in the line corresponding to password requisite `pam_cracklib.so try_first_pass`.

```
retry=3:
dcredit=-1. Require at least one digit
ucredit=-1. Require at least one upper case character
ocredit=-1. Require at least one special character
lcredit=-1. Require at least one lower case character
minlen=14. Require a minimum password length of 14.
```

For example:

```
password required pam_cracklib.so try_first_pass retry=3\minlen=14 dcredit=-1 ucredit=-1 ocredit=-1 lcredit=-1
```

These parameters can be set to reflect your security policy requirements. Note that the password restrictions are not applicable to the root password.

The `pam_tally2` PAM module provides the capability to lock out user accounts after a specified number of failed login attempts. To enforce password lockout, edit the file `/etc/pam.d/system-auth` to include the following lines:

- The first of the auth lines should include:

```
auth required pam_tally2.so deny=5 onerr=fail unlock_time=900
```

- The first of the account lines should include:

```
account required pam_tally2.so
```

Here, the `deny` parameter is set to limit the number of retries to 5 and the `unlock_time` has been set to 900 seconds to keep the account locked for 900 seconds before it is unlocked. These parameters may be configured appropriately to reflect your security policy requirements. A locked account can be manually unlocked using the `pam_tally2` utility:

```
/sbin/pam_tally2 --user {username} --reset
```

You can use PAM to limit the reuse of recent passwords. The `remember` option for the `pam_unix` module can be set to remember the recent passwords and prevent their reuse. To accomplish this, edit the appropriate line in `/etc/pam.d/system-auth` to include the `remember` option.

For example:

```
password sufficient pam_unix.so [ ... existing_options ...]
remember=5
```

You can set the number of previous passwords to remember to appropriately reflect your security policy requirements.

```
cd /etc
chown root:root passwd shadow group gshadow
chmod 644 passwd group
chmod 400 shadow gshadow
```

Parent topic: [Greenplum Database Best Practices](#)

## Encrypting Data and Database Connections

Best practices for implementing encryption and managing keys.

Encryption can be used to protect data in a Greenplum Database system in the following ways:

- Connections between clients and the master database can be encrypted with SSL. This is enabled by setting the `ssl` server configuration parameter to `on` and editing the `pg_hba.conf` file. See "Encrypting Client/Server Connections" in the *Greenplum Database Administrator Guide* for information about enabling SSL in Greenplum Database.
- Greenplum Database 4.2.1 and above allow SSL encryption of data in transit between the Greenplum parallel file distribution server, `gpfdist`, and segment hosts. See [Encrypting gpfdist Connections](#) for more information.
- Network communications between hosts in the Greenplum Database cluster can be encrypted using IPsec. An authenticated, encrypted VPN is established between every pair of hosts in the cluster. Check your operating system documentation for IPsec support, or consider a third-party solution such as that provided by [Zettaset](#).
- The `pgcrypto` module of encryption/decryption functions protects data at rest in the database. Encryption at the column level protects sensitive information, such as passwords, Social Security numbers, or credit card numbers. See [Encrypting Data in Tables using PGP](#) for an example.

## Best Practices

- Encryption ensures that data can be seen only by users who have the key required to decrypt the data.
- Encrypting and decrypting data has a performance cost; only encrypt data that requires encryption.
- Do performance testing before implementing any encryption solution in a production system.

- Server certificates in a production Greenplum Database system should be signed by a certificate authority (CA) so that clients can authenticate the server. The CA may be local if all clients are local to the organization.
- Client connections to Greenplum Database should use SSL encryption whenever the connection goes through an insecure link.
- A symmetric encryption scheme, where the same key is used to both encrypt and decrypt, has better performance than an asymmetric scheme and should be used when the key can be shared safely.
- Use functions from the `pgcrypto` module to encrypt data on disk. The data is encrypted and decrypted in the database process, so it is important to secure the client connection with SSL to avoid transmitting unencrypted data.
- Use the `gpfdists` protocol to secure ETL data as it is loaded into or unloaded from the database. See [Encrypting gpfdist Connections](#).

## Key Management

Whether you are using symmetric (single private key) or asymmetric (public and private key) cryptography, it is important to store the master or private key securely. There are many options for storing encryption keys, for example, on a file system, key vault, encrypted USB, trusted platform module (TPM), or hardware security module (HSM).

Consider the following questions when planning for key management:

- Where will the keys be stored?
- When should keys expire?
- How are keys protected?
- How are keys accessed?
- How can keys be recovered and revoked?

The Open Web Application Security Project (OWASP) provides a very comprehensive [guide to securing encryption keys](#).

## Encrypting Data at Rest with pgcrypto

The `pgcrypto` module for Greenplum Database provides functions for encrypting data at rest in the database. Administrators can encrypt columns with sensitive information, such as social security numbers or credit card numbers, to provide an extra layer of protection. Database data stored in encrypted form cannot be read by users who do not have the encryption key, and the data cannot be read directly from disk.

`pgcrypto` is installed by default when you install Greenplum Database. You must explicitly enable `pgcrypto` in each database in which you want to use the module.

`pgcrypto` allows PGP encryption using symmetric and asymmetric encryption. Symmetric encryption encrypts and decrypts data using the same key and is faster than asymmetric encryption. It is the preferred method in an environment where exchanging secret keys is not an

issue. With asymmetric encryption, a public key is used to encrypt data and a private key is used to decrypt data. This is slower than symmetric encryption and it requires a stronger key.

Using `pgcrypto` always comes at the cost of performance and maintainability. It is important to use encryption only with the data that requires it. Also, keep in mind that you cannot search encrypted data by indexing the data.

Before you implement in-database encryption, consider the following PGP limitations.

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. This practice is generally discouraged, so this limitation should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with `pgcrypto`, but create new ones, as the usage scenario is rather different.

Greenplum Database is compiled with `zlib` by default; this allows PGP encryption functions to compress data before encrypting. When compiled with `OpenSSL`, more algorithms will be available.

Because `pgcrypto` functions run inside the database server, the data and passwords move between `pgcrypto` and the client application in clear-text. For optimal security, you should connect locally or use SSL connections and you should trust both the system and database administrators.

`pgcrypto` configures itself according to the findings of the main PostgreSQL configure script.

When compiled with `zlib`, `pgcrypto` encryption functions are able to compress data before encrypting.

`Pgcrypto` has various levels of encryption ranging from basic to advanced built-in functions. The following table shows the supported encryption algorithms.

| Value Functionality     | Built-in | With OpenSSL       |
|-------------------------|----------|--------------------|
| MD5                     | yes      | yes                |
| SHA1                    | yes      | yes                |
| SHA224/256/384/512      | yes      | yes <sup>1</sup> . |
| Other digest algorithms | no       | yes <sup>2</sup>   |
| Blowfish                | yes      | yes                |
| AES                     | yes      | yes <sup>3</sup>   |
| DES/3DES/CAST5          | no       | yes                |
| Raw Encryption          | yes      | yes                |
| PGP Symmetric-Key       | yes      | yes                |
| PGP Public Key          | yes      | yes                |

## Creating PGP Keys

To use PGP asymmetric encryption in Greenplum Database, you must first create public and private keys and install them.

This section assumes you are installing Greenplum Database on a Linux machine with the Gnu Privacy Guard (`gpg`) command line tool. VMware recommends using the latest version of GPG to create keys. Download and install Gnu Privacy Guard (GPG) for your operating system from <https://www.gnupg.org/download/>. On the GnuPG website you will find installers for popular Linux distributions and links for Windows and Mac OS X installers.

1. As root, run the following command and choose option 1 from the menu:

```
# gpg --gen-key
gpg (GnuPG) 2.0.14; Copyright (C) 2009 Free Software Foundation, Inc.
This is free software: you are free to change and redistribute it.
There is NO WARRANTY, to the extent permitted by law.

gpg: directory `/root/.gnupg' created
gpg: new configuration file `/root/.gnupg/gpg.conf' created
gpg: WARNING: options in `/root/.gnupg/gpg.conf' are not yet active during this
run
gpg: keyring `/root/.gnupg/secring.gpg' created
gpg: keyring `/root/.gnupg/pubring.gpg' created
Please select what kind of key you want:
  (1) RSA and RSA (default)
  (2) DSA and Elgamal
  (3) DSA (sign only)
  (4) RSA (sign only)
Your selection? 1
```

2. Respond to the prompts and follow the instructions, as shown in this example:

```
RSA keys may be between 1024 and 4096 bits long.
What keysize do you want? (2048) Press enter to accept default key size
Requested keysize is 2048 bits
Please specify how long the key should be valid.
  0 = key does not expire
  <n> = key expires in n days
  <n>w = key expires in n weeks
  <n>m = key expires in n months
  <n>y = key expires in n years
Key is valid for? (0) 365
Key expires at Wed 13 Jan 2016 10:35:39 AM PST
Is this correct? (y/N) y

GnuPG needs to construct a user ID to identify your key.

Real name: John Doe
Email address: jdoe@email.com
Comment:
You selected this USER-ID:
  "John Doe <jdoe@email.com>"

Change (N)ame, (C)omment, (E)mail or (O)kay/(Q)uit? O
You need a Passphrase to protect your secret key.
(For this demo the passphrase is blank.)
can't connect to `/root/.gnupg/S.gpg-agent': No such file or directory
You don't want a passphrase - this is probably a *bad* idea!
```

```
I will do it anyway. You can change your passphrase at any time,
using this program with the option "--edit-key".
```

```
We need to generate a lot of random bytes. It is a good idea to perform
some other action (type on the keyboard, move the mouse, utilize the
disks) during the prime generation; this gives the random number
generator a better chance to gain enough entropy.
```

```
We need to generate a lot of random bytes. It is a good idea to perform
some other action (type on the keyboard, move the mouse, utilize the
disks) during the prime generation; this gives the random number
generator a better chance to gain enough entropy.
```

```
gpg: /root/.gnupg/trustdb.gpg: trustdb created
gpg: key 2027CC30 marked as ultimately trusted
public and secret key created and signed.
```

```
gpg: checking the trustdb:
      3 marginal(s) needed, 1 complete(s) needed, PGP trust model
gpg: depth: 0 valid: 1 signed: 0 trust: 0-, 0q, 0n, 0m, 0f, 1u
gpg: next trustdb check due at 2016-01-13
pub  2048R/2027CC30 2015-01-13 [expires: 2016-01-13]
      Key fingerprint = 7EDA 6AD0 F5E0 400F 4D45  3259 077D 725E 2027 CC30
uid                               John Doe <jdoe@email.com>
sub  2048R/4FD2EFBB 2015-01-13 [expires: 2016-01-13]
```

- List the PGP keys by entering the following command:

```
gpg --list-secret-keys
/root/.gnupg/secring.gpg
-----
sec  2048R/2027CC30 2015-01-13 [expires: 2016-01-13]
uid                               John Doe <jdoe@email.com>
ssb  2048R/4FD2EFBB 2015-01-13
```

2027CC30 is the public key and will be used to *encrypt* data in the database. 4FD2EFBB is the private (secret) key and will be used to *decrypt* data.

- Export the keys using the following commands:

```
# gpg -a --export 4FD2EFBB > public.key
# gpg -a --export-secret-keys 2027CC30 > secret.key
```

See the [pgcrypto](#) documentation for more information about PGP encryption functions.

## Encrypting Data in Tables using PGP

This section shows how to encrypt data inserted into a column using the PGP keys you generated.

- Dump the contents of the `public.key` file and then copy it to the clipboard:

```
# cat public.key
-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v2.0.14 (GNU/Linux)

mQENBFS1Zf0BCADNw8Qvkl1V1C36Kfcwd3Kpm/dijPFRyyEwB6PqKyA05jtWiXZTh
```

```

Pv2MikPS2fKOAg1R3LpMa8zDEt14w3vckPQNrQNNyUtFj6ZoCxv
=XZ8J
-----END PGP PUBLIC KEY BLOCK-----

```

2. Enable the `pgcrypto` extension:

```
CREATE EXTENSION pgcrypto;
```

3. Create a table called `userssn` and insert some sensitive data, social security numbers for Bob and Alice, in this example. Paste the public.key contents after "dearmor(".

```

CREATE TABLE userssn( ssn_id SERIAL PRIMARY KEY,
    username varchar(100), ssn bytea);

INSERT INTO userssn(username, ssn)
SELECT robotccs.username, pgp_pub_encrypt(robotccs.ssn, keys.pubkey) AS
ssn
FROM (
VALUES ('Alice', '123-45-6788'), ('Bob', '123-45-6799'))
AS robotccs(username, ssn)
CROSS JOIN (SELECT dearmor('-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v2.0.22 (GNU/Linux)

-----END PGP PUBLIC KEY BLOCK-----');

pgp_key_id | 9D4D255F4FD2EFBB

```

This shows that the PGP key ID used to encrypt the `ssn` column is 9D4D255F4FD2EFBB. It is recommended to perform this step whenever a new key is created and then store the ID for tracking.

You can use this key to see which key pair was used to encrypt the data:

```

SELECT username, pgp_key_id(ssn) As key_used
FROM userssn;
username | Bob
key_used | 9D4D255F4FD2EFBB
-----+-----
username | Alice
key_used | 9D4D255F4FD2EFBB

```

**Note:** Different keys may have the same ID. This is rare, but is a normal event. The client application should try to decrypt with each one to see which fits — like handling `ANYKEY`. See `pgp_key_id()` in the `pgcrypto` documentation.

## 6. Decrypt the data using the private key.

```

SELECT username, pgp_pub_decrypt(ssn, keys.privkey)
      AS decrypted_ssn FROM userssn
      CROSS JOIN
      (SELECT dearmor('-----BEGIN PGP PRIVATE KEY BLOCK-----
Version: GnuPG v2.0.14 (GNU/Linux)

```

If you created a key with passphrase, you may have to enter it here. However for the purpose of this example, the passphrase is blank.

## Encrypting gpfdist Connections

The `gpfdists` protocol is a secure version of the `gpfdist` protocol that securely identifies the file server and the Greenplum Database and encrypts the communications between them. Using `gpfdists` protects against eavesdropping and man-in-the-middle attacks.

The `gpfdists` protocol implements client/server SSL security with the following notable features:

- Client certificates are required.
- Multilingual certificates are not supported.
- A Certificate Revocation List (CRL) is not supported.
- The TLSv1 protocol is used with the `TLS_RSA_WITH_AES_128_CBC_SHA` encryption algorithm. These SSL parameters cannot be changed.
- SSL renegotiation is supported.
- The SSL ignore host mismatch parameter is set to false.
- Private keys containing a passphrase are not supported for the `gpfdist` file server (`server.key`) or for the Greenplum Database (`client.key`).
- It is the user's responsibility to issue certificates that are appropriate for the operating system in use. Generally, converting certificates to the required format is supported, for example using the SSL Converter at <https://www.sslshopper.com/ssl-converter.html>.

A `gpfdist` server started with the `--ssl` option can only communicate with the `gpfdists` protocol. A `gpfdist` server started without the `--ssl` option can only communicate with the `gpfdist` protocol. For more detail about `gpfdist` refer to the *Greenplum Database Administrator Guide*.

There are two ways to enable the `gpfdists` protocol:

- Run `gpfdist` with the `--ssl` option and then use the `gpfdists` protocol in the `LOCATION` clause of a `CREATE EXTERNAL TABLE` statement.
- Use a YAML control file with the SSL option set to true and run `gpload`. Running `gpload` starts the `gpfdist` server with the `--ssl` option and then uses the `gpfdists` protocol.

When using `gpfdists`, the following client certificates must be located in the `$PGDATA/gpfdists` directory on each segment:

- The client certificate file, `client.crt`
- The client private key file, `client.key`
- The trusted certificate authorities, `root.crt`

**Important:** Do not protect the private key with a passphrase. The server does not prompt for a passphrase for the private key, and loading data fails with an error if one is required.

When using `gpload` with SSL you specify the location of the server certificates in the YAML control file. When using `gpfdist` with SSL, you specify the location of the server certificates with the `--ssl` option.

The following example shows how to securely load data into an external table. The example creates a readable external table named `ext_expenses` from all files with the `txt` extension, using the `gpfdists` protocol. The files are formatted with a pipe (`|`) as the column delimiter and an empty space as null.

1. Run `gpfdist` with the `--ssl` option on the segment hosts.
2. Log into the database and run the following command:

```
=# CREATE EXTERNAL TABLE ext_expenses
  ( name text, date date, amount float4, category text, desc1 text )
LOCATION ('gpfdists://etlhost-1:8081/*.txt', 'gpfdists://etlhost-2:8082/*.txt')
FORMAT 'TEXT' ( DELIMITER '|' NULL ' ');
```

1 SHA2 algorithms were added to OpenSSL in version 0.9.8. For older versions, `pgcrypto` will use built-in code<sup>2</sup> Any digest algorithm OpenSSL supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.<sup>3</sup> AES is included in OpenSSL since version 0.9.7. For older versions, `pgcrypto` will use built-in code.

## Tuning SQL Queries

The Greenplum Database cost-based optimizer evaluates many strategies for running a query and chooses the least costly method.

Like other RDBMS optimizers, the Greenplum optimizer takes into account factors such as the number of rows in tables to be joined, availability of indexes, and cardinality of column data when calculating the costs of alternative execution plans. The optimizer also accounts for the location of the data, preferring to perform as much of the work as possible on the segments and to minimize the amount of data that must be transmitted between segments to complete the query.

When a query runs slower than you expect, you can view the plan the optimizer selected as well as the cost it calculated for each step of the plan. This will help you determine which steps are consuming the most resources and then modify the query or the schema to provide the optimizer with more efficient alternatives. You use the SQL `EXPLAIN` statement to view the plan for a query.

The optimizer produces plans based on statistics generated for tables. It is important to have accurate statistics to produce the best plan. See [Updating Statistics with ANALYZE](#) in this guide for information about updating statistics.

**Parent topic:** [Greenplum Database Best Practices](#)

## How to Generate Explain Plans

The `EXPLAIN` and `EXPLAIN ANALYZE` statements are useful tools to identify opportunities to improve query performance. `EXPLAIN` displays the query plan and estimated costs for a query, but does not

run the query. `EXPLAIN ANALYZE` runs the query in addition to displaying the query plan. `EXPLAIN ANALYZE` discards any output from the `SELECT` statement; however, other operations in the statement are performed (for example, `INSERT`, `UPDATE`, or `DELETE`). To use `EXPLAIN ANALYZE` on a DML statement without letting the command affect the data, explicitly use `EXPLAIN ANALYZE` in a transaction (`BEGIN; EXPLAIN ANALYZE ...; ROLLBACK;`).

`EXPLAIN ANALYZE` runs the statement in addition to displaying the plan with additional information as follows:

- Total elapsed time (in milliseconds) to run the query
- Number of workers (segments) involved in a plan node operation
- Maximum number of rows returned by the segment (and its segment ID) that produced the most rows for an operation
- The memory used by the operation
- Time (in milliseconds) it took to retrieve the first row from the segment that produced the most rows, and the total time taken to retrieve all rows from that segment.

## How to Read Explain Plans

An explain plan is a report detailing the steps the Greenplum Database optimizer has determined it will follow to run a query. The plan is a tree of nodes, read from bottom to top, with each node passing its result to the node directly above. Each node represents a step in the plan, and one line for each node identifies the operation performed in that step—for example, a scan, join, aggregation, or sort operation. The node also identifies the method used to perform the operation. The method for a scan operation, for example, may be a sequential scan or an index scan. A join operation may perform a hash join or nested loop join.

Following is an explain plan for a simple query. This query finds the number of rows in the contributions table stored at each segment.

```
gpadmin=# EXPLAIN SELECT gp_segment_id, count(*)
          FROM contributions
          GROUP BY gp_segment_id;
          QUERY PLAN
-----
Gather Motion 2:1 (slice2; segments: 2) (cost=0.00..431.00 rows=2 width=12)
-> GroupAggregate (cost=0.00..431.00 rows=1 width=12)
    Group By: gp_segment_id
    -> Sort (cost=0.00..431.00 rows=1 width=12)
        Sort Key: gp_segment_id
        -> Redistribute Motion 2:2 (slice1; segments: 2) (cost=0.00..431.00
rows=1 width=12)
            Hash Key: gp_segment_id
            -> Result (cost=0.00..431.00 rows=1 width=12)
                -> GroupAggregate (cost=0.00..431.00 rows=1 width=12)
                    Group By: gp_segment_id
                    -> Sort (cost=0.00..431.00 rows=7 width=4)
                        Sort Key: gp_segment_id
                        -> Seq Scan on table1 (cost=0.00..431.00 rows
=7 width=4)
```

```
Optimizer status: Pivotal Optimizer (GPORCA) version 2.56.0
(14 rows)
```

This plan has eight nodes – Seq Scan, Sort, GroupAggregate, Result, Redistribute Motion, Sort, GroupAggregate, and finally Gather Motion. Each node contains three cost estimates: cost (in sequential page reads), the number of rows, and the width of the rows.

The cost is a two-part estimate. A cost of 1.0 is equal to one sequential disk page read. The first part of the estimate is the start-up cost, which is the cost of getting the first row. The second estimate is the total cost, the cost of getting all of the rows.

The rows estimate is the number of rows output by the plan node. The number may be lower than the actual number of rows processed or scanned by the plan node, reflecting the estimated selectivity of `WHERE` clause conditions. The total cost assumes that all rows will be retrieved, which may not always be the case (for example, if you use a `LIMIT` clause).

The width estimate is the total width, in bytes, of all the columns output by the plan node.

The cost estimates in a node include the costs of all its child nodes, so the top-most node of the plan, usually a Gather Motion, has the estimated total execution costs for the plan. This is this number that the query planner seeks to minimize.

Scan operators scan through rows in a table to find a set of rows. There are different scan operators for different types of storage. They include the following:

- Seq Scan on tables — scans all rows in the table.
- Index Scan — traverses an index to fetch the rows from the table.
- Bitmap Heap Scan — gathers pointers to rows in a table from an index and sorts by location on disk. (The operator is called a Bitmap Heap Scan, even for append-only tables.)
- Dynamic Seq Scan — chooses partitions to scan using a partition selection function.

Join operators include the following:

- Hash Join – builds a hash table from the smaller table with the join column(s) as hash key. Then scans the larger table, calculating the hash key for the join column(s) and probing the hash table to find the rows with the same hash key. Hash joins are typically the fastest joins in Greenplum Database. The Hash Cond in the explain plan identifies the columns that are joined.
- Nested Loop – iterates through rows in the larger dataset, scanning the rows in the smaller dataset on each iteration. The Nested Loop join requires the broadcast of one of the tables so that all rows in one table can be compared to all rows in the other table. It performs well for small tables or tables that are limited by using an index. It is also used for Cartesian joins and range joins. There are performance implications when using a Nested Loop join with large tables. For plan nodes that contain a Nested Loop join operator, validate the SQL and ensure that the results are what is intended. Set the `enable_nestloop` server configuration parameter to OFF (default) to favor Hash Join.
- Merge Join – sorts both datasets and merges them together. A merge join is fast for pre-ordered data, but is very rare in the real world. To favor Merge Joins over Hash Joins, set the `enable_mergejoin` system configuration parameter to ON.

Some query plan nodes specify motion operations. Motion operations move rows between segments when required to process the query. The node identifies the method used to perform the motion operation. Motion operators include the following:

- Broadcast motion – each segment sends its own, individual rows to all other segments so that every segment instance has a complete local copy of the table. A Broadcast motion may not be as optimal as a Redistribute motion, so the optimizer typically only selects a Broadcast motion for small tables. A Broadcast motion is not acceptable for large tables. In the case where data was not distributed on the join key, a dynamic redistribution of the needed rows from one of the tables to another segment is performed.
- Redistribute motion – each segment rehashes the data and sends the rows to the appropriate segments according to hash key.
- Gather motion – result data from all segments is assembled into a single stream. This is the final operation for most query plans.

Other operators that occur in query plans include the following:

- Materialize – the planner materializes a subselect once so it does not have to repeat the work for each top-level row.
- InitPlan – a pre-query, used in dynamic partition elimination, performed when the values the planner needs to identify partitions to scan are unknown until execution time.
- Sort – sort rows in preparation for another operation requiring ordered rows, such as an Aggregation or Merge Join.
- Group By – groups rows by one or more columns.
- Group/Hash Aggregate – aggregates rows using a hash.
- Append – concatenates data sets, for example when combining rows scanned from partitions in a partitioned table.
- Filter – selects rows using criteria from a `WHERE` clause.
- Limit – limits the number of rows returned.

## Optimizing Greenplum Queries

This topic describes Greenplum Database features and programming practices that can be used to enhance system performance in some situations.

To analyze query plans, first identify the plan nodes where the estimated cost to perform the operation is very high. Determine if the estimated number of rows and cost seems reasonable relative to the number of rows for the operation performed.

If using partitioning, validate that partition elimination is achieved. To achieve partition elimination the query predicate (`WHERE` clause) must be the same as the partitioning criteria. Also, the `WHERE` clause must not contain an explicit value and cannot contain a subquery.

Review the execution order of the query plan tree. Review the estimated number of rows. You want the execution order to build on the smaller tables or hash join result and probe with larger tables. Optimally, the largest table is used for the final join or probe to reduce the number of rows being passed up the tree to the topmost plan nodes. If the analysis reveals that the order of

execution builds and/or probes is not optimal ensure that database statistics are up to date. Running `ANALYZE` will likely address this and produce an optimal query plan.

Look for evidence of computational skew. Computational skew occurs during query execution when execution of operators such as Hash Aggregate and Hash Join cause uneven execution on the segments. More CPU and memory are used on some segments than others, resulting in less than optimal execution. The cause could be joins, sorts, or aggregations on columns that have low cardinality or non-uniform distributions. You can detect computational skew in the output of the `EXPLAIN ANALYZE` statement for a query. Each node includes a count of the maximum rows processed by any one segment and the average rows processed by all segments. If the maximum row count is much higher than the average, at least one segment has performed much more work than the others and computational skew should be suspected for that operator.

Identify plan nodes where a Sort or Aggregate operation is performed. Hidden inside an Aggregate operation is a Sort. If the Sort or Aggregate operation involves a large number of rows, there is an opportunity to improve query performance. A HashAggregate operation is preferred over Sort and Aggregate operations when a large number of rows are required to be sorted. Usually a Sort operation is chosen by the optimizer due to the SQL construct; that is, due to the way the SQL is written. Most Sort operations can be replaced with a HashAggregate if the query is rewritten. To favor a HashAggregate operation over a Sort and Aggregate operation ensure that the `enable_groupagg` server configuration parameter is set to `ON`.

When an explain plan shows a broadcast motion with a large number of rows, you should attempt to eliminate the broadcast motion. One way to do this is to use the `gp_segments_for_planner` server configuration parameter to increase the cost estimate of the motion so that alternatives are favored. The `gp_segments_for_planner` variable tells the query planner how many primary segments to use in its calculations. The default value is zero, which tells the planner to use the actual number of primary segments in estimates. Increasing the number of primary segments increases the cost of the motion, thereby favoring a redistribute motion over a broadcast motion. For example, setting `gp_segments_for_planner = 100000` tells the planner that there are 100,000 segments. Conversely, to influence the optimizer to broadcast a table and not redistribute it, set `gp_segments_for_planner` to a low number, for example 2.

## Greenplum Grouping Extensions

Greenplum Database aggregation extensions to the `GROUP BY` clause can perform some common calculations in the database more efficiently than in application or procedure code:

- `GROUP BY ROLLUP(*col1*, *col2*, *col3*)`
- `GROUP BY CUBE(*col1*, *col2*, *col3*)`
- `GROUP BY GROUPING SETS((*col1*, *col2*), (*col1*, *col3*))`

A `ROLLUP` grouping creates aggregate subtotals that roll up from the most detailed level to a grand total, following a list of grouping columns (or expressions). `ROLLUP` takes an ordered list of grouping columns, calculates the standard aggregate values specified in the `GROUP BY` clause, then creates progressively higher-level subtotals, moving from right to left through the list. Finally, it creates a grand total.

A `CUBE` grouping creates subtotals for all of the possible combinations of the given list of grouping columns (or expressions). In multidimensional analysis terms, `CUBE` generates all the subtotals that could be calculated for a data cube with the specified dimensions.

You can selectively specify the set of groups that you want to create using a `GROUPING SETS` expression. This allows precise specification across multiple dimensions without computing a whole `ROLLUP` or `CUBE`.

Refer to the *Greenplum Database Reference Guide* for details of these clauses.

## Window Functions

Window functions apply an aggregation or ranking function over partitions of the result set—for example, `sum(population) over (partition by city)`. Window functions are powerful and, because they do all of the work in the database, they have performance advantages over front-end tools that produce similar results by retrieving detail rows from the database and reprocessing them.

- The `row_number()` window function produces row numbers for the rows in a partition, for example, `row_number() over (order by id)`.
- When a query plan indicates that a table is scanned in more than one operation, you may be able to use window functions to reduce the number of scans.
- It is often possible to eliminate self joins by using window functions.

## High Availability

Greenplum Database supports highly available, fault-tolerant database services when you enable and properly configure Greenplum high availability features. To guarantee a required level of service, each component must have a standby ready to take its place if it should fail.

**Parent topic:** [Greenplum Database Best Practices](#)

## Disk Storage

With the Greenplum Database "shared-nothing" MPP architecture, the master host and segment hosts each have their own dedicated memory and disk storage, and each master or segment instance has its own independent data directory. For both reliability and high performance, VMware recommends a hardware RAID storage solution with from 8 to 24 disks. A larger number of disks improves I/O throughput when using RAID 5 (or 6) because striping increases parallel disk I/O. The RAID controller can continue to function with a failed disk because it saves parity data on each disk in a way that it can reconstruct the data on any failed member of the array. If a hot spare is configured (or an operator replaces the failed disk with a new one) the controller rebuilds the failed disk automatically.

RAID 1 exactly mirrors disks, so if a disk fails, a replacement is immediately available with performance equivalent to that before the failure. With RAID 5 each I/O for data on the failed array member must be reconstructed from data on the remaining active drives until the replacement disk is rebuilt, so there is a temporary performance degradation. If the Greenplum master and segments are mirrored, you can switch any affected Greenplum instances to their mirrors during the rebuild to maintain acceptable performance.

A RAID disk array can still be a single point of failure, for example, if the entire RAID volume fails. At the hardware level, you can protect against a disk array failure by mirroring the array, using either host operating system mirroring or RAID controller mirroring, if supported.

It is important to regularly monitor available disk space on each segment host. Query the `gp_disk_free` external table in the `gptoolkit` schema to view disk space available on the segments. This view runs the Linux `df` command. Be sure to check that there is sufficient disk space before performing operations that consume large amounts of disk, such as copying a large table.

See `gp_toolkit.gp_disk_free` in the *Greenplum Database Reference Guide*.

## Best Practices

- Use a hardware RAID storage solution with 8 to 24 disks.
- Use RAID 1, 5, or 6 so that the disk array can tolerate a failed disk.
- Configure a hot spare in the disk array to allow rebuild to begin automatically when disk failure is detected.
- Protect against failure of the entire disk array and degradation during rebuilds by mirroring the RAID volume.
- Monitor disk utilization regularly and add additional space when needed.
- Monitor segment skew to ensure that data is distributed evenly and storage is consumed evenly at all segments.

## Master Mirroring

The Greenplum Database master instance is clients' single point of access to the system. The master instance stores the global system catalog, the set of system tables that store metadata about the database instance, but no user data. If an unmirrored master instance fails or becomes inaccessible, the Greenplum instance is effectively off-line, since the entry point to the system has been lost. For this reason, a standby master must be ready to take over if the primary master fails.

Master mirroring uses two processes, a sender on the active master host and a receiver on the mirror host, to synchronize the mirror with the master. As changes are applied to the master system catalogs, the active master streams its write-ahead log (WAL) to the mirror so that each transaction applied on the master is applied on the mirror.

The mirror is a *warm standby*. If the primary master fails, switching to the standby requires an administrative user to run the `gpactivatestandby` utility on the standby host so that it begins to accept client connections. Clients must reconnect to the new master and will lose any work that was not committed when the primary failed.

See "Enabling High Availability Features" in the *Greenplum Database Administrator Guide* for more information.

## Best Practices

- Set up a standby master instance—a *mirror*—to take over if the primary master fails.
- The standby can be on the same host or on a different host, but it is best practice to place it on a different host from the primary master to protect against host failure.
- Plan how to switch clients to the new master instance when a failure occurs, for example, by updating the master address in DNS.

- Set up monitoring to send notifications in a system monitoring application or by email when the primary fails.

## Segment Mirroring

Greenplum Database segment instances each store and manage a portion of the database data, with coordination from the master instance. If any unmirrored segment fails, the database may have to be shutdown and recovered, and transactions occurring after the most recent backup could be lost. Mirroring segments is, therefore, an essential element of a high availability solution.

A segment mirror is a hot standby for a primary segment. Greenplum Database detects when a segment is unavailable and automatically activates the mirror. During normal operation, when the primary segment instance is active, data is replicated from the primary to the mirror in two ways:

- The transaction commit log is replicated from the primary to the mirror before the transaction is committed. This ensures that if the mirror is activated, the changes made by the last successful transaction at the primary are present at the mirror. When the mirror is activated, transactions in the log are applied to tables in the mirror.
- Second, segment mirroring uses physical file replication to update heap tables. Greenplum Server stores table data on disk as fixed-size blocks packed with tuples. To optimize disk I/O, blocks are cached in memory until the cache fills and some blocks must be evicted to make room for newly updated blocks. When a block is evicted from the cache it is written to disk and replicated over the network to the mirror. Because of the caching mechanism, table updates at the mirror can lag behind the primary. However, because the transaction log is also replicated, the mirror remains consistent with the primary. If the mirror is activated, the activation process updates the tables with any unapplied changes in the transaction commit log.

When the acting primary is unable to access its mirror, replication stops and state of the primary changes to "Change Tracking." The primary saves changes that have not been replicated to the mirror in a system table to be replicated to the mirror when it is back on-line.

The master automatically detects segment failures and activates the mirror. Transactions in progress at the time of failure are restarted using the new primary. Depending on how mirrors are deployed on the hosts, the database system may be unbalanced until the original primary segment is recovered. For example, if each segment host has four primary segments and four mirror segments, and a mirror is activated on one host, that host will have five active primary segments. Queries are not complete until the last segment has finished its work, so performance can be degraded until the balance is restored by recovering the original primary.

Administrators perform the recovery while Greenplum Database is up and running by running the `gprecoverseg` utility. This utility locates the failed segments, verifies they are valid, and compares the transactional state with the currently active segment to determine changes made while the segment was offline. `gprecoverseg` synchronizes the changed database files with the active segment and brings the segment back online.

It is important to reserve enough memory and CPU resources on segment hosts to allow for increased activity from mirrors that assume the primary role during a failure. The formulas provided in [Configuring Memory for Greenplum Database](#) for configuring segment host memory include a factor for the maximum number of primary hosts on any one segment during a failure. The

arrangement of mirrors on the segment hosts affects this factor and how the system will respond during a failure. See [Segment Mirroring Configurations](#) for a discussion of segment mirroring options.

## Best Practices

- Set up mirrors for all segments.
- Locate primary segments and their mirrors on different hosts to protect against host failure.
- Mirrors can be on a separate set of hosts or co-located on hosts with primary segments.
- Set up monitoring to send notifications in a system monitoring application or by email when a primary segment fails.
- Recover failed segments promptly, using the `gprecoverseg` utility, to restore redundancy and return the system to optimal balance.

## Dual Clusters

For some use cases, an additional level of redundancy can be provided by maintaining two Greenplum Database clusters that store the same data. The decision to implement dual clusters should be made with business requirements in mind.

There are two recommended methods for keeping the data synchronized in a dual cluster configuration. The first method is called Dual ETL. ETL (extract, transform, and load) is the common data warehousing process of cleansing, transforming, validating, and loading data into a data warehouse. With Dual ETL, the ETL processes are performed twice, in parallel on each cluster, and validated each time. Dual ETL provides for a complete standby cluster with the same data. It also provides the capability to query the data on both clusters, doubling the processing throughput. The application can take advantage of both clusters as needed and also ensure that the ETL is successful and validated on both sides.

The second mechanism for maintaining dual clusters is backup and restore. The data is backed up on the primary cluster, then the backup is replicated to and restored on the second cluster. The backup and restore mechanism has higher latency than Dual ETL, but requires less application logic to be developed. Backup and restore is ideal for use cases where data modifications and ETL are done daily or less frequently.

## Best Practices

- Consider a Dual Cluster configuration to provide an additional level of redundancy and additional query processing throughput.

## Backup and Restore

Backups are recommended for Greenplum Database databases unless the data in the database can be easily and cleanly regenerated from source data. Backups protect from operational, software, or hardware errors.

The `gpbackup` utility makes backups in parallel across the segments, so that backups scale as the cluster grows in hardware size.

A backup strategy must consider where the backups will be written and where they will be stored. Backups can be taken to the local cluster disks, but they should not be stored there permanently. If the database and its backup are on the same storage, they can be lost simultaneously. The backup also occupies space that could be used for database storage or operations. After performing a local backup, the files should be copied to a safe, off-cluster location.

An alternative is to back up directly to an NFS mount. If each host in the cluster has an NFS mount, the backups can be written directly to NFS storage. A scale-out NFS solution is recommended to ensure that backups do not bottleneck on the IO throughput of the NFS device. Dell EMC Isilon is an example of this type of solution and can scale alongside the Greenplum cluster.

Finally, through native API integration, Greenplum Database can stream backups directly to the Dell EMC Data Domain enterprise backup platform.

## Best Practices

- Back up Greenplum databases regularly unless the data is easily restored from sources.
- Use the `gpbackup` command to specify only the schema and tables that you want backed up. See the [gpbackup](#) reference for more information.
- `gpbackup` places `SHARED ACCESS` locks on the set of tables to back up. Backups with fewer tables are more efficient for selectively restoring schemas and tables, since `gprestore` does not have to search through the entire database.
- If backups are saved to local cluster storage, move the files to a safe, off-cluster location when the backup is complete. Backup files and database files that reside on the same storage can be lost simultaneously.
- If backups are saved to NFS mounts, use a scale-out NFS solution such as Dell EMC Isilon to prevent IO bottlenecks.
- Tanzu Greenplum customers should consider streaming backups to the Dell EMC Data Domain enterprise backup platform.

## Detecting Failed Master and Segment Instances

Recovering from system failures requires intervention from a system administrator, even when the system detects a failure and activates a standby for the failed component. In each case, the failed component must be replaced or recovered to restore full redundancy. Until the failed component is recovered, the active component lacks a standby, and the system may not be performing optimally. For these reasons, it is important to perform recovery operations promptly. Constant system monitoring ensures that administrators are aware of failures that demand their attention.

The Greenplum Database server `ftsprobe` subprocess handles fault detection. `ftsprobe` connects to and scans all segments and database processes at intervals that you can configure with the `gp_fts_probe_interval` configuration parameter. If `ftsprobe` cannot connect to a segment, it marks the segment “down” in the Greenplum Database system catalog. The segment remains down until an administrator runs the `gprecoverseg` recovery utility.

## Best Practices

- Run the `gpstate` utility to see the overall state of the Greenplum system.

## Segment Mirroring Configurations

Segment mirroring allows database queries to fail over to a backup segment if the primary segment fails or becomes unavailable. VMware requires mirroring for supported production Greenplum Database systems.

A primary segment and its mirror must be on different hosts to ensure high availability. Each host in a Greenplum Database system has the same number of primary segments and mirror segments. Multi-homed hosts should have the same numbers of primary and mirror segments on each interface. This ensures that segment hosts and network resources are equally loaded when all primary segments are operational and brings the most resources to bear on query processing.

When a segment becomes unavailable, its mirror segment on another host becomes the active primary and processing continues. The additional load on the host creates skew and degrades performance, but should allow the system to continue. A database query is not complete until all segments return results, so a single host with an additional active primary segment has the same effect as adding an additional primary segment to every host in the cluster.

The least amount of performance degradation in a failover scenario occurs when no host has more than one mirror assuming the primary role. If multiple segments or hosts fail, the amount of degradation is determined by the host or hosts with the largest number of mirrors assuming the primary role. Spreading a host's mirrors across the remaining hosts minimizes degradation when any single host fails.

It is important, too, to consider the cluster's tolerance for multiple host failures and how to maintain a mirror configuration when expanding the cluster by adding hosts. There is no mirror configuration that is ideal for every situation.

You can allow Greenplum Database to arrange mirrors on the hosts in the cluster using one of two standard configurations, or you can design your own mirroring configuration.

The two standard mirroring arrangements are *group mirroring* and *spread mirroring*:

- **Group mirroring** — Each host mirrors another host's primary segments. This is the default for `gpinitssystem` and `gpaddmirrors`.

- **Spread mirroring** — Mirrors are spread across the available hosts. This requires that the number of hosts in the cluster is greater than the number of segments per host.

You can design a custom mirroring configuration and use the Greenplum `gpaddmirrors` or `gpmovemirrors` utilities to set up the configuration.

*Block mirroring* is a custom mirror configuration that divides hosts in the cluster into equally sized blocks and distributes mirrors evenly to hosts within the block. If a primary segment fails, its mirror on another host within the same block becomes the active primary. If a segment host fails, mirror segments on each of the other hosts in the block become active.

The following sections compare the group, spread, and block mirroring configurations.

## Group Mirroring

Group mirroring is easiest to set up and is the default Greenplum mirroring configuration. It is least expensive to expand, since it can be done by adding as few as two hosts. There is no need to move mirrors after expansion to maintain a consistent mirror configuration.

The following diagram shows a group mirroring configuration with eight primary segments on four hosts.

Unless both the primary and mirror of the same segment instance fail, up to half of your hosts can fail and the cluster will continue to run as long as resources (CPU, memory, and IO) are sufficient to meet the needs.

Any host failure will degrade performance by half or more because the host with the mirrors will have twice the number of active primaries. If your resource utilization is normally greater than 50%, you will have to adjust your workload until the failed host is recovered or replaced. If you normally

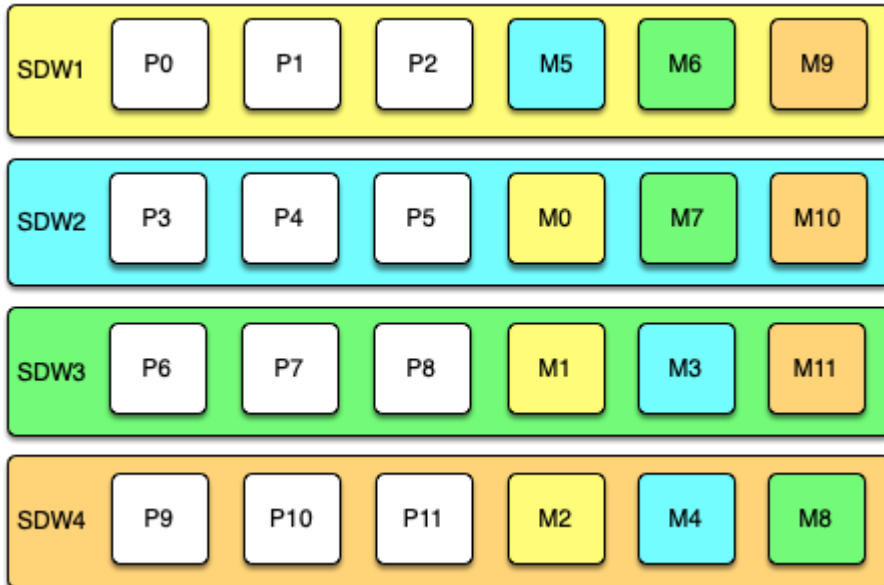

run at less than 50% resource utilization the cluster can continue to operate at a degraded level of performance until the failure is corrected.

## Spread Mirroring

With spread mirroring, mirrors for each host's primary segments are spread across as many hosts as there are segments per host. Spread mirroring is easy to set up when the cluster is initialized, but requires that the cluster have at least one more host than there are segments per host.

The following diagram shows the spread mirroring configuration for a cluster with three primaries on four hosts.

Expanding a cluster with spread mirroring requires more planning and may take more time. You must either add a set of hosts equal to the number of primaries per host plus one, or you can add two nodes in a group mirroring configuration and, when the expansion is complete, move mirrors to recreate the spread mirror configuration.

Spread mirroring has the least performance impact for a single failed host because each host's mirrors are spread across the maximum number of hosts. Load is increased by  $1/Nth$ , where  $N$  is the number of primaries per host. Spread mirroring is, however, the most likely configuration to have a catastrophic failure if two or more hosts fail simultaneously.

## Block Mirroring

With block mirroring, nodes are divided into blocks, for example a block of four or eight hosts, and the mirrors for segments on each host are placed on other hosts within the block. Depending on the number of hosts in the block and the number of primary segments per host, each host maintains more than one mirror for each other host's segments.

The following diagram shows a single block mirroring configuration for a block of four hosts, each with eight primary segments:

If there are eight hosts, an additional four-host block is added with the mirrors for primary segments 32 through 63 set up in the same pattern.

A cluster with block mirroring is easy to expand because each block is a self-contained primary mirror group. The cluster is expanded by adding one or more blocks. There is no need to move mirrors after expansion to maintain a consistent mirror setup. This configuration is able to survive multiple host failures as long as the failed hosts are in different blocks.

Because each host in a block has multiple mirror instances for each other host in the block, block mirroring has a higher performance impact for host failures than spread mirroring, but a lower impact than group mirroring. The expected performance impact varies by block size and primary segments per node. As with group mirroring, if the resources are available, performance will be negatively impacted but the cluster will remain available. If resources are insufficient to accommodate the added load you must reduce the workload until the failed node is replaced.

## Implementing Block Mirroring

Block mirroring is not one of the automatic options Greenplum Database offers when you set up or expand a cluster. To use it, you must create your own configuration.

For a new Greenplum system, you can initialize the cluster without mirrors, and then run `gpaddmirrors -i mirror_config_file` with a custom mirror configuration file to create the mirrors for each block. You must create the file system locations for the mirror segments before you run `gpaddmirrors`. See the `gpaddmirrors` reference page in the *Greenplum Database Management Utility Guide* for details.

If you expand a system that has block mirroring or you want to implement block mirroring at the same time you expand a cluster, it is recommended that you complete the expansion first, using

the default grouping mirror configuration, and then use the `gpmovemirrors` utility to move mirrors into the block configuration.

To implement block mirroring with an existing system that has a different mirroring scheme, you must first determine the desired location for each mirror according to your block configuration, and then determine which of the existing mirrors must be relocated. Follow these steps:

1. Run the following query to find the current locations of the primary and mirror segments:

```
SELECT dbid, content, role, port, hostname, datadir FROM gp_segment_configuration
WHERE content > -1 ;
```

The `gp_segment_configuration` system catalog table contains the current segment configuration.

2. Create a list with the current mirror location and the desired block mirroring location, then remove any mirrors from the list that are already on the correct host.
3. Create an input file for the `gpmovemirrors` utility with an entry for each mirror that must be moved.

The `gpmovemirrors` input file has the following format:

```
old_address|port|data_dir new_address|port|data_dir
```

Where `old_address` is the host name or IP address of the segment host, `port` is the communication port, and `data_dir` is the segment instance data directory.

The following example `gpmovemirrors` input file specifies three mirror segments to move.

```
sdw2|50001|/data2/mirror/gpseg1 sdw3|50001|/data/mirror/gpseg1
sdw2|50001|/data2/mirror/gpseg2 sdw4|50001|/data/mirror/gpseg2
sdw3|50001|/data2/mirror/gpseg3 sdw1|50001|/data/mirror/gpseg3
```

4. Run `gpmovemirrors` with a command like the following:

```
gpmovemirrors -i mirror_config_file
```

The `gpmovemirrors` utility validates the input file, calls `gprecoverseg` to relocate each specified mirror, and removes the original mirror. It creates a backout configuration file which can be used as input to `gpmovemirrors` to undo the changes that were made. The backout file has the same name as the input file, with the suffix `_backout_timestamp` added.

See the *Greenplum Database Management Utility Reference* for complete information about the `gpmovemirrors` utility.

# Greenplum Database Reference Guide

Reference information for Greenplum Database systems including SQL commands, system catalogs, environment variables, server configuration parameters, character set support, datatypes, and Greenplum Database extensions.

Parent topic: [Greenplum Database Reference Guide](#)

## SQL Syntax Summary

## ABORT

Terminates the current transaction.

```
ABORT [WORK | TRANSACTION]
```

See [ABORT](#) for more information.

## ALTER AGGREGATE

Changes the definition of an aggregate function

```
ALTER AGGREGATE <name> ( <aggregate_signature> ) RENAME TO <new_name>

ALTER AGGREGATE <name> ( <aggregate_signature> ) OWNER TO <new_owner>

ALTER AGGREGATE <name> ( <aggregate_signature> ) SET SCHEMA <new_schema>
```

See [ALTER AGGREGATE](#) for more information.

## ALTER COLLATION

Changes the definition of a collation.

```
ALTER COLLATION <name> RENAME TO <new_name>

ALTER COLLATION <name> OWNER TO <new_owner>

ALTER COLLATION <name> SET SCHEMA <new_schema>
```

See [ALTER COLLATION](#) for more information.

## ALTER CONVERSION

Changes the definition of a conversion.

```
ALTER CONVERSION <name> RENAME TO <newname>

ALTER CONVERSION <name> OWNER TO <newowner>

ALTER CONVERSION <name> SET SCHEMA <new_schema>
```

See [ALTER CONVERSION](#) for more information.

## ALTER DATABASE

Changes the attributes of a database.

```
ALTER DATABASE <name> [ WITH CONNECTION LIMIT <connlimit> ]

ALTER DATABASE <name> RENAME TO <newname>
```

```

ALTER DATABASE <name> OWNER TO <new_owner>

ALTER DATABASE <name> SET TABLESPACE <new_tablespace>

ALTER DATABASE <name> SET <parameter> { TO | = } { <value> | DEFAULT }
ALTER DATABASE <name> SET <parameter> FROM CURRENT
ALTER DATABASE <name> RESET <parameter>
ALTER DATABASE <name> RESET ALL

```

See [ALTER DATABASE](#) for more information.

## ALTER DEFAULT PRIVILEGES

Changes default access privileges.

```

ALTER DEFAULT PRIVILEGES
  [ FOR { ROLE | USER } <target_role> [, ...] ]
  [ IN SCHEMA <schema_name> [, ...] ]
  <abbreviated_grant_or_revoke>

where <abbreviated_grant_or_revoke> is one of:

GRANT { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER }
  [, ...] | ALL [ PRIVILEGES ] }
  ON TABLES
  TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { { USAGE | SELECT | UPDATE }
  [, ...] | ALL [ PRIVILEGES ] }
  ON SEQUENCES
  TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { EXECUTE | ALL [ PRIVILEGES ] }
  ON FUNCTIONS
  TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
  ON TYPES
  TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

REVOKE [ GRANT OPTION FOR ]
  { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER }
  [, ...] | ALL [ PRIVILEGES ] }
  ON TABLES
  FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]
  [ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
  { { USAGE | SELECT | UPDATE }
  [, ...] | ALL [ PRIVILEGES ] }
  ON SEQUENCES
  FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]
  [ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]

```

```

{ EXECUTE | ALL [ PRIVILEGES ] }
ON FUNCTIONS
FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]
[ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
{ USAGE | ALL [ PRIVILEGES ] }
ON TYPES
FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]
[ CASCADE | RESTRICT ]

```

See [ALTER DEFAULT PRIVILEGES](#) for more information.

## ALTER DOMAIN

Changes the definition of a domain.

```

ALTER DOMAIN <name> { SET DEFAULT <expression> | DROP DEFAULT }

ALTER DOMAIN <name> { SET | DROP } NOT NULL

ALTER DOMAIN <name> ADD <domain_constraint> [ NOT VALID ]

ALTER DOMAIN <name> DROP CONSTRAINT [ IF EXISTS ] <constraint_name> [RESTRICT | CASCAD
E]

ALTER DOMAIN <name> RENAME CONSTRAINT <constraint_name> TO <new_constraint_name>

ALTER DOMAIN <name> VALIDATE CONSTRAINT <constraint_name>

ALTER DOMAIN <name> OWNER TO <new_owner>

ALTER DOMAIN <name> RENAME TO <new_name>

ALTER DOMAIN <name> SET SCHEMA <new_schema>

```

See [ALTER DOMAIN](#) for more information.

## ALTER EXTENSION

Change the definition of an extension that is registered in a Greenplum database.

```

ALTER EXTENSION <name> UPDATE [ TO <new_version> ]
ALTER EXTENSION <name> SET SCHEMA <new_schema>
ALTER EXTENSION <name> ADD <member_object>
ALTER EXTENSION <name> DROP <member_object>

where <member_object> is:

ACCESS METHOD <object_name> |
AGGREGATE <aggregate_name> ( <aggregate_signature> ) |
CAST (<source_type> AS <target_type>) |
COLLATION <object_name> |
CONVERSION <object_name> |
DOMAIN <object_name> |

```

```

EVENT TRIGGER <object_name> |
FOREIGN DATA WRAPPER <object_name> |
FOREIGN TABLE <object_name> |
FUNCTION <function_name> ( [ [ <argmode> ] [ <argname> ] <argtype> [ , ... ] ] ) |
MATERIALIZED VIEW <object_name> |
OPERATOR <operator_name> (<left_type>, <right_type>) |
OPERATOR CLASS <object_name> USING <index_method> |
OPERATOR FAMILY <object_name> USING <index_method> |
[ PROCEDURAL ] LANGUAGE <object_name> |
SCHEMA <object_name> |
SEQUENCE <object_name> |
SERVER <object_name> |
TABLE <object_name> |
TEXT SEARCH CONFIGURATION <object_name> |
TEXT SEARCH DICTIONARY <object_name> |
TEXT SEARCH PARSER <object_name> |
TEXT SEARCH TEMPLATE <object_name> |
TRANSFORM FOR <type_name> LANGUAGE <lang_name> |
TYPE <object_name> |
VIEW <object_name>

and <aggregate_signature> is:

* |
[ <argmode> ] [ <argname> ] <argtype> [ , ... ] |
[ [ <argmode> ] [ <argname> ] <argtype> [ , ... ] ] ORDER BY [ <argmode> ] [ <argname> ]
] <argtype> [ , ... ]

```

See [ALTER EXTENSION](#) for more information.

## ALTER EXTERNAL TABLE

Changes the definition of an external table.

```
ALTER EXTERNAL TABLE <name> <action> [ , ... ]
```

where action is one of:

```

ADD [COLUMN] <new_column> <type>
DROP [COLUMN] <column> [RESTRICT|CASCADE]
ALTER [COLUMN] <column> TYPE <type>
OWNER TO <new_owner>

```

See [ALTER EXTERNAL TABLE](#) for more information.

## ALTER FOREIGN DATA WRAPPER

Changes the definition of a foreign-data wrapper.

```

ALTER FOREIGN DATA WRAPPER <name>
  [ HANDLER <handler_function> | NO HANDLER ]
  [ VALIDATOR <validator_function> | NO VALIDATOR ]
  [ OPTIONS ( [ ADD | SET | DROP ] <option> ['<value>'] [ , ... ] ) ]

```

```
ALTER FOREIGN DATA WRAPPER <name> OWNER TO <new_owner>
ALTER FOREIGN DATA WRAPPER <name> RENAME TO <new_name>
```

See [ALTER FOREIGN DATA WRAPPER](#) for more information.

## ALTER FOREIGN TABLE

Changes the definition of a foreign table.

```
ALTER FOREIGN TABLE [ IF EXISTS ] <name>
    <action> [, ... ]
ALTER FOREIGN TABLE [ IF EXISTS ] <name>
    RENAME [ COLUMN ] <column_name> TO <new_column_name>
ALTER FOREIGN TABLE [ IF EXISTS ] <name>
    RENAME TO <new_name>
ALTER FOREIGN TABLE [ IF EXISTS ] <name>
    SET SCHEMA <new_schema>
```

See [ALTER FOREIGN TABLE](#) for more information.

## ALTER FUNCTION

Changes the definition of a function.

```
ALTER FUNCTION <name> ( [ [<argmode>] [<argname>] <argtype> [, ...] ] )
    <action> [, ... ] [RESTRICT]

ALTER FUNCTION <name> ( [ [<argmode>] [<argname>] <argtype> [, ...] ] )
    RENAME TO <new_name>

ALTER FUNCTION <name> ( [ [<argmode>] [<argname>] <argtype> [, ...] ] )
    OWNER TO <new_owner>

ALTER FUNCTION <name> ( [ [<argmode>] [<argname>] <argtype> [, ...] ] )
    SET SCHEMA <new_schema>
```

See [ALTER FUNCTION](#) for more information.

## ALTER GROUP

Changes a role name or membership.

```
ALTER GROUP <groupname> ADD USER <username> [, ... ]

ALTER GROUP <groupname> DROP USER <username> [, ... ]

ALTER GROUP <groupname> RENAME TO <newname>
```

See [ALTER GROUP](#) for more information.

## ALTER INDEX

Changes the definition of an index.

```
ALTER INDEX [ IF EXISTS ] <name> RENAME TO <new_name>

ALTER INDEX [ IF EXISTS ] <name> SET TABLESPACE <tablespace_name>

ALTER INDEX [ IF EXISTS ] <name> SET ( <storage_parameter> = <value> [, ... ] )

ALTER INDEX [ IF EXISTS ] <name> RESET ( <storage_parameter> [, ... ] )

ALTER INDEX ALL IN TABLESPACE <name> [ OWNED BY <role_name> [, ... ] ]
SET TABLESPACE <new_tablespace> [ NOWAIT ]
```

See [ALTER INDEX](#) for more information.

## ALTER LANGUAGE

Changes the name of a procedural language.

```
ALTER LANGUAGE <name> RENAME TO <newname>
ALTER LANGUAGE <name> OWNER TO <new_owner>
```

See [ALTER LANGUAGE](#) for more information.

## ALTER MATERIALIZED VIEW

Changes the definition of a materialized view.

```
ALTER MATERIALIZED VIEW [ IF EXISTS ] <name> <action> [, ... ]
ALTER MATERIALIZED VIEW [ IF EXISTS ] <name>
    RENAME [ COLUMN ] <column_name> TO <new_column_name>
ALTER MATERIALIZED VIEW [ IF EXISTS ] <name>
    RENAME TO <new_name>
ALTER MATERIALIZED VIEW [ IF EXISTS ] <name>
    SET SCHEMA <new_schema>
ALTER MATERIALIZED VIEW ALL IN TABLESPACE <name> [ OWNED BY <role_name> [, ... ] ]
    SET TABLESPACE <new_tablespace> [ NOWAIT ]

where <action> is one of:

ALTER [ COLUMN ] <column_name> SET STATISTICS <integer>
ALTER [ COLUMN ] <column_name> SET ( <attribute_option> = <value> [, ... ] )
ALTER [ COLUMN ] <column_name> RESET ( <attribute_option> [, ... ] )
ALTER [ COLUMN ] <column_name> SET STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN }
CLUSTER ON <index_name>
SET WITHOUT CLUSTER
SET ( <storage_parameter>r = <value> [, ... ] )
RESET ( <storage_parameter> [, ... ] )
OWNER TO <new_owner>
```

See [ALTER MATERIALIZED VIEW](#) for more information.

## ALTER OPERATOR

Changes the definition of an operator.

```
ALTER OPERATOR <name> ( {<left_type> | NONE} , {<right_type> | NONE} )
    OWNER TO <new_owner>

ALTER OPERATOR <name> ( {<left_type> | NONE} , {<right_type> | NONE} )
    SET SCHEMA <new_schema>
```

See [ALTER OPERATOR](#) for more information.

## ALTER OPERATOR CLASS

Changes the definition of an operator class.

```
ALTER OPERATOR CLASS <name> USING <index_method> RENAME TO <new_name>

ALTER OPERATOR CLASS <name> USING <index_method> OWNER TO <new_owner>

ALTER OPERATOR CLASS <name> USING <index_method> SET SCHEMA <new_schema>
```

See [ALTER OPERATOR CLASS](#) for more information.

## ALTER OPERATOR FAMILY

Changes the definition of an operator family.

```
ALTER OPERATOR FAMILY <name> USING <index_method> ADD
    { OPERATOR <strategy_number> <operator_name> ( <op_type>, <op_type> ) [ FOR SEARCH
    | FOR ORDER BY <sort_family_name> ]
      | FUNCTION <support_number> [ ( <op_type> [ , <op_type> ] ) ] <funcname> ( <argument_type> [, ...] )
    } [, ... ]

ALTER OPERATOR FAMILY <name> USING <index_method> DROP
    { OPERATOR <strategy_number> ( <op_type>, <op_type> )
      | FUNCTION <support_number> [ ( <op_type> [ , <op_type> ] ) ]
    } [, ... ]

ALTER OPERATOR FAMILY <name> USING <index_method> RENAME TO <new_name>

ALTER OPERATOR FAMILY <name> USING <index_method> OWNER TO <new_owner>

ALTER OPERATOR FAMILY <name> USING <index_method> SET SCHEMA <new_schema>
```

See [ALTER OPERATOR FAMILY](#) for more information.

## ALTER PROTOCOL

Changes the definition of a protocol.

```
ALTER PROTOCOL <name> RENAME TO <newname>

ALTER PROTOCOL <name> OWNER TO <newowner>
```

See [ALTER PROTOCOL](#) for more information.

## ALTER RESOURCE GROUP

Changes the limits of a resource group.

```
ALTER RESOURCE GROUP <name> SET <group_attribute> <value>
```

See [ALTER RESOURCE GROUP](#) for more information.

## ALTER RESOURCE QUEUE

Changes the limits of a resource queue.

```
ALTER RESOURCE QUEUE <name> WITH ( <queue_attribute>=<value> [, ... ] )
```

See [ALTER RESOURCE QUEUE](#) for more information.

## ALTER ROLE

Changes a database role (user or group).

```
ALTER ROLE <name> [ [ WITH ] <option> [ ... ] ]
```

where <option> can be:

```

SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| CREATEEXTTABLE | NOCREATEEXTTABLE [ ( attribute='value' [, ...] )
  where attributes and values are:
    type='readable'|'writable'
    protocol='gpfdist'|'http'
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| REPLICATION | NOREPLICATION
| CONNECTION LIMIT <connlimit>
| [ ENCRYPTED | UNENCRYPTED ] PASSWORD '<password>'
| VALID UNTIL '<timestamp>'

```

```
ALTER ROLE <name> RENAME TO <new_name>
```

```
ALTER ROLE { <name> | ALL } [ IN DATABASE <database_name> ] SET <configuration_paramet
er> { TO | = } { <value> | DEFAULT }
```

```
ALTER ROLE { <name> | ALL } [ IN DATABASE <database_name> ] SET <configuration_paramet
er> FROM CURRENT
```

```
ALTER ROLE { <name> | ALL } [ IN DATABASE <database_name> ] RESET <configuration_param
eter>
```

```
ALTER ROLE { <name> | ALL } [ IN DATABASE <database_name> ] RESET ALL
```

```
ALTER ROLE <name> RESOURCE QUEUE {<queue_name> | NONE}
```

```
ALTER ROLE <name> RESOURCE GROUP {<group_name> | NONE}
```

See [ALTER ROLE](#) for more information.

## ALTER RULE

Changes the definition of a rule.

```
ALTER RULE name ON table\_name RENAME TO new\_name
```

See [ALTER RULE](#) for more information.

## ALTER SCHEMA

Changes the definition of a schema.

```
ALTER SCHEMA <name> RENAME TO <newname>

ALTER SCHEMA <name> OWNER TO <newowner>
```

See [ALTER SCHEMA](#) for more information.

## ALTER SEQUENCE

Changes the definition of a sequence generator.

```
ALTER SEQUENCE [ IF EXISTS ] <name> [ INCREMENT [ BY ] <increment> ]
    [ MINVALUE <minvalue> | NO MINVALUE ]
    [ MAXVALUE <maxvalue> | NO MAXVALUE ]
    [ START [ WITH ] <start> ]
    [ RESTART [ [ WITH ] <restart> ] ]
    [ CACHE <cache> ] [ [ NO ] CYCLE ]
    [ OWNED BY {<table.column> | NONE} ]

ALTER SEQUENCE [ IF EXISTS ] <name> OWNER TO <new_owner>

ALTER SEQUENCE [ IF EXISTS ] <name> RENAME TO <new_name>

ALTER SEQUENCE [ IF EXISTS ] <name> SET SCHEMA <new_schema>
```

See [ALTER SEQUENCE](#) for more information.

## ALTER SERVER

Changes the definition of a foreign server.

```
ALTER SERVER <server_name> [ VERSION '<new_version>' ]
    [ OPTIONS ( [ ADD | SET | DROP ] <option> ['<value>'] [, ... ] ) ]

ALTER SERVER <server_name> OWNER TO <new_owner>

ALTER SERVER <server_name> RENAME TO <new_name>
```

See [ALTER SERVER](#) for more information.

## ALTER TABLE

## Changes the definition of a table.

```

ALTER TABLE [IF EXISTS] [ONLY] <name>
    <action> [, ... ]

ALTER TABLE [IF EXISTS] [ONLY] <name>
    RENAME [COLUMN] <column_name> TO <new_column_name>

ALTER TABLE [ IF EXISTS ] [ ONLY ] <name>
    RENAME CONSTRAINT <constraint_name> TO <new_constraint_name>

ALTER TABLE [IF EXISTS] <name>
    RENAME TO <new_name>

ALTER TABLE [IF EXISTS] <name>
    SET SCHEMA <new_schema>

ALTER TABLE ALL IN TABLESPACE <name> [ OWNED BY <role_name> [, ... ] ]
    SET TABLESPACE <new_tablespace> [ NOWAIT ]

ALTER TABLE [IF EXISTS] [ONLY] <name> SET
    WITH (REORGANIZE=true|false)
    | DISTRIBUTED BY ({<column_name> [<opclass>]} [, ... ] )
    | DISTRIBUTED RANDOMLY
    | DISTRIBUTED REPLICATED

ALTER TABLE <name>
    [ ALTER PARTITION { <partition_name> | FOR (RANK(<number>))
    | FOR (<value> ) [...] ] <partition_action>

where <action> is one of:

    ADD [COLUMN] <column_name data_type> [ DEFAULT <default_expr> ]
        [<column_constraint> [ ... ] ]
        [ COLLATE <collation> ]
        [ ENCODING ( <storage_parameter> [,...] ) ]
    DROP [COLUMN] [IF EXISTS] <column_name> [RESTRICT | CASCADE]
    ALTER [COLUMN] <column_name> [ SET DATA ] TYPE <type> [COLLATE <collation>] [USING <
expression>]
    ALTER [COLUMN] <column_name> SET DEFAULT <expression>
    ALTER [COLUMN] <column_name> DROP DEFAULT
    ALTER [COLUMN] <column_name> { SET | DROP } NOT NULL
    ALTER [COLUMN] <column_name> SET STATISTICS <integer>
    ALTER [COLUMN] column SET ( <attribute_option> = <value> [, ... ] )
    ALTER [COLUMN] column RESET ( <attribute_option> [, ... ] )
    ADD <table_constraint> [NOT VALID]
    ADD <table_constraint_using_index>
    VALIDATE CONSTRAINT <constraint_name>
    DROP CONSTRAINT [IF EXISTS] <constraint_name> [RESTRICT | CASCADE]
    DISABLE TRIGGER [<trigger_name> | ALL | USER]
    ENABLE TRIGGER [<trigger_name> | ALL | USER]
    CLUSTER ON <index_name>
    SET WITHOUT CLUSTER
    SET WITHOUT OIDS
    SET (<storage_parameter> = <value>)
    RESET (<storage_parameter> [, ... ] )
    INHERIT <parent_table>
    NO INHERIT <parent_table>
    OF `type_name`

```

```

NOT OF
OWNER TO <new_owner>
SET TABLESPACE <new_tablespace>

```

See [ALTER TABLE](#) for more information.

## ALTER TABLESPACE

Changes the definition of a tablespace.

```

ALTER TABLESPACE <name> RENAME TO <new_name>

ALTER TABLESPACE <name> OWNER TO <new_owner>

ALTER TABLESPACE <name> SET ( <tablespace_option> = <value> [, ... ] )

ALTER TABLESPACE <name> RESET ( <tablespace_option> [, ... ] )

```

See [ALTER TABLESPACE](#) for more information.

## ALTER TEXT SEARCH CONFIGURATION

Changes the definition of a text search configuration.

```

ALTER TEXT SEARCH CONFIGURATION <name>
    ALTER MAPPING FOR <token_type> [, ... ] WITH <dictionary_name> [, ... ]
ALTER TEXT SEARCH CONFIGURATION <name>
    ALTER MAPPING REPLACE <old_dictionary> WITH <new_dictionary>
ALTER TEXT SEARCH CONFIGURATION <name>
    ALTER MAPPING FOR <token_type> [, ... ] REPLACE <old_dictionary> WITH <new_diction
ary>
ALTER TEXT SEARCH CONFIGURATION <name>
    DROP MAPPING [ IF EXISTS ] FOR <token_type> [, ... ]
ALTER TEXT SEARCH CONFIGURATION <name> RENAME TO <new_name>
ALTER TEXT SEARCH CONFIGURATION <name> OWNER TO <new_owner>
ALTER TEXT SEARCH CONFIGURATION <name> SET SCHEMA <new_schema>

```

See [ALTER TEXT SEARCH CONFIGURATION](#) for more information.

## ALTER TEXT SEARCH DICTIONARY

Changes the definition of a text search dictionary.

```

ALTER TEXT SEARCH DICTIONARY <name> (
    <option> [ = <value> ] [, ... ]
)
ALTER TEXT SEARCH DICTIONARY <name> RENAME TO <new_name>
ALTER TEXT SEARCH DICTIONARY <name> OWNER TO <new_owner>
ALTER TEXT SEARCH DICTIONARY <name> SET SCHEMA <new_schema>

```

See [ALTER TEXT SEARCH DICTIONARY](#) for more information.

## ALTER TEXT SEARCH PARSER

Changes the definition of a text search parser.

```
ALTER TEXT SEARCH PARSER <name> RENAME TO <new_name>
ALTER TEXT SEARCH PARSER <name> SET SCHEMA <new_schema>
```

See [ALTER TEXT SEARCH PARSER](#) for more information.

## ALTER TEXT SEARCH TEMPLATE

Changes the definition of a text search template.

```
ALTER TEXT SEARCH TEMPLATE <name> RENAME TO <new_name>
ALTER TEXT SEARCH TEMPLATE <name> SET SCHEMA <new_schema>
```

See [ALTER TEXT SEARCH TEMPLATE](#) for more information.

## ALTER TYPE

Changes the definition of a data type.

```
ALTER TYPE <name> <action> [, ... ]
ALTER TYPE <name> OWNER TO <new_owner>
ALTER TYPE <name> RENAME ATTRIBUTE <attribute_name> TO <new_attribute_name> [ CASCADE
| RESTRICT ]
ALTER TYPE <name> RENAME TO <new_name>
ALTER TYPE <name> SET SCHEMA <new_schema>
ALTER TYPE <name> ADD VALUE [ IF NOT EXISTS ] <new_enum_value> [ { BEFORE | AFTER } <e
xisting_enum_value> ]
ALTER TYPE <name> SET DEFAULT ENCODING ( <storage_directive> )
```

where <action> is one of:

```
ADD ATTRIBUTE <attribute_name> <data_type> [ COLLATE <collation> ] [ CASCADE | RESTR
ICT ]
DROP ATTRIBUTE [ IF EXISTS ] <attribute_name> [ CASCADE | RESTRICT ]
ALTER ATTRIBUTE <attribute_name> [ SET DATA ] TYPE <data_type> [ COLLATE <collation>
] [ CASCADE | RESTRICT ]
```

See [ALTER TYPE](#) for more information.

## ALTER USER

Changes the definition of a database role (user).

```
ALTER USER <name> RENAME TO <newname>

ALTER USER <name> SET <config_parameter> {TO | =} {<value> | DEFAULT}

ALTER USER <name> RESET <config_parameter>
```

```
ALTER USER <name> RESOURCE QUEUE {<queue_name> | NONE}

ALTER USER <name> RESOURCE GROUP {<group_name> | NONE}

ALTER USER <name> [ [WITH] <option> [ ... ] ]
```

See [ALTER USER](#) for more information.

## ALTER USER MAPPING

Changes the definition of a user mapping for a foreign server.

```
ALTER USER MAPPING FOR { <username> | USER | CURRENT_USER | PUBLIC }
    SERVER <servername>
    OPTIONS ( [ ADD | SET | DROP ] <option> ['<value>'] [, ... ] )
```

See [ALTER USER MAPPING](#) for more information.

## ALTER VIEW

Changes properties of a view.

```
ALTER VIEW [ IF EXISTS ] <name> ALTER [ COLUMN ] <column_name> SET DEFAULT <expression>
>

ALTER VIEW [ IF EXISTS ] <name> ALTER [ COLUMN ] <column_name> DROP DEFAULT

ALTER VIEW [ IF EXISTS ] <name> OWNER TO <new_owner>

ALTER VIEW [ IF EXISTS ] <name> RENAME TO <new_name>

ALTER VIEW [ IF EXISTS ] <name> SET SCHEMA <new_schema>

ALTER VIEW [ IF EXISTS ] <name> SET ( <view_option_name> [= <view_option_value>] [,
... ] )

ALTER VIEW [ IF EXISTS ] <name> RESET ( <view_option_name> [, ... ] )
```

See [ALTER VIEW](#) for more information.

## ANALYZE

Collects statistics about a database.

```
ANALYZE [VERBOSE] [<table> [ (<column> [, ...] ) ] ]

ANALYZE [VERBOSE] {<root_partition_table_name>|<leaf_partition_table_name>} [ (<column>
> [, ...] ) ]

ANALYZE [VERBOSE] ROOTPARTITION {ALL | <root_partition_table_name> [ (<column> [, ...]
) ] }
```

See [ANALYZE](#) for more information.

## BEGIN

Starts a transaction block.

```
BEGIN [WORK | TRANSACTION] [<transaction_mode>]
```

See [BEGIN](#) for more information.

## CHECKPOINT

Forces a transaction log checkpoint.

```
CHECKPOINT
```

See [CHECKPOINT](#) for more information.

## CLOSE

Closes a cursor.

```
CLOSE <cursor_name>
```

See [CLOSE](#) for more information.

## CLUSTER

Physically reorders a heap storage table on disk according to an index. Not a recommended operation in Greenplum Database.

```
CLUSTER <indexname> ON <tablename>

CLUSTER [VERBOSE] <tablename> [ USING index_name ]

CLUSTER [VERBOSE]
```

See [CLUSTER](#) for more information.

## COMMENT

Defines or changes the comment of an object.

```
COMMENT ON
{ TABLE <object_name> |
  COLUMN <relation_name.column_name> |
  AGGREGATE <agg_name> (<agg_signature>) |
  CAST (<source_type> AS <target_type>) |
  COLLATION <object_name>
  CONSTRAINT <constraint_name> ON <table_name> |
  CONVERSION <object_name> |
  DATABASE <object_name> |
  DOMAIN <object_name> |
  EXTENSION <object_name> |
```

```

FOREIGN DATA WRAPPER <object_name> |
FOREIGN TABLE <object_name> |
FUNCTION <func_name> ([[<argmode>] [<argname>] <argtype> [, ...]]) |
INDEX <object_name> |
LARGE OBJECT <large_object_oid> |
MATERIALIZED VIEW <object_name> |
OPERATOR <operator_name> (<left_type>, <right_type>) |
OPERATOR CLASS <object_name> USING <index_method> |
[PROCEDURAL] LANGUAGE <object_name> |
RESOURCE GROUP <object_name> |
RESOURCE QUEUE <object_name> |
ROLE <object_name> |
RULE <rule_name> ON <table_name> |
SCHEMA <object_name> |
SEQUENCE <object_name> |
SERVER <object_name> |
TABLESPACE <object_name> |
TEXT SEARCH CONFIGURATION <object_name> |
TEXT SEARCH DICTIONARY <object_name> |
TEXT SEARCH PARSER <object_name> |
TEXT SEARCH TEMPLATE <object_name> |
TRIGGER <trigger_name> ON <table_name> |
TYPE <object_name> |
VIEW <object_name> }
IS '<text>'

```

See [COMMENT](#) for more information.

## COMMIT

Commits the current transaction.

```
COMMIT [WORK | TRANSACTION]
```

See [COMMIT](#) for more information.

## COPY

Copies data between a file and a table.

```

COPY <table_name> [( <column_name> [, ...] )]
  FROM { '<filename>' | PROGRAM '<command>' | STDIN }
  [ [ WITH ] ( <option> [, ...] ) ]
  [ ON SEGMENT ]

COPY { <table_name> [( <column_name> [, ...] )] | (<query> ) }
  TO { '<filename>' | PROGRAM '<command>' | STDOUT }
  [ [ WITH ] ( <option> [, ...] ) ]
  [ ON SEGMENT ]

```

See [COPY](#) for more information.

## CREATE AGGREGATE

Defines a new aggregate function.

```

CREATE AGGREGATE <name> ( [ <argmode> ] [ <argname> ] <arg_data_type> [ , ... ] ) (
    SFUNC = <statefunc>,
    STYPE = <state_data_type>
    [ , SSPACE = <state_data_size> ]
    [ , FINALFUNC = <ffunc> ]
    [ , FINALFUNC_EXTRA ]
    [ , COMBINEFUNC = <combinefunc> ]
    [ , SERIALFUNC = <serialfunc> ]
    [ , DESERIALFUNC = <deserialfunc> ]
    [ , INITCOND = <initial_condition> ]
    [ , MSFUNC = <msfunc> ]
    [ , MINVFUNC = <minvfunc> ]
    [ , MSTYPE = <mstate_data_type> ]
    [ , MSSPACE = <mstate_data_size> ]
    [ , MFINALFUNC = <mffunc> ]
    [ , MFINALFUNC_EXTRA ]
    [ , MINITCOND = <minitial_condition> ]
    [ , SORTOP = <sort_operator> ]
)

CREATE AGGREGATE <name> ( [ [ <argmode> ] [ <argname> ] <arg_data_type> [ , ... ] ]
    ORDER BY [ <argmode> ] [ <argname> ] <arg_data_type> [ , ... ] ) (
    SFUNC = <statefunc>,
    STYPE = <state_data_type>
    [ , SSPACE = <state_data_size> ]
    [ , FINALFUNC = <ffunc> ]
    [ , FINALFUNC_EXTRA ]
    [ , COMBINEFUNC = <combinefunc> ]
    [ , SERIALFUNC = <serialfunc> ]
    [ , DESERIALFUNC = <deserialfunc> ]
    [ , INITCOND = <initial_condition> ]
    [ , HYPOTHETICAL ]
)

or the old syntax

CREATE AGGREGATE <name> (
    BASETYPE = <base_type>,
    SFUNC = <statefunc>,
    STYPE = <state_data_type>
    [ , SSPACE = <state_data_size> ]
    [ , FINALFUNC = <ffunc> ]
    [ , FINALFUNC_EXTRA ]
    [ , COMBINEFUNC = <combinefunc> ]
    [ , SERIALFUNC = <serialfunc> ]
    [ , DESERIALFUNC = <deserialfunc> ]
    [ , INITCOND = <initial_condition> ]
    [ , MSFUNC = <msfunc> ]
    [ , MINVFUNC = <minvfunc> ]
    [ , MSTYPE = <mstate_data_type> ]
    [ , MSSPACE = <mstate_data_size> ]
    [ , MFINALFUNC = <mffunc> ]
    [ , MFINALFUNC_EXTRA ]
    [ , MINITCOND = <minitial_condition> ]
    [ , SORTOP = <sort_operator> ]
)

```

See [CREATE AGGREGATE](#) for more information.

## CREATE CAST

Defines a new cast.

```
CREATE CAST (<sourcetype> AS <targettype>)
    WITH FUNCTION <funcname> (<argtype> [, ...])
    [AS ASSIGNMENT | AS IMPLICIT]

CREATE CAST (<sourcetype> AS <targettype>)
    WITHOUT FUNCTION
    [AS ASSIGNMENT | AS IMPLICIT]

CREATE CAST (<sourcetype> AS <targettype>)
    WITH INOUT
    [AS ASSIGNMENT | AS IMPLICIT]
```

See [CREATE CAST](#) for more information.

## CREATE COLLATION

Defines a new collation using the specified operating system locale settings, or by copying an existing collation.

```
CREATE COLLATION <name> (
    [ LOCALE = <locale>, ]
    [ LC_COLLATE = <lc_collate>, ]
    [ LC_CTYPE = <lc_ctype> ])

CREATE COLLATION <name> FROM <existing_collation>
```

See [CREATE COLLATION](#) for more information.

## CREATE CONVERSION

Defines a new encoding conversion.

```
CREATE [DEFAULT] CONVERSION <name> FOR <source_encoding> TO
    <dest_encoding> FROM <funcname>
```

See [CREATE CONVERSION](#) for more information.

## CREATE DATABASE

Creates a new database.

```
CREATE DATABASE name [ [WITH] [OWNER [=] <user_name>]
    [TEMPLATE [=] <template>]
    [ENCODING [=] <encoding>]
    [LC_COLLATE [=] <lc_collate>]
    [LC_CTYPE [=] <lc_ctype>]
    [TABLESPACE [=] <tablespace>]
    [CONNECTION LIMIT [=] connlimit ] ]
```

See [CREATE DATABASE](#) for more information.

## CREATE DOMAIN

Defines a new domain.

```
CREATE DOMAIN <name> [AS] <data_type> [DEFAULT <expression>]
  [ COLLATE <collation> ]
  [ CONSTRAINT <constraint_name>
  | NOT NULL | NULL
  | CHECK (<expression>) [...]]
```

See [CREATE DOMAIN](#) for more information.

## CREATE EXTENSION

Registers an extension in a Greenplum database.

```
CREATE EXTENSION [ IF NOT EXISTS ] <extension_name>
  [ WITH ] [ SCHEMA <schema_name> ]
  [ VERSION <version> ]
  [ FROM <old_version> ]
  [ CASCADE ]
```

See [CREATE EXTENSION](#) for more information.

## CREATE EXTERNAL TABLE

Defines a new external table.

```
CREATE [READABLE] EXTERNAL [TEMPORARY | TEMP] TABLE <table_name>
  ( <column_name> <data_type> [, ...] | LIKE <other_table> )
  LOCATION ('file://<seghost>[:<port>]/<path>/<file>' [, ...])
  | ('gpfdist://<filehost>[:<port>]/<file_pattern>[#transform=<trans_name>]'
  [, ...])
  | ('gpfdists://<filehost>[:<port>]/<file_pattern>[#transform=<trans_name>]'
  [, ...])
  | ('pxf://<path-to-data>?PROFILE=<profile_name>[&SERVER=<server_name>][&<custom-
-option>=<value>[...]]')
  | ('s3://<S3_endpoint>[:<port>]/<bucket_name>/[<S3_prefix>] [region=<S3-region
>] [config=<config_file> | config_server=<url>]')
  [ON MASTER]
  FORMAT 'TEXT'
  [( [HEADER]
  [DELIMITER [AS] '<delimiter>' | 'OFF']
  [NULL [AS] '<>null string>']
  [ESCAPE [AS] '<escape>' | 'OFF']
  [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
  [FILL MISSING FIELDS] )]
  | 'CSV'
  [( [HEADER]

      [ESCAPE [AS] '<escape>'] )]
  | 'CUSTOM' (Formatter=<<formatter specifications>>)
  [ ENCODING '<write_encoding>' ]
  [ DISTRIBUTED BY ({<column> [<opclass>}}, [ ... ] ) | DISTRIBUTED RANDOMLY ]

```

See [CREATE EXTERNAL TABLE](#) for more information.

## CREATE FOREIGN DATA WRAPPER

Defines a new foreign-data wrapper.

```

CREATE FOREIGN DATA WRAPPER <name>
  [ HANDLER <handler_function> | NO HANDLER ]
  [ VALIDATOR <validator_function> | NO VALIDATOR ]
  [ OPTIONS ( [ mpp_execute { 'master' | 'any' | 'all segments' } [, ] ] <option> '<
value>' [, ... ] ) ]

```

See [CREATE FOREIGN DATA WRAPPER](#) for more information.

## CREATE FOREIGN TABLE

Defines a new foreign table.

```

CREATE FOREIGN TABLE [ IF NOT EXISTS ] <table_name> ( [
  <column_name> <data_type> [ OPTIONS ( <option> '<value>' [, ... ] ) ] [ COLLATE <c
ollation> ] [ <column_constraint> [ ... ] ]
  [, ... ]
] )
  SERVER <server_name>

```

```
[ OPTIONS ( [ mpp_execute { 'master' | 'any' | 'all segments' } [, ] ] <option> '<value>' [, ... ] ) ]
```

See [CREATE FOREIGN TABLE](#) for more information.

## CREATE FUNCTION

Defines a new function.

```
CREATE [OR REPLACE] FUNCTION <name>
  ( [ [<argmode>] [<argname>] <argtype> [ { DEFAULT | = } <default_expr> ] [, ...] ]
)
  [ RETURNS <rettype>
  | RETURNS TABLE ( <column_name> <column_type> [, ...] ) ]
[ LANGUAGE <langname>
| WINDOW
| IMMUTABLE | STABLE | VOLATILE | [NOT] LEAKPROOF
| CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT
| NO SQL | CONTAINS SQL | READS SQL DATA | MODIFIES SQL
| [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER
| EXECUTE ON { ANY | MASTER | ALL SEGMENTS | INITPLAN }
| COST <execution_cost>
| SET <configuration_parameter> { TO <value> | = <value> | FROM CURRENT }
| AS '<definition>'
| AS '<obj_file>', '<link_symbol>' } ...
[ WITH ( { DESCRIBE = describe_function
        } [, ...] ) ]
```

See [CREATE FUNCTION](#) for more information.

## CREATE GROUP

Defines a new database role.

```
CREATE GROUP <name> [[WITH] <option> [ ... ]]
```

See [CREATE GROUP](#) for more information.

## CREATE INDEX

Defines a new index.

```
CREATE [UNIQUE] INDEX [<name>] ON <table_name> [USING <method>]
  ( {<column_name> | (<expression>)} [COLLATE <parameter>] [<opclass>] [ ASC | DESC ] [ NULLS { FIRST | LAST } ] [, ...] )
  [ WITH ( <storage_parameter> = <value> [, ...] ) ]
  [ TABLESPACE <tablespace> ]
  [ WHERE <predicate> ]
```

See [CREATE INDEX](#) for more information.

## CREATE LANGUAGE

Defines a new procedural language.

```
CREATE [ OR REPLACE ] [ PROCEDURAL ] LANGUAGE <name>

CREATE [ OR REPLACE ] [ TRUSTED ] [ PROCEDURAL ] LANGUAGE <name>
  HANDLER <call_handler> [ INLINE <inline_handler> ]
  [ VALIDATOR <valfunction> ]
```

See [CREATE LANGUAGE](#) for more information.

## CREATE MATERIALIZED VIEW

Defines a new materialized view.

```
CREATE MATERIALIZED VIEW <table_name>
  [ (<column_name> [, ...] ) ]
  [ WITH ( <storage_parameter> [= <value>] [, ... ] ) ]
  [ TABLESPACE <tablespace_name> ]
  AS <query>
  [ WITH [ NO ] DATA ]
  [ DISTRIBUTED { | BY <column> [<opclass>], [ ... ] | RANDOMLY | REPLICATED } ]
```

See [CREATE MATERIALIZED VIEW](#) for more information.

## CREATE OPERATOR

Defines a new operator.

```
CREATE OPERATOR <name> (
  PROCEDURE = <funcname>
  [, LEFTARG = <lefttype>] [, RIGHTARG = <righttype>]
  [, COMMUTATOR = <com_op>] [, NEGATOR = <neg_op>]
  [, RESTRICT = <res_proc>] [, JOIN = <join_proc>]
  [, HASHES] [, MERGES] )
```

See [CREATE OPERATOR](#) for more information.

## CREATE OPERATOR CLASS

Defines a new operator class.

```
CREATE OPERATOR CLASS <name> [DEFAULT] FOR TYPE <data_type>
  USING <index_method> [ FAMILY <family_name> ] AS
  { OPERATOR <strategy_number> <operator_name> [ ( <op_type>, <op_type> ) ] [ FOR SEARCH | FOR ORDER BY <sort_family_name> ]
  | FUNCTION <support_number> <funcname> (<argument_type> [, ...] )
  | STORAGE <storage_type>
  } [, ... ]
```

See [CREATE OPERATOR CLASS](#) for more information.

## CREATE OPERATOR FAMILY

Defines a new operator family.

```
CREATE OPERATOR FAMILY <name> USING <index_method>
```

See [CREATE OPERATOR FAMILY](#) for more information.

## CREATE PROTOCOL

Registers a custom data access protocol that can be specified when defining a Greenplum Database external table.

```
CREATE [TRUSTED] PROTOCOL <name> (
  [readfunc='<read_call_handler>'] [, writefunc='<write_call_handler>']
  [, validatorfunc='<validate_handler>' ])
```

See [CREATE PROTOCOL](#) for more information.

## CREATE RESOURCE GROUP

Defines a new resource group.

```
CREATE RESOURCE GROUP <name> WITH (<group_attribute>=<value> [, ... ])
```

See [CREATE RESOURCE GROUP](#) for more information.

## CREATE RESOURCE QUEUE

Defines a new resource queue.

```
CREATE RESOURCE QUEUE <name> WITH (<queue_attribute>=<value> [, ... ])
```

See [CREATE RESOURCE QUEUE](#) for more information.

## CREATE ROLE

Defines a new database role (user or group).

```
CREATE ROLE <name> [[WITH] <option> [ ... ]]
```

See [CREATE ROLE](#) for more information.

## CREATE RULE

Defines a new rewrite rule.

```
CREATE [OR REPLACE] RULE <name> AS ON <event>
  TO <table_name> [WHERE <condition>]
  DO [ALSO | INSTEAD] { NOTHING | <command> | (<command>; <command>
  ... ) }
```

See [CREATE RULE](#) for more information.

## CREATE SCHEMA

Defines a new schema.

```
CREATE SCHEMA <schema_name> [AUTHORIZATION <username>]
  [<schema_element> [ ... ]]

CREATE SCHEMA AUTHORIZATION <rolename> [<schema_element> [ ... ]]

CREATE SCHEMA IF NOT EXISTS <schema_name> [ AUTHORIZATION <user_name> ]

CREATE SCHEMA IF NOT EXISTS AUTHORIZATION <user_name>
```

See [CREATE SCHEMA](#) for more information.

## CREATE SEQUENCE

Defines a new sequence generator.

```
CREATE [TEMPORARY | TEMP] SEQUENCE <name>
  [INCREMENT [BY] <value>]
  [MINVALUE <minvalue> | NO MINVALUE]
  [MAXVALUE <maxvalue> | NO MAXVALUE]
  [START [ WITH ] <start>]
  [CACHE <cache>]
  [[NO] CYCLE]
  [OWNED BY { <table>.<column> | NONE }]
```

See [CREATE SEQUENCE](#) for more information.

## CREATE SERVER

Defines a new foreign server.

```
CREATE SERVER <server_name> [ TYPE '<server_type>' ] [ VERSION '<server_version>' ]
  FOREIGN DATA WRAPPER <fdw_name>
  [ OPTIONS ( [ mpp_execute { 'master' | 'any' | 'all segments' } [, ] ]
    [ num_segments '<num>' [, ] ]
    [ <option> '<value>' [, ... ] ] ) ]
```

See [CREATE SERVER](#) for more information.

## CREATE TABLE

Defines a new table.

```
CREATE [ [GLOBAL | LOCAL] {TEMPORARY | TEMP } | UNLOGGED] TABLE [IF NOT EXISTS]
  <table_name> (
  [ { <column_name> <data_type> [ COLLATE <collation> ] [<column_constraint> [ ... ] ]
```

```

[ ENCODING ( <storage_directive> [, ...] ) ]
  | <table_constraint>
  | LIKE <source_table> [ <like_option> ... ] }
  | [ <column_reference_storage_directive> [, ...]
    [, ... ]
] )
[ INHERITS ( <parent_table> [, ... ] ) ]
[ WITH ( <storage_parameter> [=<value>] [, ... ] ) ]
[ ON COMMIT { PRESERVE ROWS | DELETE ROWS | DROP } ]
[ TABLESPACE <tablespace_name> ]
[ DISTRIBUTED BY ( <column> [<opclass>], [ ... ] )
  | DISTRIBUTED RANDOMLY | DISTRIBUTED REPLICATED ]

{ --partitioned table using SUBPARTITION TEMPLATE
[ PARTITION BY <partition_type> ( <column> )
  { [ SUBPARTITION BY <partition_type> ( <column1> )
    SUBPARTITION TEMPLATE ( <template_spec> ) ]
    [ SUBPARTITION BY <partition_type> ( <column2> )
    SUBPARTITION TEMPLATE ( <template_spec> ) ]
    [...] }
  ( <partition_spec> ) ]
} |

{ **-- partitioned table without SUBPARTITION TEMPLATE
**[ PARTITION BY <partition_type> ( <column> )
  [ SUBPARTITION BY <partition_type> ( <column1> ) ]
  [ SUBPARTITION BY <partition_type> ( <column2> ) ]
  [...]
  ( <partition_spec>
    [ ( <subpartition_spec_column1>
      [ ( <subpartition_spec_column2>
        [...] ) ] ) ] ),
  [ <partition_spec>
    [ ( <subpartition_spec_column1>
      [ ( <subpartition_spec_column2>
        [...] ) ] ) ] ), ]
  [...]
  ) ]
}

CREATE [ [GLOBAL | LOCAL] {TEMPORARY | TEMP} | UNLOGGED ] TABLE [IF NOT EXISTS]
  <table_name>
  OF <type_name> [ (
  { <column_name> WITH OPTIONS [ <column_constraint> [ ... ] ]
    | <table_constraint> }
  [, ... ]
  ) ]
[ WITH ( <storage_parameter> [=<value>] [, ... ] ) ]
[ ON COMMIT { PRESERVE ROWS | DELETE ROWS | DROP } ]
[ TABLESPACE <tablespace_name> ]

```

See [CREATE TABLE](#) for more information.

## CREATE TABLE AS

Defines a new table from the results of a query.

```
CREATE [ [ GLOBAL | LOCAL ] { TEMPORARY | TEMP } | UNLOGGED ] TABLE <table_name>
  [ ( <column_name> [, ... ] ) ]
  [ WITH ( <storage_parameter> [= <value>] [, ... ] ) | WITHOUT OIDS ]
  [ ON COMMIT { PRESERVE ROWS | DELETE ROWS | DROP } ]
  [ TABLESPACE <tablespace_name> ]
AS <query>
  [ WITH [ NO ] DATA ]
  [ DISTRIBUTED BY (column [, ... ] ) | DISTRIBUTED RANDOMLY | DISTRIBUTED REPLICATED ]
```

See [CREATE TABLE AS](#) for more information.

## CREATE TABLESPACE

Defines a new tablespace.

```
CREATE TABLESPACE <tablespace_name> [OWNER <username>] LOCATION '</path/to/dir>'
  [WITH (content<ID_1>='</path/to/dir1>' [, content<ID_2>='</path/to/dir2>' ... ])]
```

See [CREATE TABLESPACE](#) for more information.

## CREATE TEXT SEARCH CONFIGURATION

Defines a new text search configuration.

```
CREATE TEXT SEARCH CONFIGURATION <name> (
  PARSER = <parser_name> |
  COPY = <source_config>
)
```

See [CREATE TEXT SEARCH CONFIGURATION](#) for more information.

## CREATE TEXT SEARCH DICTIONARY

Defines a new text search dictionary.

```
CREATE TEXT SEARCH DICTIONARY <name> (
  TEMPLATE = <template>
  [, <option> = <value> [, ... ] ]
)
```

See [CREATE TEXT SEARCH DICTIONARY](#) for more information.

## CREATE TEXT SEARCH PARSER

Defines a new text search parser.

```
CREATE TEXT SEARCH PARSER name (
  START = start_function ,
  GETTOKEN = gettoken_function ,
  END = end_function ,
```

```

    LEXTYPES = lextypes_function
    [, HEADLINE = headline_function ]
)

```

See [CREATE TEXT SEARCH PARSER](#) for more information.

## CREATE TEXT SEARCH TEMPLATE

Defines a new text search template.

```

CREATE TEXT SEARCH TEMPLATE <name> (
    [ INIT = <init_function> , ]
    LEXIZE = <lexize_function>
)

```

See [CREATE TEXT SEARCH TEMPLATE](#) for more information.

## CREATE TYPE

Defines a new data type.

```

CREATE TYPE <name> AS
    ( <attribute_name> <data_type> [ COLLATE <collation> ] [, ... ] )

CREATE TYPE <name> AS ENUM
    ( [ '<label>' [, ... ] ] )

CREATE TYPE <name> AS RANGE (
    SUBTYPE = <subtype>
    [ , SUBTYPE_OPCCLASS = <subtype_operator_class> ]
    [ , COLLATION = <collation> ]
    [ , CANONICAL = <canonical_function> ]
    [ , SUBTYPE_DIFF = <subtype_diff_function> ]
)

CREATE TYPE <name> (
    INPUT = <input_function>,
    OUTPUT = <output_function>
    [, RECEIVE = <receive_function>]
    [, SEND = <send_function>]
    [, TYPMOD_IN = <type_modifier_input_function> ]
    [, TYPMOD_OUT = <type_modifier_output_function> ]
    [, INTERNALLENGTH = {<internallength> | VARIABLE}]
    [, PASSEDBYVALUE]
    [, ALIGNMENT = <alignment>]
    [, STORAGE = <storage>]
    [, LIKE = <like_type>]
    [, CATEGORY = <category>]
    [, PREFERRED = <preferred>]
    [, DEFAULT = <default>]
    [, ELEMENT = <element>]
    [, DELIMITER = <delimiter>]
    [, COLLATABLE = <collatable>]
    [, COMPRESSTYPE = <compression_type>]
    [, COMPRESSLEVEL = <compression_level>]
    [, BLOCKSIZE = <blocksize> ]
)

```

```
CREATE TYPE <name>
```

See [CREATE TYPE](#) for more information.

## CREATE USER

Defines a new database role with the `LOGIN` privilege by default.

```
CREATE USER <name> [[WITH] <option> [ ... ]]
```

See [CREATE USER](#) for more information.

## CREATE USER MAPPING

Defines a new mapping of a user to a foreign server.

```
CREATE USER MAPPING FOR { <username> | USER | CURRENT_USER | PUBLIC }
    SERVER <servername>
    [ OPTIONS ( <option> '<value>' [, ... ] ) ]
```

See [CREATE USER MAPPING](#) for more information.

## CREATE VIEW

Defines a new view.

```
CREATE [OR REPLACE] [TEMP | TEMPORARY] [RECURSIVE] VIEW <name> [ ( <column_name> [,
... ] ) ]
    [ WITH ( view_option_name [= view_option_value] [, ... ] ) ]
    AS <query>
    [ WITH [ CASCADED | LOCAL ] CHECK OPTION ]
```

See [CREATE VIEW](#) for more information.

## DEALLOCATE

Deallocates a prepared statement.

```
DEALLOCATE [PREPARE] <name>
```

See [DEALLOCATE](#) for more information.

## DECLARE

Defines a cursor.

```
DECLARE <name> [BINARY] [INSENSITIVE] [NO SCROLL] [PARALLEL RETRIEVE] CURSOR
    [{WITH | WITHOUT} HOLD]
    FOR <query> [FOR READ ONLY]
```

See [DECLARE](#) for more information.

## DELETE

Deletes rows from a table.

```
[ WITH [ RECURSIVE ] <with_query> [, ...] ]
DELETE FROM [ONLY] <table> [[AS] <alias>]
    [USING <usinglist>]
    [WHERE <condition> | WHERE CURRENT OF <cursor_name>]
    [RETURNING * | <output_expression> [[AS] <output_name>] [, ...]]
```

See [DELETE](#) for more information.

## DISCARD

Discards the session state.

```
DISCARD { ALL | PLANS | TEMPORARY | TEMP }
```

See [DISCARD](#) for more information.

## DROP AGGREGATE

Removes an aggregate function.

```
DROP AGGREGATE [IF EXISTS] <name> ( <aggregate_signature> ) [CASCADE | RESTRICT]
```

See [DROP AGGREGATE](#) for more information.

## DO

Runs anonymous code block as a transient anonymous function.

```
DO [ LANGUAGE <lang_name> ] <code>
```

See [DO](#) for more information.

## DROP CAST

Removes a cast.

```
DROP CAST [IF EXISTS] (<sourcetype> AS <targettype>) [CASCADE | RESTRICT]
```

See [DROP CAST](#) for more information.

## DROP COLLATION

Removes a previously defined collation.

```
DROP COLLATION [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

See [DROP COLLATION](#) for more information.

## DROP CONVERSION

Removes a conversion.

```
DROP CONVERSION [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

See [DROP CONVERSION](#) for more information.

## DROP DATABASE

Removes a database.

```
DROP DATABASE [ IF EXISTS ] <name>
```

See [DROP DATABASE](#) for more information.

## DROP DOMAIN

Removes a domain.

```
DROP DOMAIN [ IF EXISTS ] <name> [, ...] [ CASCADE | RESTRICT ]
```

See [DROP DOMAIN](#) for more information.

## DROP EXTENSION

Removes an extension from a Greenplum database.

```
DROP EXTENSION [ IF EXISTS ] <name> [, ...] [ CASCADE | RESTRICT ]
```

See [DROP EXTENSION](#) for more information.

## DROP EXTERNAL TABLE

Removes an external table definition.

```
DROP EXTERNAL [WEB] TABLE [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

See [DROP EXTERNAL TABLE](#) for more information.

## DROP FOREIGN DATA WRAPPER

Removes a foreign-data wrapper.

```
DROP FOREIGN DATA WRAPPER [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

See [DROP FOREIGN DATA WRAPPER](#) for more information.

## DROP FOREIGN TABLE

Removes a foreign table.

```
DROP FOREIGN TABLE [ IF EXISTS ] <name> [, ...] [ CASCADE | RESTRICT ]
```

See [DROP FOREIGN TABLE](#) for more information.

## DROP FUNCTION

Removes a function.

```
DROP FUNCTION [IF EXISTS] name ( [ [argmode] [argname] argtype  
[, ...] ] ) [CASCADE | RESTRICT]
```

See [DROP FUNCTION](#) for more information.

## DROP GROUP

Removes a database role.

```
DROP GROUP [IF EXISTS] <name> [, ...]
```

See [DROP GROUP](#) for more information.

## DROP INDEX

Removes an index.

```
DROP INDEX [ CONCURRENTLY ] [ IF EXISTS ] <name> [, ...] [ CASCADE | RESTRICT ]
```

See [DROP INDEX](#) for more information.

## DROP LANGUAGE

Removes a procedural language.

```
DROP [PROCEDURAL] LANGUAGE [IF EXISTS] <name> [CASCADE | RESTRICT]
```

See [DROP LANGUAGE](#) for more information.

## DROP MATERIALIZED VIEW

Removes a materialized view.

```
DROP MATERIALIZED VIEW [ IF EXISTS ] <name> [, ...] [ CASCADE | RESTRICT ]
```

See [DROP MATERIALIZED VIEW](#) for more information.

## DROP OPERATOR

Removes an operator.

```
DROP OPERATOR [IF EXISTS] <name> ( {<lefttype> | NONE} ,
    {<righttype> | NONE} ) [CASCADE | RESTRICT]
```

See [DROP OPERATOR](#) for more information.

## DROP OPERATOR CLASS

Removes an operator class.

```
DROP OPERATOR CLASS [IF EXISTS] <name> USING <index_method> [CASCADE | RESTRICT]
```

See [DROP OPERATOR CLASS](#) for more information.

## DROP OPERATOR FAMILY

Removes an operator family.

```
DROP OPERATOR FAMILY [IF EXISTS] <name> USING <index_method> [CASCADE | RESTRICT]
```

See [DROP OPERATOR FAMILY](#) for more information.

## DROP OWNED

Removes database objects owned by a database role.

```
DROP OWNED BY <name> [, ...] [CASCADE | RESTRICT]
```

See [DROP OWNED](#) for more information.

## DROP PROTOCOL

Removes a external table data access protocol from a database.

```
DROP PROTOCOL [IF EXISTS] <name>
```

See [DROP PROTOCOL](#) for more information.

## DROP RESOURCE GROUP

Removes a resource group.

```
DROP RESOURCE GROUP <group_name>
```

See [DROP RESOURCE GROUP](#) for more information.

## DROP RESOURCE QUEUE

Removes a resource queue.

```
DROP RESOURCE QUEUE <queue_name>
```

See [DROP RESOURCE QUEUE](#) for more information.

## DROP ROLE

Removes a database role.

```
DROP ROLE [IF EXISTS] <name> [, ...]
```

See [DROP ROLE](#) for more information.

## DROP RULE

Removes a rewrite rule.

```
DROP RULE [IF EXISTS] <name> ON <table_name> [CASCADE | RESTRICT]
```

See [DROP RULE](#) for more information.

## DROP SCHEMA

Removes a schema.

```
DROP SCHEMA [IF EXISTS] <name> [, ...] [CASCADE | RESTRICT]
```

See [DROP SCHEMA](#) for more information.

## DROP SEQUENCE

Removes a sequence.

```
DROP SEQUENCE [IF EXISTS] <name> [, ...] [CASCADE | RESTRICT]
```

See [DROP SEQUENCE](#) for more information.

## DROP SERVER

Removes a foreign server descriptor.

```
DROP SERVER [ IF EXISTS ] <servername> [ CASCADE | RESTRICT ]
```

See [DROP SERVER](#) for more information.

## DROP TABLE

Removes a table.

```
DROP TABLE [IF EXISTS] <name> [, ...] [CASCADE | RESTRICT]
```

See [DROP TABLE](#) for more information.

## DROP TABLESPACE

Removes a tablespace.

```
DROP TABLESPACE [IF EXISTS] <tablespacename>
```

See [DROP TABLESPACE](#) for more information.

## DROP TEXT SEARCH CONFIGURATION

Removes a text search configuration.

```
DROP TEXT SEARCH CONFIGURATION [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

See [DROP TEXT SEARCH CONFIGURATION](#) for more information.

## DROP TEXT SEARCH DICTIONARY

Removes a text search dictionary.

```
DROP TEXT SEARCH DICTIONARY [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

See [DROP TEXT SEARCH DICTIONARY](#) for more information.

## DROP TEXT SEARCH PARSER

Remove a text search parser.

```
DROP TEXT SEARCH PARSER [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

See [DROP TEXT SEARCH PARSER](#) for more information.

## DROP TEXT SEARCH TEMPLATE

Removes a text search template.

```
DROP TEXT SEARCH TEMPLATE [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

See [DROP TEXT SEARCH TEMPLATE](#) for more information.

## DROP TYPE

Removes a data type.

```
DROP TYPE [IF EXISTS] <name> [, ...] [CASCADE | RESTRICT]
```

See [DROP TYPE](#) for more information.

## DROP USER

Removes a database role.

```
DROP USER [IF EXISTS] <name> [, ...]
```

See [DROP USER](#) for more information.

## DROP USER MAPPING

Removes a user mapping for a foreign server.

```
DROP USER MAPPING [ IF EXISTS ] { <username> | USER | CURRENT_USER | PUBLIC }
    SERVER <servername>
```

See [DROP USER MAPPING](#) for more information.

## DROP VIEW

Removes a view.

```
DROP VIEW [IF EXISTS] <name> [, ...] [CASCADE | RESTRICT]
```

See [DROP VIEW](#) for more information.

## END

Commits the current transaction.

```
END [WORK | TRANSACTION]
```

See [END](#) for more information.

## EXECUTE

Runs a prepared SQL statement.

```
EXECUTE <name> [ (<parameter> [, ...] ) ]
```

See [EXECUTE](#) for more information.

## EXPLAIN

Shows the query plan of a statement.

```
EXPLAIN [ ( <option> [, ...] ) ] <statement>
EXPLAIN [ANALYZE] [VERBOSE] <statement>
```

See [EXPLAIN](#) for more information.

## FETCH

Retrieves rows from a query using a cursor.

```
FETCH [ <forward_direction> { FROM | IN } ] <cursor_name>
```

See [FETCH](#) for more information.

## GRANT

Defines access privileges.

```
GRANT { {SELECT | INSERT | UPDATE | DELETE | REFERENCES |
TRIGGER | TRUNCATE } [, ...] | ALL [PRIVILEGES] }
    ON { [TABLE] <table_name> [, ...]
        | ALL TABLES IN SCHEMA <schema_name> [, ...] }
    TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { { SELECT | INSERT | UPDATE | REFERENCES } ( <column_name> [, ...] )
    [, ...] | ALL [ PRIVILEGES ] ( <column_name> [, ...] ) }
    ON [ TABLE ] <table_name> [, ...]
    TO { <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { {USAGE | SELECT | UPDATE} [, ...] | ALL [PRIVILEGES] }
    ON { SEQUENCE <sequence_name> [, ...]
        | ALL SEQUENCES IN SCHEMA <schema_name> [, ...] }
    TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { {CREATE | CONNECT | TEMPORARY | TEMP} [, ...] | ALL
[PRIVILEGES] }
    ON DATABASE <database_name> [, ...]
    TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
    ON DOMAIN <domain_name> [, ...]
    TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
    ON FOREIGN DATA WRAPPER <fdw_name> [, ...]
    TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
    ON FOREIGN SERVER <server_name> [, ...]
    TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { EXECUTE | ALL [PRIVILEGES] }
    ON { FUNCTION <function_name> ( [ [ <argmode> ] [ <argname> ] <argtype> [, ...]
] ) [, ...]
        | ALL FUNCTIONS IN SCHEMA <schema_name> [, ...] }
    TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]
```

```

GRANT { USAGE | ALL [PRIVILEGES] }
  ON LANGUAGE <lang_name> [, ...]
  TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { { CREATE | USAGE } [, ...] | ALL [PRIVILEGES] }
  ON SCHEMA <schema_name> [, ...]
  TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { CREATE | ALL [PRIVILEGES] }
  ON TABLESPACE <tablespace_name> [, ...]
  TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
  ON TYPE <type_name> [, ...]
  TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT <parent_role> [, ...]
  TO <member_role> [, ...] [WITH ADMIN OPTION]

GRANT { SELECT | INSERT | ALL [PRIVILEGES] }
  ON PROTOCOL <protocolname>
  TO <username>

```

See [GRANT](#) for more information.

## INSERT

Creates new rows in a table.

```

[ WITH [ RECURSIVE ] <with_query> [, ...] ]
INSERT INTO <table> [( <column> [, ...] )]
  {DEFAULT VALUES | VALUES ( {<expression> | DEFAULT} [, ...] ) [, ...] | <query>}
  [RETURNING * | <output_expression> [[AS] <output_name>] [, ...]]

```

See [INSERT](#) for more information.

## LOAD

Loads or reloads a shared library file.

```
LOAD '<filename>'
```

See [LOAD](#) for more information.

## LOCK

Locks a table.

```
LOCK [TABLE] [ONLY] name [ * ] [, ...] [IN <lockmode> MODE] [NOWAIT]
```

See [LOCK](#) for more information.

## MOVE

Positions a cursor.

```
MOVE [ <forward_direction> [ FROM | IN ] ] <cursor_name>
```

See [MOVE](#) for more information.

## PREPARE

Prepare a statement for execution.

```
PREPARE <name> [ (<datatype> [, ...] ) ] AS <statement>
```

See [PREPARE](#) for more information.

## REASSIGN OWNED

Changes the ownership of database objects owned by a database role.

```
REASSIGN OWNED BY <old_role> [, ...] TO <new_role>
```

See [REASSIGN OWNED](#) for more information.

## REFRESH MATERIALIZED VIEW

Replaces the contents of a materialized view.

```
REFRESH MATERIALIZED VIEW [ CONCURRENTLY ] <name>  
[ WITH [ NO ] DATA ]
```

See [REFRESH MATERIALIZED VIEW](#) for more information.

## REINDEX

Rebuilds indexes.

```
REINDEX {INDEX | TABLE | DATABASE | SYSTEM} <name>
```

See [REINDEX](#) for more information.

## RELEASE SAVEPOINT

Destroys a previously defined savepoint.

```
RELEASE [SAVEPOINT] <savepoint_name>
```

See [RELEASE SAVEPOINT](#) for more information.

## RESET

Restores the value of a system configuration parameter to the default value.

```
RESET <configuration_parameter>

RESET ALL
```

See [RESET](#) for more information.

## RETRIEVE

Retrieves rows from a query using a parallel retrieve cursor.

```
RETRIEVE { <count> | ALL } FROM ENDPOINT <endpoint_name>
```

See [RETRIEVE](#) for more information.

## REVOKE

Removes access privileges.

```
REVOKE [GRANT OPTION FOR] { {SELECT | INSERT | UPDATE | DELETE
    | REFERENCES | TRIGGER | TRUNCATE } [, ...] | ALL [PRIVILEGES] }

    ON { [TABLE] <table_name> [, ...]
        | ALL TABLES IN SCHEMA schema_name [, ...] }
    FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]
    [CASCADE | RESTRICT]

REVOKE [ GRANT OPTION FOR ] { { SELECT | INSERT | UPDATE
    | REFERENCES } ( <column_name> [, ...] )
    [, ...] | ALL [ PRIVILEGES ] ( <column_name> [, ...] ) }
    ON [ TABLE ] <table_name> [, ...]
    FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]
    [ CASCADE | RESTRICT ]

REVOKE [GRANT OPTION FOR] { {USAGE | SELECT | UPDATE} [, ...]
    | ALL [PRIVILEGES] }
    ON { SEQUENCE <sequence_name> [, ...]
        | ALL SEQUENCES IN SCHEMA schema_name [, ...] }
    FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]

[CASCADE | RESTRICT]

```

See [REVOKE](#) for more information.

## ROLLBACK

Stops the current transaction.

```
ROLLBACK [WORK | TRANSACTION]
```

See [ROLLBACK](#) for more information.

## ROLLBACK TO SAVEPOINT

Rolls back the current transaction to a savepoint.

```
ROLLBACK [WORK | TRANSACTION] TO [SAVEPOINT] <savepoint_name>
```

See [ROLLBACK TO SAVEPOINT](#) for more information.

## SAVEPOINT

Defines a new savepoint within the current transaction.

```
SAVEPOINT <savepoint_name>
```

See [SAVEPOINT](#) for more information.

## SELECT

Retrieves rows from a table or view.

```
[ WITH [ RECURSIVE ] <with_query> [, ... ] ]
SELECT [ ALL | DISTINCT [ ON ( <expression> [, ...] ) ] ]
  * | <expression > [[AS] <output_name>] [, ...]
  [FROM <from_item> [, ...]]
  [WHERE <condition>]
  [GROUP BY <grouping_element> [, ...]]
  [HAVING <condition> [, ...]]
  [WINDOW <window_name> AS ( <window_definition> ) [, ... ] ]
  [{ UNION | INTERSECT | EXCEPT } [ ALL | DISTINCT ] <select>]
  [ORDER BY <expression> [ ASC | DESC | USING <operator> ] [ NULLS { FIRST | LAST } ] [,
...]]
  [LIMIT { <count> | ALL } ]
  [OFFSET <start> [ ROW | ROWS ] ]
  [FETCH { FIRST | NEXT } [ <count> ] { ROW | ROWS } ONLY]
  [FOR { UPDATE | NO KEY UPDATE | SHARE | KEY SHARE } [ OF <table_name> [, ...] ] [NOWAIT]
...]]

TABLE { [ ONLY ] <table_name> [ * ] | <with_query_name> }
```

See [SELECT](#) for more information.

## SELECT INTO

Defines a new table from the results of a query.

```
[ WITH [ RECURSIVE ] <with_query> [, ... ] ]
SELECT [ ALL | DISTINCT [ ON ( <expression> [, ...] ) ] ]
  * | <expression> [AS <output_name>] [, ...]
  INTO [TEMPORARY | TEMP | UNLOGGED ] [TABLE] <new_table>
  [FROM <from_item> [, ...]]
  [WHERE <condition>]
  [GROUP BY <expression> [, ...]]
  [HAVING <condition> [, ...]]
  [{ UNION | INTERSECT | EXCEPT } [ ALL | DISTINCT ] <select>]
  [ORDER BY <expression> [ ASC | DESC | USING <operator> ] [ NULLS { FIRST | LAST } ] [,
...]]
  [LIMIT { <count> | ALL } ]
```

```
[OFFSET <start> [ ROW | ROWS ] ]
[FETCH { FIRST | NEXT } [ <count> ] { ROW | ROWS } ONLY ]
[FOR {UPDATE | SHARE} [OF <table_name> [, ...]] [NOWAIT]
[...]]
```

See [SELECT INTO](#) for more information.

## SET

Changes the value of a Greenplum Database configuration parameter.

```
SET [SESSION | LOCAL] <configuration_parameter> {TO | =} <value> |
'<value>' | DEFAULT}

SET [SESSION | LOCAL] TIME ZONE {<timezone> | LOCAL | DEFAULT}
```

See [SET](#) for more information.

## SET CONSTRAINTS

Sets constraint check timing for the current transaction.

```
SET CONSTRAINTS { ALL | <name> [, ...] } { DEFERRED | IMMEDIATE }
```

See [SET CONSTRAINTS](#) for more information.

## SET ROLE

Sets the current role identifier of the current session.

```
SET [SESSION | LOCAL] ROLE <rolename>

SET [SESSION | LOCAL] ROLE NONE

RESET ROLE
```

See [SET ROLE](#) for more information.

## SET SESSION AUTHORIZATION

Sets the session role identifier and the current role identifier of the current session.

```
SET [SESSION | LOCAL] SESSION AUTHORIZATION <rolename>

SET [SESSION | LOCAL] SESSION AUTHORIZATION DEFAULT

RESET SESSION AUTHORIZATION
```

See [SET SESSION AUTHORIZATION](#) for more information.

## SET TRANSACTION

Sets the characteristics of the current transaction.

```
SET TRANSACTION [<transaction_mode>] [READ ONLY | READ WRITE]

SET TRANSACTION SNAPSHOT <snapshot_id>

SET SESSION CHARACTERISTICS AS TRANSACTION <transaction_mode>
    [READ ONLY | READ WRITE]
    [NOT] DEFERRABLE
```

See [SET TRANSACTION](#) for more information.

## SHOW

Shows the value of a system configuration parameter.

```
SHOW <configuration_parameter>

SHOW ALL
```

See [SHOW](#) for more information.

## START TRANSACTION

Starts a transaction block.

```
START TRANSACTION [<transaction_mode>] [READ WRITE | READ ONLY]
```

See [START TRANSACTION](#) for more information.

## TRUNCATE

Empties a table of all rows.

```
TRUNCATE [TABLE] [ONLY] <name> [ * ] [, ...]
    [ RESTART IDENTITY | CONTINUE IDENTITY ] [CASCADE | RESTRICT]
```

See [TRUNCATE](#) for more information.

## UPDATE

Updates rows of a table.

```
[ WITH [ RECURSIVE ] <with_query> [, ...] ]
UPDATE [ONLY] <table> [[AS] <alias>]
    SET {<column> = {<expression> | DEFAULT} |
        (<column> [, ...]) = ({<expression> | DEFAULT} [, ...])} [, ...]
    [FROM <fromlist>]
    [WHERE <condition> | WHERE CURRENT OF <cursor_name> ]
```

See [UPDATE](#) for more information.

# VACUUM

Garbage-collects and optionally analyzes a database.

```
VACUUM [( { FULL | FREEZE | VERBOSE | ANALYZE } [, ...] )] [<table> [( <column> [, ...] )]]

VACUUM [FULL] [FREEZE] [VERBOSE] [<table>]

VACUUM [FULL] [FREEZE] [VERBOSE] ANALYZE
      [<table> [( <column> [, ...] )]]
```

See [VACUUM](#) for more information.

# VALUES

Computes a set of rows.

```
VALUES ( <expression> [, ...] ) [, ...]
      [ORDER BY <sort_expression> [ ASC | DESC | USING <operator> ] [, ...] ]
      [LIMIT { <count> | ALL } ]
      [OFFSET <start> [ ROW | ROWS ] ]
      [FETCH { FIRST | NEXT } [<count> ] { ROW | ROWS } ONLY ]
```

See [VALUES](#) for more information.

Parent topic: [SQL Commands](#)

# ABORT

Terminates the current transaction.

## Synopsis

```
ABORT [WORK | TRANSACTION]
```

## Description

**ABORT** rolls back the current transaction and causes all the updates made by the transaction to be discarded. This command is identical in behavior to the standard SQL command [ROLLBACK](#), and is present only for historical reasons.

## Parameters

WORK

TRANSACTION

Optional key words. They have no effect.

## Notes

Use `COMMIT` to successfully terminate a transaction.

Issuing `ABORT` when not inside a transaction does no harm, but it will provoke a warning message.

## Compatibility

This command is a Greenplum Database extension present for historical reasons. `ROLLBACK` is the equivalent standard SQL command.

## See Also

[BEGIN](#), [COMMIT](#), [ROLLBACK](#)

Parent topic: [SQL Commands](#)

## ALTER AGGREGATE

Changes the definition of an aggregate function

## Synopsis

```
ALTER AGGREGATE <name> ( <aggregate_signature> ) RENAME TO <new_name>

ALTER AGGREGATE <name> ( <aggregate_signature> ) OWNER TO <new_owner>

ALTER AGGREGATE <name> ( <aggregate_signature> ) SET SCHEMA <new_schema>
```

where `aggregate_signature` is:

```
* |
[ <argmode> ] [ <argname> ] <argtype> [ , ... ] |
[ [ <argmode> ] [ <argname> ] <argtype> [ , ... ] ] ORDER BY [ <argmode> ] [ <argname> ]
<argtype> [ , ... ]
```

## Description

`ALTER AGGREGATE` changes the definition of an aggregate function.

You must own the aggregate function to use `ALTER AGGREGATE`. To change the schema of an aggregate function, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the aggregate function's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the aggregate function. However, a superuser can alter ownership of any aggregate function anyway.)

## Parameters

`name`

The name (optionally schema-qualified) of an existing aggregate function.

`argmode`

The mode of an argument: `IN` or `VARIADIC`. If omitted, the default is `IN`.

`argname`

The name of an argument. Note that `ALTER AGGREGATE` does not actually pay any attention to argument names, since only the argument data types are needed to determine the aggregate function's identity.

`argtype`

An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write `*` in place of the list of input data types. To reference an ordered-set aggregate function, write `ORDER BY` between the direct and aggregated argument specifications.

`new_name`

The new name of the aggregate function.

`new_owner`

The new owner of the aggregate function.

`new_schema`

The new schema for the aggregate function.

## Notes

The recommended syntax for referencing an ordered-set aggregate is to write `ORDER BY` between the direct and aggregated argument specifications, in the same style as in `CREATE AGGREGATE`. However, it will also work to omit `ORDER BY` and just run the direct and aggregated argument specifications into a single list. In this abbreviated form, if `VARIADIC "any"` was used in both the direct and aggregated argument lists, write `VARIADIC "any"` only once.

## Examples

To rename the aggregate function `myavg` for type `integer` to `my_average`:

```
ALTER AGGREGATE myavg(integer) RENAME TO my_average;
```

To change the owner of the aggregate function `myavg` for type `integer` to `joe`:

```
ALTER AGGREGATE myavg(integer) OWNER TO joe;
```

To move the aggregate function `myavg` for type `integer` into schema `myschema`:

```
ALTER AGGREGATE myavg(integer) SET SCHEMA myschema;
```

## Compatibility

There is no `ALTER AGGREGATE` statement in the SQL standard.

## See Also

[CREATE AGGREGATE](#), [DROP AGGREGATE](#)

Parent topic: [SQL Commands](#)

# ALTER COLLATION

Changes the definition of a collation.

## Synopsis

```
ALTER COLLATION <name> RENAME TO <new_name>

ALTER COLLATION <name> OWNER TO <new_owner>

ALTER COLLATION <name> SET SCHEMA <new_schema>
```

## Parameters

name

The name (optionally schema-qualified) of an existing collation.

new\_name

The new name of the collation.

new\_owner

The new owner of the collation.

new\_schema

The new schema for the collation.

## Description

You must own the collation to use `ALTER COLLATION`. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the collation's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the collation. However, a superuser can alter ownership of any collation anyway.)

## Examples

To rename the collation `de_DE` to `german`:

```
ALTER COLLATION "de_DE" RENAME TO german;
```

To change the owner of the collation `en_US` to `joe`:

```
ALTER COLLATION "en_US" OWNER TO joe;
```

## Compatibility

There is no `ALTER COLLATION` statement in the SQL standard.

## See Also

[CREATE COLLATION](#), [DROP COLLATION](#)

Parent topic: [SQL Commands](#)

# ALTER CONVERSION

Changes the definition of a conversion.

## Synopsis

```
ALTER CONVERSION <name> RENAME TO <newname>

ALTER CONVERSION <name> OWNER TO <newowner>

ALTER CONVERSION <name> SET SCHEMA <new_schema>
```

## Description

`ALTER CONVERSION` changes the definition of a conversion.

You must own the conversion to use `ALTER CONVERSION`. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the conversion's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the conversion. However, a superuser can alter ownership of any conversion anyway.)

## Parameters

name

The name (optionally schema-qualified) of an existing conversion.

newname

The new name of the conversion.

newowner

The new owner of the conversion.

new\_schema

The new schema for the conversion.

## Examples

To rename the conversion `iso_8859_1_to_utf8` to `latin1_to_unicode`:

```
ALTER CONVERSION iso_8859_1_to_utf8 RENAME TO
latin1_to_unicode;
```

To change the owner of the conversion `iso_8859_1_to_utf8` to `joe`:

```
ALTER CONVERSION iso_8859_1_to_utf8 OWNER TO joe;
```

## Compatibility

There is no `ALTER CONVERSION` statement in the SQL standard.

## See Also

[CREATE CONVERSION](#), [DROP CONVERSION](#)

Parent topic: [SQL Commands](#)

## ALTER DATABASE

Changes the attributes of a database.

### Synopsis

```
ALTER DATABASE <name> [ WITH CONNECTION LIMIT <connlimit> ]

ALTER DATABASE <name> RENAME TO <newname>

ALTER DATABASE <name> OWNER TO <new_owner>

ALTER DATABASE <name> SET TABLESPACE <new_tablespace>

ALTER DATABASE <name> SET <parameter> { TO | = } { <value> | DEFAULT }
ALTER DATABASE <name> SET <parameter> FROM CURRENT
ALTER DATABASE <name> RESET <parameter>
ALTER DATABASE <name> RESET ALL
```

### Description

`ALTER DATABASE` changes the attributes of a database.

The first form changes the allowed connection limit for a database. Only the database owner or a superuser can change this setting.

The second form changes the name of the database. Only the database owner or a superuser can rename a database; non-superuser owners must also have the `CREATEDB` privilege. You cannot rename the current database. Connect to a different database first.

The third form changes the owner of the database. To alter the owner, you must own the database and also be a direct or indirect member of the new owning role, and you must have the `CREATEDE` privilege. (Note that superusers have all these privileges automatically.)

The fourth form changes the default tablespace of the database. Only the database owner or a superuser can do this; you must also have create privilege for the new tablespace. This command physically moves any tables or indexes in the database's old default tablespace to the new tablespace. Note that tables and indexes in non-default tablespaces are not affected.

The remaining forms change the session default for a configuration parameter for a Greenplum database. Whenever a new session is subsequently started in that database, the specified value becomes the session default value. The database-specific default overrides whatever setting is present in the server configuration file (`postgresql.conf`). Only the database owner or a superuser

can change the session defaults for a database. Certain parameters cannot be set this way, or can only be set by a superuser.

## Parameters

name

The name of the database whose attributes are to be altered.

conlimit

The maximum number of concurrent connections possible. The default of -1 means there is no limitation.

parameter value

Set this database's session default for the specified configuration parameter to the given value. If value is `DEFAULT` or, equivalently, `RESET` is used, the database-specific setting is removed, so the system-wide default setting will be inherited in new sessions. Use `RESET ALL` to clear all database-specific settings. See [Server Configuration Parameters](#) for information about all user-settable configuration parameters.

newname

The new name of the database.

new\_owner

The new owner of the database.

new\_tablespace

The new default tablespace of the database.

## Notes

It is also possible to set a configuration parameter session default for a specific role (user) rather than to a database. Role-specific settings override database-specific ones if there is a conflict. See [ALTER ROLE](#).

## Examples

To set the default schema search path for the `mydatabase` database:

```
ALTER DATABASE mydatabase SET search_path TO myschema,
public, pg_catalog;
```

## Compatibility

The [ALTER DATABASE](#) statement is a Greenplum Database extension.

## See Also

[CREATE DATABASE](#), [DROP DATABASE](#), [SET](#), [CREATE TABLESPACE](#)

Parent topic: [SQL Commands](#)

## ALTER DEFAULT PRIVILEGES

Changes default access privileges.

## Synopsis

```
ALTER DEFAULT PRIVILEGES
  [ FOR { ROLE | USER } <target_role> [, ...] ]
  [ IN SCHEMA <schema_name> [, ...] ]
  <abbreviated_grant_or_revoke>

where <abbreviated_grant_or_revoke> is one of:

GRANT { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER }
  [, ...] | ALL [ PRIVILEGES ] }
  ON TABLES
  TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { { USAGE | SELECT | UPDATE }
  [, ...] | ALL [ PRIVILEGES ] }
  ON SEQUENCES
  TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { EXECUTE | ALL [ PRIVILEGES ] }
  ON FUNCTIONS
  TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

GRANT { USAGE | ALL [ PRIVILEGES ] }
  ON TYPES
  TO { [ GROUP ] <role_name> | PUBLIC } [, ...] [ WITH GRANT OPTION ]

REVOKE [ GRANT OPTION FOR ]
  { { SELECT | INSERT | UPDATE | DELETE | TRUNCATE | REFERENCES | TRIGGER }
  [, ...] | ALL [ PRIVILEGES ] }
  ON TABLES
  FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]
  [ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
  { { USAGE | SELECT | UPDATE }
  [, ...] | ALL [ PRIVILEGES ] }
  ON SEQUENCES
  FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]
  [ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
  { EXECUTE | ALL [ PRIVILEGES ] }
  ON FUNCTIONS
  FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]
  [ CASCADE | RESTRICT ]

REVOKE [ GRANT OPTION FOR ]
  { USAGE | ALL [ PRIVILEGES ] }
  ON TYPES
  FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]
  [ CASCADE | RESTRICT ]
```

## Description

`ALTER DEFAULT PRIVILEGES` allows you to set the privileges that will be applied to objects created in the future. (It does not affect privileges assigned to already-existing objects.) Currently, only the privileges for tables (including views and foreign tables), sequences, functions, and types (including domains) can be altered.

You can change default privileges only for objects that will be created by yourself or by roles that you are a member of. The privileges can be set globally (i.e., for all objects created in the current database), or just for objects created in specified schemas. Default privileges that are specified per-schema are added to whatever the global default privileges are for the particular object type.

As explained under [GRANT](#), the default privileges for any object type normally grant all grantable permissions to the object owner, and may grant some privileges to `PUBLIC` as well. However, this behavior can be changed by altering the global default privileges with `ALTER DEFAULT PRIVILEGES`.

## Parameters

`target_role`

The name of an existing role of which the current role is a member. If `FOR ROLE` is omitted, the current role is assumed.

`schema_name`

The name of an existing schema. If specified, the default privileges are altered for objects later created in that schema. If `IN SCHEMA` is omitted, the global default privileges are altered.

`role_name`

The name of an existing role to grant or revoke privileges for. This parameter, and all the other parameters in `abbreviated_grant_or_revoke`, act as described under [GRANT](#) or [REVOKE](#), except that one is setting permissions for a whole class of objects rather than specific named objects.

## Notes

Use `psql`'s `\ddp` command to obtain information about existing assignments of default privileges. The meaning of the privilege values is the same as explained for `\dp` under [GRANT](#).

If you wish to drop a role for which the default privileges have been altered, it is necessary to reverse the changes in its default privileges or use `DROP OWNED BY` to get rid of the default privileges entry for the role.

## Examples

Grant `SELECT` privilege to everyone for all tables (and views) you subsequently create in schema `myschema`, and allow role `webuser` to `INSERT` into them too:

```
ALTER DEFAULT PRIVILEGES IN SCHEMA myschema GRANT SELECT ON TABLES TO PUBLIC;
ALTER DEFAULT PRIVILEGES IN SCHEMA myschema GRANT INSERT ON TABLES TO webuser;
```

Undo the above, so that subsequently-created tables won't have any more permissions than normal:

```
ALTER DEFAULT PRIVILEGES IN SCHEMA myschema REVOKE SELECT ON TABLES FROM PUBLIC;
ALTER DEFAULT PRIVILEGES IN SCHEMA myschema REVOKE INSERT ON TABLES FROM webuser;
```

Remove the public EXECUTE permission that is normally granted on functions, for all functions subsequently created by role `admin`:

```
ALTER DEFAULT PRIVILEGES FOR ROLE admin REVOKE EXECUTE ON FUNCTIONS FROM PUBLIC;
```

## Compatibility

There is no `ALTER DEFAULT PRIVILEGES` statement in the SQL standard.

## See Also

[GRANT, REVOKE](#)

Parent topic: [SQL Commands](#)

## ALTER DOMAIN

Changes the definition of a domain.

## Synopsis

```
ALTER DOMAIN <name> { SET DEFAULT <expression> | DROP DEFAULT }

ALTER DOMAIN <name> { SET | DROP } NOT NULL

ALTER DOMAIN <name> ADD <domain_constraint> [ NOT VALID ]

ALTER DOMAIN <name> DROP CONSTRAINT [ IF EXISTS ] <constraint_name> [RESTRICT | CASCADE]

ALTER DOMAIN <name> RENAME CONSTRAINT <constraint_name> TO <new_constraint_name>

ALTER DOMAIN <name> VALIDATE CONSTRAINT <constraint_name>

ALTER DOMAIN <name> OWNER TO <new_owner>

ALTER DOMAIN <name> RENAME TO <new_name>

ALTER DOMAIN <name> SET SCHEMA <new_schema>
```

## Description

**ALTER DOMAIN** changes the definition of an existing domain. There are several sub-forms:

- **SET/DROP DEFAULT** — These forms set or remove the default value for a domain. Note that defaults only apply to subsequent **INSERT** commands. They do not affect rows already in a table using the domain.
- **SET/DROP NOT NULL** — These forms change whether a domain is marked to allow **NULL** values or to reject **NULL** values. You may only **SET NOT NULL** when the columns using the domain contain no null values.
- **ADD domain\_constraint [ NOT VALID ]** — This form adds a new constraint to a domain using the same syntax as **CREATE DOMAIN**. When a new constraint is added to a domain, all columns using that domain will be checked against the newly added constraint. These checks can be suppressed by adding the new constraint using the **NOT VALID** option; the constraint can later be made valid using **ALTER DOMAIN ... VALIDATE CONSTRAINT**. Newly inserted or updated rows are always checked against all constraints, even those marked **NOT VALID**. **NOT VALID** is only accepted for **CHECK** constraints.
- **DROP CONSTRAINT [ IF EXISTS ]** — This form drops constraints on a domain. If **IF EXISTS** is specified and the constraint does not exist, no error is thrown. In this case a notice is issued instead.
- **RENAME CONSTRAINT** — This form changes the name of a constraint on a domain.
- **VALIDATE CONSTRAINT** — This form validates a constraint previously added as **NOT VALID**, that is, verify that all data in columns using the domain satisfy the specified constraint.
- **OWNER** — This form changes the owner of the domain to the specified user.
- **RENAME** — This form changes the name of the domain.
- **SET SCHEMA** — This form changes the schema of the domain. Any constraints associated with the domain are moved into the new schema as well.

You must own the domain to use **ALTER DOMAIN**. To change the schema of a domain, you must also have **CREATE** privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have **CREATE** privilege on the domain's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the domain. However, a superuser can alter ownership of any domain anyway.)

## Parameters

name

The name (optionally schema-qualified) of an existing domain to alter.

domain\_constraint

New domain constraint for the domain.

constraint\_name

Name of an existing constraint to drop or rename.

NOT VALID

Do not verify existing column data for constraint validity.

CASCADE

Automatically drop objects that depend on the constraint.

**RESTRICT**

Refuse to drop the constraint if there are any dependent objects. This is the default behavior.

**new\_name**

The new name for the domain.

**new\_constraint\_name**

The new name for the constraint.

**new\_owner**

The user name of the new owner of the domain.

**new\_schema**

The new schema for the domain.

## Examples

To add a **NOT NULL** constraint to a domain:

```
ALTER DOMAIN zipcode SET NOT NULL;
```

To remove a **NOT NULL** constraint from a domain:

```
ALTER DOMAIN zipcode DROP NOT NULL;
```

To add a check constraint to a domain:

```
ALTER DOMAIN zipcode ADD CONSTRAINT zipchk CHECK (char_length(VALUE) = 5);
```

To remove a check constraint from a domain:

```
ALTER DOMAIN zipcode DROP CONSTRAINT zipchk;
```

To rename a check constraint on a domain:

```
ALTER DOMAIN zipcode RENAME CONSTRAINT zipchk TO zip_check;
```

To move the domain into a different schema:

```
ALTER DOMAIN zipcode SET SCHEMA customers;
```

## Compatibility

**ALTER DOMAIN** conforms to the SQL standard, except for the **OWNER**, **RENAME**, **SET SCHEMA**, and **VALIDATE CONSTRAINT** variants, which are Greenplum Database extensions. The **NOT VALID** clause of the **ADD CONSTRAINT** variant is also a Greenplum Database extension.

and <aggregate_signature> is:

* |
[ <argmode> ] [ <argname> ] <argtype> [ , ... ] |
[ [ <argmode> ] [ <argname> ] <argtype> [ , ... ] ] ORDER BY [ <argmode> ] [ <argname> ]
] <argtype> [ , ... ]
```

## Description

**ALTER EXTENSION** changes the definition of an installed extension. These are the subforms:

### UPDATE

This form updates the extension to a newer version. The extension must supply a suitable update script (or series of scripts) that can modify the currently-installed version into the requested version.

## SET SCHEMA

This form moves the extension member objects into another schema. The extension must be *relocatable*.

## ADD member\_object

This form adds an existing object to the extension. This is useful in extension update scripts. The added object is treated as a member of the extension. The object can only be dropped by dropping the extension.

## DROP member\_object

This form removes a member object from the extension. This is mainly useful in extension update scripts. The object is not dropped, only disassociated from the extension.

See [Packaging Related Objects into an Extension](#) for more information about these operations.

You must own the extension to use `ALTER EXTENSION`. The `ADD` and `DROP` forms also require ownership of the object that is being added or dropped.

## Parameters

### name

The name of an installed extension.

### new\_version

The new version of the extension. The `new_version` can be either an identifier or a string literal. If not specified, the command attempts to update to the default version in the extension control file.

### new\_schema

The new schema for the extension.

### object\_name

### aggregate\_name

### function\_name

### operator\_name

The name of an object to be added to or removed from the extension. Names of tables, aggregates, domains, foreign tables, functions, operators, operator classes, operator families, sequences, text search objects, types, and views can be schema-qualified.

### source\_type

The name of the source data type of the cast.

### target\_type

The name of the target data type of the cast.

### argmode

The mode of a function or aggregate argument: `IN`, `OUT`, `INOUT`, or `VARIADIC`. The default is `IN`.

The command ignores the `OUT` arguments. Only the input arguments are required to determine the function identity. It is sufficient to list the `IN`, `INOUT`, and `VARIADIC` arguments.

### argname

The name of a function or aggregate argument.

The command ignores argument names, since only the argument data types are required to determine the function identity.

### argtype

The data type of a function or aggregate argument.

left\_type

right\_type

The data types of the operator's arguments (optionally schema-qualified) . Specify **NONE** for the missing argument of a prefix or postfix operator.

PROCEDURAL

This is a noise word.

type\_name

The name of the data type of the transform.

lang\_name

The name of the language of the transform.

## Examples

To update the hstore extension to version 2.0:

```
ALTER EXTENSION hstore UPDATE TO '2.0';
```

To change the schema of the **hstore** extension to **utils**:

```
ALTER EXTENSION hstore SET SCHEMA utils;
```

To add an existing function to the **hstore** extension:

```
ALTER EXTENSION hstore ADD FUNCTION populate_record(anyelement, hstore);
```

## Compatibility

**ALTER EXTENSION** is a Greenplum Database extension.

## See Also

[CREATE EXTENSION](#), [DROP EXTENSION](#)

Parent topic: [SQL Commands](#)

## ALTER EXTERNAL TABLE

Changes the definition of an external table.

## Synopsis

```
ALTER EXTERNAL TABLE <name> <action> [, ... ]
```

where action is one of:

```
ADD [COLUMN] <new_column> <type>
DROP [COLUMN] <column> [RESTRICT|CASCADE]
```

```
ALTER [COLUMN] <column> TYPE <type>
OWNER TO <new_owner>
```

## Description

`ALTER EXTERNAL TABLE` changes the definition of an existing external table. These are the supported `ALTER EXTERNAL TABLE` actions:

- **ADD COLUMN** — Adds a new column to the external table definition.
- **DROP COLUMN** — Drops a column from the external table definition. If you drop readable external table columns, it only changes the table definition in Greenplum Database. The `CASCADE` keyword is required if anything outside the table depends on the column, such as a view that references the column.
- **ALTER COLUMN TYPE** — Changes the data type of a table column.
- **OWNER** — Changes the owner of the external table to the specified user.

Use the `ALTER TABLE` command to perform these actions on an external table.

- Set (change) the table schema.
- Rename the table.
- Rename a table column.

You must own the external table to use `ALTER EXTERNAL TABLE` or `ALTER TABLE`. To change the schema of an external table, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the external table's schema. A superuser has these privileges automatically.

Changes to the external table definition with either `ALTER EXTERNAL TABLE` or `ALTER TABLE` do not affect the external data.

The `ALTER EXTERNAL TABLE` and `ALTER TABLE` commands cannot modify the type external table (read, write, web), the table `FORMAT` information, or the location of the external data. To modify this information, you must drop and recreate the external table definition.

## Parameters

name

The name (possibly schema-qualified) of an existing external table definition to alter.

column

Name of an existing column.

new\_column

Name of a new column.

type

Data type of the new column, or new data type for an existing column.

new\_owner

The role name of the new owner of the external table.

CASCADE

Automatically drop objects that depend on the dropped column, such as a view that references the column.

#### RESTRICT

Refuse to drop the column or constraint if there are any dependent objects. This is the default behavior.

## Examples

Add a new column to an external table definition:

```
ALTER EXTERNAL TABLE ext_expenses ADD COLUMN manager text;
```

Change the owner of an external table:

```
ALTER EXTERNAL TABLE ext_data OWNER TO jojo;
```

Change the data type of an external table:

```
ALTER EXTERNAL TABLE ext_leads ALTER COLUMN acct_code TYPE integer
```

## Compatibility

`ALTER EXTERNAL TABLE` is a Greenplum Database extension. There is no `ALTER EXTERNAL TABLE` statement in the SQL standard or regular PostgreSQL.

## See Also

[CREATE EXTERNAL TABLE](#), [DROP EXTERNAL TABLE](#), [ALTER TABLE](#)

Parent topic: [SQL Commands](#)

## ALTER FOREIGN DATA WRAPPER

Changes the definition of a foreign-data wrapper.

### Synopsis

```
ALTER FOREIGN DATA WRAPPER <name>
  [ HANDLER <handler_function> | NO HANDLER ]
  [ VALIDATOR <validator_function> | NO VALIDATOR ]
  [ OPTIONS ( [ ADD | SET | DROP ] <option> ['<value>'] [, ... ] ) ]

ALTER FOREIGN DATA WRAPPER <name> OWNER TO <new_owner>
ALTER FOREIGN DATA WRAPPER <name> RENAME TO <new_name>
```

### Description

`ALTER FOREIGN DATA WRAPPER` changes the definition of a foreign-data wrapper. The first form of the command changes the support functions or generic options of the foreign-data wrapper.

Greenplum Database requires at least one clause. The second and third forms of the command change the owner or name of the foreign-data wrapper.

Only superusers can alter foreign-data wrappers. Additionally, only superusers can own foreign-data wrappers

## Parameters

name

The name of an existing foreign-data wrapper.

HANDLER handler\_function

Specifies a new handler function for the foreign-data wrapper.

NO HANDLER

Specifies that the foreign-data wrapper should no longer have a handler function.

**Note:** You cannot access a foreign table that uses a foreign-data wrapper with no handler.

VALIDATOR validator\_function

Specifies a new validator function for the foreign-data wrapper.

Options to the foreign-data wrapper, servers, and user mappings may become invalid when you change the validator function. You must make sure that these options are correct before using the modified foreign-data wrapper. Note that Greenplum Database checks any options specified in this `ALTER FOREIGN DATA WRAPPER` command using the new validator.

NO VALIDATOR

Specifies that the foreign-data wrapper should no longer have a validator function.

OPTIONS ( [ ADD | SET | DROP ] option ['value'] [, ... ] )

Change the foreign-data wrapper's options. `ADD`, `SET`, and `DROP` specify the action to perform. If no operation is explicitly specified, the default operation is `ADD`. Option names must be unique. Greenplum Database validates names and values using the foreign-data wrapper's validator function, if any.

OWNER TO new\_owner

Specifies the new owner of the foreign-data wrapper. Only superusers can own foreign-data wrappers.

RENAME TO new\_name

Specifies the new name of the foreign-data wrapper.

## Examples

Change the definition of a foreign-data wrapper named `dbi` by adding a new option named `foo`, and removing the option named `bar`:

```
ALTER FOREIGN DATA WRAPPER dbi OPTIONS (ADD foo '1', DROP 'bar');
```

Change the validator function for a foreign-data wrapper named `dbi` to `bob.myvalidator`:

```
ALTER FOREIGN DATA WRAPPER dbi VALIDATOR bob.myvalidator;
```

## Compatibility

`ALTER FOREIGN DATA WRAPPER` conforms to ISO/IEC 9075-9 (SQL/MED), with the exception that the `HANDLER`, `VALIDATOR`, `OWNER TO`, and `RENAME TO` clauses are Greenplum Database extensions.

## See Also

[CREATE FOREIGN DATA WRAPPER](#), [DROP FOREIGN DATA WRAPPER](#)

Parent topic: [SQL Commands](#)

## ALTER FOREIGN TABLE

Changes the definition of a foreign table.

## Synopsis

```
ALTER FOREIGN TABLE [ IF EXISTS ] <name>
    <action> [, ... ]
ALTER FOREIGN TABLE [ IF EXISTS ] <name>
    RENAME [ COLUMN ] <column_name> TO <new_column_name>
ALTER FOREIGN TABLE [ IF EXISTS ] <name>
    RENAME TO <new_name>
ALTER FOREIGN TABLE [ IF EXISTS ] <name>
    SET SCHEMA <new_schema>
```

where action is one of:

```
    ADD [ COLUMN ] <column_name> <column_type> [ COLLATE <collation> ] [ <column_constraint> [ ... ] ]
    DROP [ COLUMN ] [ IF EXISTS ] <column_name> [ RESTRICT | CASCADE ]
    ALTER [ COLUMN ] <column_name> [ SET DATA ] TYPE <data_type>
    ALTER [ COLUMN ] <column_name> SET DEFAULT <expression>
    ALTER [ COLUMN ] <column_name> DROP DEFAULT
    ALTER [ COLUMN ] <column_name> { SET | DROP } NOT NULL
    ALTER [ COLUMN ] <column_name> SET STATISTICS <integer>
    ALTER [ COLUMN ] <column_name> SET ( <attribute_option> = <value> [, ... ] )
    ALTER [ COLUMN ] <column_name> RESET ( <attribute_option> [, ... ] )
    ALTER [ COLUMN ] <column_name> OPTIONS ( [ ADD | SET | DROP ] <option> ['<value>']
[, ... ] )
    DISABLE TRIGGER [ <trigger_name> | ALL | USER ]
    ENABLE TRIGGER [ <trigger_name> | ALL | USER ]
    ENABLE REPLICA TRIGGER <trigger_name>
    ENABLE ALWAYS TRIGGER <trigger_name>
    OWNER TO <new_owner>
    OPTIONS ( [ ADD | SET | DROP ] <option> ['<value>'] [, ... ] )
```

## Description

`ALTER FOREIGN TABLE` changes the definition of an existing foreign table. There are several subforms of the command:

**ADD COLUMN**

This form adds a new column to the foreign table, using the same syntax as **CREATE FOREIGN TABLE**. Unlike the case when you add a column to a regular table, nothing happens to the underlying storage: this action simply declares that some new column is now accessible through the foreign table.

**DROP COLUMN [ IF EXISTS ]**

This form drops a column from a foreign table. You must specify **CASCADE** if any objects outside of the table depend on the column; for example, views. If you specify **IF EXISTS** and the column does not exist, no error is thrown. Greenplum Database issues a notice instead.

**IF EXISTS**

If you specify **IF EXISTS** and the foreign table does not exist, no error is thrown. Greenplum Database issues a notice instead.

**SET DATA TYPE**

This form changes the type of a column of a foreign table.

**SET/DROP DEFAULT**

These forms set or remove the default value for a column. Default values apply only in subsequent **INSERT** or **UPDATE** commands; they do not cause rows already in the table to change.

**SET/DROP NOT NULL**

Mark a column as allowing, or not allowing, null values.

**SET STATISTICS**

This form sets the per-column statistics-gathering target for subsequent **ANALYZE** operations. See the similar form of **ALTER TABLE** for more details.

**SET ( attribute\_option = value [, ... ] )****RESET ( attribute\_option [, ... ] )**

This form sets or resets per-attribute options. See the similar form of **ALTER TABLE** for more details.

**DISABLE/ENABLE [ REPLICAS | ALWAYS ] TRIGGER**

These forms configure the firing of trigger(s) belonging to the foreign table. See the similar form of **ALTER TABLE** for more details.

**OWNER**

This form changes the owner of the foreign table to the specified user.

**RENAME**

The **RENAME** forms change the name of a foreign table or the name of an individual column in a foreign table.

**SET SCHEMA**

This form moves the foreign table into another schema.

**OPTIONS ( [ ADD | SET | DROP ] option ['value'] [, ... ] )**

Change options for the foreign table. **ADD**, **SET**, and **DROP** specify the action to perform. If no operation is explicitly specified, the default operation is **ADD**. Option names must be unique. Greenplum Database validates names and values using the server's foreign-data wrapper.

You can combine all of the actions except **RENAME** and **SET SCHEMA** into a list of multiple alterations for Greenplum Database to apply in parallel. For example, it is possible to add several columns and/or alter the type of several columns in a single command.

You must own the table to use **ALTER FOREIGN TABLE**. To change the schema of a foreign table, you must also have **CREATE** privilege on the new schema. To alter the owner, you must also be a direct

or indirect member of the new owning role, and that role must have `CREATE` privilege on the table's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the table. However, a superuser can alter ownership of any table anyway.) To add a column or to alter a column type, you must also have `USAGE` privilege on the data type.

## Parameters

`name`

The name (possibly schema-qualified) of an existing foreign table to alter.

`column_name`

The name of a new or existing column.

`new_column_name`

The new name for an existing column.

`new_name`

The new name for the foreign table.

`data_type`

The data type of the new column, or new data type for an existing column.

`CASCADE`

Automatically drop objects that depend on the dropped column (for example, views referencing the column).

`RESTRICT`

Refuse to drop the column if there are any dependent objects. This is the default behavior.

`trigger_name`

Name of a single trigger to deactivate or enable.

`ALL`

Deactivate or activate all triggers belonging to the foreign table. (This requires superuser privilege if any of the triggers are internally generated triggers. The core system does not add such triggers to foreign tables, but add-on code could do so.)

`USER`

Deactivate or activate all triggers belonging to the foreign table except for internally generated triggers.

`new_owner`

The user name of the new owner of the foreign table.

`new_schema`

The name of the schema to which the foreign table will be moved.

## Notes

The key word `COLUMN` is noise and can be omitted.

Consistency with the foreign server is not checked when a column is added or removed with `ADD COLUMN` or `DROP COLUMN`, a `NOT NULL` constraint is added, or a column type is changed with `SET DATA TYPE`. It is your responsibility to ensure that the table definition matches the remote side.

Refer to `CREATE FOREIGN TABLE` for a further description of valid parameters.

## Examples

To mark a column as not-null:

```
ALTER FOREIGN TABLE distributors ALTER COLUMN street SET NOT NULL;
```

To change the options of a foreign table:

```
ALTER FOREIGN TABLE myschema.distributors
    OPTIONS (ADD opt1 'value', SET opt2 'value2', DROP opt3 'value3');
```

## Compatibility

The forms `ADD`, `DROP`, and `SET DATA TYPE` conform with the SQL standard. The other forms are Greenplum Database extensions of the SQL standard. The ability to specify more than one manipulation in a single `ALTER FOREIGN TABLE` command is also a Greenplum Database extension.

You can use `ALTER FOREIGN TABLE ... DROP COLUMN` to drop the only column of a foreign table, leaving a zero-column table. This is an extension of SQL, which disallows zero-column foreign tables.

## See Also

[ALTER TABLE](#), [CREATE FOREIGN TABLE](#), [DROP FOREIGN TABLE](#)

Parent topic: [SQL Commands](#)

## ALTER FUNCTION

Changes the definition of a function.

## Synopsis

```
ALTER FUNCTION <name> ( [ [<argmode>] [<argname>] <argtype> [, ...] ] )
    <action> [, ... ] [RESTRICT]

ALTER FUNCTION <name> ( [ [<argmode>] [<argname>] <argtype> [, ...] ] )
    RENAME TO <new_name>

ALTER FUNCTION <name> ( [ [<argmode>] [<argname>] <argtype> [, ...] ] )
    OWNER TO <new_owner>

ALTER FUNCTION <name> ( [ [<argmode>] [<argname>] <argtype> [, ...] ] )
    SET SCHEMA <new_schema>
```

where action is one of:

```
{ CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT }
{ IMMUTABLE | STABLE | VOLATILE | [ NOT ] LEAKPROOF }
{ [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER }
EXECUTE ON { ANY | MASTER | ALL SEGMENTS | INITPLAN }
COST <execution_cost>
SET <configuration_parameter> { TO | = } { <value> | DEFAULT }
SET <configuration_parameter> FROM CURRENT
```

```
RESET <configuration_parameter>
RESET ALL
```

## Description

`ALTER FUNCTION` changes the definition of a function.

You must own the function to use `ALTER FUNCTION`. To change a function's schema, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the function's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the function. However, a superuser can alter ownership of any function anyway.)

## Parameters

name

The name (optionally schema-qualified) of an existing function.

argmode

The mode of an argument: either `IN`, `OUT`, `INOUT`, or `VARIADIC`. If omitted, the default is `IN`.

Note that `ALTER FUNCTION` does not actually pay any attention to `OUT` arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the `IN`, `INOUT`, and `VARIADIC` arguments.

argname

The name of an argument. Note that `ALTER FUNCTION` does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

argtype

The data type(s) of the function's arguments (optionally schema-qualified), if any.

new\_name

The new name of the function.

new\_owner

The new owner of the function. Note that if the function is marked `SECURITY DEFINER`, it will subsequently run as the new owner.

new\_schema

The new schema for the function.

CALLED ON NULL INPUT

RETURNS NULL ON NULL INPUT

STRICT

`CALLED ON NULL INPUT` changes the function so that it will be invoked when some or all of its arguments are null. `RETURNS NULL ON NULL INPUT` or `STRICT` changes the function so that it is not invoked if any of its arguments are null; instead, a null result is assumed automatically.

See [CREATE FUNCTION](#) for more information.

IMMUTABLE

STABLE

VOLATILE

Change the volatility of the function to the specified setting. See [CREATE FUNCTION](#) for details.

[ EXTERNAL ] SECURITY INVOKER

[ EXTERNAL ] SECURITY DEFINER

Change whether the function is a security definer or not. The key word `EXTERNAL` is ignored for SQL conformance. See [CREATE FUNCTION](#) for more information about this capability.

LEAKPROOF

Change whether the function is considered leakproof or not. See [CREATE FUNCTION](#) for more information about this capability.

EXECUTE ON ANY

EXECUTE ON MASTER

EXECUTE ON ALL SEGMENTS

EXECUTE ON INITPLAN

The `EXECUTE ON` attributes specify where (master or segment instance) a function runs when it is invoked during the query execution process.

`EXECUTE ON ANY` (the default) indicates that the function can be run on the master, or any segment instance, and it returns the same result regardless of where it is run. Greenplum Database determines where the function runs.

`EXECUTE ON MASTER` indicates that the function must run only on the master instance.

`EXECUTE ON ALL SEGMENTS` indicates that the function must run on all primary segment instances, but not the master, for each invocation. The overall result of the function is the `UNION ALL` of the results from all segment instances.

`EXECUTE ON INITPLAN` indicates that the function contains an SQL command that dispatches queries to the segment instances and requires special processing on the master instance by Greenplum Database when possible.

For more information about the `EXECUTE ON` attributes, see [CREATE FUNCTION](#).

COST execution\_cost

Change the estimated execution cost of the function. See [CREATE FUNCTION](#) for more information.

configuration\_parameter

value

Set or change the value of a configuration parameter when the function is called. If value is `DEFAULT` or, equivalently, `RESET` is used, the function-local setting is removed, and the function runs with the value present in its environment. Use `RESET ALL` to clear all function-local settings. `SET FROM CURRENT` saves the value of the parameter that is current when `ALTER FUNCTION` is run as the value to be applied when the function is entered.

RESTRICT

Ignored for conformance with the SQL standard.

## Notes

Greenplum Database has limitations on the use of functions defined as `STABLE` or `VOLATILE`. See [CREATE FUNCTION](#) for more information.

## Examples

To rename the function `sqrt` for type `integer` to `square_root`:

```
ALTER FUNCTION sqrt(integer) RENAME TO square_root;
```

To change the owner of the function `sqrt` for type `integer` to `joe`:

```
ALTER FUNCTION sqrt(integer) OWNER TO joe;
```

To change the schema of the function `sqrt` for type `integer` to `math`:

```
ALTER FUNCTION sqrt(integer) SET SCHEMA math;
```

To adjust the search path that is automatically set for a function:

```
ALTER FUNCTION check_password(text) RESET search_path;
```

## Compatibility

This statement is partially compatible with the `ALTER FUNCTION` statement in the SQL standard. The standard allows more properties of a function to be modified, but does not provide the ability to rename a function, make a function a security definer, or change the owner, schema, or volatility of a function. The standard also requires the `RESTRICT` key word, which is optional in Greenplum Database.

## See Also

[CREATE FUNCTION](#), [DROP FUNCTION](#)

Parent topic: [SQL Commands](#)

## ALTER GROUP

Changes a role name or membership.

## Synopsis

```
ALTER GROUP <groupname> ADD USER <username> [, ... ]

ALTER GROUP <groupname> DROP USER <username> [, ... ]

ALTER GROUP <groupname> RENAME TO <newname>
```

## Description

`ALTER GROUP` changes the attributes of a user group. This is an obsolete command, though still accepted for backwards compatibility, because users and groups are superseded by the more general concept of roles. See [ALTER ROLE](#) for more information.

The first two variants add users to a group or remove them from a group. Any role can play the part of `groupname` or `username`. The preferred method for accomplishing these tasks is to use [GRANT](#) and [REVOKE](#).

## Parameters

groupname

The name of the group (role) to modify.

username

Users (roles) that are to be added to or removed from the group. The users (roles) must already exist.

newname

The new name of the group (role).

## Examples

To add users to a group:

```
ALTER GROUP staff ADD USER karl, john;
```

To remove a user from a group:

```
ALTER GROUP workers DROP USER beth;
```

## Compatibility

There is no `ALTER GROUP` statement in the SQL standard.

## See Also

[ALTER ROLE](#), [GRANT](#), [REVOKE](#)

Parent topic: [SQL Commands](#)

## ALTER INDEX

Changes the definition of an index.

## Synopsis

```
ALTER INDEX [ IF EXISTS ] <name> RENAME TO <new_name>

ALTER INDEX [ IF EXISTS ] <name> SET TABLESPACE <tablespace_name>

ALTER INDEX [ IF EXISTS ] <name> SET ( <storage_parameter> = <value> [, ...] )

ALTER INDEX [ IF EXISTS ] <name> RESET ( <storage_parameter> [, ...] )

ALTER INDEX ALL IN TABLESPACE <name> [ OWNED BY <role_name> [, ...] ]
SET TABLESPACE <new_tablespace> [ NOWAIT ]
```

## Description

**ALTER INDEX** changes the definition of an existing index. There are several subforms:

- **RENAME** — Changes the name of the index. There is no effect on the stored data.
- **SET TABLESPACE** — Changes the index's tablespace to the specified tablespace and moves the data file(s) associated with the index to the new tablespace. To change the tablespace of an index, you must own the index and have **CREATE** privilege on the new tablespace. All indexes in the current database in a tablespace can be moved by using the **ALL IN TABLESPACE** form, which will lock all indexes to be moved and then move each one. This form also supports **OWNED BY**, which will only move indexes owned by the roles specified. If the **NOWAIT** option is specified then the command will fail if it is unable to acquire all of the locks required immediately. Note that system catalogs will not be moved by this command, use **ALTER DATABASE** or explicit **ALTER INDEX** invocations instead if desired. See also **CREATE TABLESPACE**.
- **IF EXISTS** — Do not throw an error if the index does not exist. A notice is issued in this case.
- **SET** — Changes the index-method-specific storage parameters for the index. The built-in index methods all accept a single parameter: fillfactor. The fillfactor for an index is a percentage that determines how full the index method will try to pack index pages. Index contents will not be modified immediately by this command. Use **REINDEX** to rebuild the index to get the desired effects.
- **RESET** — Resets storage parameters for the index to their defaults. The built-in index methods all accept a single parameter: fillfactor. As with **SET**, a **REINDEX** may be needed to update the index entirely.

## Parameters

name

The name (optionally schema-qualified) of an existing index to alter.

new\_name

New name for the index.

tablespace\_name

The tablespace to which the index will be moved.

storage\_parameter

The name of an index-method-specific storage parameter.

value

The new value for an index-method-specific storage parameter. This might be a number or a word depending on the parameter.

## Notes

These operations are also possible using **ALTER TABLE**.

Changing any part of a system catalog index is not permitted.

## Examples

To rename an existing index:

```
ALTER INDEX distributors RENAME TO suppliers;
```

To move an index to a different tablespace:

```
ALTER INDEX distributors SET TABLESPACE fasttablespace;
```

To change an index's fill factor (assuming that the index method supports it):

```
ALTER INDEX distributors SET (fillfactor = 75);
REINDEX INDEX distributors;
```

## Compatibility

`ALTER INDEX` is a Greenplum Database extension.

## See Also

[CREATE INDEX](#), [REINDEX](#), [ALTER TABLE](#)

Parent topic: [SQL Commands](#)

## ALTER LANGUAGE

Changes the name of a procedural language.

## Synopsis

```
ALTER LANGUAGE <name> RENAME TO <newname>
ALTER LANGUAGE <name> OWNER TO <new_owner>
```

## Description

`ALTER LANGUAGE` changes the definition of a procedural language for a specific database. Definition changes supported include renaming the language or assigning a new owner. You must be superuser or the owner of the language to use `ALTER LANGUAGE`.

## Parameters

name

Name of a language.

newname

The new name of the language.

new\_owner

The new owner of the language.

## Compatibility

There is no `ALTER LANGUAGE` statement in the SQL standard.

## See Also

[CREATE LANGUAGE, DROP LANGUAGE](#)

Parent topic: [SQL Commands](#)

## ALTER MATERIALIZED VIEW

Changes the definition of a materialized view.

### Synopsis

```
ALTER MATERIALIZED VIEW [ IF EXISTS ] <name> <action> [, ... ]
ALTER MATERIALIZED VIEW [ IF EXISTS ] <name>
    RENAME [ COLUMN ] <column_name> TO <new_column_name>
ALTER MATERIALIZED VIEW [ IF EXISTS ] <name>
    RENAME TO <new_name>
ALTER MATERIALIZED VIEW [ IF EXISTS ] <name>
    SET SCHEMA <new_schema>
ALTER MATERIALIZED VIEW ALL IN TABLESPACE <name> [ OWNED BY <role_name> [, ... ] ]
    SET TABLESPACE <new_tablespace> [ NOWAIT ]
```

where <action> is one of:

```
ALTER [ COLUMN ] <column_name> SET STATISTICS <integer>
ALTER [ COLUMN ] <column_name> SET ( <attribute_option> = <value> [, ... ] )
ALTER [ COLUMN ] <column_name> RESET ( <attribute_option> [, ... ] )
ALTER [ COLUMN ] <column_name> SET STORAGE { PLAIN | EXTERNAL | EXTENDED | MAIN }
CLUSTER ON <index_name>
SET WITHOUT CLUSTER
SET ( <storage_parameter>r = <value> [, ... ] )
RESET ( <storage_parameter> [, ... ] )
OWNER TO <new_owner>
```

## Description

**ALTER MATERIALIZED VIEW** changes various auxiliary properties of an existing materialized view.

You must own the materialized view to use **ALTER MATERIALIZED VIEW**. To change a materialized view's schema, you must also have **CREATE** privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have **CREATE** privilege on the materialized view's schema. (These restrictions enforce that altering the owner doesn't do anything you couldn't do by dropping and recreating the materialized view. However, a superuser can alter ownership of any view anyway.)

The statement subforms and actions available for **ALTER MATERIALIZED VIEW** are a subset of those available for **ALTER TABLE**, and have the same meaning when used for materialized views. See the descriptions for **ALTER TABLE** for details.

## Parameters

name

The name (optionally schema-qualified) of an existing materialized view.

column\_name

Name of a new or existing column.

new\_column\_name

New name for an existing column.

new\_owner

The user name of the new owner of the materialized view.

new\_name

The new name for the materialized view.

new\_schema

The new schema for the materialized view.

## Examples

To rename the materialized view foo to bar:

```
ALTER MATERIALIZED VIEW foo RENAME TO bar;
```

## Compatibility

`ALTER MATERIALIZED VIEW` is a Greenplum Database extension of the SQL standard.

## See Also

[CREATE MATERIALIZED VIEW](#), [DROP MATERIALIZED VIEW](#), [REFRESH MATERIALIZED VIEW](#)

Parent topic: [SQL Commands](#)

## ALTER OPERATOR

Changes the definition of an operator.

## Synopsis

```
ALTER OPERATOR <name> ( {<left_type> | NONE} , {<right_type> | NONE} )
    OWNER TO <new_owner>

ALTER OPERATOR <name> ( {<left_type> | NONE} , {<right_type> | NONE} )
    SET SCHEMA <new_schema>
```

## Description

`ALTER OPERATOR` changes the definition of an operator. The only currently available functionality is to change the owner of the operator.

You must own the operator to use `ALTER OPERATOR`. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the operator's schema. (These restrictions enforce that altering the owner does not do anything you

could not do by dropping and recreating the operator. However, a superuser can alter ownership of any operator anyway.)

## Parameters

**name**

The name (optionally schema-qualified) of an existing operator.

**left\_type**

The data type of the operator's left operand; write `NONE` if the operator has no left operand.

**right\_type**

The data type of the operator's right operand; write `NONE` if the operator has no right operand.

**new\_owner**

The new owner of the operator.

**new\_schema**

The new schema for the operator.

## Examples

Change the owner of a custom operator `a @@ b` for type `text`:

```
ALTER OPERATOR @@ (text, text) OWNER TO joe;
```

## Compatibility

There is no `ALTER OPERATOR` statement in the SQL standard.

## See Also

Parent topic: [SQL Commands](#)

## ALTER OPERATOR CLASS

Changes the definition of an operator class.

## Synopsis

```
ALTER OPERATOR CLASS <name> USING <index_method> RENAME TO <new_name>

ALTER OPERATOR CLASS <name> USING <index_method> OWNER TO <new_owner>

ALTER OPERATOR CLASS <name> USING <index_method> SET SCHEMA <new_schema>
```

## Description

`ALTER OPERATOR CLASS` changes the definition of an operator class.

You must own the operator class to use `ALTER OPERATOR CLASS`. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the operator class's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the operator class. However, a superuser can alter ownership of any operator class anyway.)

## Parameters

name

The name (optionally schema-qualified) of an existing operator class.

index\_method

The name of the index method this operator class is for.

new\_name

The new name of the operator class.

new\_owner

The new owner of the operator class

new\_schema

The new schema for the operator class.

## Compatibility

There is no `ALTER OPERATOR CLASS` statement in the SQL standard.

## See Also

## ALTER OPERATOR FAMILY

Changes the definition of an operator family.

## Synopsis

```
ALTER OPERATOR FAMILY <name> USING <index_method> ADD
  { OPERATOR <strategy_number> <operator_name> ( <op_type>, <op_type> ) [ FOR SEARCH
  | FOR ORDER BY <sort_family_name> ]
  | FUNCTION <support_number> [ ( <op_type> [ , <op_type> ] ) ] <funcname> ( <argument_type> [ , ... ] )
  } [ , ... ]

ALTER OPERATOR FAMILY <name> USING <index_method> DROP
  { OPERATOR <strategy_number> ( <op_type>, <op_type> )
  | FUNCTION <support_number> [ ( <op_type> [ , <op_type> ] ) ]
  } [ , ... ]

ALTER OPERATOR FAMILY <name> USING <index_method> RENAME TO <new_name>

ALTER OPERATOR FAMILY <name> USING <index_method> OWNER TO <new_owner>
```

```
ALTER OPERATOR FAMILY <name> USING <index_method> SET SCHEMA <new_schema>
```

## Description

`ALTER OPERATOR FAMILY` changes the definition of an operator family. You can add operators and support functions to the family, remove them from the family, or change the family's name or owner.

When operators and support functions are added to a family with `ALTER OPERATOR FAMILY`, they are not part of any specific operator class within the family, but are just "loose" within the family. This indicates that these operators and functions are compatible with the family's semantics, but are not required for correct functioning of any specific index. (Operators and functions that are so required should be declared as part of an operator class, instead; see `CREATE OPERATOR CLASS`.) You can drop loose members of a family from the family at any time, but members of an operator class cannot be dropped without dropping the whole class and any indexes that depend on it. Typically, single-data-type operators and functions are part of operator classes because they are needed to support an index on that specific data type, while cross-data-type operators and functions are made loose members of the family.

You must be a superuser to use `ALTER OPERATOR FAMILY`. (This restriction is made because an erroneous operator family definition could confuse or even crash the server.)

`ALTER OPERATOR FAMILY` does not presently check whether the operator family definition includes all the operators and functions required by the index method, nor whether the operators and functions form a self-consistent set. It is the user's responsibility to define a valid operator family.

`OPERATOR` and `FUNCTION` clauses can appear in any order.

## Parameters

`name`

The name (optionally schema-qualified) of an existing operator family.

`index_method`

The name of the index method this operator family is for.

`strategy_number`

The index method's strategy number for an operator associated with the operator family.

`operator_name`

The name (optionally schema-qualified) of an operator associated with the operator family.

`op_type`

In an `OPERATOR` clause, the operand data type(s) of the operator, or `NONE` to signify a left-unary or right-unary operator. Unlike the comparable syntax in `CREATE OPERATOR CLASS`, the operand data types must always be specified. In an `ADD FUNCTION` clause, the operand data type(s) the function is intended to support, if different from the input data type(s) of the function. For B-tree comparison functions it is not necessary to specify `op_type` since the function's input data type(s) are always the correct ones to use. For B-tree sort support functions and all functions in GiST, SP-GiST, and GIN operator classes, it is necessary to specify the operand data type(s) the function is to be used with.

`sort_family_name`

The name (optionally schema-qualified) of an existing `btree` operator family that describes the sort ordering associated with an ordering operator.

If neither `FOR SEARCH` nor `FOR ORDER BY` is specified, `FOR SEARCH` is the default.

`support_number`

The index method's support procedure number for a function associated with the operator family.

`funcname`

The name (optionally schema-qualified) of a function that is an index method support procedure for the operator family.

`argument_types`

The parameter data type(s) of the function.

`new_name`

The new name of the operator family.

`new_owner`

The new owner of the operator family.

`new_schema`

The new schema for the operator family.

## Compatibility

There is no `ALTER OPERATOR FAMILY` statement in the SQL standard.

## Notes

Notice that the `DROP` syntax only specifies the "slot" in the operator family, by strategy or support number and input data type(s). The name of the operator or function occupying the slot is not mentioned. Also, for `DROP FUNCTION` the type(s) to specify are the input data type(s) the function is intended to support; for `GIST`, `SP_GIST`, and `GIN` indexes this might have nothing to do with the actual input argument types of the function.

Because the index machinery does not check access permissions on functions before using them, including a function or operator in an operator family is tantamount to granting public execute permission on it. This is usually not an issue for the sorts of functions that are useful in an operator family.

The operators should not be defined by SQL functions. A SQL function is likely to be inlined into the calling query, which will prevent the optimizer from recognizing that the query matches an index.

Before Greenplum Database 6.0, the `OPERATOR` clause could include a `RECHECK` option. This option is no longer supported. Greenplum Database now determines whether an index operator is "lossy" on-the-fly at run time. This allows more efficient handling of cases where an operator might or might not be lossy.

## Examples

The following example command adds cross-data-type operators and support functions to an operator family that already contains B-tree operator classes for data types `int4` and `int2`:

```
ALTER OPERATOR FAMILY integer_ops USING btree ADD

-- int4 vs int2
OPERATOR 1 < (int4, int2) ,
OPERATOR 2 <= (int4, int2) ,
OPERATOR 3 = (int4, int2) ,
OPERATOR 4 >= (int4, int2) ,
OPERATOR 5 > (int4, int2) ,
FUNCTION 1 btint42cmp(int4, int2) ,

-- int2 vs int4
OPERATOR 1 < (int2, int4) ,
OPERATOR 2 <= (int2, int4) ,
OPERATOR 3 = (int2, int4) ,
OPERATOR 4 >= (int2, int4) ,
OPERATOR 5 > (int2, int4) ,
FUNCTION 1 btint24cmp(int2, int4) ;
```

To remove these entries:

```
ALTER OPERATOR FAMILY integer_ops USING btree DROP

-- int4 vs int2
OPERATOR 1 (int4, int2) ,
OPERATOR 2 (int4, int2) ,
OPERATOR 3 (int4, int2) ,
OPERATOR 4 (int4, int2) ,
OPERATOR 5 (int4, int2) ,
FUNCTION 1 (int4, int2) ,

-- int2 vs int4
OPERATOR 1 (int2, int4) ,
OPERATOR 2 (int2, int4) ,
OPERATOR 3 (int2, int4) ,
OPERATOR 4 (int2, int4) ,
OPERATOR 5 (int2, int4) ,
FUNCTION 1 (int2, int4) ;
```

## ALTER PROTOCOL

Changes the definition of a protocol.

## Synopsis

```
ALTER PROTOCOL <name> RENAME TO <newname>

ALTER PROTOCOL <name> OWNER TO <newowner>
```

## Description

`ALTER PROTOCOL` changes the definition of a protocol. Only the protocol name or owner can be altered.

You must own the protocol to use `ALTER PROTOCOL`. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on schema of the conversion.

These restrictions are in place to ensure that altering the owner only makes changes that could be made by dropping and recreating the protocol. Note that a superuser can alter ownership of any protocol.

## Parameters

name

The name (optionally schema-qualified) of an existing protocol.

newname

The new name of the protocol.

newowner

The new owner of the protocol.

## Examples

To rename the conversion `GPDBauth` to `GPDB_authentication`:

```
ALTER PROTOCOL GPDBauth RENAME TO GPDB_authentication;
```

To change the owner of the conversion `GPDB_authentication` to `joe`:

```
ALTER PROTOCOL GPDB_authentication OWNER TO joe;
```

## Compatibility

There is no `ALTER PROTOCOL` statement in the SQL standard.

## See Also

[CREATE EXTERNAL TABLE](#), [CREATE PROTOCOL](#), [DROP PROTOCOL](#)

Parent topic: [SQL Commands](#)

## ALTER RESOURCE GROUP

Changes the limits of a resource group.

## Synopsis

```
ALTER RESOURCE GROUP <name> SET <group_attribute> <value>
```

where `group_attribute` is one of:

```
CONCURRENCY <integer>
CPU_RATE_LIMIT <integer>
CPUSET <tuple>
MEMORY_LIMIT <integer>
MEMORY_SHARED_QUOTA <integer>
MEMORY_SPILL_RATIO <integer>
```

## Description

`ALTER RESOURCE GROUP` changes the limits of a resource group. Only a superuser can alter a resource group.

You can set or reset the concurrency limit of a resource group that you create for roles to control the maximum number of active concurrent statements in that group. You can also reset the memory or CPU resources of a resource group to control the amount of memory or CPU resources that all queries submitted through the group can consume on each segment host.

When you alter the CPU resource management mode or limit of a resource group, the new mode or limit is immediately applied.

When you alter a memory limit of a resource group that you create for roles, the new resource limit is immediately applied if current resource usage is less than or equal to the new value and there are no running transactions in the resource group. If the current resource usage exceeds the new memory limit value, or if there are running transactions in other resource groups that hold some of the resource, then Greenplum Database defers assigning the new limit until resource usage falls within the range of the new value.

When you increase the memory limit of a resource group that you create for external components, the new resource limit is phased in as system memory resources become available. If you decrease the memory limit of a resource group that you create for external components, the behavior is component-specific. For example, if you decrease the memory limit of a resource group that you create for a PL/Container runtime, queries in a running container may fail with an out of memory error.

You can alter one limit type in a single `ALTER RESOURCE GROUP` call.

## Parameters

name

The name of the resource group to alter.

CONCURRENCY integer

The maximum number of concurrent transactions, including active and idle transactions, that are permitted for resource groups that you assign to roles. Any transactions submitted after the `CONCURRENCY` value limit is reached are queued. When a running transaction completes, the earliest queued transaction is run.

The `CONCURRENCY` value must be an integer in the range `[0 .. max_connections]`. The default `CONCURRENCY` value for a resource group that you create for roles is 20.

**Note:** You cannot set the `CONCURRENCY` value for the `admin_group` to zero (0).

### CPU\_RATE\_LIMIT integer

The percentage of CPU resources to allocate to this resource group. The minimum CPU percentage for a resource group is 1. The maximum is 100. The sum of the `CPU_RATE_LIMITS` of all resource groups defined in the Greenplum Database cluster must not exceed 100.

If you alter the `CPU_RATE_LIMIT` of a resource group in which you previously configured a `CPUSET`, `CPUSET` is deactivated, the reserved CPU cores are returned to Greenplum Database, and `CPUSET` is set to -1.

### CPUSET tuple

The CPU cores to reserve for this resource group. The CPU cores that you specify in tuple must be available in the system and cannot overlap with any CPU cores that you specify for other resource groups.

tuple is a comma-separated list of single core numbers or core intervals. You must enclose tuple in single quotes, for example, '1,3-4'.

If you alter the `CPUSET` value of a resource group for which you previously configured a `CPU_RATE_LIMIT`, `CPU_RATE_LIMIT` is deactivated, the reserved CPU resources are returned to Greenplum Database, and `CPU_RATE_LIMIT` is set to -1.

You can alter `CPUSET` for a resource group only after you have enabled resource group-based resource management for your Greenplum Database cluster.

### MEMORY\_LIMIT integer

The percentage of Greenplum Database memory resources to reserve for this resource group. The minimum memory percentage for a resource group is 0. The maximum is 100. The default value is 0.

When `MEMORY_LIMIT` is 0, Greenplum Database reserves no memory for the resource group, but uses global shared memory to fulfill all memory requests in the group. If `MEMORY_LIMIT` is 0, `MEMORY_SPILL_RATIO` must also be 0.

The sum of the `MEMORY_LIMITS` of all resource groups defined in the Greenplum Database cluster must not exceed 100. If this sum is less than 100, Greenplum Database allocates any unreserved memory to a resource group global shared memory pool.

### MEMORY\_SHARED\_QUOTA integer

The percentage of memory resources to share among transactions in the resource group. The minimum memory shared quota percentage for a resource group is 0. The maximum is 100. The default `MEMORY_SHARED_QUOTA` value is 80.

### MEMORY\_SPILL\_RATIO integer

The memory usage threshold for memory-intensive operators in a transaction. You can specify an integer percentage value from 0 to 100 inclusive. The default `MEMORY_SPILL_RATIO` value is 0. When `MEMORY_SPILL_RATIO` is 0, Greenplum Database uses the `statement_mem` server configuration parameter value to control initial query operator memory.

## Notes

Use `CREATE ROLE` or `ALTER ROLE` to assign a specific resource group to a role (user).

You cannot submit an `ALTER RESOURCE GROUP` command in an explicit transaction or sub-transaction.

## Examples

Change the active transaction limit for a resource group:

```
ALTER RESOURCE GROUP rgroup1 SET CONCURRENCY 13;
```

Update the CPU limit for a resource group:

```
ALTER RESOURCE GROUP rgroup2 SET CPU_RATE_LIMIT 45;
```

Update the memory limit for a resource group:

```
ALTER RESOURCE GROUP rgroup3 SET MEMORY_LIMIT 30;
```

Update the memory spill ratio for a resource group:

```
ALTER RESOURCE GROUP rgroup4 SET MEMORY_SPILL_RATIO 25;
```

Reserve CPU core 1 for a resource group:

```
ALTER RESOURCE GROUP rgroup5 SET CPUSSET '1';
```

## Compatibility

The `ALTER RESOURCE GROUP` statement is a Greenplum Database extension. This command does not exist in standard PostgreSQL.

## ALTER RESOURCE QUEUE

Changes the limits of a resource queue.

## Synopsis

```
ALTER RESOURCE QUEUE <name> WITH ( <queue_attribute>=<value> [, ... ] )
```

where `queue_attribute` is:

```
ACTIVE_STATEMENTS=<integer>
MEMORY_LIMIT='<memory_units>'
MAX_COST=<float>
COST_OVERCOMMIT={TRUE|FALSE}
MIN_COST=<float>
PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX}
```

```
ALTER RESOURCE QUEUE <name> WITHOUT ( <queue_attribute> [, ... ] )
```

where `queue_attribute` is:

```
ACTIVE_STATEMENTS
MEMORY_LIMIT
MAX_COST
COST_OVERCOMMIT
MIN_COST
```

**Note:** A resource queue must have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value. Do not remove both these `queue_attributes` from a resource queue.

## Description

`ALTER RESOURCE QUEUE` changes the limits of a resource queue. Only a superuser can alter a resource queue. A resource queue must have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value (or it can have both). You can also set or reset priority for a resource queue to control the relative share of available CPU resources used by queries associated with the queue, or memory limit of a resource queue to control the amount of memory that all queries submitted through the queue can consume on a segment host.

`ALTER RESOURCE QUEUE WITHOUT` removes the specified limits on a resource that were previously set. A resource queue must have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value. Do not remove both these `queue_attributes` from a resource queue.

## Parameters

name

The name of the resource queue whose limits are to be altered.

`ACTIVE_STATEMENTS` integer

The number of active statements submitted from users in this resource queue allowed on the system at any one time. The value for `ACTIVE_STATEMENTS` should be an integer greater than 0. To reset `ACTIVE_STATEMENTS` to have no limit, enter a value of `-1`.

`MEMORY_LIMIT` 'memory\_units'

Sets the total memory quota for all statements submitted from users in this resource queue. Memory units can be specified in kB, MB or GB. The minimum memory quota for a resource queue is 10MB. There is no maximum; however the upper boundary at query execution time is limited by the physical memory of a segment host. The default value is no limit (`-1`).

`MAX_COST` float

The total query optimizer cost of statements submitted from users in this resource queue allowed on the system at any one time. The value for `MAX_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2). To reset `MAX_COST` to have no limit, enter a value of `-1.0`.

`COST_OVERCOMMIT` boolean

If a resource queue is limited based on query cost, then the administrator can allow cost overcommit (`COST_OVERCOMMIT=TRUE`, the default). This means that a query that exceeds the allowed cost threshold will be allowed to run but only when the system is idle. If

`COST_OVERCOMMIT=FALSE` is specified, queries that exceed the cost limit will always be rejected and never allowed to run.

#### MIN\_COST float

Queries with a cost under this limit will not be queued and run immediately. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for `MIN_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2). To reset `MIN_COST` to have no limit, enter a value of `-1.0`.

#### PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX}

Sets the priority of queries associated with a resource queue. Queries or statements in queues with higher priority levels will receive a larger share of available CPU resources in case of contention. Queries in low-priority queues may be delayed while higher priority queries are run.

## Notes

GPORCA and the Postgres planner utilize different query costing models and may compute different costs for the same query. The Greenplum Database resource queue management scheme neither differentiates nor aligns costs between GPORCA and the Postgres Planner; it uses the literal cost value returned from the optimizer to throttle queries.

When resource queue-based resource management is active, use the `MEMORY_LIMIT` and `ACTIVE_STATEMENTS` limits for resource queues rather than configuring cost-based limits. Even when using GPORCA, Greenplum Database may fall back to using the Postgres Planner for certain queries, so using cost-based limits can lead to unexpected results.

## Examples

Change the active query limit for a resource queue:

```
ALTER RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20);
```

Change the memory limit for a resource queue:

```
ALTER RESOURCE QUEUE myqueue WITH (MEMORY_LIMIT='2GB');
```

Reset the maximum and minimum query cost limit for a resource queue to no limit:

```
ALTER RESOURCE QUEUE myqueue WITH (MAX_COST=-1.0,
MIN_COST= -1.0);
```

Reset the query cost limit for a resource queue to 310 (or 30000000000.0) and do not allow overcommit:

```
ALTER RESOURCE QUEUE myqueue WITH (MAX_COST=3e+10,
COST_OVERCOMMIT=FALSE);
```

Reset the priority of queries associated with a resource queue to the minimum level:

```
ALTER RESOURCE QUEUE myqueue WITH (PRIORITY=MIN);
```

Remove the `MAX_COST` and `MEMORY_LIMIT` limits from a resource queue:

```
ALTER RESOURCE QUEUE myqueue WITHOUT (MAX_COST, MEMORY_LIMIT);
```

## Compatibility

The `ALTER RESOURCE QUEUE` statement is a Greenplum Database extension. This command does not exist in standard PostgreSQL.

```

```
ALTER ROLE <name> RESOURCE QUEUE {<queue_name> | NONE}
```

```
ALTER ROLE <name> RESOURCE GROUP {<group_name> | NONE}
```

## Description

**ALTER ROLE** changes the attributes of a Greenplum Database role. There are several variants of this command.

### WITH option

Changes many of the role attributes that can be specified in **CREATE ROLE**. (All of the possible attributes are covered, except that there are no options for adding or removing memberships; use **GRANT** and **REVOKE** for that.) Attributes not mentioned in the command retain their previous settings. Database superusers can change any of these settings for any role. Roles having **CREATEROLE** privilege can change any of these settings, but only for non-superuser and non-replication roles. Ordinary roles can only change their own password.

### RENAME

Changes the name of the role. Database superusers can rename any role. Roles having **CREATEROLE** privilege can rename non-superuser roles. The current session user cannot be renamed (connect as a different user to rename a role). Because MD5-encrypted passwords use the role name as cryptographic salt, renaming a role clears its password if the password is MD5-encrypted.

### SET | RESET

Changes a role's session default for a specified configuration parameter, either for all databases or, when the **IN DATABASE** clause is specified, only for sessions in the named database. If **ALL** is specified instead of a role name, this changes the setting for all roles. Using **ALL** with **IN DATABASE** is effectively the same as using the command **ALTER DATABASE...SET...**

Whenever the role subsequently starts a new session, the specified value becomes the session default, overriding whatever setting is present in the server configuration file (`postgresql.conf`) or has been received from the `postgres` command line. This only happens at login time; running **SET ROLE** or **SET SESSION AUTHORIZATION** does not cause new configuration values to be set.

Database-specific settings attached to a role override settings for all databases. Settings for specific databases or specific roles override settings for all roles.

For a role without **LOGIN** privilege, session defaults have no effect. Ordinary roles can change their own session defaults. Superusers can change anyone's session defaults. Roles having **CREATEROLE** privilege can change defaults for non-superuser roles. Ordinary roles can only set defaults for themselves. Certain configuration variables cannot be set this way, or can only be set if a superuser issues the command. See the *Greenplum Database Reference Guide* for information about all user-settable configuration parameters. Only superusers can change a setting for all roles in all databases.

### RESOURCE QUEUE

Assigns the role to a resource queue. The role would then be subject to the limits assigned to the resource queue when issuing queries. Specify **NONE** to assign the role to the default resource queue. A role can only belong to one resource queue. For a role without **LOGIN** privilege, resource queues have no effect. See **CREATE RESOURCE QUEUE** for more information.

### RESOURCE GROUP

Assigns a resource group to the role. The role would then be subject to the concurrent transaction, memory, and CPU limits configured for the resource group. You can assign a single resource group to one or more roles. You cannot assign a resource group that you create for an external component to a role. See [CREATE RESOURCE GROUP](#) for additional information.

## Parameters

name

The name of the role whose attributes are to be altered.

new\_name

The new name of the role.

database\_name

The name of the database in which to set the configuration parameter.

config\_parameter=value

Set this role's session default for the specified configuration parameter to the given value. If value is `DEFAULT` or if `RESET` is used, the role-specific parameter setting is removed, so the role will inherit the system-wide default setting in new sessions. Use `RESET ALL` to clear all role-specific settings. `SET FROM CURRENT` saves the session's current value of the parameter as the role-specific value. If `IN DATABASE` is specified, the configuration parameter is set or removed for the given role and database only. Whenever the role subsequently starts a new session, the specified value becomes the session default, overriding whatever setting is present in `postgresql.conf` or has been received from the `postgres` command line.

Role-specific variable settings take effect only at login; `SET ROLE` and `SET SESSION AUTHORIZATION` do not process role-specific variable settings.

See [Server Configuration Parameters](#) for information about user-settable configuration parameters.

group\_name

The name of the resource group to assign to this role. Specifying the `group_name` `NONE` removes the role's current resource group assignment and assigns a default resource group based on the role's capability. `SUPERUSER` roles are assigned the `admin_group` resource group, while the `default_group` resource group is assigned to non-admin roles.

You cannot assign a resource group that you create for an external component to a role.

queue\_name

The name of the resource queue to which the user-level role is to be assigned. Only roles with `LOGIN` privilege can be assigned to a resource queue. To unassign a role from a resource queue and put it in the default resource queue, specify `NONE`. A role can only belong to one resource queue.

`SUPERUSER` | `NOSUPERUSER`

`CREATEDB` | `NOCREATEDB`

`CREATEROLE` | `NOCREATEROLE`

`CREATEUSER` | `NOCREATEUSER`

`CREATEUSER` and `NOCREATEUSER` are obsolete, but still accepted, spellings of `SUPERUSER` and

`NOSUPERUSER`. Note that they are not equivalent to the `CREATEROLE` and `NOCREATEROLE` clauses.

`CREATEEXTTABLE` | `NOCREATEEXTTABLE` [(attribute='value')]

If `CREATEEXTTABLE` is specified, the role being defined is allowed to create external tables. The default `type` is `readable` and the default `protocol` is `gpfdist` if not specified.

`NOCREATEEXTTABLE` (the default) denies the role the ability to create external tables. Note that external tables that use the `file` or `execute` protocols can only be created by superusers.

INHERIT | NOINHERIT

LOGIN | NOLOGIN

REPLICATION

NOREPLICATION

CONNECTION LIMIT `conlimit`

PASSWORD `password`

ENCRYPTED | UNENCRYPTED

VALID UNTIL 'timestamp'

These clauses alter role attributes originally set by `CREATE ROLE`.

DENY `deny_point`

DENY BETWEEN `deny_point` AND `deny_point`

The `DENY` and `DENY BETWEEN` keywords set time-based constraints that are enforced at login. `DENY` sets a day or a day and time to deny access. `DENY BETWEEN` sets an interval during which access is denied. Both use the parameter `deny_point` that has following format:

```
DAY day [ TIME 'time' ]
```

The two parts of the `deny_point` parameter use the following formats:

For day:

```
{ 'Sunday' | 'Monday' | 'Tuesday' | 'Wednesday' | 'Thursday' | 'Friday' |  
'Saturday' | 0-6 }
```

For time:

```
{ 00-23 : 00-59 | 01-12 : 00-59 { AM | PM } }
```

The `DENY BETWEEN` clause uses two `deny_point` parameters which must indicate day and time.

```
DENY BETWEEN <deny_point> AND <deny_point>
```

For example:

```
ALTER USER user1 DENY BETWEEN day 'Sunday' time '00:00' AND day 'Monday' time '0  
0:00';
```

For more information about time-based constraints and examples, see "Managing Roles and Privileges" in the *Greenplum Database Administrator Guide*.

DROP DENY FOR `deny_point`

The `DROP DENY FOR` clause removes a time-based constraint from the role. It uses the `deny_point` parameter described above.

For more information about time-based constraints and examples, see "Managing Roles and Privileges" in the *Greenplum Database Administrator Guide*.

## Notes

Use [CREATE ROLE](#) to add new roles, and [DROP ROLE](#) to remove a role.

Use [GRANT](#) and [REVOKE](#) for adding and removing role memberships.

Caution must be exercised when specifying an unencrypted password with this command. The password will be transmitted to the server in clear text, and it might also be logged in the client's command history or the server log. The `psql` command-line client contains a meta-command `\password` that can be used to change a role's password without exposing the clear text password.

It is also possible to tie a session default to a specific database rather than to a role; see [ALTER DATABASE](#). If there is a conflict, database-role-specific settings override role-specific ones, which in turn override database-specific ones.

## Examples

Change the password for a role:

```
ALTER ROLE daria WITH PASSWORD 'passwd123';
```

Remove a role's password:

```
ALTER ROLE daria WITH PASSWORD NULL;
```

Change a password expiration date:

```
ALTER ROLE scott VALID UNTIL 'May 4 12:00:00 2015 +1';
```

Make a password valid forever:

```
ALTER ROLE luke VALID UNTIL 'infinity';
```

Give a role the ability to create other roles and new databases:

```
ALTER ROLE joelle CREATEROLE CREATEDB;
```

Give a role a non-default setting of the `maintenance_work_mem` parameter:

```
ALTER ROLE admin SET maintenance_work_mem = 100000;
```

Give a role a non-default, database-specific setting of the `client_min_messages` parameter:

```
ALTER ROLE fred IN DATABASE devel SET client_min_messages = DEBUG;
```

Assign a role to a resource queue:

```
ALTER ROLE sammy RESOURCE QUEUE poweruser;
```

Give a role permission to create writable external tables:

```
ALTER ROLE load CREATEEXTTABLE (type='writable');
```

Alter a role so it does not allow login access on Sundays:

```
ALTER ROLE user3 DENY DAY 'Sunday';
```

Alter a role to remove the constraint that does not allow login access on Sundays:

```
ALTER ROLE user3 DROP DENY FOR DAY 'Sunday';
```

Assign a new resource group to a role:

```
ALTER ROLE parttime_user RESOURCE GROUP rg_light;
```

## Compatibility

The `ALTER ROLE` statement is a Greenplum Database extension.

## ALTER RULE

Changes the definition of a rule.

## Synopsis

```
ALTER RULE name ON table\_name RENAME TO new\_name
```

## Description

`ALTER RULE` changes properties of an existing rule. Currently, the only available action is to change the rule's name.

To use `ALTER RULE`, you must own the table or view that the rule applies to.

## Parameters

`name`

The name of an existing rule to alter.

`table_name`

The name (optionally schema-qualified) of the table or view that the rule applies to.

`new_name`

The new name for the rule.

## Compatibility

`ALTER RULE` is a Greenplum Database language extension, as is the entire query rewrite system.

## See Also

[CREATE RULE](#), [DROP RULE](#)

Parent topic: [SQL Commands](#)

## ALTER SCHEMA

Changes the definition of a schema.

## Synopsis

```
ALTER SCHEMA <name> RENAME TO <newname>
```

```
ALTER SCHEMA <name> OWNER TO <newowner>
```

## Description

`ALTER SCHEMA` changes the definition of a schema.

You must own the schema to use `ALTER SCHEMA`. To rename a schema you must also have the `CREATE` privilege for the database. To alter the owner, you must also be a direct or indirect member of the new owning role, and you must have the `CREATE` privilege for the database. Note that superusers have all these privileges automatically.

## Parameters

name

The name of an existing schema.

newname

The new name of the schema. The new name cannot begin with `pg_`, as such names are reserved for system schemas.

newowner

The new owner of the schema.

## Compatibility

There is no `ALTER SCHEMA` statement in the SQL standard.

## See Also

[CREATE SCHEMA](#), [DROP SCHEMA](#)

Parent topic: [SQL Commands](#)

## ALTER SEQUENCE

Changes the definition of a sequence generator.

## Synopsis

```
ALTER SEQUENCE [ IF EXISTS ] <name> [ INCREMENT [ BY ] <increment> ]
    [ MINVALUE <minvalue> | NO MINVALUE ]
    [ MAXVALUE <maxvalue> | NO MAXVALUE ]
    [ START [ WITH ] <start> ]
    [ RESTART [ [ WITH ] <restart> ] ]
    [ CACHE <cache> ] [[ NO ] CYCLE]
    [ OWNED BY {<table.column> | NONE} ]

ALTER SEQUENCE [ IF EXISTS ] <name> OWNER TO <new_owner>

ALTER SEQUENCE [ IF EXISTS ] <name> RENAME TO <new_name>

ALTER SEQUENCE [ IF EXISTS ] <name> SET SCHEMA <new_schema>
```

## Description

**ALTER SEQUENCE** changes the parameters of an existing sequence generator. Any parameters not specifically set in the **ALTER SEQUENCE** command retain their prior settings.

You must own the sequence to use **ALTER SEQUENCE**. To change a sequence's schema, you must also have **CREATE** privilege on the new schema. Note that superusers have all these privileges automatically.

To alter the owner, you must be a direct or indirect member of the new owning role, and that role must have **CREATE** privilege on the sequence's schema. (These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the sequence. However, a superuser can alter ownership of any sequence anyway.)

## Parameters

name

The name (optionally schema-qualified) of a sequence to be altered.

IF EXISTS

Do not throw an error if the sequence does not exist. A notice is issued in this case.

increment

The clause **INCREMENT BY increment** is optional. A positive value will make an ascending sequence, a negative one a descending sequence. If unspecified, the old increment value will be maintained.

minvalue

NO MINVALUE

The optional clause **MINVALUE minvalue** determines the minimum value a sequence can generate. If **NO MINVALUE** is specified, the defaults of 1 and -263-1 for ascending and descending sequences, respectively, will be used. If neither option is specified, the current minimum value will be maintained.

maxvalue

NO MAXVALUE

The optional clause `MAXVALUE maxvalue` determines the maximum value for the sequence. If `NO MAXVALUE` is specified, the defaults are 263-1 and -1 for ascending and descending sequences, respectively, will be used. If neither option is specified, the current maximum value will be maintained.

#### start

The optional clause `START WITH start` changes the recorded start value of the sequence. This has no effect on the *current* sequence value; it simply sets the value that future `ALTER SEQUENCE RESTART` commands will use.

#### restart

The optional clause `RESTART [ WITH restart ]` changes the current value of the sequence. This is equivalent to calling the `setval(sequence, start_val, is_called)` function with `is_called = false`. The specified value will be returned by the next call of the `nextval(sequence)` function. Writing `RESTART` with no restart value is equivalent to supplying the start value that was recorded by `CREATE SEQUENCE` or last set by `ALTER SEQUENCE START WITH`.

#### new\_owner

The user name of the new owner of the sequence.

#### cache

The clause `CACHE cache` enables sequence numbers to be preallocated and stored in memory for faster access. The minimum value is 1 (only one value can be generated at a time, i.e., no cache). If unspecified, the old cache value will be maintained.

#### CYCLE

The optional `CYCLE` key word may be used to enable the sequence to wrap around when the maxvalue or minvalue has been reached by an ascending or descending sequence. If the limit is reached, the next number generated will be the respective minvalue or maxvalue.

#### NO CYCLE

If the optional `NO CYCLE` key word is specified, any calls to `nextval()` after the sequence has reached its maximum value will return an error. If neither `CYCLE` or `NO CYCLE` are specified, the old cycle behavior will be maintained.

#### OWNED BY table.column

#### OWNED BY NONE

The `OWNED BY` option causes the sequence to be associated with a specific table column, such that if that column (or its whole table) is dropped, the sequence will be automatically dropped as well. If specified, this association replaces any previously specified association for the sequence. The specified table must have the same owner and be in the same schema as the sequence. Specifying `OWNED BY NONE` removes any existing table column association.

#### new\_name

The new name for the sequence.

#### new\_schema

The new schema for the sequence.

## Notes

To avoid blocking of concurrent transactions that obtain numbers from the same sequence, `ALTER SEQUENCE`'s effects on the sequence generation parameters are never rolled back; those changes take effect immediately and are not reversible. However, the `OWNED BY`, `OWNER TO`, `RENAME TO`, and `SET SCHEMA` clauses are ordinary catalog updates and can be rolled back.

`ALTER SEQUENCE` will not immediately affect `nextval()` results in sessions, other than the current one, that have preallocated (cached) sequence values. They will use up all cached values prior to noticing the changed sequence generation parameters. The current session will be affected immediately.

For historical reasons, `ALTER TABLE` can be used with sequences too; but the only variants of `ALTER TABLE` that are allowed with sequences are equivalent to the forms shown above.

## Examples

Restart a sequence called `serial` at 105:

```
ALTER SEQUENCE serial RESTART WITH 105;
```

## Compatibility

`ALTER SEQUENCE` conforms to the SQL standard, except for the `START WITH`, `OWNED BY`, `OWNER TO`, `RENAME TO`, and `SET SCHEMA` clauses, which are Greenplum Database extensions.

## ALTER SERVER

Changes the definition of a foreign server.

## Synopsis

```
ALTER SERVER <server_name> [ VERSION '<new_version>' ]
    [ OPTIONS ( [ ADD | SET | DROP ] <option> ['<value>'] [, ... ] ) ]

ALTER SERVER <server_name> OWNER TO <new_owner>

ALTER SERVER <server_name> RENAME TO <new_name>
```

## Description

`ALTER SERVER` changes the definition of a foreign server. The first form of the command changes the version string or the generic options of the server. Greenplum Database requires at least one clause. The second and third forms of the command change the owner or the name of the server.

To alter the server, you must be the owner of the server. To alter the owner you must:

- Own the server.
- Be a direct or indirect member of the new owning role.
- Have `USAGE` privilege on the server's foreign-data wrapper.

Superusers automatically satisfy all of these criteria.

## Parameters

`server_name`

The name of an existing server.

`new_version`

The new server version.

`OPTIONS ( [ ADD | SET | DROP ] option ['value'] [, ... ] )`

Change the server's options. `ADD`, `SET`, and `DROP` specify the action to perform. If no operation is explicitly specified, the default operation is `ADD`. Option names must be unique. Greenplum Database validates names and values using the server's foreign-data wrapper library.

`OWNER TO new_owner`

Specifies the new owner of the foreign server.

`RENAME TO new_name`

Specifies the new name of the foreign server.

## Examples

Change the definition of a server named `foo` by adding connection options:

```
ALTER SERVER foo OPTIONS (host 'foo', dbname 'foodb');
```

Change the option named `host` for a server named `foo`, and set the server version:

```
ALTER SERVER foo VERSION '9.1' OPTIONS (SET host 'baz');
```

## Compatibility

`ALTER SERVER` conforms to ISO/IEC 9075-9 (SQL/MED). The `OWNER TO` and `RENAME` forms are Greenplum Database extensions.

## See Also

[ TABLESPACE <tablespace> ]
```

where `subpartition_spec` is:

```
<subpartition_element> [, ...]
```

and `subpartition_element` is:

```
DEFAULT SUBPARTITION <subpartition_name>
| [SUBPARTITION <subpartition_name>] VALUES (<list_value> [,... ] )
| [SUBPARTITION <subpartition_name>]
  START ([<datatype>] '<start_value>') [INCLUSIVE | EXCLUSIVE]
  [ END ([<datatype>] '<end_value>') [INCLUSIVE | EXCLUSIVE] ]
  [ EVERY ( [<number | datatype>] '<interval_value>' ) ]
```

```

| [SUBPARTITION <subpartition_name>]
  END ([<datatype>] '<end_value>') [INCLUSIVE | EXCLUSIVE]
  [ EVERY ( [<number | datatype>] '<interval_value>' ) ]
[ WITH ( <partition_storage_parameter>=<value> [, ... ] ) ]
[ TABLESPACE <tablespace> ]

```

where `storage_parameter` is:

```

appendoptimized={TRUE|FALSE}
blocksize={8192-2097152}
orientation={COLUMN|ROW}
compresstype={ZLIB|ZSTD|QUICKLZ|RLE_TYPE|NONE}
compresslevel={0-9}
fillfactor={10-100}
[oids=FALSE]

```

## Description

**ALTER TABLE** changes the definition of an existing table. There are several subforms:

- **ADD COLUMN** — Adds a new column to the table, using the same syntax as **CREATE TABLE**. The **ENCODING** clause is valid only for append-optimized, column-oriented tables.

When you add a column to an append-optimized, column-oriented table, Greenplum Database sets each data compression parameter for the column (**compresstype**, **compresslevel**, and **blocksize**) based on the following setting, in order of preference.

1. The compression parameter setting specified in the **ALTER TABLE** command **ENCODING** clause.
  2. If the server configuration parameter **gp\_add\_column\_inherits\_table\_setting** is **on**, use the table's data compression parameters specified in the **WITH** clause when the table was created. The default server configuration parameter default is **off**, the **WITH** clause parameters are ignored.
  3. The compression parameter setting specified in the server configuration parameter **gp\_default\_storage\_option**.
  4. The default compression parameter value. For append-optimized and hash tables, **ADD COLUMN** requires a table rewrite. For information about table rewrites performed by **ALTER TABLE**, see **Notes**.
- **DROP COLUMN [IF EXISTS]** — Drops a column from a table. Note that if you drop table columns that are being used as the Greenplum Database distribution key, the distribution policy for the table will be changed to **DISTRIBUTED RANDOMLY**. Indexes and table constraints involving the column are automatically dropped as well. You need to say **CASCADE** if anything outside the table depends on the column (such as views). If **IF EXISTS** is specified and the column does not exist, no error is thrown; a notice is issued instead.
  - **IF EXISTS** — Do not throw an error if the table does not exist. A notice is issued in this case.
  - **SET DATA TYPE** — This form changes the data type of a column of a table. Note that you cannot alter column data types that are being used as distribution or partitioning keys. Indexes and simple table constraints involving the column will be automatically converted to

use the new column type by reparsing the originally supplied expression. The optional `COLLATE` clause specifies a collation for the new column; if omitted, the collation is the default for the new column type. The optional `USING` clause specifies how to compute the new column value from the old. If omitted, the default conversion is the same as an assignment cast from old data type to new. A `USING` clause must be provided if there is no implicit or assignment cast from old to new type.

**Note:** GPORCA supports collation only when all columns in the query use the same collation. If columns in the query use different collations, then Greenplum uses the Postgres Planner.

Changing a column data type requires a table rewrite. For information about table rewrites performed by `ALTER TABLE`, see [Notes](#).

- **SET/DROP DEFAULT** — Sets or removes the default value for a column. Default values only apply in subsequent `INSERT` or `UPDATE` commands; they do not cause rows already in the table to change.
- **SET/DROP NOT NULL** — Changes whether a column is marked to allow null values or to reject null values. You can only use `SET NOT NULL` when the column contains no null values.
- **SET STATISTICS** — Sets the per-column statistics-gathering target for subsequent `ANALYZE` operations. The target can be set in the range 0 to 10000, or set to -1 to revert to using the system default statistics target (`default_statistics_target`). When set to 0, no statistics are collected.

- **SET ( attribute\_option = value [, ... ] )**

**RESET ( attribute\_option [, ... ] )**— Sets or resets per-attribute options. Currently, the only defined per-attribute options are `n_distinct` and `n_distinct_inherited`, which override the number-of-distinct-values estimates made by subsequent `ANALYZE` operations.

`n_distinct` affects the statistics for the table itself, while `n_distinct_inherited` affects the statistics gathered for the table plus its inheritance children. When set to a positive value, `ANALYZE` will assume that the column contains exactly the specified number of distinct non-null values. When set to a negative value, which must be greater than or equal to -1, `ANALYZE` will assume that the number of distinct non-null values in the column is linear in the size of the table; the exact count is to be computed by multiplying the estimated table size by the absolute value of the given number. For example, a value of -1 implies that all values in the column are distinct, while a value of -0.5 implies that each value appears twice on the average. This can be useful when the size of the table changes over time, since the multiplication by the number of rows in the table is not performed until query planning time. Specify a value of 0 to revert to estimating the number of distinct values normally.

- **ADD table\_constraint [NOT VALID]** — Adds a new constraint to a table (not just a partition) using the same syntax as `CREATE TABLE`. The `NOT VALID` option is currently only allowed for foreign key and `CHECK` constraints. If the constraint is marked `NOT VALID`, Greenplum Database skips the potentially-lengthy initial check to verify that all rows in the table satisfy the constraint. The constraint will still be enforced against subsequent inserts or updates (that is, they'll fail unless there is a matching row in the referenced table, in the case of foreign keys; and they'll fail unless the new row matches the specified check constraints). But the database will not assume that the constraint holds for all rows in the

table, until it is validated by using the `VALIDATE CONSTRAINT` option. Constraint checks are skipped at create table time, so the `CREATE TABLE` syntax does not include this option.

- **VALIDATE CONSTRAINT** — This form validates a foreign key constraint that was previously created as `NOT VALID`, by scanning the table to ensure there are no rows for which the constraint is not satisfied. Nothing happens if the constraint is already marked valid. The advantage of separating validation from initial creation of the constraint is that validation requires a lesser lock on the table than constraint creation does.
- **ADD table\_constraint\_using\_index** — Adds a new `PRIMARY KEY` or `UNIQUE` constraint to a table based on an existing unique index. All the columns of the index will be included in the constraint. The index cannot have expression columns nor be a partial index. Also, it must be a b-tree index with default sort ordering. These restrictions ensure that the index is equivalent to one that would be built by a regular `ADD PRIMARY KEY` or `ADD UNIQUE` command.

Adding a `PRIMARY KEY` or `UNIQUE` constraint to a table based on an existing unique index is not supported on a partitioned table.

If `PRIMARY KEY` is specified, and the index's columns are not already marked `NOT NULL`, then this command will attempt to do `ALTER COLUMN SET NOT NULL` against each such column. That requires a full table scan to verify the column(s) contain no nulls. In all other cases, this is a fast operation.

If a constraint name is provided then the index will be renamed to match the constraint name. Otherwise the constraint will be named the same as the index.

After this command is run, the index is "owned" by the constraint, in the same way as if the index had been built by a regular `ADD PRIMARY KEY` or `ADD UNIQUE` command. In particular, dropping the constraint will make the index disappear too.

- **DROP CONSTRAINT [IF EXISTS]** — Drops the specified constraint on a table. If `IF EXISTS` is specified and the constraint does not exist, no error is thrown. In this case a notice is issued instead.
- **DISABLE/ENABLE TRIGGER** — Deactivates or activates trigger(s) belonging to the table. A deactivated trigger is still known to the system, but is not run when its triggering event occurs. For a deferred trigger, the enable status is checked when the event occurs, not when the trigger function is actually run. One may deactivate or activate a single trigger specified by name, or all triggers on the table, or only user-created triggers. Deactivating or activating constraint triggers requires superuser privileges.

**Note:** triggers are not supported in Greenplum Database. Triggers in general have very limited functionality due to the parallelism of Greenplum Database.

- **CLUSTER ON/SET WITHOUT CLUSTER** — Selects or removes the default index for future `CLUSTER` operations. It does not actually re-cluster the table. Note that `CLUSTER` is not the recommended way to physically reorder a table in Greenplum Database because it takes so long. It is better to recreate the table with `CREATE TABLE AS` and order it by the index column(s).

**Note:** `CLUSTER ON` is not supported on append-optimized tables.

- **SET WITHOUT OIDS** — Removes the OID system column from the table.

**Warning:** VMware does not support using `SET WITH OIDS` or `oids=TRUE` to assign an OID system column. On large tables, such as those in a typical Greenplum Database system, using OIDs for table rows can cause wrap-around of the 32-bit OID counter. Once the counter wraps around, OIDs can no longer be assumed to be unique, which not only makes them useless to user applications, but can also cause problems in the Greenplum Database system catalog tables. In addition, excluding OIDs from a table reduces the space required to store the table on disk by 4 bytes per row, slightly improving performance. You cannot create OIDs on a partitioned or column-oriented table (an error is displayed). This syntax is deprecated and will be removed in a future Greenplum release.

- **SET ( FILLFACTOR = value) / RESET (FILLFACTOR)** — Changes the fillfactor for the table. The fillfactor for a table is a percentage between 10 and 100. 100 (complete packing) is the default. When a smaller fillfactor is specified, `INSERT` operations pack table pages only to the indicated percentage; the remaining space on each page is reserved for updating rows on that page. This gives `UPDATE` a chance to place the updated copy of a row on the same page as the original, which is more efficient than placing it on a different page. For a table whose entries are never updated, complete packing is the best choice, but in heavily updated tables smaller fillfactors are appropriate. Note that the table contents will not be modified immediately by this command. You will need to rewrite the table to get the desired effects. That can be done with `VACUUM` or one of the forms of `ALTER TABLE` that forces a table rewrite. For information about the forms of `ALTER TABLE` that perform a table rewrite, see [Notes](#).
- **SET DISTRIBUTED** — Changes the distribution policy of a table. Changing a hash distribution policy, or changing to or from a replicated policy, will cause the table data to be physically redistributed on disk, which can be resource intensive.
- **INHERIT parent\_table / NO INHERIT parent\_table** — Adds or removes the target table as a child of the specified parent table. Queries against the parent will include records of its child table. To be added as a child, the target table must already contain all the same columns as the parent (it could have additional columns, too). The columns must have matching data types, and if they have `NOT NULL` constraints in the parent then they must also have `NOT NULL` constraints in the child. There must also be matching child-table constraints for all `CHECK` constraints of the parent, except those marked non-inheritable (that is, created with `ALTER TABLE ... ADD CONSTRAINT ... NO INHERIT`) in the parent, which are ignored; all child-table constraints matched must not be marked non-inheritable. Currently `UNIQUE`, `PRIMARY KEY`, and `FOREIGN KEY` constraints are not considered, but this may change in the future.
- **OF type\_name** — This form links the table to a composite type as though `CREATE TABLE OF` had formed it. The table's list of column names and types must precisely match that of the composite type; the presence of an `oid` system column is permitted to differ. The table must not inherit from any other table. These restrictions ensure that `CREATE TABLE OF` would permit an equivalent table definition.
- **NOT OF** — This form dissociates a typed table from its type.
- **OWNER** — Changes the owner of the table, sequence, or view to the specified user.
- **SET TABLESPACE** — Changes the table's tablespace to the specified tablespace and moves the data file(s) associated with the table to the new tablespace. Indexes on the

table, if any, are not moved; but they can be moved separately with additional `SET TABLESPACE` commands. All tables in the current database in a tablespace can be moved by using the `ALL IN TABLESPACE` form, which will lock all tables to be moved first and then move each one. This form also supports `OWNED BY`, which will only move tables owned by the roles specified. If the `NOWAIT` option is specified then the command will fail if it is unable to acquire all of the locks required immediately. Note that system catalogs are not moved by this command, use `ALTER DATABASE` or explicit `ALTER TABLE` invocations instead if desired. The `information_schema` relations are not considered part of the system catalogs and will be moved. See also `CREATE TABLESPACE`. If changing the tablespace of a partitioned table, all child table partitions will also be moved to the new tablespace.

- **RENAME** — Changes the name of a table (or an index, sequence, view, or materialized view), the name of an individual column in a table, or the name of a constraint of the table. There is no effect on the stored data. Note that Greenplum Database distribution key columns cannot be renamed.
- **SET SCHEMA** — Moves the table into another schema. Associated indexes, constraints, and sequences owned by table columns are moved as well.
- **ALTER PARTITION | DROP PARTITION | RENAME PARTITION | TRUNCATE PARTITION | ADD PARTITION | SPLIT PARTITION | EXCHANGE PARTITION | SET SUBPARTITION TEMPLATE**— Changes the structure of a partitioned table. In most cases, you must go through the parent table to alter one of its child table partitions.

**Note:** If you add a partition to a table that has subpartition encodings, the new partition inherits the storage directives for the subpartitions. For more information about the precedence of compression settings, see [Using Compression](#).

All the forms of `ALTER TABLE` that act on a single table, except `RENAME` and `SET SCHEMA`, can be combined into a list of multiple alterations to apply together. For example, it is possible to add several columns and/or alter the type of several columns in a single command. This is particularly useful with large tables, since only one pass over the table need be made.

You must own the table to use `ALTER TABLE`. To change the schema or tablespace of a table, you must also have `CREATE` privilege on the new schema or tablespace. To add the table as a new child of a parent table, you must own the parent table as well. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the table's schema. To add a column or alter a column type or use the `OF` clause, you must also have `USAGE` privilege on the data type. A superuser has these privileges automatically.

**Note:** Memory usage increases significantly when a table has many partitions, if a table has compression, or if the blocksize for a table is large. If the number of relations associated with the table is large, this condition can force an operation on the table to use more memory. For example, if the table is a CO table and has a large number of columns, each column is a relation. An operation like `ALTER TABLE ALTER COLUMN` opens all the columns in the table allocates associated buffers. If a CO table has 40 columns and 100 partitions, and the columns are compressed and the blocksize is 2 MB (with a system factor of 3), the system attempts to allocate 24 GB, that is  $(40 \times 100) \times (2 \times 3)$  MB or 24 GB.

## Parameters

**ONLY**

Only perform the operation on the table name specified. If the **ONLY** keyword is not used, the operation will be performed on the named table and any child table partitions associated with that table.

**Note:** Adding or dropping a column, or changing a column's type, in a parent or descendant table only is not permitted. The parent table and its descendents must always have the same columns and types.

**name**

The name (possibly schema-qualified) of an existing table to alter. If **ONLY** is specified, only that table is altered. If **ONLY** is not specified, the table and all its descendant tables (if any) are updated.

**Note:** Constraints can only be added to an entire table, not to a partition. Because of that restriction, the name parameter can only contain a table name, not a partition name.

**column\_name**

Name of a new or existing column. Note that Greenplum Database distribution key columns must be treated with special care. Altering or dropping these columns can change the distribution policy for the table.

**new\_column\_name**

New name for an existing column.

**new\_name**

New name for the table.

**type**

Data type of the new column, or new data type for an existing column. If changing the data type of a Greenplum distribution key column, you are only allowed to change it to a compatible type (for example, **text** to **varchar** is OK, but **text** to **int** is not).

**table\_constraint**

New table constraint for the table. Note that foreign key constraints are currently not supported in Greenplum Database. Also a table is only allowed one unique constraint and the uniqueness must be within the Greenplum Database distribution key.

**constraint\_name**

Name of an existing constraint to drop.

**CASCADE**

Automatically drop objects that depend on the dropped column or constraint (for example, views referencing the column).

**RESTRICT**

Refuse to drop the column or constraint if there are any dependent objects. This is the default behavior.

**trigger\_name**

Name of a single trigger to deactivate or enable. Note that Greenplum Database does not support triggers.

**ALL**

Deactivate or activate all triggers belonging to the table including constraint related triggers. This requires superuser privilege if any of the triggers are internally generated constraint triggers such as those that are used to implement foreign key constraints or deferrable uniqueness and exclusion constraints.

**USER**

Deactivate or activate all triggers belonging to the table except for internally generated constraint triggers such as those that are used to implement foreign key constraints or deferrable uniqueness and exclusion constraints.

**index\_name**

The index name on which the table should be marked for clustering. Note that `CLUSTER` is not the recommended way to physically reorder a table in Greenplum Database because it takes so long. It is better to recreate the table with `CREATE TABLE AS` and order it by the index column(s).

**FILLFACTOR**

Set the fillfactor percentage for a table.

**value**

The new value for the `FILLFACTOR` parameter, which is a percentage between 10 and 100. 100 is the default.

**DISTRIBUTED BY ((column\_name [opclass])) | DISTRIBUTED RANDOMLY | DISTRIBUTED REPLICATED**

Specifies the distribution policy for a table. Changing a hash distribution policy causes the table data to be physically redistributed, which can be resource intensive. If you declare the same hash distribution policy or change from hash to random distribution, data will not be redistributed unless you declare `SET WITH (REORGANIZE=true)`.

Changing to or from a replicated distribution policy causes the table data to be redistributed.

**REORGANIZE=true|false**

Use `REORGANIZE=true` when the hash distribution policy has not changed or when you have changed from a hash to a random distribution, and you want to redistribute the data anyways.

**parent\_table**

A parent table to associate or de-associate with this table.

**new\_owner**

The role name of the new owner of the table.

**new\_tablespace**

The name of the tablespace to which the table will be moved.

**new\_schema**

The name of the schema to which the table will be moved.

**parent\_table\_name**

When altering a partitioned table, the name of the top-level parent table.

**ALTER [DEFAULT] PARTITION**

If altering a partition deeper than the first level of partitions, use `ALTER PARTITION` clauses to specify which subpartition in the hierarchy you want to alter. For each partition level in the table hierarchy that is above the target partition, specify the partition that is related to the target partition in an `ALTER PARTITION` clause.

**DROP [DEFAULT] PARTITION**

Drops the specified partition. If the partition has subpartitions, the subpartitions are automatically dropped as well.

**TRUNCATE [DEFAULT] PARTITION**

Truncates the specified partition. If the partition has subpartitions, the subpartitions are automatically truncated as well.

**RENAME [DEFAULT] PARTITION**

Changes the partition name of a partition (not the relation name). Partitioned tables are created using the naming convention: <parentname>\_<level>\_prt\_<partition\_name>.

**ADD DEFAULT PARTITION**

Adds a default partition to an existing partition design. When data does not match to an existing partition, it is inserted into the default partition. Partition designs that do not have a default partition will reject incoming rows that do not match to an existing partition. Default partitions must be given a name.

**ADD PARTITION**

**partition\_element** - Using the existing partition type of the table (range or list), defines the boundaries of new partition you are adding.

**name** - A name for this new partition.

**VALUES** - For list partitions, defines the value(s) that the partition will contain.

**START** - For range partitions, defines the starting range value for the partition. By default, start values are **INCLUSIVE**. For example, if you declared a start date of '2016-01-01', then the partition would contain all dates greater than or equal to '2016-01-01'. Typically the data type of the **START** expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

**END** - For range partitions, defines the ending range value for the partition. By default, end values are **EXCLUSIVE**. For example, if you declared an end date of '2016-02-01', then the partition would contain all dates less than but not equal to '2016-02-01'. Typically the data type of the **END** expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

**WITH** - Sets the table storage options for a partition. For example, you may want older partitions to be append-optimized tables and newer partitions to be regular heap tables. See [CREATE TABLE](#) for a description of the storage options.

**TABLESPACE** - The name of the tablespace in which the partition is to be created.

**subpartition\_spec** - Only allowed on partition designs that were created without a subpartition template. Declares a subpartition specification for the new partition you are adding. If the partitioned table was originally defined using a subpartition template, then the template will be used to generate the subpartitions automatically.

**EXCHANGE [DEFAULT] PARTITION**

Exchanges another table into the partition hierarchy into the place of an existing partition. In a multi-level partition design, you can only exchange the lowest level partitions (those that contain data).

The Greenplum Database server configuration parameter

`gp_enable_exchange_default_partition` controls availability of the **EXCHANGE DEFAULT PARTITION** clause. The default value for the parameter is `off`. The clause is not available and Greenplum Database returns an error if the clause is specified in an **ALTER TABLE** command.

For information about the parameter, see [Server Configuration Parameters](#).

**Warning:** Before you exchange the default partition, you must ensure the data in the table to be exchanged, the new default partition, is valid for the default partition. For example, the

data in the new default partition must not contain data that would be valid in other leaf child partitions of the partitioned table. Otherwise, queries against the partitioned table with the exchanged default partition that are run by GPORCA might return incorrect results.

**WITH TABLE** *table\_name* - The name of the table you are swapping into the partition design. You can exchange a table where the table data is stored in the database. For example, the table is created with the `CREATE TABLE` command. The table must have the same number of columns, column order, column names, column types, and distribution policy as the parent table.

With the `EXCHANGE PARTITION` clause, you can also exchange a readable external table (created with the `CREATE EXTERNAL TABLE` command) into the partition hierarchy in the place of an existing leaf child partition. If you specify a readable external table, you must also specify the `WITHOUT VALIDATION` clause to skip table validation against the `CHECK` constraint of the partition you are exchanging.

Exchanging a leaf child partition with an external table is not supported if the partitioned table contains a column with a check constraint or a `NOT NULL` constraint.

You cannot exchange a partition with a replicated table. Exchanging a partition with a partitioned table or a child partition of a partitioned table is not supported.

**WITH | WITHOUT VALIDATION** - Validates that the data in the table matches the `CHECK` constraint of the partition you are exchanging. The default is to validate the data against the `CHECK` constraint.

**Warning:** If you specify the `WITHOUT VALIDATION` clause, you must ensure that the data in table that you are exchanging for an existing child leaf partition is valid against the `CHECK` constraints on the partition. Otherwise, queries against the partitioned table might return incorrect results.

#### SET SUBPARTITION TEMPLATE

Modifies the subpartition template for an existing partition. After a new subpartition template is set, all new partitions added will have the new subpartition design (existing partitions are not modified).

#### SPLIT DEFAULT PARTITION

Splits a default partition. In a multi-level partition, only a range partition can be split, not a list partition, and you can only split the lowest level default partitions (those that contain data). Splitting a default partition creates a new partition containing the values specified and leaves the default partition containing any values that do not match to an existing partition.

**AT** - For list partitioned tables, specifies a single list value that should be used as the criteria for the split.

**START** - For range partitioned tables, specifies a starting value for the new partition.

**END** - For range partitioned tables, specifies an ending value for the new partition.

**INTO** - Allows you to specify a name for the new partition. When using the `INTO` clause to split a default partition, the second partition name specified should always be that of the existing default partition. If you do not know the name of the default partition, you can look it up using the `pg_partitions` view.

#### SPLIT PARTITION

Splits an existing partition into two partitions. In a multi-level partition, only a range partition can be split, not a list partition, and you can only split the lowest level partitions (those that contain data).

**AT** - Specifies a single value that should be used as the criteria for the split. The partition will be divided into two new partitions with the split value specified being the starting range for the latter partition.

**INTO** - Allows you to specify names for the two new partitions created by the split.

partition\_name

The given name of a partition. The given partition name is the `partitionname` column value in the `pg_partitions` system view.

FOR (RANK(number))

For range partitions, the rank of the partition in the range.

FOR ('value')

Specifies a partition by declaring a value that falls within the partition boundary specification.

If the value declared with **FOR** matches to both a partition and one of its subpartitions (for example, if the value is a date and the table is partitioned by month and then by day), then **FOR** will operate on the first level where a match is found (for example, the monthly partition).

If your intent is to operate on a subpartition, you must declare so as follows: `ALTER TABLE name ALTER PARTITION FOR ('2016-10-01') DROP PARTITION FOR ('2016-10-01');`

## Notes

The table name specified in the `ALTER TABLE` command cannot be the name of a partition within a table.

Take special care when altering or dropping columns that are part of the Greenplum Database distribution key as this can change the distribution policy for the table.

Greenplum Database does not currently support foreign key constraints. For a unique constraint to be enforced in Greenplum Database, the table must be hash-distributed (not `DISTRIBUTED RANDOMLY`), and all of the distribution key columns must be the same as the initial columns of the unique constraint columns.

Adding a `CHECK` or `NOT NULL` constraint requires scanning the table to verify that existing rows meet the constraint, but does not require a table rewrite.

This table lists the `ALTER TABLE` operations that require a table rewrite when performed on tables defined with the specified type of table storage.

| Operation (See Note)           | Append-Optimized, Column-Oriented | Append-Optimized | Heap |
|--------------------------------|-----------------------------------|------------------|------|
| <code>ALTER COLUMN TYPE</code> | Yes                               | Yes              | Yes  |
| <code>ADD COLUMN</code>        | No                                | Yes              | Yes  |

**Note:** Dropping a system `oid` column also requires a table rewrite.

When a column is added with `ADD COLUMN`, all existing rows in the table are initialized with the column's default value, or `NULL` if no `DEFAULT` clause is specified. Adding a column with a non-null default or changing the type of an existing column will require the entire table and indexes to be rewritten. As an exception, if the `USING` clause does not change the column contents and the old

type is either binary coercible to the new type or an unconstrained domain over the new type, a table rewrite is not needed, but any indexes on the affected columns must still be rebuilt. Table and/or index rebuilds may take a significant amount of time for a large table; and will temporarily require as much as double the disk space.

**Important:** The forms of `ALTER TABLE` that perform a table rewrite on an append-optimized table are not MVCC-safe. After a table rewrite, the table will appear empty to concurrent transactions if they are using a snapshot taken before the rewrite occurred. See [MVCC Caveats](#) for more details.

You can specify multiple changes in a single `ALTER TABLE` command, which will be done in a single pass over the table.

The `DROP COLUMN` form does not physically remove the column, but simply makes it invisible to SQL operations. Subsequent insert and update operations in the table will store a null value for the column. Thus, dropping a column is quick but it will not immediately reduce the on-disk size of your table, as the space occupied by the dropped column is not reclaimed. The space will be reclaimed over time as existing rows are updated. If you drop the system `oid` column, however, the table is rewritten immediately.

To force immediate reclamation of space occupied by a dropped column, you can run one of the forms of `ALTER TABLE` that performs a rewrite of the whole table. This results in reconstructing each row with the dropped column replaced by a null value.

The `USING` option of `SET DATA TYPE` can actually specify any expression involving the old values of the row; that is, it can refer to other columns as well as the one being converted. This allows very general conversions to be done with the `SET DATA TYPE` syntax. Because of this flexibility, the `USING` expression is not applied to the column's default value (if any); the result might not be a constant expression as required for a default. This means that when there is no implicit or assignment cast from old to new type, `SET DATA TYPE` might fail to convert the default even though a `USING` clause is supplied. In such cases, drop the default with `DROP DEFAULT`, perform the `ALTER TYPE`, and then use `SET DEFAULT` to add a suitable new default. Similar considerations apply to indexes and constraints involving the column.

If a table is partitioned or has any descendant tables, it is not permitted to add, rename, or change the type of a column, or rename an inherited constraint in the parent table without doing the same to the descendants. This ensures that the descendants always have columns matching the parent.

To see the structure of a partitioned table, you can use the view `pg_partitions`. This view can help identify the particular partitions you may want to alter.

A recursive `DROP COLUMN` operation will remove a descendant table's column only if the descendant does not inherit that column from any other parents and never had an independent definition of the column. A nonrecursive `DROP COLUMN (ALTER TABLE ONLY ... DROP COLUMN)` never removes any descendant columns, but instead marks them as independently defined rather than inherited.

The `TRIGGER`, `CLUSTER`, `OWNER`, and `TABLESPACE` actions never recurse to descendant tables; that is, they always act as though `ONLY` were specified. Adding a constraint recurses only for `CHECK` constraints that are not marked `NO INHERIT`.

These `ALTER PARTITION` operations are supported if no data is changed on a partitioned table that contains a leaf child partition that has been exchanged to use an external table. Otherwise, an error is returned.

- Adding or dropping a column.

- Changing the data type of column.

These `ALTER PARTITION` operations are not supported for a partitioned table that contains a leaf child partition that has been exchanged to use an external table:

- Setting a subpartition template.
- Altering the partition properties.
- Creating a default partition.
- Setting a distribution policy.
- Setting or dropping a `NOT NULL` constraint of column.
- Adding or dropping constraints.
- Splitting an external partition.

Changing any part of a system catalog table is not permitted.

## Examples

Add a column to a table:

```
ALTER TABLE distributors ADD COLUMN address varchar(30);
```

Rename an existing column:

```
ALTER TABLE distributors RENAME COLUMN address TO city;
```

Rename an existing table:

```
ALTER TABLE distributors RENAME TO suppliers;
```

Add a not-null constraint to a column:

```
ALTER TABLE distributors ALTER COLUMN street SET NOT NULL;
```

Rename an existing constraint:

```
ALTER TABLE distributors RENAME CONSTRAINT zipchk TO zip_check;
```

Add a check constraint to a table and all of its children:

```
ALTER TABLE distributors ADD CONSTRAINT zipchk CHECK
(char_length(zipcode) = 5);
```

To add a check constraint only to a table and not to its children:

```
ALTER TABLE distributors ADD CONSTRAINT zipchk CHECK (char_length(zipcode) = 5) NO INH
ERIT;
```

(The check constraint will not be inherited by future children, either.)

Remove a check constraint from a table and all of its children:

```
ALTER TABLE distributors DROP CONSTRAINT zipchk;
```

Remove a check constraint from one table only:

```
ALTER TABLE ONLY distributors DROP CONSTRAINT zipchk;
```

(The check constraint remains in place for any child tables that inherit `distributors`.)

Move a table to a different schema:

```
ALTER TABLE myschema.distributors SET SCHEMA yourschema;
```

Change the distribution policy of a table to replicated:

```
ALTER TABLE myschema.distributors SET DISTRIBUTED REPLICATED;
```

Add a new partition to a partitioned table:

```
ALTER TABLE sales ADD PARTITION
    START (date '2017-02-01') INCLUSIVE
    END (date '2017-03-01') EXCLUSIVE;
```

Add a default partition to an existing partition design:

```
ALTER TABLE sales ADD DEFAULT PARTITION other;
```

Rename a partition:

```
ALTER TABLE sales RENAME PARTITION FOR ('2016-01-01') TO
    jan08;
```

Drop the first (oldest) partition in a range sequence:

```
ALTER TABLE sales DROP PARTITION FOR (RANK(1));
```

Exchange a table into your partition design:

```
ALTER TABLE sales EXCHANGE PARTITION FOR ('2016-01-01') WITH
    TABLE jan08;
```

Split the default partition (where the existing default partition's name is `other`) to add a new monthly partition for January 2017:

```
ALTER TABLE sales SPLIT DEFAULT PARTITION
    START ('2017-01-01') INCLUSIVE
    END ('2017-02-01') EXCLUSIVE
    INTO (PARTITION jan09, PARTITION other);
```

Split a monthly partition into two with the first partition containing dates January 1-15 and the second partition containing dates January 16-31:

```
ALTER TABLE sales SPLIT PARTITION FOR ('2016-01-01')
    AT ('2016-01-16')
```

```
INTO (PARTITION jan081to15, PARTITION jan0816to31);
```

For a multi-level partitioned table that consists of three levels, year, quarter, and region, exchange a leaf partition `region` with the table `region_new`.

```
ALTER TABLE sales ALTER PARTITION year_1 ALTER PARTITION quarter_4 EXCHANGE PARTITION
region WITH TABLE region_new ;
```

In the previous command, the two `ALTER PARTITION` clauses identify which `region` partition to exchange. Both clauses are required to identify the specific partition to exchange.

## Compatibility

The forms `ADD` (without `USING INDEX`), `DROP`, `SET DEFAULT`, and `SET DATA TYPE` (without `USING`) conform with the SQL standard. The other forms are Greenplum Database extensions of the SQL standard. Also, the ability to specify more than one manipulation in a single `ALTER TABLE` command is an extension.

`ALTER TABLE DROP COLUMN` can be used to drop the only column of a table, leaving a zero-column table. This is an extension of SQL, which disallows zero-column tables.

## ALTER TABLESPACE

Changes the definition of a tablespace.

## Synopsis

```
ALTER TABLESPACE <name> RENAME TO <new_name>

ALTER TABLESPACE <name> OWNER TO <new_owner>

ALTER TABLESPACE <name> SET ( <tablespace_option> = <value> [, ... ] )

ALTER TABLESPACE <name> RESET ( <tablespace_option> [, ... ] )
```

## Description

`ALTER TABLESPACE` changes the definition of a tablespace.

You must own the tablespace to use `ALTER TABLESPACE`. To alter the owner, you must also be a direct or indirect member of the new owning role. (Note that superusers have these privileges automatically.)

## Parameters

name

The name of an existing tablespace.

new\_name

The new name of the tablespace. The new name cannot begin with pg\_ or gp\_ (reserved for system tablespaces).

new\_owner

The new owner of the tablespace.

tablespace\_parameter

A tablespace parameter to be set or reset. Currently, the only available parameters are seq\_page\_cost and random\_page\_cost. Setting either value for a particular tablespace will override the planner's usual estimate of the cost of reading pages from tables in that tablespace, as established by the configuration parameters of the same name (see [seq-page-cost](#), [random-page-cost](#)). This may be useful if one tablespace is located on a disk which is faster or slower than the remainder of the I/O subsystem.

## Examples

Rename tablespace `index_space` to `fast_raid`:

```
ALTER TABLESPACE index_space RENAME TO fast_raid;
```

Change the owner of tablespace `index_space`:

```
ALTER TABLESPACE index_space OWNER TO mary;
```

## Compatibility

There is no `ALTER TABLESPACE` statement in the SQL standard.

## See Also

[CREATE TABLESPACE, DROP TABLESPACE](#)

Parent topic: [SQL Commands](#)

## ALTER TEXT SEARCH CONFIGURATION

Changes the definition of a text search configuration.

## Synopsis

```
ALTER TEXT SEARCH CONFIGURATION <name>
    ALTER MAPPING FOR <token_type> [, ... ] WITH <dictionary_name> [, ... ]
ALTER TEXT SEARCH CONFIGURATION <name>
    ALTER MAPPING REPLACE <old_dictionary> WITH <new_dictionary>
ALTER TEXT SEARCH CONFIGURATION <name>
    ALTER MAPPING FOR <token_type> [, ... ] REPLACE <old_dictionary> WITH <new_diction
```

```

ary>
ALTER TEXT SEARCH CONFIGURATION <name>
    DROP MAPPING [ IF EXISTS ] FOR <token_type> [, ... ]
ALTER TEXT SEARCH CONFIGURATION <name> RENAME TO <new_name>
ALTER TEXT SEARCH CONFIGURATION <name> OWNER TO <new_owner>
ALTER TEXT SEARCH CONFIGURATION <name> SET SCHEMA <new_schema>

```

## Description

`ALTER TEXT SEARCH CONFIGURATION` changes the definition of a text search configuration. You can modify its mappings from token types to dictionaries, or change the configuration's name or owner.

You must be the owner of the configuration to use `ALTER TEXT SEARCH CONFIGURATION`.

## Parameters

`name`

The name (optionally schema-qualified) of an existing text search configuration.

`token\_type`

The name of a token type that is emitted by the configuration's parser.

`dictionary\_name`

The name of a text search dictionary to be consulted for the specified token type(s). If multiple dictionaries are listed, they are consulted in the specified order.

`old\_dictionary`

The name of a text search dictionary to be replaced in the mapping.

`new\_dictionary`

The name of a text search dictionary to be substituted for `old\_dictionary`.

`new\_name`

The new name of the text search configuration.

`new\_owner`

The new owner of the text search configuration.

`new\_schema`

The new schema for the text search configuration.

The `ADD MAPPING FOR` form installs a list of dictionaries to be consulted for the specified token type(s); it is an error if there is already a mapping for any of the token types. The `ALTER MAPPING FOR` form does the same, but first removing any existing mapping for those token types. The `ALTER MAPPING REPLACE` forms substitute `new\_dictionary` for `old\_dictionary` anywhere the latter appears. This is done for only the specified token types when `FOR` appears, or for all mappings of the configuration when it doesn't. The `DROP MAPPING` form removes all dictionaries for the specified token type(s), causing tokens of those types to be ignored by the text search configuration. It is an error if there is no mapping for the token types, unless `IF EXISTS` appears.

## Examples

The following example replaces the `english` dictionary with the `swedish` dictionary anywhere that `english` is used within `my_config`.

```
ALTER TEXT SEARCH CONFIGURATION my_config
ALTER MAPPING REPLACE english WITH swedish;
```

## Compatibility

There is no `ALTER TEXT SEARCH CONFIGURATION` statement in the SQL standard.

## See Also

[CREATE TEXT SEARCH CONFIGURATION](#), [DROP TEXT SEARCH CONFIGURATION](#)

Parent topic: [SQL Commands](#)

## ALTER TEXT SEARCH DICTIONARY

Changes the definition of a text search dictionary.

## Synopsis

```
ALTER TEXT SEARCH DICTIONARY <name> (
    <option> [ = <value> ] [, ... ]
)
ALTER TEXT SEARCH DICTIONARY <name> RENAME TO <new_name>
ALTER TEXT SEARCH DICTIONARY <name> OWNER TO <new_owner>
ALTER TEXT SEARCH DICTIONARY <name> SET SCHEMA <new_schema>
```

## Description

`ALTER TEXT SEARCH DICTIONARY` changes the definition of a text search dictionary. You can change the dictionary's template-specific options, or change the dictionary's name or owner.

You must be the owner of the dictionary to use `ALTER TEXT SEARCH DICTIONARY`.

## Parameters

`name`

The name (optionally schema-qualified) of an existing text search dictionary.

`option`

The name of a template-specific option to be set for this dictionary.

`value`

The new value to use for a template-specific option. If the equal sign and value are omitted, then any previous setting for the option is removed from the dictionary, allowing the default to be used.

`new\_name`

The new name of the text search dictionary.

`new\_owner`

The new owner of the text search dictionary.

`new\_schema`

The new schema for the text search dictionary.

Template-specific options can appear in any order.

## Examples

The following example command changes the stopword list for a Snowball-based dictionary. Other parameters remain unchanged.

```
ALTER TEXT SEARCH DICTIONARY my_dict ( StopWords = newrussian );
```

The following example command changes the language option to `dutch`, and removes the stopword option entirely.

```
ALTER TEXT SEARCH DICTIONARY my_dict ( language = dutch, StopWords );
```

The following example command "updates" the dictionary's definition without actually changing anything.

```
ALTER TEXT SEARCH DICTIONARY my_dict ( dummy );
```

(The reason this works is that the option removal code doesn't complain if there is no such option.) This trick is useful when changing configuration files for the dictionary: the ALTER will force existing database sessions to re-read the configuration files, which otherwise they would never do if they had read them earlier.

## Compatibility

There is no `ALTER TEXT SEARCH DICTIONARY` statement in the SQL standard.

## See Also

[CREATE TEXT SEARCH DICTIONARY](#), [DROP TEXT SEARCH DICTIONARY](#)

Parent topic: [SQL Commands](#)

## ALTER TEXT SEARCH PARSER

### Description

Changes the definition of a text search parser.

### Synopsis

```
ALTER TEXT SEARCH PARSER <name> RENAME TO <new_name>
ALTER TEXT SEARCH PARSER <name> SET SCHEMA <new_schema>
```

### Description

`ALTER TEXT SEARCH PARSER` changes the definition of a text search parser. Currently, the only supported functionality is to change the parser's name.

You must be a superuser to use `ALTER TEXT SEARCH PARSER`.

## Parameters

name

The name (optionally schema-qualified) of an existing text search parser.

new\_name

The new name of the text search parser.

new\_schema

The new schema for the text search parser.

## Compatibility

There is no `ALTER TEXT SEARCH PARSER` statement in the SQL standard.

## See Also

[CREATE TEXT SEARCH PARSER](#), [DROP TEXT SEARCH PARSER](#)

Parent topic: [SQL Commands](#)

# ALTER TEXT SEARCH TEMPLATE

## Description

Changes the definition of a text search template.

## Synopsis

```
ALTER TEXT SEARCH TEMPLATE <name> RENAME TO <new_name>
ALTER TEXT SEARCH TEMPLATE <name> SET SCHEMA <new_schema>
```

## Description

`ALTER TEXT SEARCH TEMPLATE` changes the definition of a text search parser. Currently, the only supported functionality is to change the parser's name.

You must be a superuser to use `ALTER TEXT SEARCH TEMPLATE`.

## Parameters

name

The name (optionally schema-qualified) of an existing text search template.

new\_name

The new name of the text search template.

new\_schema

The new schema for the text search template.

## Compatibility

There is no `ALTER TEXT SEARCH TEMPLATE` statement in the SQL standard.

## See Also

[CREATE TEXT SEARCH TEMPLATE](#), [DROP TEXT SEARCH TEMPLATE](#)

Parent topic: [SQL Commands](#)

## ALTER TYPE

Changes the definition of a data type.

## Synopsis

```
ALTER TYPE <name> <action> [, ... ]
ALTER TYPE <name> OWNER TO <new_owner>
ALTER TYPE <name> RENAME ATTRIBUTE <attribute_name> TO <new_attribute_name> [ CASCADE
| RESTRICT ]
ALTER TYPE <name> RENAME TO <new_name>
ALTER TYPE <name> SET SCHEMA <new_schema>
ALTER TYPE <name> ADD VALUE [ IF NOT EXISTS ] <new_enum_value> [ { BEFORE | AFTER } <e
xisting_enum_value> ]
ALTER TYPE <name> SET DEFAULT ENCODING ( <storage_directive> )
```

where <action> is one of:

```
ADD ATTRIBUTE <attribute_name> <data_type> [ COLLATE <collation> ] [ CASCADE | RESTR
ICT ]
DROP ATTRIBUTE [ IF EXISTS ] <attribute_name> [ CASCADE | RESTRICT ]
ALTER ATTRIBUTE <attribute_name> [ SET DATA ] TYPE <data_type> [ COLLATE <collation>
] [ CASCADE | RESTRICT ]
```

where storage\_directive is:

```
COMPRESSTYPE={ZLIB | ZSTD | QUICKLZ | RLE_TYPE | NONE}
COMPRESSLEVEL={0-19}
BLOCKSIZE={8192-2097152}
```

## Description

`ALTER TYPE` changes the definition of an existing type. There are several subforms:

- `ADD ATTRIBUTE` — Adds a new attribute to a composite type, using the same syntax as `CREATE TYPE`.

- `DROP ATTRIBUTE [ IF EXISTS ]` — Drops an attribute from a composite type. If `IF EXISTS` is specified and the attribute does not exist, no error is thrown. In this case a notice is issued instead.
- `SET DATA TYPE` — Changes the type of an attribute of a composite type.
- `OWNER` — Changes the owner of the type.
- `RENAME` — Changes the name of the type or the name of an individual attribute of a composite type.
- `SET SCHEMA` — Moves the type into another schema.
- `ADD VALUE [ IF NOT EXISTS ] [ BEFORE | AFTER ]` — Adds a new value to an enum type. The new value's place in the enum's ordering can be specified as being `BEFORE` or `AFTER` one of the existing values. Otherwise, the new item is added at the end of the list of values. If `IF NOT EXISTS` is specified, it is not an error if the type already contains the new value; a notice is issued but no other action is taken. Otherwise, an error will occur if the new value is already present.
- `CASCADE` — Automatically propagate the operation to typed tables of the type being altered, and their descendants.
- `RESTRICT` — Refuse the operation if the type being altered is the type of a typed table. This is the default.

The `ADD ATTRIBUTE`, `DROP ATTRIBUTE`, and `ALTER ATTRIBUTE` actions can be combined into a list of multiple alterations to apply in parallel. For example, it is possible to add several attributes and/or alter the type of several attributes in a single command.

You can change the name, the owner, and the schema of a type. You can also add or update storage options for a scalar type.

**Note:** Greenplum Database does not support adding storage options for row or composite types.

You must own the type to use `ALTER TYPE`. To change the schema of a type, you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the type's schema. (These restrictions enforce that altering the owner does not do anything that could be done by dropping and recreating the type. However, a superuser can alter ownership of any type.) To add an attribute or alter an attribute type, you must also have `USAGE` privilege on the data type.

`ALTER TYPE ... ADD VALUE` (the form that adds a new value to an enum type) cannot be run inside a transaction block.

Comparisons involving an added enum value will sometimes be slower than comparisons involving only original members of the enum type. This will usually only occur if `BEFORE` or `AFTER` is used to set the new value's sort position somewhere other than at the end of the list. However, sometimes it will happen even though the new value is added at the end (this occurs if the OID counter "wrapped around" since the original creation of the enum type). The slowdown is usually insignificant; but if it matters, optimal performance can be regained by dropping and recreating the enum type, or by dumping and reloading the database.

## Parameters

name

The name (optionally schema-qualified) of an existing type to alter.

new\_name

The new name for the type.

new\_owner

The user name of the new owner of the type.

new\_schema

The new schema for the type.

attribute\_name

The name of the attribute to add, alter, or drop.

new\_attribute\_name

The new name of the attribute to be renamed.

data\_type

The data type of the attribute to add, or the new type of the attribute to alter.

new\_enum\_value

The new value to be added to an enum type's list of values. Like all enum literals, it needs to be quoted.

existing\_enum\_value

The existing enum value that the new value should be added immediately before or after in the enum type's sort ordering. Like all enum literals, it needs to be quoted.

storage\_directive

Identifies default storage options for the type when specified in a table column definition.

Options include `COMPRESSTYPE`, `COMPRESSLEVEL`, and `BLOCKSIZE`.

**COMPRESSTYPE** — Set to `ZLIB` (the default), `ZSTD`, `RLE_TYPE`, or `QUICKLZ1` to specify the type of compression used.

**Note:** QuickLZ compression is available only in the commercial release of Tanzu Greenplum.

**COMPRESSLEVEL** — For Zstd compression, set to an integer value from 1 (fastest compression) to 19 (highest compression ratio). For zlib compression, the valid range is from 1 to 9. The QuickLZ compression level can only be set to 1. For `RLE_TYPE`, the compression level can be set to an integer value from 1 (fastest compression) to 4 (highest compression ratio). The default compression level is 1.

**BLOCKSIZE** — Set to the size, in bytes, for each block in the column. The `BLOCKSIZE` must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default block size is 32768.

**Note:** `storage_directives` defined at the table- or column-level override the default storage options defined for a type.

## Examples

To rename the data type named `electronic_mail`:

```
ALTER TYPE electronic_mail RENAME TO email;
```

To change the owner of the user-defined type `email` to `joe`:

```
ALTER TYPE email OWNER TO joe;
```

To change the schema of the user-defined type `email` to `customers`:

```
ALTER TYPE email SET SCHEMA customers;
```

To set or alter the compression type and compression level of the user-defined type named `int33`:

```
ALTER TYPE int33 SET DEFAULT ENCODING (compressstype=zlib, compresslevel=7);
```

To add a new attribute to a type:

```
ALTER TYPE compfoo ADD ATTRIBUTE f3 int;
```

To add a new value to an enum type in a particular sort position:

```
ALTER TYPE colors ADD VALUE 'orange' AFTER 'red';
```

## Compatibility

The variants to add and drop attributes are part of the SQL standard; the other variants are Greenplum Database extensions.

## See Also

[CREATE TYPE, DROP TYPE](#)

Parent topic: [SQL Commands](#)

## ALTER USER

Changes the definition of a database role (user).

## Synopsis

```
ALTER USER <name> RENAME TO <newname>

ALTER USER <name> SET <config_parameter> {TO | =} {<value> | DEFAULT}

ALTER USER <name> RESET <config_parameter>

ALTER USER <name> RESOURCE QUEUE {<queue_name> | NONE}

ALTER USER <name> RESOURCE GROUP {<group_name> | NONE}

ALTER USER <name> [ [WITH] <option> [ ... ] ]
```

where option can be:

```
SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
```

```

| CREATEROLE | NOCREATEROLE
| CREATEUSER | NOCREATEUSER
| CREATEEXTTABLE | NOCREATEEXTTABLE
| [ ( <attribute>='<value>' [, ...] ) ]
|     where <attributes> and <value> are:
|     type='readable' | 'writable'
|     protocol='gpfdist' | 'http'
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| REPLICATION | NOREPLICATION
| CONNECTION LIMIT <connlimit>
| [ ENCRYPTED | UNENCRYPTED ] PASSWORD '<password>'
| VALID UNTIL '<timestamp>'
| [ DENY <deny_point> ]
| [ DENY BETWEEN <deny_point> AND <deny_point> ]
| [ DROP DENY FOR <deny_point> ]

```

## Description

`ALTER USER` is an alias for `ALTER ROLE`. See `ALTER ROLE` for more information.

## Compatibility

The `ALTER USER` statement is a Greenplum Database extension. The SQL standard leaves the definition of users to the implementation.

## See Also

[ALTER ROLE](#), [CREATE USER](#), [DROP USER](#)

Parent topic: [SQL Commands](#)

## ALTER USER MAPPING

Changes the definition of a user mapping for a foreign server.

## Synopsis

```

ALTER USER MAPPING FOR { <username> | USER | CURRENT_USER | PUBLIC }
    SERVER <servername>
    OPTIONS ( [ ADD | SET | DROP ] <option> ['<value>'] [, ... ] )

```

## Description

`ALTER USER MAPPING` changes the definition of a user mapping for a foreign server.

The owner of a foreign server can alter user mappings for that server for any user. Also, a user granted `USAGE` privilege on the server can alter a user mapping for their own user name.

## Parameters

**username**

User name of the mapping. `CURRENT_USER` and `USER` match the name of the current user. `PUBLIC` is used to match all present and future user names in the system.

**servername**

Server name of the user mapping.

**OPTIONS ( [ ADD | SET | DROP ] option ['value'] [, ... ] )**

Change options for the user mapping. The new options override any previously specified options. `ADD`, `SET`, and `DROP` specify the action to perform. If no operation is explicitly specified, the default operation is `ADD`. Option names must be unique. Greenplum Database validates names and values using the server's foreign-data wrapper.

## Examples

Change the password for user mapping `bob`, server `foo`:

```
ALTER USER MAPPING FOR bob SERVER foo OPTIONS (SET password 'public');
```

## Compatibility

`ALTER USER MAPPING` conforms to ISO/IEC 9075-9 (SQL/MED). There is a subtle syntax issue: The standard omits the `FOR` key word. Since both `CREATE USER MAPPING` and `DROP USER MAPPING` use `FOR` in analogous positions, Greenplum Database diverges from the standard here in the interest of consistency and interoperability.

## See Also

[CREATE USER MAPPING](#), [DROP USER MAPPING](#)

Parent topic: [SQL Commands](#)

## ALTER VIEW

Changes properties of a view.

## Synopsis

```
ALTER VIEW [ IF EXISTS ] <name> ALTER [ COLUMN ] <column_name> SET DEFAULT <expression
>

ALTER VIEW [ IF EXISTS ] <name> ALTER [ COLUMN ] <column_name> DROP DEFAULT

ALTER VIEW [ IF EXISTS ] <name> OWNER TO <new_owner>

ALTER VIEW [ IF EXISTS ] <name> RENAME TO <new_name>

ALTER VIEW [ IF EXISTS ] <name> SET SCHEMA <new_schema>

ALTER VIEW [ IF EXISTS ] <name> SET ( <view_option_name> [= <view_option_value>] [,
... ] )
```

```
ALTER VIEW [ IF EXISTS ] <name> RESET ( <view_option_name> [, ... ] )
```

## Description

`ALTER VIEW` changes various auxiliary properties of a view. (If you want to modify the view's defining query, use `CREATE OR REPLACE VIEW`.)

To run this command you must be the owner of the view. To change a view's schema you must also have `CREATE` privilege on the new schema. To alter the owner, you must also be a direct or indirect member of the new owning role, and that role must have `CREATE` privilege on the view's schema. These restrictions enforce that altering the owner does not do anything you could not do by dropping and recreating the view. However, a superuser can alter ownership of any view.

## Parameters

`name`

The name (optionally schema-qualified) of an existing view.

`IF EXISTS`

Do not throw an error if the view does not exist. A notice is issued in this case.

`SET/DROP DEFAULT`

These forms set or remove the default value for a column. A view column's default value is substituted into any `INSERT` or `UPDATE` command whose target is the view, before applying any rules or triggers for the view. The view's default will therefore take precedence over any default values from underlying relations.

`new_owner`

The new owner for the view.

`new_name`

The new name of the view.

`new_schema`

The new schema for the view.

`SET ( view\_option\_name [= view\_option\_value] [, ... ] )`

`RESET ( view\_option\_name [, ... ] )`

Sets or resets a view option. Currently supported options are:

`check_option` (string)

Changes the check option of the view. The value must be `local` or `cascaded`.

`security_barrier` (boolean)

Changes the security-barrier property of the view. The value must be a Boolean value, such as `true` or `false`.

## Notes

For historical reasons, `ALTER TABLE` can be used with views, too; however, the only variants of `ALTER TABLE` that are allowed with views are equivalent to the statements shown above.

Rename the view `myview` to `newview`:

```
ALTER VIEW myview RENAME TO newview;
```

## Examples

To rename the view `foo` to `bar`:

```
ALTER VIEW foo RENAME TO bar;
```

To attach a default column value to an updatable view:

```
CREATE TABLE base_table (id int, ts timestamptz);
CREATE VIEW a_view AS SELECT * FROM base_table;
ALTER VIEW a_view ALTER COLUMN ts SET DEFAULT now();
INSERT INTO base_table(id) VALUES(1); -- ts will receive a NULL
INSERT INTO a_view(id) VALUES(2); -- ts will receive the current time
```

## Compatibility

`ALTER VIEW` is a Greenplum Database extension of the SQL standard.

[CREATE VIEW](#), [DROP VIEW](#) in the *Greenplum Database Utility Guide*

Parent topic: [SQL Commands](#)

## ANALYZE

Collects statistics about a database.

## Synopsis

```
ANALYZE [VERBOSE] [<table> [ (<column> [, ...] ) ] ]

ANALYZE [VERBOSE] {<root_partition_table_name>|<leaf_partition_table_name>} [ (<column>
> [, ...] ) ]

ANALYZE [VERBOSE] ROOTPARTITION {ALL | <root_partition_table_name> [ (<column> [, ...]
) ] }
```

## Description

`ANALYZE` collects statistics about the contents of tables in the database, and stores the results in the system table `pg_statistic`. Subsequently, Greenplum Database uses these statistics to help determine the most efficient execution plans for queries. For information about the table statistics that are collected, see [Notes](#).

With no parameter, `ANALYZE` collects statistics for every table in the current database. You can specify a table name to collect statistics for a single table. You can specify a set of column names in

a specific table, in which case the statistics only for those columns from that table are collected.

`ANALYZE` does not collect statistics on external tables.

For partitioned tables, `ANALYZE` collects additional statistics, HyperLogLog (HLL) statistics, on the leaf child partitions. HLL statistics are used to derive number of distinct values (NDV) for queries against partitioned tables.

- When aggregating NDV estimates across multiple leaf child partitions, HLL statistics generate a more accurate NDV estimates than the standard table statistics.
- When updating HLL statistics, `ANALYZE` operations are required only on leaf child partitions that have changed. For example, `ANALYZE` is required if the leaf child partition data has changed, or if the leaf child partition has been exchanged with another table. For more information about updating partitioned table statistics, see [Notes](#).

**Important:** If you intend to run queries on partitioned tables with GPORCA enabled (the default), then you must collect statistics on the root partition of the partitioned table with the `ANALYZE` or `ANALYZE ROOTPARTITION` command. For information about collecting statistics on partitioned tables and when the `ROOTPARTITION` keyword is required, see [Notes](#). For information about GPORCA, see [Overview of GPORCA](#) in the *Greenplum Database Administrator Guide*.

**Note:** You can also use the Greenplum Database utility `analyzedb` to update table statistics. The `analyzedb` utility can update statistics for multiple tables concurrently. The utility can also check table statistics and update statistics only if the statistics are not current or do not exist. For information about the utility, see the *Greenplum Database Utility Guide*.

## Parameters

```
{ root_partition_table_name | leaf_partition_table_name } [ (column [, ...]) ]
```

Collect statistics for partitioned tables including HLL statistics. HLL statistics are collected only on leaf child partitions.

`ANALYZE root\_partition\_table\_name`, collects statistics on all leaf child partitions and the root partition.

`ANALYZE leaf\_partition\_table\_name`, collects statistics on the leaf child partition.

By default, if you specify a leaf child partition, and all other leaf child partitions have statistics, `ANALYZE` updates the root partition statistics. If not all leaf child partitions have statistics, `ANALYZE` logs information about the leaf child partitions that do not have statistics. For information about when root partition statistics are collected, see [Notes](#).

`ROOTPARTITION [ALL]`

Collect statistics only on the root partition of partitioned tables based on the data in the partitioned table. If possible, `ANALYZE` uses leaf child partition statistics to generate root partition statistics. Otherwise, `ANALYZE` collects the statistics by sampling leaf child partition data. Statistics are not collected on the leaf child partitions, the data is only sampled. HLL statistics are not collected.

For information about when the `ROOTPARTITION` keyword is required, see [Notes](#).

When you specify `ROOTPARTITION`, you must specify either `ALL` or the name of a partitioned table.

If you specify `ALL` with `ROOTPARTITION`, Greenplum Database collects statistics for the root partition of all partitioned tables in the database. If there are no partitioned tables in the database, a message stating that there are no partitioned tables is returned. For tables that are not partitioned tables, statistics are not collected.

If you specify a table name with `ROOTPARTITION` and the table is not a partitioned table, no statistics are collected for the table and a warning message is returned.

The `ROOTPARTITION` clause is not valid with `VACUUM ANALYZE`. The command `VACUUM ANALYZE ROOTPARTITION` returns an error.

The time to run `ANALYZE ROOTPARTITION` is similar to the time to analyze a non-partitioned table with the same data since `ANALYZE ROOTPARTITION` only samples the leaf child partition data.

For the partitioned table `sales_curr_yr`, this example command collects statistics only on the root partition of the partitioned table. `ANALYZE ROOTPARTITION sales_curr_yr;`

This example `ANALYZE` command collects statistics on the root partition of all the partitioned tables in the database.

```
ANALYZE ROOTPARTITION ALL;
```

## VERBOSE

Enables display of progress messages. When specified, `ANALYZE` emits this information

- The table that is being processed.
- The query that is run to generate the sample table.
- The column for which statistics is being computed.
- The queries that are issued to collect the different statistics for a single column.
- The statistics that are collected.

### table

The name (possibly schema-qualified) of a specific table to analyze. If omitted, all regular tables (but not foreign tables) in the current database are analyzed.

### column

The name of a specific column to analyze. Defaults to all columns.

## Notes

Foreign tables are analyzed only when explicitly selected. Not all foreign data wrappers support `ANALYZE`. If the table's wrapper does not support `ANALYZE`, the command prints a warning and does nothing.

It is a good idea to run `ANALYZE` periodically, or just after making major changes in the contents of a table. Accurate statistics helps Greenplum Database choose the most appropriate query plan, and thereby improve the speed of query processing. A common strategy for read-mostly databases is to run `VACUUM` and `ANALYZE` once a day during a low-usage time of day. (This will not be sufficient if there is heavy update activity.) You can check for tables with missing statistics using the `gp_stats_missing` view, which is in the `gp_toolkit` schema:

```
SELECT * from gp_toolkit.gp_stats_missing;
```

`ANALYZE` requires `SHARE UPDATE EXCLUSIVE` lock on the target table. This lock conflicts with these locks: `SHARE UPDATE EXCLUSIVE`, `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, `ACCESS EXCLUSIVE`.

If you run `ANALYZE` on a table that does not contain data, statistics are not collected for the table. For example, if you perform a `TRUNCATE` operation on a table that has statistics, and then run `ANALYZE` on the table, the statistics do not change.

For a partitioned table, specifying which portion of the table to analyze, the root partition or subpartitions (leaf child partition tables) can be useful if the partitioned table has a large number of partitions that have been analyzed and only a few leaf child partitions have changed.

**Note:** When you create a partitioned table with the `CREATE TABLE` command, Greenplum Database creates the table that you specify (the root partition or parent table), and also creates a hierarchy of tables based on the partition hierarchy that you specified (the child tables).

- When you run `ANALYZE` on the root partitioned table, statistics are collected for all the leaf child partitions. Leaf child partitions are the lowest-level tables in the hierarchy of child tables created by Greenplum Database for use by the partitioned table.
- When you run `ANALYZE` on a leaf child partition, statistics are collected only for that leaf child partition and the root partition. If data in the leaf partition has changed (for example, you made significant updates to the leaf child partition data or you exchanged the leaf child partition), then you can run `ANALYZE` on the leaf child partition to collect table statistics. By default, if all other leaf child partitions have statistics, the command updates the root partition statistics.

For example, if you collected statistics on a partitioned table with a large number partitions and then updated data in only a few leaf child partitions, you can run `ANALYZE` only on those partitions to update statistics on the partitions and the statistics on the root partition.

- When you run `ANALYZE` on a child table that is not a leaf child partition, statistics are not collected.

For example, you can create a partitioned table with partitions for the years 2006 to 2016 and subpartitions for each month in each year. If you run `ANALYZE` on the child table for the year 2013 no statistics are collected. If you run `ANALYZE` on the leaf child partition for March of 2013, statistics are collected only for that leaf child partition.

For a partitioned table that contains a leaf child partition that has been exchanged to use an external table, `ANALYZE` does not collect statistics for the external table partition:

- If `ANALYZE` is run on an external table partition, the partition is not analyzed.
- If `ANALYZE` or `ANALYZE ROOTPARTITION` is run on the root partition, external table partitions are not sampled and root table statistics do not include external table partition.
- If the `VERBOSE` clause is specified, an informational message is displayed: `skipping external table`.

The Greenplum Database server configuration parameter `optimizer_analyze_root_partition` affects when statistics are collected on the root partition of a partitioned table. If the parameter is `on` (the default), the `ROOTPARTITION` keyword is not required to collect statistics on the root partition when you run `ANALYZE`. Root partition statistics are collected when you run `ANALYZE` on the root partition,

or when you run `ANALYZE` on a child leaf partition of the partitioned table and the other child leaf partitions have statistics. If the parameter is `off`, you must run `ANALYZE ROOTPARTITION` to collect root partition statistics.

The statistics collected by `ANALYZE` usually include a list of some of the most common values in each column and a histogram showing the approximate data distribution in each column. One or both of these may be omitted if `ANALYZE` deems them uninteresting (for example, in a unique-key column, there are no common values) or if the column data type does not support the appropriate operators.

For large tables, `ANALYZE` takes a random sample of the table contents, rather than examining every row. This allows even very large tables to be analyzed in a small amount of time. Note, however, that the statistics are only approximate, and will change slightly each time `ANALYZE` is run, even if the actual table contents did not change. This may result in small changes in the planner's estimated costs shown by `EXPLAIN`. In rare situations, this non-determinism will cause the query optimizer to choose a different query plan between runs of `ANALYZE`. To avoid this, raise the amount of statistics collected by `ANALYZE` by adjusting the `default_statistics_target` configuration parameter, or on a column-by-column basis by setting the per-column statistics target with `ALTER TABLE ... ALTER COLUMN ... SET (n_distinct ...)` (see `ALTER TABLE`). The target value sets the maximum number of entries in the most-common-value list and the maximum number of bins in the histogram. The default target value is 100, but this can be adjusted up or down to trade off accuracy of planner estimates against the time taken for `ANALYZE` and the amount of space occupied in `pg_statistic`. In particular, setting the statistics target to zero deactivates collection of statistics for that column. It may be useful to do that for columns that are never used as part of the `WHERE`, `GROUP BY`, or `ORDER BY` clauses of queries, since the planner will have no use for statistics on such columns.

The largest statistics target among the columns being analyzed determines the number of table rows sampled to prepare the statistics. Increasing the target causes a proportional increase in the time and space needed to do `ANALYZE`.

One of the values estimated by `ANALYZE` is the number of distinct values that appear in each column. Because only a subset of the rows are examined, this estimate can sometimes be quite inaccurate, even with the largest possible statistics target. If this inaccuracy leads to bad query plans, a more accurate value can be determined manually and then installed with `ALTER TABLE ... ALTER COLUMN ... SET STATISTICS DISTINCT` (see `ALTER TABLE`).

When Greenplum Database performs an `ANALYZE` operation to collect statistics for a table and detects that all the sampled table data pages are empty (do not contain valid data), Greenplum Database displays a message that a `VACUUM FULL` operation should be performed. If the sampled pages are empty, the table statistics will be inaccurate. Pages become empty after a large number of changes to the table, for example deleting a large number of rows. A `VACUUM FULL` operation removes the empty pages and allows an `ANALYZE` operation to collect accurate statistics.

If there are no statistics for the table, the server configuration parameter `gp_enable_resize_collection` controls whether the Postgres Planner uses a default statistics file or estimates the size of a table using the `pg_relation_size` function. By default, the Postgres Planner uses the default statistics file to estimate the number of rows if statistics are not available.

## Examples

Collect statistics for the table `mytable`:

```
ANALYZE mytable;
```

## Compatibility

There is no `ANALYZE` statement in the SQL standard.

## See Also

[ALTER TABLE](#), [EXPLAIN](#), [VACUUM](#), [analyzedb](#).

Parent topic: [SQL Commands](#)

## BEGIN

Starts a transaction block.

## Synopsis

```
BEGIN [WORK | TRANSACTION] [<transaction_mode>]
```

where `transaction_mode` is:

```
ISOLATION LEVEL {READ UNCOMMITTED | READ COMMITTED | REPEATABLE READ | SERIALIZABLE}
READ WRITE | READ ONLY
[ NOT ] DEFERRABLE
```

## Description

`BEGIN` initiates a transaction block, that is, all statements after a `BEGIN` command will be run in a single transaction until an explicit `COMMIT` or `ROLLBACK` is given. By default (without `BEGIN`), Greenplum Database runs transactions in autocommit mode, that is, each statement is run in its own transaction and a commit is implicitly performed at the end of the statement (if execution was successful, otherwise a rollback is done).

Statements are run more quickly in a transaction block, because transaction start/commit requires significant CPU and disk activity. Execution of multiple statements inside a transaction is also useful to ensure consistency when making several related changes: other sessions will be unable to see the intermediate states wherein not all the related updates have been done.

If the isolation level, read/write mode, or deferrable mode is specified, the new transaction has those characteristics, as if `SET TRANSACTION` was run.

## Parameters

`WORK`

`TRANSACTION`

Optional key words. They have no effect.

SERIALIZABLE

READ COMMITTED

READ UNCOMMITTED

The SQL standard defines four transaction isolation levels: `READ UNCOMMITTED`, `READ COMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.

`READ UNCOMMITTED` allows transactions to see changes made by uncommitted concurrent transactions. This is not possible in Greenplum Database, so `READ UNCOMMITTED` is treated the same as `READ COMMITTED`.

`READ COMMITTED`, the default isolation level in Greenplum Database, guarantees that a statement can only see rows committed before it began. The same statement run twice in a transaction can produce different results if another concurrent transaction commits after the statement is run the first time.

The `REPEATABLE READ` isolation level guarantees that a transaction can only see rows committed before it began. `REPEATABLE READ` is the strictest transaction isolation level Greenplum Database supports. Applications that use the `REPEATABLE READ` isolation level must be prepared to retry transactions due to serialization failures.

The `SERIALIZABLE` transaction isolation level guarantees that running multiple concurrent transactions produces the same effects as running the same transactions one at a time. If you specify `SERIALIZABLE`, Greenplum Database falls back to `REPEATABLE READ`.

Specifying `DEFERRABLE` has no effect in Greenplum Database, but the syntax is supported for compatibility with PostgreSQL. A transaction can only be deferred if it is `READ ONLY` and `SERIALIZABLE`, and Greenplum Database does not support `SERIALIZABLE` transactions.

## Notes

`START TRANSACTION` has the same functionality as `BEGIN`.

Use `COMMIT` or `ROLLBACK` to terminate a transaction block.

Issuing `BEGIN` when already inside a transaction block will provoke a warning message. The state of the transaction is not affected. To nest transactions within a transaction block, use savepoints (see `SAVEPOINT`).

## Examples

To begin a transaction block:

```
BEGIN;
```

To begin a transaction block with the repeatable read isolation level:

```
BEGIN TRANSACTION ISOLATION LEVEL REPEATABLE READ;
```

## Compatibility

`BEGIN` is a Greenplum Database language extension. It is equivalent to the SQL-standard command `START TRANSACTION`.

`DEFERRABLE` `transaction_mode` is a Greenplum Database language extension.

Incidentally, the `BEGIN` key word is used for a different purpose in embedded SQL. You are advised to be careful about the transaction semantics when porting database applications.

## See Also

[COMMIT](#), [ROLLBACK](#), [START TRANSACTION](#), [SAVEPOINT](#)

Parent topic: [SQL Commands](#)

## CHECKPOINT

Forces a transaction log checkpoint.

## Synopsis

```
CHECKPOINT
```

## Description

A checkpoint is a point in the transaction log sequence at which all data files have been updated to reflect the information in the log. All data files will be flushed to disk.

The `CHECKPOINT` command forces an immediate checkpoint when the command is issued, without waiting for a regular checkpoint scheduled by the system. `CHECKPOINT` is not intended for use during normal operation.

If run during recovery, the `CHECKPOINT` command will force a restartpoint rather than writing a new checkpoint.

Only superusers may call `CHECKPOINT`.

## Compatibility

The `CHECKPOINT` command is a Greenplum Database extension.

Parent topic: [SQL Commands](#)

## CLOSE

Closes a cursor.

## Synopsis

```
CLOSE <cursor_name>
```

## Description

`CLOSE` frees the resources associated with an open cursor. After the cursor is closed, no subsequent operations are allowed on it. A cursor should be closed when it is no longer needed.

Every non-holdable open cursor is implicitly closed when a transaction is terminated by `COMMIT` or `ROLLBACK`. A holdable cursor is implicitly closed if the transaction that created it is prematurely ended via `ROLLBACK`. If the creating transaction successfully commits, the holdable cursor remains open until an explicit `CLOSE` is run, or the client disconnects.

## Parameters

`cursor_name`

The name of an open cursor to close.

## Notes

Greenplum Database does not have an explicit `OPEN` cursor statement. A cursor is considered open when it is declared. Use the `DECLARE` statement to declare (and open) a cursor.

You can see all available cursors by querying the `pg_cursors` system view.

If a cursor is closed after a savepoint which is later rolled back, the `CLOSE` is not rolled back; that is the cursor remains closed.

## Examples

Close the cursor `portala`:

```
CLOSE portala;
```

## Compatibility

`CLOSE` is fully conforming with the SQL standard.

## CLUSTER

Physically reorders a heap storage table on disk according to an index. Not a recommended operation in Greenplum Database.

## Synopsis

```

CLUSTER <indexname> ON <tablename>

CLUSTER [VERBOSE] <tablename> [ USING index_name ]

CLUSTER [VERBOSE]

```

## Description

`CLUSTER` orders a heap storage table based on an index. `CLUSTER` is not supported on append-optimized storage tables. Clustering an index means that the records are physically ordered on disk according to the index information. If the records you need are distributed randomly on disk, then the database has to seek across the disk to get the records requested. If those records are stored more closely together, then the fetching from disk is more sequential. A good example for a clustered index is on a date column where the data is ordered sequentially by date. A query against a specific date range will result in an ordered fetch from the disk, which leverages faster sequential access.

Clustering is a one-time operation: when the table is subsequently updated, the changes are not clustered. That is, no attempt is made to store new or updated rows according to their index order. If you wish, you can periodically recluster by issuing the command again. Setting the table's `FILLFACTOR` storage parameter to less than 100% can aid in preserving cluster ordering during updates, because updated rows are kept on the same page if enough space is available there.

When a table is clustered using this command, Greenplum Database remembers on which index it was clustered. The form `CLUSTER tablename` reclusters the table on the same index that it was clustered before. You can use the `CLUSTER` or `SET WITHOUT CLUSTER` forms of `ALTER TABLE` to set the index to use for future cluster operations, or to clear any previous setting. `CLUSTER` without any parameter reclusters all previously clustered tables in the current database that the calling user owns, or all tables if called by a superuser. This form of `CLUSTER` cannot be run inside a transaction block.

When a table is being clustered, an `ACCESS EXCLUSIVE` lock is acquired on it. This prevents any other database operations (both reads and writes) from operating on the table until the `CLUSTER` is finished.

## Parameters

`indexname`

The name of an index.

`VERBOSE`

Prints a progress report as each table is clustered.

`tablename`

The name (optionally schema-qualified) of a table.

## Notes

In cases where you are accessing single rows randomly within a table, the actual order of the data in the table is unimportant. However, if you tend to access some data more than others, and there is an index that groups them together, you will benefit from using `CLUSTER`. If you are requesting a

range of indexed values from a table, or a single indexed value that has multiple rows that match, `CLUSTER` will help because once the index identifies the table page for the first row that matches, all other rows that match are probably already on the same table page, and so you save disk accesses and speed up the query.

`CLUSTER` can re-sort the table using either an index scan on the specified index, or (if the index is a b-tree) a sequential scan followed by sorting. It will attempt to choose the method that will be faster, based on planner cost parameters and available statistical information.

When an index scan is used, a temporary copy of the table is created that contains the table data in the index order. Temporary copies of each index on the table are created as well. Therefore, you need free space on disk at least equal to the sum of the table size and the index sizes.

When a sequential scan and sort is used, a temporary sort file is also created, so that the peak temporary space requirement is as much as double the table size, plus the index sizes. This method is often faster than the index scan method, but if the disk space requirement is intolerable, you can deactivate this choice by temporarily setting the `enable_sort` configuration parameter to `off`.

It is advisable to set `maintenance_work_mem` configuration parameter to a reasonably large value (but not more than the amount of RAM you can dedicate to the `CLUSTER` operation) before clustering.

Because the query optimizer records statistics about the ordering of tables, it is advisable to run `ANALYZE` on the newly clustered table. Otherwise, the planner may make poor choices of query plans.

Because `CLUSTER` remembers which indexes are clustered, you can cluster the tables you want clustered manually the first time, then set up a periodic maintenance script that runs `CLUSTER` without any parameters, so that the desired tables are periodically reclustered.

**Note:** `CLUSTER` is not supported with append-optimized tables.

## Examples

Cluster the table `employees` on the basis of its index `emp_ind`:

```
CLUSTER emp_ind ON emp;
```

Cluster a large table by recreating it and loading it in the correct index order:

```
CREATE TABLE newtable AS SELECT * FROM table ORDER BY column;
DROP table;
ALTER TABLE newtable RENAME TO table;
CREATE INDEX column_ix ON table (column);
VACUUM ANALYZE table;
```

## Compatibility

There is no `CLUSTER` statement in the SQL standard.

[ <argmode> ] [ <argname> ] <argtype> [ , ... ] |
[ [ <argmode> ] [ <argname> ] <argtype> [ , ... ] ] ORDER BY [ <argmode> ] [ <argname> ] <argtype> [ , ... ]
```

## Description

`COMMENT` stores a comment about a database object. Only one comment string is stored for each object. To remove a comment, write `NULL` in place of the text string. Comments are automatically dropped when the object is dropped.

For most kinds of object, only the object's owner can set the comment. Roles don't have owners, so the rule for `COMMENT ON ROLE` is that you must be superuser to comment on a superuser role, or have the `CREATEROLE` privilege to comment on non-superuser roles. Of course, a superuser can comment on anything.

Comments can be easily retrieved with the psql meta-commands `\dd`, `\d+`, and `\l+`. Other user interfaces to retrieve comments can be built atop the same built-in functions that psql uses, namely `obj_description`, `col_description`, and `shobj_description`.

## Parameters

`object_name`

`relation_name.column_name`

`agg_name`

`constraint_name`

`func_name`

`operator_name`

`rule_name`

`trigger_name`

The name of the object to be commented. Names of tables, aggregates, collations, conversions, domains, foreign tables, functions, indexes, operators, operator classes, operator families, sequences, text search objects, types, views, and materialized views can be schema-qualified. When commenting on a column, `relation_name` must refer to a table, view, materialized view, composite type, or foreign table.

**Note:** Greenplum Database does not support triggers.

`source_type`

The name of the source data type of the cast.

`target_type`

The name of the target data type of the cast.

`argmode`

The mode of a function or aggregate argument: either `IN`, `OUT`, `INOUT`, or `VARIADIC`. If omitted, the default is `IN`. Note that `COMMENT` does not actually pay any attention to `OUT` arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the `IN`, `INOUT`, and `VARIADIC` arguments.

`argname`

The name of a function or aggregate argument. Note that `COMMENT ON FUNCTION` does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

`argtype`

The data type of a function or aggregate argument.

`large_object_oid`

The OID of the large object.

**Note:** Greenplum Database does not support the PostgreSQL [large object facility](#) for streaming user data that is stored in large-object structures.

left\_type

right\_type

The data type(s) of the operator's arguments (optionally schema-qualified). Write `NONE` for the missing argument of a prefix or postfix operator.

PROCEDURAL

This is a noise word.

text

The new comment, written as a string literal; or `NULL` to drop the comment.

## Notes

There is presently no security mechanism for viewing comments: any user connected to a database can see all the comments for objects in that database. For shared objects such as databases, roles, and tablespaces, comments are stored globally so any user connected to any database in the cluster can see all the comments for shared objects. Therefore, do not put security-critical information in comments.

## Examples

Attach a comment to the table `mytable`:

```
COMMENT ON TABLE mytable IS 'This is my table.';
```

Remove it again:

```
COMMENT ON TABLE mytable IS NULL;
```

Some more examples:

```
COMMENT ON AGGREGATE my_aggregate (double precision) IS 'Computes sample variance';
COMMENT ON CAST (text AS int4) IS 'Allow casts from text to int4';
COMMENT ON COLLATION "fr_CA" IS 'Canadian French';
COMMENT ON COLUMN my_table.my_column IS 'Employee ID number';
COMMENT ON CONVERSION my_conv IS 'Conversion to UTF8';
COMMENT ON CONSTRAINT bar_col_cons ON bar IS 'Constrains column col';
COMMENT ON DATABASE my_database IS 'Development Database';
COMMENT ON DOMAIN my_domain IS 'Email Address Domain';
COMMENT ON EXTENSION hstore IS 'implements the hstore data type';
COMMENT ON FOREIGN DATA WRAPPER mywrapper IS 'my foreign data wrapper';
COMMENT ON FOREIGN TABLE my_foreign_table IS 'Employee Information in other database';
COMMENT ON FUNCTION my_function (timestamp) IS 'Returns Roman Numeral';
COMMENT ON INDEX my_index IS 'Enforces uniqueness on employee ID';
COMMENT ON LANGUAGE plpython IS 'Python support for stored procedures';
COMMENT ON LARGE OBJECT 346344 IS 'Planning document';
COMMENT ON OPERATOR ^ (text, text) IS 'Performs intersection of two texts';
COMMENT ON OPERATOR - (NONE, integer) IS 'Unary minus';
COMMENT ON OPERATOR CLASS int4ops USING btree IS '4 byte integer operators for btree
s';
COMMENT ON OPERATOR FAMILY integer_ops USING btree IS 'all integer operators for btree
s';
```

```

COMMENT ON ROLE my_role IS 'Administration group for finance tables';
COMMENT ON RULE my_rule ON my_table IS 'Logs updates of employee records';
COMMENT ON SCHEMA my_schema IS 'Departmental data';
COMMENT ON SEQUENCE my_sequence IS 'Used to generate primary keys';
COMMENT ON SERVER myserver IS 'my foreign server';
COMMENT ON TABLE my_schema.my_table IS 'Employee Information';
COMMENT ON TABLESPACE my_tablespace IS 'Tablespace for indexes';
COMMENT ON TEXT SEARCH CONFIGURATION my_config IS 'Special word filtering';
COMMENT ON TEXT SEARCH DICTIONARY swedish IS 'Snowball stemmer for Swedish language';
COMMENT ON TEXT SEARCH PARSER my_parser IS 'Splits text into words';
COMMENT ON TEXT SEARCH TEMPLATE snowball IS 'Snowball stemmer';
COMMENT ON TRIGGER my_trigger ON my_table IS 'Used for RI';
COMMENT ON TYPE complex IS 'Complex number data type';
COMMENT ON VIEW my_view IS 'View of departmental costs';

```

## Compatibility

There is no `COMMENT` statement in the SQL standard.

Parent topic: [SQL Commands](#)

## COMMIT

Commits the current transaction.

## Synopsis

```
COMMIT [WORK | TRANSACTION]
```

## Description

`COMMIT` commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs.

## Parameters

WORK

TRANSACTION

Optional key words. They have no effect.

## Notes

Use `ROLLBACK` to prematurely end a transaction.

Issuing `COMMIT` when not inside a transaction does no harm, but it will provoke a warning message.

## Examples

To commit the current transaction and make all changes permanent:

```
COMMIT;
```

## Compatibility

The SQL standard only specifies the two forms `COMMIT` and `COMMIT WORK`. Otherwise, this command is fully conforming.

## See Also

[BEGIN](#), [END](#), [START TRANSACTION](#), [ROLLBACK](#)

## COPY

Copies data between a file and a table.

## Synopsis

```
COPY <table_name> [( <column_name> [, ...] ) ]
  FROM { '<filename>' | PROGRAM '<command>' | STDIN }
  [ [ WITH ] ( <option> [, ...] ) ]
  [ ON SEGMENT ]

COPY { <table_name> [( <column_name> [, ...] ) ] | (<query> ) }
  TO { '<filename>' | PROGRAM '<command>' | STDOUT }
  [ [ WITH ] ( <option> [, ...] ) ]
  [ ON SEGMENT ]
```

where option can be one of:

```
FORMAT <format_name>
OIDS [ <boolean> ]
FREEZE [ <boolean> ]
DELIMITER '<delimiter_character>'
NULL '<>null string>'
HEADER [ <boolean> ]
QUOTE '<quote_character>'
ESCAPE '<escape_character>'
FORCE_QUOTE { ( <column_name> [, ...] ) | * }
FORCE_NOT_NULL ( <column_name> [, ...] )
FORCE_NULL ( <column_name> [, ...] )
ENCODING '<encoding_name>'
FILL MISSING FIELDS
LOG ERRORS [ SEGMENT REJECT LIMIT <count> [ ROWS | PERCENT ] ]
IGNORE EXTERNAL PARTITIONS
```

## Description

`COPY` moves data between Greenplum Database tables and standard file-system files. `COPY TO` copies the contents of a table to a file (or multiple files based on the segment ID if copying `ON SEGMENT`), while `COPY FROM` copies data from a file to a table (appending the data to whatever is in the table already). `COPY TO` can also copy the results of a `SELECT` query.

If a list of columns is specified, `COPY` will only copy the data in the specified columns to or from the file. If there are any columns in the table that are not in the column list, `COPY FROM` will insert the default values for those columns.

`COPY` with a file name instructs the Greenplum Database master host to directly read from or write to a file. The file must be accessible to the master host and the name must be specified from the viewpoint of the master host.

When `COPY` is used with the `ON SEGMENT` clause, the `COPY TO` causes segments to create individual segment-oriented files, which remain on the segment hosts. The filename argument for `ON SEGMENT` takes the string literal `<SEGID>` (required) and uses either the absolute path or the `<SEG_DATA_DIR>` string literal. When the `COPY` operation is run, the segment IDs and the paths of the segment data directories are substituted for the string literal values.

Using `COPY TO` with a replicated table (`DISTRIBUTED REPLICATED`) as source creates a file with rows from a single segment so that the target file contains no duplicate rows. Using `COPY TO` with the `ON SEGMENT` clause with a replicated table as source creates target files on segment hosts containing all table rows.

The `ON SEGMENT` clause allows you to copy table data to files on segment hosts for use in operations such as migrating data between clusters or performing a backup. Segment data created by the `ON SEGMENT` clause can be restored by tools such as `gpfdist`, which is useful for high speed data loading.

**Warning:** Use of the `ON SEGMENT` clause is recommended for expert users only.

When `PROGRAM` is specified, the server runs the given command and reads from the standard output of the program, or writes to the standard input of the program. The command must be specified from the viewpoint of the server, and be executable by the `gpadmin` user.

When `STDIN` or `STDOUT` is specified, data is transmitted via the connection between the client and the master. `STDIN` and `STDOUT` cannot be used with the `ON SEGMENT` clause.

If `SEGMENT REJECT LIMIT` is used, then a `COPY FROM` operation will operate in single row error isolation mode. In this release, single row error isolation mode only applies to rows in the input file with format errors — for example, extra or missing attributes, attributes of a wrong data type, or invalid client encoding sequences. Constraint errors such as violation of a `NOT NULL`, `CHECK`, or `UNIQUE` constraint will still be handled in 'all-or-nothing' input mode. The user can specify the number of error rows acceptable (on a per-segment basis), after which the entire `COPY FROM` operation will be cancelled and no rows will be loaded. The count of error rows is per-segment, not per entire load operation. If the per-segment reject limit is not reached, then all rows not containing an error will be loaded and any error rows discarded. To keep error rows for further examination, specify the `LOG ERRORS` clause to capture error log information. The error information and the row is stored internally in Greenplum Database.

## Outputs

On successful completion, a `COPY` command returns a command tag of the form, where count is the number of rows copied:

```
COPY <count>
```

If running a `COPY FROM` command in single row error isolation mode, the following notice message will be returned if any rows were not loaded due to format errors, where count is the number of rows rejected:

```
NOTICE: Rejected <count> badly formatted rows.
```

## Parameters

`table_name`

The name (optionally schema-qualified) of an existing table.

`column_name`

An optional list of columns to be copied. If no column list is specified, all columns of the table will be copied.

When copying in text format, the default, a row of data in a column of type `bytea` can be up to 256MB.

`query`

A `SELECT` or `VALUES` command whose results are to be copied. Note that parentheses are required around the query.

`filename`

The path name of the input or output file. An input file name can be an absolute or relative path, but an output file name must be an absolute path. Windows users might need to use an `'E'` string and double any backslashes used in the path name.

`PROGRAM 'command'`

Specify a command to run. In `COPY FROM`, the input is read from standard output of the command, and in `COPY TO`, the output is written to the standard input of the command. The command must be specified from the viewpoint of the Greenplum Database master host system, and must be executable by the Greenplum Database administrator user (`gpadmin`).

The command is invoked by a shell. When passing arguments to the shell, strip or escape any special characters that have a special meaning for the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in the string.

When `ON SEGMENT` is specified, the command must be executable on all Greenplum Database primary segment hosts by the Greenplum Database administrator user (`gpadmin`). The command is run by each Greenplum segment instance. The `<SEGID>` is required in the command.

See the `ON SEGMENT` clause for information about command syntax requirements and the data that is copied when the clause is specified.

`STDIN`

Specifies that input comes from the client application. The `ON SEGMENT` clause is not supported with `STDIN`.

`STDOUT`

Specifies that output goes to the client application. The `ON SEGMENT` clause is not supported with `STDOUT`.

`boolean`

Specifies whether the selected option should be turned on or off. You can write `TRUE`, `ON`, or `1` to enable the option, and `FALSE`, `OFF`, or `0` to deactivate it. The boolean value can also be omitted, in which case `TRUE` is assumed.

#### FORMAT

Selects the data format to be read or written: `text`, `csv` (Comma Separated Values), or `binary`. The default is `text`.

#### oids

Specifies copying the OID for each row. (An error is raised if `oids` is specified for a table that does not have OIDs, or in the case of copying a query.)

#### FREEZE

Requests copying the data with rows already frozen, just as they would be after running the `VACUUM FREEZE` command. This is intended as a performance option for initial data loading. Rows will be frozen only if the table being loaded has been created or truncated in the current subtransaction, there are no cursors open, and there are no older snapshots held by this transaction.

Note that all other sessions will immediately be able to see the data once it has been successfully loaded. This violates the normal rules of MVCC visibility and users specifying this option should be aware of the potential problems this might cause.

#### DELIMITER

Specifies the character that separates columns within each row (line) of the file. The default is a tab character in `text` format, a comma in `csv` format. This must be a single one-byte character. This option is not allowed when using `binary` format.

#### NULL

Specifies the string that represents a null value. The default is `\N` (backslash-N) in `text` format, and an unquoted empty string in `csv` format. You might prefer an empty string even in `text` format for cases where you don't want to distinguish nulls from empty strings. This option is not allowed when using `binary` format.

**Note:** When using `COPY FROM`, any data item that matches this string will be stored as a null value, so you should make sure that you use the same string as you used with `COPY TO`.

#### HEADER

Specifies that a file contains a header line with the names of each column in the file. On output, the first line contains the column names from the table, and on input, the first line is ignored. This option is allowed only when using `csv` format.

#### QUOTE

Specifies the quoting character to be used when a data value is quoted. The default is double-quote. This must be a single one-byte character. This option is allowed only when using `csv` format.

#### ESCAPE

Specifies the character that should appear before a data character that matches the `QUOTE` value. The default is the same as the `QUOTE` value (so that the quoting character is doubled if it appears in the data). This must be a single one-byte character. This option is allowed only when using `csv` format.

#### FORCE\_QUOTE

Forces quoting to be used for all non-`NULL` values in each specified column. `NULL` output is never quoted. If `*` is specified, non-`NULL` values will be quoted in all columns. This option is

allowed only in `COPY TO`, and only when using `CSV` format.

#### FORCE\_NOT\_NULL

Do not match the specified columns' values against the null string. In the default case where the null string is empty, this means that empty values will be read as zero-length strings rather than nulls, even when they are not quoted. This option is allowed only in `COPY FROM`, and only when using `CSV` format.

#### FORCE\_NULL

Match the specified columns' values against the null string, even if it has been quoted, and if a match is found set the value to `NULL`. In the default case where the null string is empty, this converts a quoted empty string into `NULL`. This option is allowed only in `COPY FROM`, and only when using `CSV` format.

#### ENCODING

Specifies that the file is encoded in the `encoding_name`. If this option is omitted, the current client encoding is used. See the Notes below for more details.

#### ON SEGMENT

Specify individual, segment data files on the segment hosts. Each file contains the table data that is managed by the primary segment instance. For example, when copying data to files from a table with a `COPY TO...ON SEGMENT` command, the command creates a file on the segment host for each segment instance on the host. Each file contains the table data that is managed by the segment instance.

The `COPY` command does not copy data from or to mirror segment instances and segment data files.

The keywords `STDIN` and `STDOUT` are not supported with `ON SEGMENT`.

The `<SEG_DATA_DIR>` and `<SEGID>` string literals are used to specify an absolute path and file name with the following syntax:

```
COPY <table> [TO|FROM] '<SEG_DATA_DIR>/<gpdumpname><SEGID>_<suffix>' ON SEGMENT;
```

#### <SEG\_DATA\_DIR>

The string literal representing the absolute path of the segment instance data directory for `ON SEGMENT` copying. The angle brackets (`<` and `>`) are part of the string literal used to specify the path. `COPY` replaces the string literal with the segment path(s) when `COPY` is run. An absolute path can be used in place of the `<SEG_DATA_DIR>` string literal.

#### <SEGID>

The string literal representing the content ID number of the segment instance to be copied when copying `ON SEGMENT`. `<SEGID>` is a required part of the file name when `ON SEGMENT` is specified. The angle brackets are part of the string literal used to specify the file name.

With `COPY TO`, the string literal is replaced by the content ID of the segment instance when the `COPY` command is run.

With `COPY FROM`, specify the segment instance content ID in the name of the file and place that file on the segment instance host. There must be a file for each primary segment instance on each host. When the `COPY FROM` command is run, the data is copied from the file to the segment instance.

When the `PROGRAM` command clause is specified, the `<SEGID>` string literal is required in the command, the `<SEG_DATA_DIR>` string literal is optional. See [Examples](#).

For a `COPY FROM...ON SEGMENT` command, the table distribution policy is checked when data is copied into the table. By default, an error is returned if a data row violates the table distribution policy. You can deactivate the distribution policy check with the server configuration parameter `gp_enable_segment_copy_checking`. See [Notes](#).

#### NEWLINE

Specifies the newline used in your data files — `LF` (Line feed, 0x0A), `CR` (Carriage return, 0x0D), or `CRLF` (Carriage return plus line feed, 0x0D 0x0A). If not specified, a Greenplum Database segment will detect the newline type by looking at the first row of data it receives and using the first newline type encountered.

#### CSV

Selects Comma Separated Value (CSV) mode. See [CSV Format](#).

#### FILL MISSING FIELDS

In `COPY FROM` mode for both `TEXT` and `CSV`, specifying `FILL MISSING FIELDS` will set missing trailing field values to `NULL` (instead of reporting an error) when a row of data has missing data fields at the end of a line or row. Blank rows, fields with a `NOT NULL` constraint, and trailing delimiters on a line will still report an error.

#### LOG ERRORS

This is an optional clause that can precede a `SEGMENT REJECT LIMIT` clause to capture error log information about rows with formatting errors.

Error log information is stored internally and is accessed with the Greenplum Database built-in SQL function `gp_read_error_log()`.

See [Notes](#) for information about the error log information and built-in functions for viewing and managing error log information.

#### SEGMENT REJECT LIMIT count [ROWS | PERCENT]

Runs a `COPY FROM` operation in single row error isolation mode. If the input rows have format errors they will be discarded provided that the reject limit count is not reached on any Greenplum Database segment instance during the load operation. The reject limit count can be specified as number of rows (the default) or percentage of total rows (1-100). If `PERCENT` is used, each segment starts calculating the bad row percentage only after the number of rows specified by the parameter `gp_reject_percent_threshold` has been processed. The default for `gp_reject_percent_threshold` is 300 rows. Constraint errors such as violation of a `NOT NULL`, `CHECK`, or `UNIQUE` constraint will still be handled in 'all-or-nothing' input mode. If the limit is not reached, all good rows will be loaded and any error rows discarded.

**Note:** Greenplum Database limits the initial number of rows that can contain formatting errors if the `SEGMENT REJECT LIMIT` is not triggered first or is not specified. If the first 1000 rows are rejected, the `COPY` operation is stopped and rolled back.

The limit for the number of initial rejected rows can be changed with the Greenplum Database server configuration parameter `gp_initial_bad_row_limit`. See [Server Configuration Parameters](#) for information about the parameter.

#### IGNORE EXTERNAL PARTITIONS

When copying data from partitioned tables, data are not copied from leaf child partitions that are external tables. A message is added to the log file when data are not copied.

If this clause is not specified and Greenplum Database attempts to copy data from a leaf child partition that is an external table, an error is returned.

See the next section "Notes" for information about specifying an SQL query to copy data from leaf child partitions that are external tables.

## Notes

`COPY` can only be used with tables, not with external tables or views. However, you can write `COPY (SELECT * FROM viewname) TO ...`.

`COPY` only deals with the specific table named; it does not copy data to or from child tables. Thus for example `COPY table TO` shows the same data as `SELECT * FROM ONLY table``. But `COPY (SELECT * FROM table) TO ...` can be used to dump all of the data in an inheritance hierarchy.

Similarly, to copy data from a partitioned table with a leaf child partition that is an external table, use an SQL query to select the data to copy. For example, if the table `my_sales` contains a leaf child partition that is an external table, this command `COPY my_sales TO stdout` returns an error. This command sends the data to `stdout`:

```
COPY (SELECT * from my_sales ) TO stdout
```

The `BINARY` keyword causes all data to be stored/read as binary format rather than as text. It is somewhat faster than the normal text mode, but a binary-format file is less portable across machine architectures and Greenplum Database versions. Also, you cannot run `COPY FROM` in single row error isolation mode if the data is in binary format.

You must have `SELECT` privilege on the table whose values are read by `COPY TO`, and `INSERT` privilege on the table into which values are inserted by `COPY FROM`. It is sufficient to have column privileges on the columns listed in the command.

Files named in a `COPY` command are read or written directly by the database server, not by the client application. Therefore, they must reside on or be accessible to the Greenplum Database master host machine, not the client. They must be accessible to and readable or writable by the Greenplum Database system user (the user ID the server runs as), not the client. Only database superusers are permitted to name files with `COPY`, because this allows reading or writing any file that the server has privileges to access.

`COPY FROM` will invoke any triggers and check constraints on the destination table. However, it will not invoke rewrite rules. Note that in this release, violations of constraints are not evaluated for single row error isolation mode.

`COPY` input and output is affected by `DateStyle`. To ensure portability to other Greenplum Database installations that might use non-default `DateStyle` settings, `DateStyle` should be set to `ISO` before using `COPY TO`. It is also a good idea to avoid dumping data with `IntervalStyle` set to `sql_standard`, because negative interval values might be misinterpreted by a server that has a different setting for `IntervalStyle`.

Input data is interpreted according to `ENCODING` option or the current client encoding, and output data is encoded in `ENCODING` or the current client encoding, even if the data does not pass through

the client but is read from or written to a file directly by the server.

When copying XML data from a file in text mode, the server configuration parameter `xmloption` affects the validation of the XML data that is copied. If the value is `content` (the default), XML data is validated as an XML content fragment. If the parameter value is `document`, XML data is validated as an XML document. If the XML data is not valid, `COPY` returns an error.

By default, `COPY` stops operation at the first error. This should not lead to problems in the event of a `COPY TO`, but the target table will already have received earlier rows in a `COPY FROM`. These rows will not be visible or accessible, but they still occupy disk space. This may amount to a considerable amount of wasted disk space if the failure happened well into a large `COPY FROM` operation. You may wish to invoke `VACUUM` to recover the wasted space. Another option would be to use single row error isolation mode to filter out error rows while still loading good rows.

`FORCE_NULL` and `FORCE_NOT_NULL` can be used simultaneously on the same column. This results in converting quoted null strings to null values and unquoted null strings to empty strings.

When a `COPY FROM...ON SEGMENT` command is run, the server configuration parameter `gp_enable_segment_copy_checking` controls whether the table distribution policy (from the table `DISTRIBUTED` clause) is checked when data is copied into the table. The default is to check the distribution policy. An error is returned if the row of data violates the distribution policy for the segment instance. For information about the parameter, see [Server Configuration Parameters](#).

Data from a table that is generated by a `COPY TO...ON SEGMENT` command can be used to restore table data with `COPY FROM...ON SEGMENT`. However, data restored to the segments is distributed according to the table distribution policy at the time the files were generated with the `COPY TO` command. The `COPY` command might return table distribution policy errors, if you attempt to restore table data and the table distribution policy was changed after the `COPY FROM...ON SEGMENT` was run.

**Note:** If you run `COPY FROM...ON SEGMENT` and the server configuration parameter `gp_enable_segment_copy_checking` is `false`, manual redistribution of table data might be required. See the `ALTER TABLE` clause `WITH REORGANIZE`.

When you specify the `LOG ERRORS` clause, Greenplum Database captures errors that occur while reading the external table data. You can view and manage the captured error log data.

- Use the built-in SQL function `gp_read_error_log('table\_name')`. It requires `SELECT` privilege on `table\_name`. This example displays the error log information for data loaded into table `ext_expenses` with a `COPY` command:

```
SELECT * from gp_read_error_log('ext_expenses');
```

For information about the error log format, see [Viewing Bad Rows in the Error Log](#) in the *Greenplum Database Administrator Guide*.

The function returns `FALSE` if `table\_name` does not exist.

- If error log data exists for the specified table, the new error log data is appended to existing error log data. The error log information is not replicated to mirror segments.
- Use the built-in SQL function `gp_truncate_error_log('table\_name')` to delete the error log data for `table\_name`. It requires the table owner privilege. This example deletes the error log information captured when moving data into the table `ext_expenses`:

```
SELECT gp_truncate_error_log('ext_expenses');
```

The function returns `FALSE` if `table_name` does not exist.

Specify the `*` wildcard character to delete error log information for existing tables in the current database. Specify the string `*.*` to delete all database error log information, including error log information that was not deleted due to previous database issues. If `*` is specified, database owner privilege is required. If `*.*` is specified, operating system super-user privilege is required.

When a Greenplum Database user who is not a superuser runs a `COPY` command, the command can be controlled by a resource queue. The resource queue must be configured with the `ACTIVE_STATEMENTS` parameter that specifies a maximum limit on the number of queries that can be run by roles assigned to that queue. Greenplum Database does not apply a cost value or memory value to a `COPY` command, resource queues with only cost or memory limits do not affect the running of `COPY` commands.

A non-superuser can run only these types of `COPY` commands:

- `COPY FROM` command where the source is `stdin`
- `COPY TO` command where the destination is `stdout`

For information about resource queues, see "Resource Management with Resource Queues" in the *Greenplum Database Administrator Guide*.

## File Formats

File formats supported by `COPY`.

### Text Format

When the `text` format is used, the data read or written is a text file with one line per table row. Columns in a row are separated by the `delimiter_character` (tab by default). The column values themselves are strings generated by the output function, or acceptable to the input function, of each attribute's data type. The specified null string is used in place of columns that are null. `COPY FROM` will raise an error if any line of the input file contains more or fewer columns than are expected. If `oids` is specified, the OID is read or written as the first column, preceding the user data columns.

The data file has two reserved characters that have special meaning to `COPY`:

- The designated delimiter character (tab by default), which is used to separate fields in the data file.
- A UNIX-style line feed (`\n` or `0x0a`), which is used to designate a new row in the data file. It is strongly recommended that applications generating `COPY` data convert data line feeds to UNIX-style line feeds rather than Microsoft Windows style carriage return line feeds (`\r\n` or `0x0a 0x0d`).

If your data contains either of these characters, you must escape the character so `COPY` treats it as data and not as a field separator or new row.

By default, the escape character is a `\` (backslash) for text-formatted files and a `"` (double quote) for csv-formatted files. If you want to use a different escape character, you can do so using the `ESCAPE`

**AS**clause. Make sure to choose an escape character that is not used anywhere in your data file as an actual data value. You can also deactivate escaping in text-formatted files by using `ESCAPE 'OFF'`.

For example, suppose you have a table with three columns and you want to load the following three fields using `COPY`.

- percentage sign = %
- vertical bar = |
- backslash = \

Your designated `delimiter_character` is | (pipe character), and your designated escape character is \* (asterisk). The formatted row in your data file would look like this:

```
percentage sign = % | vertical bar = *| | backslash = \
```

Notice how the pipe character that is part of the data has been escaped using the asterisk character (\*). Also notice that we do not need to escape the backslash since we are using an alternative escape character.

The following characters must be preceded by the escape character if they appear as part of a column value: the escape character itself, newline, carriage return, and the current delimiter character. You can specify a different escape character using the `ESCAPE AS` clause.

## CSV Format

This format option is used for importing and exporting the Comma Separated Value (CSV) file format used by many other programs, such as spreadsheets. Instead of the escaping rules used by Greenplum Database standard text format, it produces and recognizes the common CSV escaping mechanism.

The values in each record are separated by the `DELIMITER` character. If the value contains the delimiter character, the `QUOTE` character, the `ESCAPE` character (which is double quote by default), the `NULL` string, a carriage return, or line feed character, then the whole value is prefixed and suffixed by the `QUOTE` character. You can also use `FORCE_QUOTE` to force quotes when outputting non-`NULL` values in specific columns.

The CSV format has no standard way to distinguish a `NULL` value from an empty string. Greenplum Database `COPY` handles this by quoting. A `NULL` is output as the `NULL` parameter string and is not quoted, while a non-`NULL` value matching the `NULL` string is quoted. For example, with the default settings, a `NULL` is written as an unquoted empty string, while an empty string data value is written with double quotes (""). Reading values follows similar rules. You can use `FORCE_NOT_NULL` to prevent `NULL` input comparisons for specific columns. You can also use `FORCE_NULL` to convert quoted null string data values to `NULL`.

Because backslash is not a special character in the `CSV` format, `\.`, the end-of-data marker, could also appear as a data value. To avoid any misinterpretation, a `\.` data value appearing as a lone entry on a line is automatically quoted on output, and on input, if quoted, is not interpreted as the end-of-data marker. If you are loading a file created by another application that has a single unquoted column and might have a value of `\.`, you might need to quote that value in the input file.

**Note:** In `CSV` format, all characters are significant. A quoted value surrounded by white space, or any characters other than `DELIMITER`, will include those characters. This can cause errors if you

import data from a system that pads CSV lines with white space out to some fixed width. If such a situation arises you might need to preprocess the CSV file to remove the trailing white space, before importing the data into Greenplum Database.

`csv` format will both recognize and produce CSV files with quoted values containing embedded carriage returns and line feeds. Thus the files are not strictly one line per table row like text-format files

**Note:** Many programs produce strange and occasionally perverse CSV files, so the file format is more a convention than a standard. Thus you might encounter some files that cannot be imported using this mechanism, and `copy` might produce files that other programs cannot process.

## Binary Format

The `binary` format option causes all data to be stored/read as binary format rather than as text. It is somewhat faster than the text and `csv` formats, but a binary-format file is less portable across machine architectures and Greenplum Database versions. Also, the binary format is very data type specific; for example it will not work to output binary data from a `smallint` column and read it into an `integer` column, even though that would work fine in text format.

The binary file format consists of a file header, zero or more tuples containing the row data, and a file trailer. Headers and data are in network byte order.

- **File Header** — The file header consists of 15 bytes of fixed fields, followed by a variable-length header extension area. The fixed fields are:
  - **Signature** — 11-byte sequence `PGCOPY\n\377\r\n\0` — note that the zero byte is a required part of the signature. (The signature is designed to allow easy identification of files that have been munged by a non-8-bit-clean transfer. This signature will be changed by end-of-line-translation filters, dropped zero bytes, dropped high bits, or parity changes.)
  - **Flags field** — 32-bit integer bit mask to denote important aspects of the file format. Bits are numbered from 0 (LSB) to 31 (MSB). Note that this field is stored in network byte order (most significant byte first), as are all the integer fields used in the file format. Bits 16-31 are reserved to denote critical file format issues; a reader should cancel if it finds an unexpected bit set in this range. Bits 0-15 are reserved to signal backwards-compatible format issues; a reader should simply ignore any unexpected bits set in this range. Currently only one flag is defined, and the rest must be zero (Bit 16: 1 if data has OIDs, 0 if not).
  - **Header extension area length** — 32-bit integer, length in bytes of remainder of header, not including self. Currently, this is zero, and the first tuple follows immediately. Future changes to the format might allow additional data to be present in the header. A reader should silently skip over any header extension data it does not know what to do with. The header extension area is envisioned to contain a sequence of self-identifying chunks. The flags field is not intended to tell readers what is in the extension area. Specific design of header extension contents is left for a later release.
- **Tuples** — Each tuple begins with a 16-bit integer count of the number of fields in the tuple. (Presently, all tuples in a table will have the same count, but that might not always be true.) Then, repeated for each field in the tuple, there is a 32-bit length word followed by that

many bytes of field data. (The length word does not include itself, and can be zero.) As a special case, -1 indicates a NULL field value. No value bytes follow in the NULL case.

There is no alignment padding or any other extra data between fields.

Presently, all data values in a binary-format file are assumed to be in binary format (format code one). It is anticipated that a future extension may add a header field that allows per-column format codes to be specified.

If OIDs are included in the file, the OID field immediately follows the field-count word. It is a normal field except that it is not included in the field-count. In particular it has a length word — this will allow handling of 4-byte vs. 8-byte OIDs without too much pain, and will allow OIDs to be shown as null if that ever proves desirable.

- **File Trailer** — The file trailer consists of a 16-bit integer word containing `-1`. This is easily distinguished from a tuple's field-count word. A reader should report an error if a field-count word is neither `-1` nor the expected number of columns. This provides an extra check against somehow getting out of sync with the data.

## Examples

Copy a table to the client using the vertical bar (|) as the field delimiter:

```
COPY country TO STDOUT (DELIMITER '|');
```

Copy data from a file into the `country` table:

```
COPY country FROM '/home/usr1/sql/country_data';
```

Copy into a file just the countries whose names start with 'A':

```
COPY (SELECT * FROM country WHERE country_name LIKE 'A%') TO
'/home/usr1/sql/a_list_countries.copy';
```

Copy data from a file into the `sales` table using single row error isolation mode and log errors:

```
COPY sales FROM '/home/usr1/sql/sales_data' LOG ERRORS
SEGMENT REJECT LIMIT 10 ROWS;
```

To copy segment data for later use, use the `ON SEGMENT` clause. Use of the `COPY TO ON SEGMENT` command takes the form:

```
COPY <table> TO '<SEG_DATA_DIR>/<gpdumpname><SEGID>_<suffix>' ON SEGMENT;
```

The `<SEGID>` is required. However, you can substitute an absolute path for the `<SEG_DATA_DIR>` string literal in the path.

When you pass in the string literal `<SEG_DATA_DIR>` and `<SEGID>` to `COPY`, `COPY` will fill in the appropriate values when the operation is run.

For example, if you have `mytable` with the segments and mirror segments like this:

```
contentid | dbid | file segment location
0         | 1   | /home/usr1/data1/gpsegdir0
```

```

0      | 3      | /home/usr1/data_mirror1/gpsegdir0
1      | 4      | /home/usr1/data2/gpsegdir1
1      | 2      | /home/usr1/data_mirror2/gpsegdir1

```

running the command:

```
COPY mytable TO '<SEG_DATA_DIR>/gpbackup<SEGID>.txt' ON SEGMENT;
```

would result in the following files:

```

/home/usr1/data1/gpsegdir0/gpbackup0.txt
/home/usr1/data2/gpsegdir1/gpbackup1.txt

```

The content ID in the first column is the identifier inserted into the file path (for example, `gpsegdir0/gpbackup0.txt` above) Files are created on the segment hosts, rather than on the master, as they would be in a standard `COPY` operation. No data files are created for the mirror segments when using `ON SEGMENT` copying.

If an absolute path is specified, instead of `<SEG_DATA_DIR>`, such as in the statement

```
COPY mytable TO '/tmp/gpdir/gpbackup_<SEGID>.txt' ON SEGMENT;
```

files would be placed in `/tmp/gpdir` on every segment. The `gpfdist` tool can also be used to restore data files generated with `COPY TO` with the `ON SEGMENT` option if redistribution is necessary.

**Note:** Tools such as `gpfdist` can be used to restore data. The backup/restore tools will not work with files that were manually generated with `COPY TO ON SEGMENT`.

This example uses a `SELECT` statement to copy data to files on each segment:

```
COPY (SELECT * FROM testtbl) TO '/tmp/mytst<SEGID>' ON SEGMENT;
```

This example copies the data from the `lineitem` table and uses the `PROGRAM` clause to add the data to the `/tmp/lineitem_program.csv` file with `cat` utility. The file is placed on the Greenplum Database master.

```
COPY LINEITEM TO PROGRAM 'cat > /tmp/lineitem.csv' CSV;
```

This example uses the `PROGRAM` and `ON SEGMENT` clauses to copy data to files on the segment hosts. On the segment hosts, the `COPY` command replaces `<SEGID>` with the segment content ID to create a file for each segment instance on the segment host.

```
COPY LINEITEM TO PROGRAM 'cat > /tmp/lineitem_program<SEGID>.csv' ON SEGMENT CSV;
```

This example uses the `PROGRAM` and `ON SEGMENT` clauses to copy data from files on the segment hosts. The `COPY` command replaces `<SEGID>` with the segment content ID when copying data from the files. On the segment hosts, there must be a file for each segment instance where the file name contains the segment content ID on the segment host.

```
COPY LINEITEM_4 FROM PROGRAM 'cat /tmp/lineitem_program<SEGID>.csv' ON SEGMENT CSV;
```

## Compatibility

There is no `COPY` statement in the SQL standard.

The following syntax was used in earlier versions of Greenplum Database and is still supported:

```
COPY <table_name> [( <column_name> [, ...] )] FROM { '<filename>' | PROGRAM '<command>' |
STDIN}
    [ [WITH]
      [ON SEGMENT]
      [BINARY]
      [OIDS]
      [HEADER]
      [DELIMITER [ AS ] '<delimiter_character>']
      [NULL [ AS ] '<null string>']
      [ESCAPE [ AS ] '<escape>' | 'OFF']
      [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
      [CSV [QUOTE [ AS ] '<quote>']
        [FORCE NOT NULL <column_name> [, ...]]
      [FILL MISSING FIELDS]
      [[LOG ERRORS]
      SEGMENT REJECT LIMIT <count> [ROWS | PERCENT] ]

COPY { <table_name> [( <column_name> [, ...] )] | ( <query> ) } TO { '<filename>' | PROGRAM
'<command>' | STDOUT}
    [ [WITH]
      [ON SEGMENT]
      [BINARY]
      [OIDS]
      [HEADER]
      [DELIMITER [ AS ] '<delimiter_character>']
      [NULL [ AS ] '<null string>']
      [ESCAPE [ AS ] '<escape>' | 'OFF']
      [CSV [QUOTE [ AS ] '<quote>']
        [FORCE QUOTE <column_name> [, ...]] | * ]
      [IGNORE EXTERNAL PARTITIONS ]
```

Note that in this syntax, `BINARY` and `CSV` are treated as independent keywords, not as arguments of a `FORMAT` option.

)

```

## Description

`CREATE AGGREGATE` defines a new aggregate function. Some basic and commonly-used aggregate functions such as `count`, `min`, `max`, `sum`, `avg` and so on are already provided in Greenplum Database.

If you define new types or need an aggregate function not already provided, you can use `CREATE AGGREGATE` to provide the desired features.

If a schema name is given (for example, `CREATE AGGREGATE myschema.myagg ...`) then the aggregate function is created in the specified schema. Otherwise it is created in the current schema.

An aggregate function is identified by its name and input data types. Two aggregate functions in the same schema can have the same name if they operate on different input types. The name and input data types of an aggregate function must also be distinct from the name and input data types of every ordinary function in the same schema. This behavior is identical to overloading of ordinary function names. See `CREATE FUNCTION`.

A simple aggregate function is made from one, two, or three ordinary functions (which must be `IMMUTABLE` functions):

- a state transition function `statefunc`
- an optional final calculation function `ffunc`
- an optional combine function `combinefunc`

These functions are used as follows:

```
<statefunc>( internal-state, next-data-values ) ---> next-internal-state
<ffunc>( internal-state ) ---> aggregate-value
<combinefunc>( internal-state, internal-state ) ---> next-internal-state
```

Greenplum Database creates a temporary variable of data type `state_data_type` to hold the current internal state of the aggregate function. At each input row, the aggregate argument values are calculated and the state transition function is invoked with the current state value and the new argument values to calculate a new internal state value. After all the rows have been processed, the final function is invoked once to calculate the aggregate return value. If there is no final function then the ending state value is returned as-is.

**Note:** If you write a user-defined aggregate in C, and you declare the state value (`state_data_type`) as type `internal`, there is a risk of an out-of-memory error occurring. If `internal` state values are not properly managed and a query acquires too much memory for state values, an out-of-memory error could occur. To prevent this, use `mpool_alloc(mpool, size)` to have Greenplum manage and allocate memory for non-temporary state values, that is, state values that have a lifespan for the entire aggregation. The argument `mpool` of the `mpool_alloc()` function is `aggstate->hhashtable->group_buf`. For an example, see the implementation of the numeric data type aggregates in `src/backend/utils/adt/numeric.c` in the Greenplum Database open source code.

You can specify `combinefunc` as a method for optimizing aggregate execution. By specifying `combinefunc`, the aggregate can be run in parallel on segments first and then on the master. When a two-level execution is performed, the `statefunc` is run on the segments to generate partial aggregate results, and `combinefunc` is run on the master to aggregate the partial results from segments. If single-level aggregation is performed, all the rows are sent to the master and the `statefunc` is applied to the rows.

Single-level aggregation and two-level aggregation are equivalent execution strategies. Either type of aggregation can be implemented in a query plan. When you implement the functions `combinefunc` and `statefunc`, you must ensure that the invocation of the `statefunc` on the segment

instances followed by `combinefunc` on the master produce the same result as single-level aggregation that sends all the rows to the master and then applies only the `statefunc` to the rows.

An aggregate function can provide an optional initial condition, an initial value for the internal state value. This is specified and stored in the database as a value of type `text`, but it must be a valid external representation of a constant of the state value data type. If it is not supplied then the state value starts out `NULL`.

If `statefunc` is declared `STRICT`, then it cannot be called with `NULL` inputs. With such a transition function, aggregate execution behaves as follows. Rows with any null input values are ignored (the function is not called and the previous state value is retained). If the initial state value is `NULL`, then at the first row with all non-null input values, the first argument value replaces the state value, and the transition function is invoked at subsequent rows with all non-null input values. This is useful for implementing aggregates like `max`. Note that this behavior is only available when `state_data_type` is the same as the first `arg_data_type`. When these types are different, you must supply a non-null initial condition or use a nonstrict transition function.

If `statefunc` is not declared `STRICT`, then it will be called unconditionally at each input row, and must deal with `NULL` inputs and `NULL` state values for itself. This allows the aggregate author to have full control over the aggregate's handling of `NULL` values.

If the final function (`ffunc`) is declared `STRICT`, then it will not be called when the ending state value is `NULL`; instead a `NULL` result will be returned automatically. (This is the normal behavior of `STRICT` functions.) In any case the final function has the option of returning a `NULL` value. For example, the final function for `avg` returns `NULL` when it sees there were zero input rows.

Sometimes it is useful to declare the final function as taking not just the state value, but extra parameters corresponding to the aggregate's input values. The main reason for doing this is if the final function is polymorphic and the state value's data type would be inadequate to pin down the result type. These extra parameters are always passed as `NULL` (and so the final function must not be strict when the `FINALFUNC_EXTRA` option is used), but nonetheless they are valid parameters. The final function could for example make use of `get_fn_expr_argtype` to identify the actual argument type in the current call.

An aggregate can optionally support *moving-aggregate mode*, as described in [Moving-Aggregate Mode](#) in the PostgreSQL documentation. This requires specifying the `msfunc`, `minvfunc`, and `mstype` functions, and optionally the `mSPACE`, `mfinalfunc`, `mfinalfunc_extra`, and `minitcond` functions. Except for `minvfunc`, these functions work like the corresponding simple-aggregate functions without `m`; they define a separate implementation of the aggregate that includes an inverse transition function.

The syntax with `ORDER BY` in the parameter list creates a special type of aggregate called an *ordered-set aggregate*; or if `HYPOTHETICAL` is specified, then a *hypothetical-set aggregate* is created. These aggregates operate over groups of sorted values in order-dependent ways, so that specification of an input sort order is an essential part of a call. Also, they can have *direct* arguments, which are arguments that are evaluated only once per aggregation rather than once per input row. Hypothetical-set aggregates are a subclass of ordered-set aggregates in which some of the direct arguments are required to match, in number and data types, the aggregated argument columns. This allows the values of those direct arguments to be added to the collection of aggregate-input rows as an additional "hypothetical" row.

Single argument aggregate functions, such as `min` or `max`, can sometimes be optimized by looking into an index instead of scanning every input row. If this aggregate can be so optimized, indicate it by specifying a *sort operator*. The basic requirement is that the aggregate must yield the first element in the sort ordering induced by the operator; in other words:

```
SELECT <agg>(<col>) FROM <tab>;
```

must be equivalent to:

```
SELECT <col> FROM <tab> ORDER BY <col> USING <sortop> LIMIT 1;
```

Further assumptions are that the aggregate function ignores `NULL` inputs, and that it delivers a `NULL` result if and only if there were no non-null inputs. Ordinarily, a data type's `<` operator is the proper sort operator for `MIN`, and `>` is the proper sort operator for `MAX`. Note that the optimization will never actually take effect unless the specified operator is the "less than" or "greater than" strategy member of a B-tree index operator class.

To be able to create an aggregate function, you must have `USAGE` privilege on the argument types, the state type(s), and the return type, as well as `EXECUTE` privilege on the transition and final functions.

## Parameters

name

The name (optionally schema-qualified) of the aggregate function to create.

argmode

The mode of an argument: `IN` or `VARIADIC`. (Aggregate functions do not support `OUT` arguments.) If omitted, the default is `IN`. Only the last argument can be marked `VARIADIC`.

argname

The name of an argument. This is currently only useful for documentation purposes. If omitted, the argument has no name.

arg\_data\_type

An input data type on which this aggregate function operates. To create a zero-argument aggregate function, write `*` in place of the list of argument specifications. (An example of such an aggregate is `count(*)`.)

base\_type

In the old syntax for `CREATE AGGREGATE`, the input data type is specified by a `basetype` parameter rather than being written next to the aggregate name. Note that this syntax allows only one input parameter. To define a zero-argument aggregate function with this syntax, specify the `basetype` as `"ANY"` (not `*`). Ordered-set aggregates cannot be defined with the old syntax.

statefunc

The name of the state transition function to be called for each input row. For a normal N-argument aggregate function, the state transition function `statefunc` must take N+1 arguments, the first being of type `state_data_type` and the rest matching the declared input data types of the aggregate. The function must return a value of type `state_data_type`. This function takes the current state value and the current input data values, and returns the next state value.

For ordered-set (including hypothetical-set) aggregates, the state transition function `statefunc` receives only the current state value and the aggregated arguments, not the direct arguments. Otherwise it is the same.

#### `state_data_type`

The data type for the aggregate's state value.

#### `state_data_size`

The approximate average size (in bytes) of the aggregate's state value. If this parameter is omitted or is zero, a default estimate is used based on the `state_data_type`. The planner uses this value to estimate the memory required for a grouped aggregate query. Large values of this parameter discourage use of hash aggregation.

#### `ffunc`

The name of the final function called to compute the aggregate result after all input rows have been traversed. The function must take a single argument of type `state_data_type`. The return data type of the aggregate is defined as the return type of this function. If `ffunc` is not specified, then the ending state value is used as the aggregate result, and the return type is `state_data_type`.

For ordered-set (including hypothetical-set) aggregates, the final function receives not only the final state value, but also the values of all the direct arguments.

If `FINALFUNC_EXTRA` is specified, then in addition to the final state value and any direct arguments, the final function receives extra NULL values corresponding to the aggregate's regular (aggregated) arguments. This is mainly useful to allow correct resolution of the aggregate result type when a polymorphic aggregate is being defined.

#### `combinefunc`

The name of a combine function. This is a function of two arguments, both of type `state_data_type`. It must return a value of `state_data_type`. A combine function takes two transition state values and returns a new transition state value representing the combined aggregation. In Greenplum Database, if the result of the aggregate function is computed in a segmented fashion, the combine function is invoked on the individual internal states in order to combine them into an ending internal state.

Note that this function is also called in hash aggregate mode within a segment. Therefore, if you call this aggregate function without a combine function, hash aggregate is never chosen. Since hash aggregate is efficient, consider defining a combine function whenever possible.

#### `serialfunc`

An aggregate function whose `state_data_type` is `internal` can participate in parallel aggregation only if it has a `serialfunc` function, which must serialize the aggregate state into a `bytea` value for transmission to another process. This function must take a single argument of type `internal` and return type `bytea`. A corresponding `deserialfunc` is also required.

#### `deserialfunc`

Deserialize a previously serialized aggregate state back into `state_data_type`. This function must take two arguments of types `bytea` and `internal`, and produce a result of type `internal`. (Note: the second, `internal` argument is unused, but is required for type safety reasons.)

#### `initial_condition`

The initial setting for the state value. This must be a string constant in the form accepted for the data type `state_data_type`. If not specified, the state value starts out null.

**msfunc**

The name of the forward state transition function to be called for each input row in moving-aggregate mode. This is exactly like the regular transition function, except that its first argument and result are of type `mstate_data_type`, which might be different from `state_data_type`.

**minvfunc**

The name of the inverse state transition function to be used in moving-aggregate mode. This function has the same argument and result types as `msfunc`, but it is used to remove a value from the current aggregate state, rather than add a value to it. The inverse transition function must have the same strictness attribute as the forward state transition function.

**mstate\_data\_type**

The data type for the aggregate's state value, when using moving-aggregate mode.

**mstate\_data\_size**

The approximate average size (in bytes) of the aggregate's state value, when using moving-aggregate mode. This works the same as `state_data_size`.

**mffunc**

The name of the final function called to compute the aggregate's result after all input rows have been traversed, when using moving-aggregate mode. This works the same as `ffunc`, except that its first argument's type is `mstate_data_type` and extra dummy arguments are specified by writing `MFINALFUNC_EXTRA`. The aggregate result type determined by `mffunc` or `mstate_data_type` must match that determined by the aggregate's regular implementation.

**initial\_condition**

The initial setting for the state value, when using moving-aggregate mode. This works the same as `initial_condition`.

**sort\_operator**

The associated sort operator for a `MIN`- or `MAX`-like aggregate. This is just an operator name (possibly schema-qualified). The operator is assumed to have the same input data types as the aggregate (which must be a single-argument normal aggregate).

**HYPOTHETICAL**

For ordered-set aggregates only, this flag specifies that the aggregate arguments are to be processed according to the requirements for hypothetical-set aggregates: that is, the last few direct arguments must match the data types of the aggregated (`WITHIN GROUP`) arguments. The `HYPOTHETICAL` flag has no effect on run-time behavior, only on parse-time resolution of the data types and collations of the aggregate's arguments.

## Notes

The ordinary functions used to define a new aggregate function must be defined first. Note that in this release of Greenplum Database, it is required that the `statefunc`, `ffunc`, and `combinefunc` functions used to create the aggregate are defined as `IMMUTABLE`.

If the value of the Greenplum Database server configuration parameter `gp_enable_multiphase_agg` is `off`, only single-level aggregation is performed.

Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your Greenplum Database array (master and all segments). This location must also be in the `LD_LIBRARY_PATH` so that the server can locate the files.

In previous versions of Greenplum Database, there was a concept of ordered aggregates. Since version 6, any aggregate can be called as an ordered aggregate, using the syntax:

```
name ( arg [ , ... ] [ORDER BY sortspec [ , ...]] )
```

The `ORDERED` keyword is accepted for backwards compatibility, but is ignored.

In previous versions of Greenplum Database, the `COMBINEFUNC` option was called `PREFUNC`. It is still accepted for backwards compatibility, as a synonym for `COMBINEFUNC`.

## Example

The following simple example creates an aggregate function that computes the sum of two columns.

Before creating the aggregate function, create two functions that are used as the `statefunc` and `combinefunc` functions of the aggregate function.

This function is specified as the `statefunc` function in the aggregate function.

```
CREATE FUNCTION mysfunc_accum(numeric, numeric, numeric)
  RETURNS numeric
  AS 'select $1 + $2 + $3'
  LANGUAGE SQL
  IMMUTABLE
  RETURNS NULL ON NULL INPUT;
```

This function is specified as the `combinefunc` function in the aggregate function.

```
CREATE FUNCTION mycombine_accum(numeric, numeric )
  RETURNS numeric
  AS 'select $1 + $2'
  LANGUAGE SQL
  IMMUTABLE
  RETURNS NULL ON NULL INPUT;
```

This `CREATE AGGREGATE` command creates the aggregate function that adds two columns.

```
CREATE AGGREGATE agg_prefunc(numeric, numeric) (
  SFUNC = mysfunc_accum,
  STYPE = numeric,
  COMBINEFUNC = mycombine_accum,
  INITCOND = 0 );
```

The following commands create a table, adds some rows, and runs the aggregate function.

```
create table t1 (a int, b int) DISTRIBUTED BY (a);
insert into t1 values
  (10, 1),
  (20, 2),
  (30, 3);
select agg_prefunc(a, b) from t1;
```

This `EXPLAIN` command shows two phase aggregation.

```

explain select agg_pfunc(a, b) from t1;

QUERY PLAN
-----
Aggregate (cost=1.10..1.11 rows=1 width=32)
-> Gather Motion 2:1 (slicel1; segments: 2) (cost=1.04..1.08 rows=1
    width=32)
    -> Aggregate (cost=1.04..1.05 rows=1 width=32)
        -> Seq Scan on t1 (cost=0.00..1.03 rows=2 width=8)
Optimizer: Pivotal Optimizer (GPORCA)
(5 rows)

```

## Compatibility

**CREATE AGGREGATE** is a Greenplum Database language extension. The SQL standard does not provide for user-defined aggregate functions.

## See Also

[ALTER AGGREGATE](#), [DROP AGGREGATE](#), [CREATE FUNCTION](#)

Parent topic: [SQL Commands](#)

## CREATE CAST

Defines a new cast.

## Synopsis

```

CREATE CAST (<sourcetype> AS <targettype>)
    WITH FUNCTION <funcname> (<argtype> [, ...])
    [AS ASSIGNMENT | AS IMPLICIT]

CREATE CAST (<sourcetype> AS <targettype>)
    WITHOUT FUNCTION
    [AS ASSIGNMENT | AS IMPLICIT]

CREATE CAST (<sourcetype> AS <targettype>)
    WITH INOUT
    [AS ASSIGNMENT | AS IMPLICIT]

```

## Description

**CREATE CAST** defines a new cast. A cast specifies how to perform a conversion between two data types. For example,

```
SELECT CAST(42 AS float8);
```

converts the integer constant `42` to type `float8` by invoking a previously specified function, in this case `float8(int4)`. If no suitable cast has been defined, the conversion fails.

Two types may be binary coercible, which means that the types can be converted into one another without invoking any function. This requires that corresponding values use the same internal representation. For instance, the types `text` and `varchar` are binary coercible in both directions. Binary coercibility is not necessarily a symmetric relationship. For example, the cast from `xml` to `text` can be performed for free in the present implementation, but the reverse direction requires a function that performs at least a syntax check. (Two types that are binary coercible both ways are also referred to as binary compatible.)

You can define a cast as an *I/O conversion cast* by using the `WITH INOUT` syntax. An I/O conversion cast is performed by invoking the output function of the source data type, and passing the resulting string to the input function of the target data type. In many common cases, this feature avoids the need to write a separate cast function for conversion. An I/O conversion cast acts the same as a regular function-based cast; only the implementation is different.

By default, a cast can be invoked only by an explicit cast request, that is an explicit `CAST(x AS typename)` or `x:: typename` construct.

If the cast is marked `AS ASSIGNMENT` then it can be invoked implicitly when assigning a value to a column of the target data type. For example, supposing that `foo.f1` is a column of type `text`, then:

```
INSERT INTO foo (f1) VALUES (42);
```

will be allowed if the cast from type `integer` to type `text` is marked `AS ASSIGNMENT`, otherwise not. The term *assignment cast* is typically used to describe this kind of cast.

If the cast is marked `AS IMPLICIT` then it can be invoked implicitly in any context, whether assignment or internally in an expression. The term *implicit cast* is typically used to describe this kind of cast. For example, consider this query:

```
SELECT 2 + 4.0;
```

The parser initially marks the constants as being of type `integer` and `numeric`, respectively. There is no `integer + numeric` operator in the system catalogs, but there is a `numeric + numeric` operator. This query succeeds if a cast from `integer` to `numeric` exists (it does) and is marked `AS IMPLICIT`, which in fact it is. The parser applies only the implicit cast and resolves the query as if it had been written as the following:

```
SELECT CAST ( 2 AS numeric ) + 4.0;
```

The catalogs also provide a cast from `numeric` to `integer`. If that cast were marked `AS IMPLICIT`, which it is not, then the parser would be faced with choosing between the above interpretation and the alternative of casting the `numeric` constant to `integer` and applying the `integer + integer` operator. Lacking any knowledge of which choice to prefer, the parser would give up and declare the query ambiguous. The fact that only one of the two casts is implicit is the way in which we teach the parser to prefer resolution of a mixed `numeric-and-integer` expression as `numeric`; the parser has no built-in knowledge about that.

It is wise to be conservative about marking casts as implicit. An overabundance of implicit casting paths can cause Greenplum Database to choose surprising interpretations of commands, or to be unable to resolve commands at all because there are multiple possible interpretations. A good general rule is to make a cast implicitly invocable only for information-preserving transformations

between types in the same general type category. For example, the cast from `int2` to `int4` can reasonably be implicit, but the cast from `float8` to `int4` should probably be assignment-only. Cross-type-category casts, such as `text` to `int4`, are best made explicit-only.

**Note:** Sometimes it is necessary for usability or standards-compliance reasons to provide multiple implicit casts among a set of types, resulting in ambiguity that cannot be avoided as described above. The parser uses a fallback heuristic based on type categories and preferred types that helps to provide desired behavior in such cases. See [CREATE TYPE](#) for more information.

To be able to create a cast, you must own the source or the target data type and have `USAGE` privilege on the other type. To create a binary-coercible cast, you must be superuser. (This restriction is made because an erroneous binary-coercible cast conversion can easily crash the server.)

## Parameters

`sourcetype`

The name of the source data type of the cast.

`targettype`

The name of the target data type of the cast.

`funcname(argtype [, ...])`

The function used to perform the cast. The function name may be schema-qualified. If it is not, Greenplum Database looks for the function in the schema search path. The function's result data type must match the target type of the cast.

Cast implementation functions may have one to three arguments. The first argument type must be identical to or binary-coercible from the cast's source type. The second argument, if present, must be type `integer`; it receives the type modifier associated with the destination type, or `-1` if there is none. The third argument, if present, must be type `boolean`; it receives `true` if the cast is an explicit cast, `false` otherwise. The SQL specification demands different behaviors for explicit and implicit casts in some cases. This argument is supplied for functions that must implement such casts. It is not recommended that you design your own data types this way.

The return type of a cast function must be identical to or binary-coercible to the cast's target type.

Ordinarily a cast must have different source and target data types. However, you are permitted to declare a cast with identical source and target types if it has a cast implementation function that takes more than one argument. This is used to represent type-specific length coercion functions in the system catalogs. The named function is used to coerce a value of the type to the type modifier value given by its second argument.

When a cast has different source and target types and a function that takes more than one argument, the cast converts from one type to another and applies a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

A cast to or from a domain type currently has no effect. Casting to or from a domain uses the casts associated with its underlying type.

WITHOUT FUNCTION

Indicates that the source type is binary-coercible to the target type, so no function is required to perform the cast.

#### WITH INOUT

Indicates that the cast is an I/O conversion cast, performed by invoking the output function of the source data type, and passing the resulting string to the input function of the target data type.

#### AS ASSIGNMENT

Indicates that the cast may be invoked implicitly in assignment contexts.

#### AS IMPLICIT

Indicates that the cast may be invoked implicitly in any context.

## Notes

Note that in this release of Greenplum Database, user-defined functions used in a user-defined cast must be defined as `IMMUTABLE`. Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your Greenplum Database array (master and all segments). This location must also be in the `LD_LIBRARY_PATH` so that the server can locate the files.

Remember that if you want to be able to convert types both ways you need to declare casts both ways explicitly.

It is normally not necessary to create casts between user-defined types and the standard string types (`text`, `varchar`, and `char(*n*)`), as well as user-defined types that are defined to be in the string category). Greenplum Database provides automatic I/O conversion casts for these. The automatic casts to string types are treated as assignment casts, while the automatic casts from string types are explicit-only. You can override this behavior by declaring your own cast to replace an automatic cast, but usually the only reason to do so is if you want the conversion to be more easily invocable than the standard assignment-only or explicit-only setting. Another possible reason is that you want the conversion to behave differently from the type's I/O function - think twice before doing this. (A small number of the built-in types do indeed have different behaviors for conversions, mostly because of requirements of the SQL standard.)

It is recommended that you follow the convention of naming cast implementation functions after the target data type, as the built-in cast implementation functions are named. Many users are used to being able to cast data types using a function-style notation, that is `typename(x)`.

There are two cases in which a function-call construct is treated as a cast request without having matched it to an actual function. If a function call `*name\(x\)` does not exactly match any existing function, but `*name*` is the name of a data type and `pg_cast` provides a binary-coercible cast to this type from the type of `*x*`, then the call will be construed as a binary-coercible cast. Greenplum Database makes this exception so that binary-coercible casts can be invoked using functional syntax, even though they lack any function. Likewise, if there is no `pg_cast` entry but the cast would be to or from a string type, the call is construed as an I/O conversion cast. This exception allows I/O conversion casts to be invoked using functional syntax.

There is an exception to the exception above: I/O conversion casts from composite types to string types cannot be invoked using functional syntax, but must be written in explicit cast syntax (either `CAST` or `::` notation). This exception exists because after the introduction of automatically-provided I/O conversion casts, it was found to be too easy to accidentally invoke such a cast when you intended a function or column reference.

## Examples

To create an assignment cast from type `bigint` to type `int4` using the function `int4(bigint)` (This cast is already predefined in the system.):

```
CREATE CAST (bigint AS int4) WITH FUNCTION int4(bigint) AS ASSIGNMENT;
```

## Compatibility

The `CREATE CAST` command conforms to the SQL standard, except that SQL does not make provisions for binary-coercible types or extra arguments to implementation functions. `AS IMPLICIT` is a Greenplum Database extension, too.

## See Also

[CREATE FUNCTION](#), [CREATE TYPE](#), [DROP CAST](#)

Parent topic: [SQL Commands](#)

## CREATE COLLATION

Defines a new collation using the specified operating system locale settings, or by copying an existing collation.

## Synopsis

```
CREATE COLLATION <name> (
    [ LOCALE = <locale>, ]
    [ LC_COLLATE = <lc_collate>, ]
    [ LC_CTYPE = <lc_ctype> ])

CREATE COLLATION <name> FROM <existing_collation>
```

## Description

To be able to create a collation, you must have `CREATE` privilege on the destination schema.

## Parameters

`name`

The name of the collation. The collation name can be schema-qualified. If it is not, the collation is defined in the current schema. The collation name must be unique within that schema. (The system catalogs can contain collations with the same name for other encodings, but these are ignored if the database encoding does not match.)

`locale`

This is a shortcut for setting `LC_COLLATE` and `LC_CTYPE` at once. If you specify this, you cannot specify either of those parameters.

`lc_collate`

Use the specified operating system locale for the `LC_COLLATE` locale category. The locale must be applicable to the current database encoding. (See [CREATE DATABASE](#) for the precise rules.)

`lc_ctype`

Use the specified operating system locale for the `LC_CTYPE` locale category. The locale must be applicable to the current database encoding. (See [CREATE DATABASE](#) for the precise rules.)

`existing_collation`

The name of an existing collation to copy. The new collation will have the same properties as the existing one, but it will be an independent object.

## Notes

To be able to create a collation, you must have `CREATE` privilege on the destination schema.

Use `DROP COLLATION` to remove user-defined collations.

See [Collation Support](#) in the PostgreSQL documentation for more information about collation support in Greenplum Database.

## Examples

To create a collation from the operating system locale `fr_FR.utf8` (assuming the current database encoding is `UTF8`):

```
CREATE COLLATION french (LOCALE = 'fr_FR.utf8');
```

To create a collation from an existing collation:

```
CREATE COLLATION german FROM "de_DE";
```

This can be convenient to be able to use operating-system-independent collation names in applications.

## Compatibility

There is a `CREATE COLLATION` statement in the SQL standard, but it is limited to copying an existing collation. The syntax to create a new collation is a Greenplum Database extension.

## See Also

[ALTER COLLATION](#), [DROP COLLATION](#)

Parent topic: [SQL Commands](#)

## CREATE CONVERSION

Defines a new encoding conversion.

## Synopsis

```
CREATE [DEFAULT] CONVERSION <name> FOR <source_encoding> TO
    <dest_encoding> FROM <funcname>
```

## Description

`CREATE CONVERSION` defines a new conversion between character set encodings. Conversion names may be used in the `convert` function to specify a particular encoding conversion. Also, conversions that are marked `DEFAULT` can be used for automatic encoding conversion between client and server. For this purpose, two conversions, from encoding A to B and from encoding B to A, must be defined.

To create a conversion, you must have `EXECUTE` privilege on the function and `CREATE` privilege on the destination schema.

## Parameters

### DEFAULT

Indicates that this conversion is the default for this particular source to destination encoding. There should be only one default encoding in a schema for the encoding pair.

### name

The name of the conversion. The conversion name may be schema-qualified. If it is not, the conversion is defined in the current schema. The conversion name must be unique within a schema.

### source\_encoding

The source encoding name.

### dest\_encoding

The destination encoding name.

### funcname

The function used to perform the conversion. The function name may be schema-qualified. If it is not, the function will be looked up in the path. The function must have the following signature:

```
conv_proc(
integer, -- source encoding ID
integer, -- destination encoding ID
cstring, -- source string (null terminated C string)
internal, -- destination (fill with a null terminated C string)
integer -- source string length
) RETURNS void;
```

## Notes

Note that in this release of Greenplum Database, user-defined functions used in a user-defined conversion must be defined as `IMMUTABLE`. Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your Greenplum Database array

(master and all segments). This location must also be in the `LD_LIBRARY_PATH` so that the server can locate the files.

## Examples

To create a conversion from encoding `UTF8` to `LATIN1` using `myfunc`:

```
CREATE CONVERSION myconv FOR 'UTF8' TO 'LATIN1' FROM myfunc;
```

## Compatibility

There is no `CREATE CONVERSION` statement in the SQL standard, but there is a `CREATE TRANSLATION` statement that is very similar in purpose and syntax.

## See Also

[ALTER CONVERSION](#), [CREATE FUNCTION](#), [DROP CONVERSION](#)

Parent topic: [SQL Commands](#)

## CREATE DATABASE

Creates a new database.

## Synopsis

```
CREATE DATABASE name [ [WITH] [OWNER [=] <user_name>]
                    [TEMPLATE [=] <template>]
                    [ENCODING [=] <encoding>]
                    [LC_COLLATE [=] <lc_collate>]
                    [LC_CTYPE [=] <lc_ctype>]
                    [TABLESPACE [=] <tablespace>]
                    [CONNECTION LIMIT [=] connlimit ] ]
```

## Description

`CREATE DATABASE` creates a new database. To create a database, you must be a superuser or have the special `CREATEDB` privilege.

The creator becomes the owner of the new database by default. Superusers can create databases owned by other users by using the `OWNER` clause. They can even create databases owned by users with no special privileges. Non-superusers with `CREATEDB` privilege can only create databases owned by themselves.

By default, the new database will be created by cloning the standard system database `template1`. A different template can be specified by writing `TEMPLATE name`. In particular, by writing `TEMPLATE template0`, you can create a clean database containing only the standard objects predefined by Greenplum Database. This is useful if you wish to avoid copying any installation-local objects that may have been added to `template1`.

## Parameters

name

The name of a database to create.

user\_name

The name of the database user who will own the new database, or `DEFAULT` to use the default owner (the user running the command).

template

The name of the template from which to create the new database, or `DEFAULT` to use the default template (template1).

encoding

Character set encoding to use in the new database. Specify a string constant (such as `'SQL_ASCII'`), an integer encoding number, or `DEFAULT` to use the default encoding. For more information, see [Character Set Support](#).

lc\_collate

The collation order (`LC_COLLATE`) to use in the new database. This affects the sort order applied to strings, e.g. in queries with `ORDER BY`, as well as the order used in indexes on text columns. The default is to use the collation order of the template database. See the Notes section for additional restrictions.

lc\_ctype

The character classification (`LC_CTYPE`) to use in the new database. This affects the categorization of characters, e.g. lower, upper and digit. The default is to use the character classification of the template database. See below for additional restrictions.

tablespace

The name of the tablespace that will be associated with the new database, or `DEFAULT` to use the template database's tablespace. This tablespace will be the default tablespace used for objects created in this database.

conlimit

The maximum number of concurrent connections possible. The default of -1 means there is no limitation.

## Notes

`CREATE DATABASE` cannot be run inside a transaction block.

When you copy a database by specifying its name as the template, no other sessions can be connected to the template database while it is being copied. New connections to the template database are locked out until `CREATE DATABASE` completes.

The `CONNECTION LIMIT` is not enforced against superusers.

The character set encoding specified for the new database must be compatible with the chosen locale settings (`LC_COLLATE` and `LC_CTYPE`). If the locale is `C` (or equivalently `POSIX`), then all encodings are allowed, but for other locale settings there is only one encoding that will work properly. `CREATE DATABASE` will allow superusers to specify `SQL_ASCII` encoding regardless of the locale settings, but this choice is deprecated and may result in misbehavior of character-string functions if data that is not encoding-compatible with the locale is stored in the database.

The encoding and locale settings must match those of the template database, except when `template0` is used as template. This is because `COLLATE` and `CTYPE` affect the ordering in indexes, so

that any indexes copied from the template database would be invalid in the new database with different settings. `template0`, however, is known to not contain any data or indexes that would be affected.

## Examples

To create a new database:

```
CREATE DATABASE gpdb;
```

To create a database `sales` owned by user `salesapp` with a default tablespace of `salesspace`:

```
CREATE DATABASE sales OWNER salesapp TABLESPACE salesspace;
```

To create a database `music` which supports the ISO-8859-1 character set:

```
CREATE DATABASE music ENCODING 'LATIN1' TEMPLATE template0;
```

In this example, the `TEMPLATE template0` clause would only be required if `template1`'s encoding is not ISO-8859-1. Note that changing encoding might require selecting new `LC_COLLATE` and `LC_CTYPE` settings as well.

## Compatibility

There is no `CREATE DATABASE` statement in the SQL standard. Databases are equivalent to catalogs, whose creation is implementation-defined.

## See Also

[ALTER DATABASE, DROP DATABASE](#)

Parent topic: [SQL Commands](#)

## CREATE DOMAIN

Defines a new domain.

## Synopsis

```
CREATE DOMAIN <name> [AS] <data_type> [DEFAULT <expression>]
    [ COLLATE <collation> ]
    [ CONSTRAINT <constraint_name>
    | NOT NULL | NULL
    | CHECK (<expression>) [...]]
```

## Description

`CREATE DOMAIN` creates a new domain. A domain is essentially a data type with optional constraints (restrictions on the allowed set of values). The user who defines a domain becomes its owner. The

domain name must be unique among the data types and domains existing in its schema.

If a schema name is given (for example, `CREATE DOMAIN myschema.mydomain ...`) then the domain is created in the specified schema. Otherwise it is created in the current schema.

Domains are useful for abstracting common constraints on fields into a single location for maintenance. For example, several tables might contain email address columns, all requiring the same `CHECK` constraint to verify the address syntax. It is easier to define a domain rather than setting up a column constraint for each table that has an email column.

To be able to create a domain, you must have `USAGE` privilege on the underlying type.

## Parameters

**name**

The name (optionally schema-qualified) of a domain to be created.

**data\_type**

The underlying data type of the domain. This may include array specifiers.

**DEFAULT expression**

Specifies a default value for columns of the domain data type. The value is any variable-free expression (but subqueries are not allowed). The data type of the default expression must match the data type of the domain. If no default value is specified, then the default value is the null value. The default expression will be used in any insert operation that does not specify a value for the column. If a default value is defined for a particular column, it overrides any default associated with the domain. In turn, the domain default overrides any default value associated with the underlying data type.

**COLLATE collation**

An optional collation for the domain. If no collation is specified, the underlying data type's default collation is used. The underlying type must be collatable if `COLLATE` is specified.

**CONSTRAINT constraint\_name**

An optional name for a constraint. If not specified, the system generates a name.

**NOT NULL**

Values of this domain are normally prevented from being null. However, it is still possible for a domain with this constraint to take a null value if it is assigned a matching domain type that has become null, e.g. via a left outer join, or a command such as `INSERT INTO tab (domcol) VALUES ((SELECT domcol FROM tab WHERE false))`.

**NULL**

Values of this domain are allowed to be null. This is the default. This clause is only intended for compatibility with nonstandard SQL databases. Its use is discouraged in new applications.

**CHECK (expression)**

`CHECK` clauses specify integrity constraints or tests which values of the domain must satisfy. Each constraint must be an expression producing a Boolean result. It should use the key word `VALUE` to refer to the value being tested. Currently, `CHECK` expressions cannot contain subqueries nor refer to variables other than `VALUE`.

## Examples

Create the `us_zip_code` data type. A regular expression test is used to verify that the value looks like a valid US zip code.

```
CREATE DOMAIN us_zip_code AS TEXT CHECK
  ( VALUE ~ '^\\d{5}$' OR VALUE ~ '^\\d{5}-\\d{4}$' );
```

## Compatibility

`CREATE DOMAIN` conforms to the SQL standard.

## See Also

[ALTER DOMAIN](#), [DROP DOMAIN](#)

## CREATE EXTENSION

Registers an extension in a Greenplum database.

## Synopsis

```
CREATE EXTENSION [ IF NOT EXISTS ] <extension_name>
  [ WITH ] [ SCHEMA <schema_name> ]
  [ VERSION <version> ]
  [ FROM <old_version> ]
  [ CASCADE ]
```

## Description

`CREATE EXTENSION` loads a new extension into the current database. There must not be an extension of the same name already loaded.

Loading an extension essentially amounts to running the extension script file. The script typically creates new SQL objects such as functions, data types, operators and index support methods. The `CREATE EXTENSION` command also records the identities of all the created objects, so that they can be dropped again if `DROP EXTENSION` is issued.

Loading an extension requires the same privileges that would be required to create the component extension objects. For most extensions this means superuser or database owner privileges are required. The user who runs `CREATE EXTENSION` becomes the owner of the extension for purposes of later privilege checks, as well as the owner of any objects created by the extension script.

## Parameters

### IF NOT EXISTS

Do not throw an error if an extension with the same name already exists. A notice is issued in this case. There is no guarantee that the existing extension is similar to the extension that would have been installed.

`extension_name`

The name of the extension to be installed. The name must be unique within the database. An extension is created from the details in the extension control file `SHAREDIR/extension/extension\_name.control`.

SHAREDIR is the installation shared-data directory, for example `/usr/local/greenplum-db/share/postgresql`. The command `pg_config --sharedir` displays the directory.

#### SCHEMA `schema_name`

The name of the schema in which to install the extension objects. This assumes that the extension allows its contents to be relocated. The named schema must already exist. If not specified, and the extension control file does not specify a schema, the current default object creation schema is used.

If the extension specifies a schema parameter in its control file, then that schema cannot be overridden with a `SCHEMA` clause. Normally, an error is raised if a `SCHEMA` clause is given and it conflicts with the extension schema parameter. However, if the `CASCADE` clause is also given, then `schema_name` is ignored when it conflicts. The given `schema_name` is used for the installation of any needed extensions that do not specify a schema in their control files.

The extension itself is not within any schema. Extensions have unqualified names that must be unique within the database. But objects belonging to the extension can be within a schema.

#### VERSION `version`

The version of the extension to install. This can be written as either an identifier or a string literal. The default version is value that is specified in the extension control file.

#### FROM `old_version`

Specify `FROM old\_version` only if you are attempting to install an extension that replaces an *old-style* module that is a collection of objects that is not packaged into an extension. If specified, `CREATE EXTENSION` runs an alternative installation script that absorbs the existing objects into the extension, instead of creating new objects. Ensure that `SCHEMA` clause specifies the schema containing these pre-existing objects.

The value to use for `old_version` is determined by the extension author, and might vary if there is more than one version of the old-style module that can be upgraded into an extension. For the standard additional modules supplied with pre-9.1 PostgreSQL, specify `unpackaged` for the `old_version` when updating a module to extension style.

#### CASCADE

Automatically install dependent extensions are not already installed. Dependent extensions are checked recursively and those dependencies are also installed automatically. If the `SCHEMA` clause is specified, the schema applies to the extension and all dependent extensions that are installed. Other options that are specified are not applied to the automatically-installed dependent extensions. In particular, default versions are always selected when installing dependent extensions.

## Notes

The extensions currently available for loading can be identified from the `pg_available_extensions` or `pg_available_extension_versions` system views.

Before you use `CREATE EXTENSION` to load an extension into a database, the supporting extension files must be installed including an extension control file and at least one SQL script file. The support files must be installed in the same location on all Greenplum Database hosts. For information about creating new extensions, see PostgreSQL information about [Packaging Related Objects into an Extension](#).

## Compatibility

`CREATE EXTENSION` is a Greenplum Database extension.

  [ ENCODING '<write_encoding>' ]
  [ DISTRIBUTED BY ({<column> [<opclass>]}, [ ... ] ) | DISTRIBUTED RANDOMLY ]

```

## Description

`CREATE EXTERNAL TABLE` or `CREATE EXTERNAL WEB TABLE` creates a new readable external table definition in Greenplum Database. Readable external tables are typically used for fast, parallel data loading. Once an external table is defined, you can query its data directly (and in parallel) using SQL commands. For example, you can select, join, or sort external table data. You can also create views for external tables. DML operations (`UPDATE`, `INSERT`, `DELETE`, or `TRUNCATE`) are not allowed on readable external tables, and you cannot create indexes on readable external tables.

`CREATE WRITABLE EXTERNAL TABLE` or `CREATE WRITABLE EXTERNAL WEB TABLE` creates a new writable external table definition in Greenplum Database. Writable external tables are typically used for unloading data from the database into a set of files or named pipes. Writable external web tables can also be used to output data to an executable program. Writable external tables can also be used as output targets for Greenplum parallel MapReduce calculations. Once a writable external table is defined, data can be selected from database tables and inserted into the writable external table. Writable external tables only allow `INSERT` operations – `SELECT`, `UPDATE`, `DELETE` or `TRUNCATE` are not allowed.

The main difference between regular external tables and external web tables is their data sources. Regular readable external tables access static flat files, whereas external web tables access dynamic data sources – either on a web server or by running OS commands or scripts.

See [Working with External Data](#) for detailed information about working with external tables.

## Parameters

READABLE | WRITABLE

Specifies the type of external table, readable being the default. Readable external tables are used for loading data into Greenplum Database. Writable external tables are used for unloading data.

## WEB

Creates a readable or writable external web table definition in Greenplum Database. There are two forms of readable external web tables – those that access files via the `http://` protocol or those that access data by running OS commands. Writable external web tables output data to an executable program that can accept an input stream of data. External web tables are not rescannable during query execution.

The `s3` protocol does not support external web tables. You can, however, create an external web table that runs a third-party tool to read data from or write data to S3 directly.

## TEMPORARY | TEMP

If specified, creates a temporary readable or writable external table definition in Greenplum Database. Temporary external tables exist in a special schema; you cannot specify a schema name when you create the table. Temporary external tables are automatically dropped at the end of a session.

An existing permanent table with the same name is not visible to the current session while the temporary table exists, unless you reference the permanent table with its schema-qualified name.

### table\_name

The name of the new external table.

### column\_name

The name of a column to create in the external table definition. Unlike regular tables, external tables do not have column constraints or default values, so do not specify those.

### LIKE other\_table

The `LIKE` clause specifies a table from which the new external table automatically copies all column names, data types and Greenplum distribution policy. If the original table specifies any column constraints or default column values, those will not be copied over to the new external table definition.

### data\_type

The data type of the column.

### LOCATION ('protocol://[host[:port]]/path/file' [, ...])

If you use the `pxf` protocol to access an external data source, refer to [pxf:// Protocol](#) for information about the `pxf` protocol.

If you use the `s3` protocol to read or write to S3, refer to [s3:// Protocol](#) for additional information about the `s3` protocol `LOCATION` clause syntax.

For readable external tables, specifies the URI of the external data source(s) to be used to populate the external table or web table. Regular readable external tables allow the `gpfdist` or `file` protocols. External web tables allow the `http` protocol. If `port` is omitted, port `8080` is assumed for `http` and `gpfdist` protocols. If using the `gpfdist` protocol, the `path` is relative to the directory from which `gpfdist` is serving files (the directory specified when you started the `gpfdist` program). Also, `gpfdist` can use wildcards or other C-style pattern matching (for example, a whitespace character is `[:space:]`) to denote multiple files in a directory. For example:

```
'gpfdist://filehost:8081/*'
'gpfdist://masterhost/my_load_file'
'file://segghost1/dbfast1/external/myfile.txt'
'http://intranet.example.com/finance/expenses.csv'
```

For writable external tables, specifies the URI location of the `gpfdist` process or S3 protocol that will collect data output from the Greenplum segments and write it to one or more named files. For `gpfdist` the `path` is relative to the directory from which `gpfdist` is serving files (the directory specified when you started the `gpfdist` program). If multiple `gpfdist` locations are listed, the segments sending data will be evenly divided across the available output locations. For example:

```
'gpfdist://outputhost:8081/data1.out',
'gpfdist://outputhost:8081/data2.out'
```

With two `gpfdist` locations listed as in the above example, half of the segments would send their output data to the `data1.out` file and the other half to the `data2.out` file.

With the option `#transform=trans\_name`, you can specify a transform to apply when loading or extracting data. The `trans\_name` is the name of the transform in the YAML configuration file you specify with the you run the `gpfdist` utility. For information about specifying a transform, see `gpfdist` in the *Greenplum Utility Guide*.

## ON MASTER

Restricts all table-related operations to the Greenplum master segment. Permitted only on readable and writable external tables created with the `s3` or custom protocols. The `gpfdist`, `gpfdists`, `pxf`, and `file` protocols do not support `ON MASTER`.

**Note:** Be aware of potential resource impacts when reading from or writing to external tables you create with the `ON MASTER` clause. You may encounter performance issues when you restrict table operations solely to the Greenplum master segment.

## EXECUTE 'command' [ON ...]

Allowed for readable external web tables or writable external tables only. For readable external web tables, specifies the OS command to be run by the segment instances. The command can be a single OS command or a script. The `ON` clause is used to specify which segment instances will run the given command.

- `ON ALL` is the default. The command will be run by every active (primary) segment instance on all segment hosts in the Greenplum Database system. If the command runs a script, that script must reside in the same location on all of the segment hosts and be executable by the Greenplum superuser (`gpadmin`).
- `ON MASTER` runs the command on the master host only.

```
**Note:** Logging is not supported for external web tables when the `ON MASTER` c
lause is specified.
```

- `ON number` means the command will be run by the specified number of segments. The particular segments are chosen randomly at runtime by the Greenplum Database system. If the command runs a script, that script must reside in the same location on all of the segment hosts and be executable by the Greenplum superuser (`gpadmin`).

- HOST means the command will be run by one segment on each segment host (once per segment host), regardless of the number of active segment instances per host.
- HOST segment\_hostname means the command will be run by all active (primary) segment instances on the specified segment host.
- SEGMENT segment\_id means the command will be run only once by the specified segment. You can determine a segment instance's ID by looking at the content number in the system catalog table `gp_segment_configuration`. The content ID of the Greenplum Database master is always `-1`.

For writable external tables, the command specified in the `EXECUTE` clause must be prepared to have data piped into it. Since all segments that have data to send will write their output to the specified command or program, the only available option for the `ON` clause is `ON ALL`.

#### FORMAT 'TEXT | CSV' (options)

When the `FORMAT` clause identifies delimited text (`TEXT`) or comma separated values (`CSV`) format, formatting options are similar to those available with the PostgreSQL `COPY` command. If the data in the file does not use the default column delimiter, escape character, null string and so on, you must specify the additional formatting options so that the data in the external file is read correctly by Greenplum Database. For information about using a custom format, see "Loading and Unloading Data" in the *Greenplum Database Administrator Guide*.

If you use the `pxf` protocol to access an external data source, refer to [Accessing External Data with PXF](#) for information about using PXF.

#### FORMAT 'CUSTOM' (formatter=formatter\_specification)

Specifies a custom data format. The `formatter_specification` specifies the function to use to format the data, followed by comma-separated parameters to the formatter function. The length of the formatter specification, the string including `Formatter=`, can be up to approximately 50K bytes.

If you use the `pxf` protocol to access an external data source, refer to [Accessing External Data with PXF](#) for information about using PXF.

For general information about using a custom format, see "Loading and Unloading Data" in the *Greenplum Database Administrator Guide*.

#### DELIMITER

Specifies a single ASCII character that separates columns within each row (line) of data. The default is a tab character in `TEXT` mode, a comma in `CSV` mode. In `TEXT` mode for readable external tables, the delimiter can be set to `OFF` for special use cases in which unstructured data is loaded into a single-column table.

For the `s3` protocol, the delimiter cannot be a newline character (`\n`) or a carriage return character (`\r`).

#### NULL

Specifies the string that represents a `NULL` value. The default is `\N` (backslash-N) in `TEXT` mode, and an empty value with no quotations in `CSV` mode. You might prefer an empty string even in `TEXT` mode for cases where you do not want to distinguish `NULL` values from empty strings. When using external and web tables, any data item that matches this string will be considered a `NULL` value.

As an example for the `text` format, this `FORMAT` clause can be used to specify that the string of two single quotes (`' '`) is a `NULL` value.

```
FORMAT 'text' (delimiter ',' null '\'\'' )
```

## ESCAPE

Specifies the single character that is used for C escape sequences (such as `\n`, `\t`, `\100`, and so on) and for escaping data characters that might otherwise be taken as row or column delimiters. Make sure to choose an escape character that is not used anywhere in your actual column data. The default escape character is a `\` (backslash) for text-formatted files and a `"` (double quote) for csv-formatted files, however it is possible to specify another character to represent an escape. It is also possible to deactivate escaping in text-formatted files by specifying the value `'OFF'` as the escape value. This is very useful for data such as text-formatted web log data that has many embedded backslashes that are not intended to be escapes.

## NEWLINE

Specifies the newline used in your data files – `LF` (Line feed, `0x0A`), `CR` (Carriage return, `0x0D`), or `CRLF` (Carriage return plus line feed, `0x0D 0x0A`). If not specified, a Greenplum Database segment will detect the newline type by looking at the first row of data it receives and using the first newline type encountered.

## HEADER

For readable external tables, specifies that the first line in the data file(s) is a header row (contains the names of the table columns) and should not be included as data for the table. If using multiple data source files, all files must have a header row.

For the `s3` protocol, the column names in the header row cannot contain a newline character (`\n`) or a carriage return (`\r`).

The `pxf` protocol does not support the `HEADER` formatting option.

## QUOTE

Specifies the quotation character for `CSV` mode. The default is double-quote (`"`).

## FORCE NOT NULL

In `CSV` mode, processes each specified column as though it were quoted and hence not a `NULL` value. For the default null string in `CSV` mode (nothing between two delimiters), this causes missing values to be evaluated as zero-length strings.

## FORCE QUOTE

In `CSV` mode for writable external tables, forces quoting to be used for all non-`NULL` values in each specified column. If `*` is specified then non-`NULL` values will be quoted in all columns. `NULL` output is never quoted.

## FILL MISSING FIELDS

In both `TEXT` and `CSV` mode for readable external tables, specifying `FILL MISSING FIELDS` will set missing trailing field values to `NULL` (instead of reporting an error) when a row of data has missing data fields at the end of a line or row. Blank rows, fields with a `NOT NULL` constraint, and trailing delimiters on a line will still report an error.

## ENCODING 'encoding'

Character set encoding to use for the external table. Specify a string constant (such as `'SQL_ASCII'`), an integer encoding number, or `DEFAULT` to use the default server encoding. See [Character Set Support](#).

## LOG ERRORS [PERSISTENTLY]

This is an optional clause that can precede a `SEGMENT REJECT LIMIT` clause to log information about rows with formatting errors. The error log data is stored internally. If error log data exists for a specified external table, new data is appended to existing error log data. The error log data is not replicated to mirror segments.

The data is deleted when the external table is dropped unless you specify the keyword `PERSISTENTLY`. If the keyword is specified, the log data persists after the external table is dropped.

The error log data is accessed with the Greenplum Database built-in SQL function `gp_read_error_log()`, or with the SQL function `gp_read_persistent_error_log()` if the `PERSISTENTLY` keyword is specified.

If you use the `PERSISTENTLY` keyword, you must install the functions that manage the persistent error log information.

See [Notes](#) for information about the error log information and built-in functions for viewing and managing error log information.

## SEGMENT REJECT LIMIT count [ROWS | PERCENT]

Runs a `COPY FROM` operation in single row error isolation mode. If the input rows have format errors they will be discarded provided that the reject limit count is not reached on any Greenplum segment instance during the load operation. The reject limit count can be specified as number of rows (the default) or percentage of total rows (1-100). If `PERCENT` is used, each segment starts calculating the bad row percentage only after the number of rows specified by the parameter `gp_reject_percent_threshold` has been processed. The default for `gp_reject_percent_threshold` is 300 rows. Constraint errors such as violation of a `NOT NULL`, `CHECK`, or `UNIQUE` constraint will still be handled in "all-or-nothing" input mode. If the limit is not reached, all good rows will be loaded and any error rows discarded.

**Note:** When reading an external table, Greenplum Database limits the initial number of rows that can contain formatting errors if the `SEGMENT REJECT LIMIT` is not triggered first or is not specified. If the first 1000 rows are rejected, the `COPY` operation is stopped and rolled back.

The limit for the number of initial rejected rows can be changed with the Greenplum Database server configuration parameter `gp_initial_bad_row_limit`. See [Server Configuration Parameters](#) for information about the parameter.

DISTRIBUTED BY ({column [opclass]}, [ ... ])

DISTRIBUTED RANDOMLY

Used to declare the Greenplum Database distribution policy for a writable external table. By default, writable external tables are distributed randomly. If the source table you are exporting data from has a hash distribution policy, defining the same distribution key column(s) and operator class(es), `opclass`, for the writable external table will improve unload performance by eliminating the need to move rows over the interconnect. When you issue an unload command such as `INSERT INTO wex\_table SELECT * FROM source\_table`, the rows that are unloaded can be sent directly from the segments to the output location if the two tables have the same hash distribution policy.

## Examples

Start the `gpfdist` file server program in the background on port `8081` serving files from directory `/var/data/staging`:

```
gpfdist -p 8081 -d /var/data/staging -l /home/<gpadmin>/log &
```

Create a readable external table named `ext_customer` using the `gpfdist` protocol and any text formatted files (`*.txt`) found in the `gpfdist` directory. The files are formatted with a pipe (`|`) as the column delimiter and an empty space as `NULL`. Also access the external table in single row error isolation mode:

```
CREATE EXTERNAL TABLE ext_customer
  (id int, name text, sponsor text)
  LOCATION ( 'gpfdist://filehost:8081/*.txt' )
  FORMAT 'TEXT' ( DELIMITER '|' NULL ' ' )
  LOG ERRORS SEGMENT REJECT LIMIT 5;
```

Create the same readable external table definition as above, but with CSV formatted files:

```
CREATE EXTERNAL TABLE ext_customer
  (id int, name text, sponsor text)
  LOCATION ( 'gpfdist://filehost:8081/*.csv' )
  FORMAT 'CSV' ( DELIMITER ',' );
```

Create a readable external table named `ext_expenses` using the `file` protocol and several CSV formatted files that have a header row:

```
CREATE EXTERNAL TABLE ext_expenses (name text, date date,
amount float4, category text, description text)
LOCATION (
'file://seghost1/dbfast/external/expenses1.csv',
'file://seghost1/dbfast/external/expenses2.csv',
'file://seghost2/dbfast/external/expenses3.csv',
'file://seghost2/dbfast/external/expenses4.csv',
'file://seghost3/dbfast/external/expenses5.csv',
'file://seghost3/dbfast/external/expenses6.csv'
)
FORMAT 'CSV' ( HEADER );
```

Create a readable external web table that runs a script once per segment host:

```
CREATE EXTERNAL WEB TABLE log_output (linenum int, message
text) EXECUTE '/var/load_scripts/get_log_data.sh' ON HOST
FORMAT 'TEXT' (DELIMITER '|');
```

Create a writable external table named `sales_out` that uses `gpfdist` to write output data to a file named `sales.out`. The files are formatted with a pipe (`|`) as the column delimiter and an empty space as `NULL`.

```
CREATE WRITABLE EXTERNAL TABLE sales_out (LIKE sales)
  LOCATION ('gpfdist://etl1:8081/sales.out')
  FORMAT 'TEXT' ( DELIMITER '|' NULL ' ' )
  DISTRIBUTED BY (txn_id);
```

Create a writable external web table that pipes output data received by the segments to an executable script named `to_adreport_etl.sh`:

```
CREATE WRITABLE EXTERNAL WEB TABLE campaign_out
(LIKE campaign)
EXECUTE '/var/unload_scripts/to_adreport_etl.sh'
FORMAT 'TEXT' (DELIMITER '|');
```

Use the writable external table defined above to unload selected data:

```
INSERT INTO campaign_out SELECT * FROM campaign WHERE
customer_id=123;
```

## Notes

When you specify the `LOG ERRORS` clause, Greenplum Database captures errors that occur while reading the external table data. For information about the error log format, see [Viewing Bad Rows in the Error Log](#).

You can view and manage the captured error log data. The functions to manage log data depend on whether the data is persistent (the `PERSISTENTLY` keyword is used with the `LOG ERRORS` clause).

- Functions that manage non-persistent error log data from external tables that were defined without the `PERSISTENTLY` keyword.
  - The built-in SQL function `gp_read_error_log('table_name')` displays error log information for an external table. This example displays the error log data from the external table `ext_expenses`.

```
SELECT * from gp_read_error_log('ext_expenses');
```

The function returns no data if you created the external table with the `LOG ERRORS PERSISTENTLY` clause, or if the external table does not exist.

- The built-in SQL function `gp_truncate_error_log('table_name')` deletes the error log data for `table_name`. This example deletes the error log data captured from the external table `ext_expenses`:

```
SELECT gp_truncate_error_log('ext_expenses');
```

Dropping the table also deletes the table's log data. The function does not truncate log data if the external table is defined with the `LOG ERRORS PERSISTENTLY` clause.

The function returns `FALSE` if the table does not exist.

- Functions that manage persistent error log data from external tables that were defined with the `PERSISTENTLY` keyword.

**Note:** The functions that manage persistent error log data from external tables are defined in the file `$GPHOME/share/postgresql/contrib/gpexterrorhandle.sql`. The functions must be installed in the databases that use persistent error log data from an external table. This `psql` command installs the functions into the database `testdb`.

```
psql -d test -U gpadmin -f $GPHOME/share/postgresql/contrib/gpexterrorhandle.sql
```

- o The SQL function `gp_read_persistent_error_log('table\_name')` displays persistent log data for an external table.  
The function returns no data if you created the external table without the `PERSISTENTLY` keyword. The function returns persistent log data for an external table even after the table has been dropped.
  - o The SQL function `gp_truncate_persistent_error_log('table\_name')` truncates persistent log data for a table.  
For persistent log data, you must manually delete the data. Dropping the external table does not delete persistent log data.
- These items apply to both non-persistent and persistent error log data and the related functions.
  - o The `gp_read_*` functions require `SELECT` privilege on the table.
  - o The `gp_truncate_*` functions require owner privilege on the table.
  - o You can use the `*` wildcard character to delete error log information for existing tables in the current database. Specify the string `*.*` to delete all database error log information, including error log information that was not deleted due to previous database issues. If `*` is specified, database owner privilege is required. If `*.*` is specified, operating system super-user privilege is required. Non-persistent and persistent error log data must be deleted with their respective `gp_truncate_*` functions.

When multiple Greenplum Database external tables are defined with the `gpfdist`, `gpfdists`, or `file` protocol and access the same named pipe a Linux system, Greenplum Database restricts access to the named pipe to a single reader. An error is returned if a second reader attempts to access the named pipe.

## Compatibility

`CREATE EXTERNAL TABLE` is a Greenplum Database extension. The SQL standard makes no provisions for external tables.

## CREATE FOREIGN DATA WRAPPER

Defines a new foreign-data wrapper.

## Synopsis

```
CREATE FOREIGN DATA WRAPPER <name>
  [ HANDLER <handler_function> | NO HANDLER ]
  [ VALIDATOR <validator_function> | NO VALIDATOR ]
  [ OPTIONS ( [ mpp_execute { 'master' | 'any' | 'all segments' } [, ] ] <option> '<
value>' [, ... ] ) ]
```

## Description

`CREATE FOREIGN DATA WRAPPER` creates a new foreign-data wrapper in the current database. The user who defines the foreign-data wrapper becomes its owner.

Only superusers can create foreign-data wrappers.

## Parameters

name

The name of the foreign-data wrapper to create. The name must be unique within the database.

HANDLER handler\_function

The name of a previously registered function that Greenplum Database calls to retrieve the execution functions for foreign tables. handler\_function must take no arguments, and its return type must be `fdw_handler`.

It is possible to create a foreign-data wrapper with no handler function, but you can only declare, not access, foreign tables using such a wrapper.

VALIDATOR validator\_function

The name of a previously registered function that Greenplum Database calls to check the options provided to the foreign-data wrapper. This function also checks the options for foreign servers, user mappings, and foreign tables that use the foreign-data wrapper. If no validator function or `NO VALIDATOR` is specified, Greenplum Database does not check options at creation time. (Depending upon the implementation, foreign-data wrappers may ignore or reject invalid options at runtime.)

validator\_function must take two arguments: one of type `text[]`, which contains the array of options as stored in the system catalogs, and one of type `oid`, which identifies the OID of the system catalog containing the options.

The return type is ignored; validator\_function should report invalid options using the `ereport(ERROR)` function.

OPTIONS ( option 'value' [, ... ] )

The options for the new foreign-data wrapper. Option names must be unique. The option names and values are foreign-data wrapper-specific and are validated using the foreign-data wrappers' validator\_function.

mpp\_execute { 'master' | 'any' | 'all segments' }

An option that identifies the host from which the foreign-data wrapper reads or writes data:

- `master` (the default)—Read or write data from the master host.

- `any`—Read data from either the master host or any one segment, depending on which path costs less.
- `all segments`—Read or write data from all segments. To support this option value, the foreign-data wrapper must have a policy that matches the segments to data.

**Note:** Greenplum Database supports parallel writes to foreign tables only when you set `mpp_execute 'all segments'`.

Support for the foreign-data wrapper `mpp_execute` option, and the specific modes, is foreign-data wrapper-specific.

The `mpp_execute` option can be specified in multiple commands: `CREATE FOREIGN TABLE`, `CREATE SERVER`, and `CREATE FOREIGN DATA WRAPPER`. The foreign table setting takes precedence over the foreign server setting, followed by the foreign-data wrapper setting.

## Notes

The foreign-data wrapper functionality is still under development. Optimization of queries is primitive (and mostly left to the wrapper).

## Examples

Create a useless foreign-data wrapper named `dummy`:

```
CREATE FOREIGN DATA WRAPPER dummy;
```

Create a foreign-data wrapper named `file` with a handler function named `file_fdw_handler`:

```
CREATE FOREIGN DATA WRAPPER file HANDLER file_fdw_handler;
```

Create a foreign-data wrapper named `mywrapper` that includes an option:

```
CREATE FOREIGN DATA WRAPPER mywrapper OPTIONS (debug 'true');
```

## Compatibility

`CREATE FOREIGN DATA WRAPPER` conforms to ISO/IEC 9075-9 (SQL/MED), with the exception that the `HANDLER` and `VALIDATOR` clauses are extensions, and the standard clauses `LIBRARY` and `LANGUAGE` are not implemented in Greenplum Database.

Note, however, that the SQL/MED functionality as a whole is not yet conforming.

# CREATE FOREIGN TABLE

Defines a new foreign table.

## Synopsis

```
CREATE FOREIGN TABLE [ IF NOT EXISTS ] <table_name> ( [
    <column_name> <data_type> [ OPTIONS ( <option> '<value>' [, ... ] ) ] [ COLLATE <c
ollation> ] [ <column_constraint> [ ... ] ]
    [, ... ]
] )
    SERVER <server_name>
    [ OPTIONS ( [ mpp_execute { 'master' | 'any' | 'all segments' } [, ] ] <option> '<va
lue>' [, ... ] ) ]
```

where `column_constraint` is:

```
[ CONSTRAINT <constraint_name> ]
{ NOT NULL |
  NULL |
  DEFAULT <default_expr> }
```

## Description

`CREATE FOREIGN TABLE` creates a new foreign table in the current database. The user who creates the foreign table becomes its owner.

If you schema-qualify the table name (for example, `CREATE FOREIGN TABLE myschema.mytable ...`), Greenplum Database creates the table in the specified schema. Otherwise, the foreign table is created in the current schema. The name of the foreign table must be distinct from the name of any other foreign table, table, sequence, index, or view in the same schema.

Because `CREATE FOREIGN TABLE` automatically creates a data type that represents the composite type corresponding to one row of the foreign table, foreign tables cannot have the same name as any existing data type in the same schema.

To create a foreign table, you must have `USAGE` privilege on the foreign server, as well as `USAGE` privilege on all column types used in the table.

## Parameters

### IF NOT EXISTS

Do not throw an error if a relation with the same name already exists. Greenplum Database issues a notice in this case. Note that there is no guarantee that the existing relation is anything like the one that would have been created.

### table\_name

The name (optionally schema-qualified) of the foreign table to create.

### column\_name

The name of a column to create in the new foreign table.

### data\_type

The data type of the column, including array specifiers.

#### NOT NULL

The column is not allowed to contain null values.

#### NULL

The column is allowed to contain null values. This is the default.

This clause is provided only for compatibility with non-standard SQL databases. Its use is discouraged in new applications.

#### DEFAULT default\_expr

The `DEFAULT` clause assigns a default value for the column whose definition it appears within. The value is any variable-free expression; Greenplum Database does not allow subqueries and cross-references to other columns in the current table. The data type of the default expression must match the data type of the column.

Greenplum Database uses the default expression in any insert operation that does not specify a value for the column. If there is no default for a column, then the default is null.

#### server\_name

The name of an existing server to use for the foreign table. For details on defining a server, see [CREATE SERVER](#).

#### OPTIONS ( option 'value' [, ... ] )

The options for the new foreign table or one of its columns. While option names must be unique, a table option and a column option may have the same name. The option names and values are foreign-data wrapper-specific. Greenplum Database validates the options and values using the foreign-data wrapper's `validator_function`.

#### mpp\_execute { 'master' | 'any' | 'all segments' }

A Greenplum Database-specific option that identifies the host from which the foreign-data wrapper reads or writes data:

- `master` (the default)—Read or write data from the master host.
- `any`—Read data from either the master host or any one segment, depending on which path costs less.
- `all segments`—Read or write data from all segments. To support this option value, the foreign-data wrapper must have a policy that matches the segments to data.

**Note:** Greenplum Database supports parallel writes to foreign tables only when you set `mpp_execute 'all segments'`.

Support for the foreign table `mpp_execute` option, and the specific modes, is foreign-data wrapper-specific.

The `mpp_execute` option can be specified in multiple commands: `CREATE FOREIGN TABLE`, `CREATE SERVER`, and `CREATE FOREIGN DATA WRAPPER`. The foreign table setting takes precedence over the foreign server setting, followed by the foreign-data wrapper setting.

## Notes

The Tanzu Greenplum Query Optimizer, GPORCA, does not support foreign tables. A query on a foreign table always falls back to the Postgres Planner.

## Examples

Create a foreign table named `films` with the server named `film_server`:

```
CREATE FOREIGN TABLE films (
    code          char(5) NOT NULL,
    title         varchar(40) NOT NULL,
    did           integer NOT NULL,
    date_prod    date,
    kind          varchar(10),
    len           interval hour to minute
)
SERVER film_server;
```

## Compatibility

`CREATE FOREIGN TABLE` largely conforms to the SQL standard; however, much as with `CREATE TABLE`, Greenplum Database permits `NULL` constraints and zero-column foreign tables. The ability to specify a default value is a Greenplum Database extension, as is the `mpp_execute` option.

## CREATE FUNCTION

Defines a new function.

## Synopsis

```
CREATE [OR REPLACE] FUNCTION <name>
    ( [ [<argmode>] [<argname>] <argtype> [ { DEFAULT | = } <default_expr> ] [, ...] ]
)
    [ RETURNS <rettype>
      | RETURNS TABLE ( <column_name> <column_type> [, ...] ) ]
{ LANGUAGE <langname>
| WINDOW
| IMMUTABLE | STABLE | VOLATILE | [NOT] LEAKPROOF
| CALLED ON NULL INPUT | RETURNS NULL ON NULL INPUT | STRICT
| NO SQL | CONTAINS SQL | READS SQL DATA | MODIFIES SQL
| [EXTERNAL] SECURITY INVOKER | [EXTERNAL] SECURITY DEFINER
| EXECUTE ON { ANY | MASTER | ALL SEGMENTS | INITPLAN }
| COST <execution_cost>
| SET <configuration_parameter> { TO <value> | = <value> | FROM CURRENT }
| AS '<definition>'
| AS '<obj_file>', '<link_symbol>' } ...
```

```
[ WITH ( { DESCRIBE = describe_function
        } [, ...] ) ]
```

## Description

`CREATE FUNCTION` defines a new function. `CREATE OR REPLACE FUNCTION` either creates a new function, or replaces an existing definition.

The name of the new function must not match any existing function with the same input argument types in the same schema. However, functions of different argument types may share a name (overloading).

To update the definition of an existing function, use `CREATE OR REPLACE FUNCTION`. It is not possible to change the name or argument types of a function this way (this would actually create a new, distinct function). Also, `CREATE OR REPLACE FUNCTION` will not let you change the return type of an existing function. To do that, you must drop and recreate the function. When using `OUT` parameters, that means you cannot change the types of any `OUT` parameters except by dropping the function. If you drop and then recreate a function, you will have to drop existing objects (rules, views, triggers, and so on) that refer to the old function. Use `CREATE OR REPLACE FUNCTION` to change a function definition without breaking objects that refer to the function.

The user that creates the function becomes the owner of the function.

To be able to create a function, you must have `USAGE` privilege on the argument types and the return type.

For more information about creating functions, see the [User Defined Functions](#) section of the PostgreSQL documentation.

### Limited Use of `VOLATILE` and `STABLE` Functions

To prevent data from becoming out-of-sync across the segments in Greenplum Database, any function classified as `STABLE` or `VOLATILE` cannot be run at the segment level if it contains SQL or modifies the database in any way. For example, functions such as `random()` or `timeofday()` are not allowed to run on distributed data in Greenplum Database because they could potentially cause inconsistent data between the segment instances.

To ensure data consistency, `VOLATILE` and `STABLE` functions can safely be used in statements that are evaluated on and run from the master. For example, the following statements are always run on the master (statements without a `FROM` clause):

```
SELECT setval('myseq', 201);
SELECT foo();
```

In cases where a statement has a `FROM` clause containing a distributed table and the function used in the `FROM` clause simply returns a set of rows, execution may be allowed on the segments:

```
SELECT * FROM foo();
```

One exception to this rule are functions that return a table reference (`rangeFuncs`) or functions that use the `refCursor` data type. Note that you cannot return a `refcursor` from any kind of function in Greenplum Database.

### Function Volatility and `EXECUTE ON` Attributes

Volatility attributes (`IMMUTABLE`, `STABLE`, `VOLATILE`) and `EXECUTE ON` attributes specify two different aspects of function execution. In general, volatility indicates when the function is run, and `EXECUTE ON` indicates where it is run.

For example, a function defined with the `IMMUTABLE` attribute can be run at query planning time, while a function with the `VOLATILE` attribute must be run for every row in the query. A function with the `EXECUTE ON MASTER` attribute is run only on the master segment and a function with the `EXECUTE ON ALL SEGMENTS` attribute is run on all primary segment instances (not the master).

See [Using Functions and Operators](#) in the *Greenplum Database Administrator Guide*.

## Functions And Replicated Tables

A user-defined function that runs only `SELECT` commands on replicated tables can run on segments. Replicated tables, created with the `DISTRIBUTED REPLICATED` clause, store all of their rows on every segment. It is safe for a function to read them on the segments, but updates to replicated tables must run on the master instance.

## Parameters

name

The name (optionally schema-qualified) of the function to create.

argmode

The mode of an argument: either `IN`, `OUT`, `INOUT`, or `VARIADIC`. If omitted, the default is `IN`. Only `OUT` arguments can follow an argument declared as `VARIADIC`. Also, `OUT` and `INOUT` arguments cannot be used together with the `RETURNS TABLE` notation.

argname

The name of an argument. Some languages (currently only SQL and PL/pgSQL) let you use the name in the function body. For other languages the name of an input argument is just extra documentation, so far as the function itself is concerned; but you can use input argument names when calling a function to improve readability. In any case, the name of an output argument is significant, since it defines the column name in the result row type. (If you omit the name for an output argument, the system will choose a default column name.)

argtype

The data type(s) of the function's arguments (optionally schema-qualified), if any. The argument types may be base, composite, or domain types, or may reference the type of a table column.

Depending on the implementation language it may also be allowed to specify pseudotypes such as `cstring`. Pseudotypes indicate that the actual argument type is either incompletely specified, or outside the set of ordinary SQL data types.

The type of a column is referenced by writing `tablename.columnname%TYPE`. Using this feature can sometimes help make a function independent of changes to the definition of a table.

default\_expr

An expression to be used as the default value if the parameter is not specified. The expression must be coercible to the argument type of the parameter. Only `IN` and `INOUT` parameters can have a default value. Each input parameter in the argument list that follows a parameter with a default value must have a default value as well.

rettype

The return data type (optionally schema-qualified). The return type can be a base, composite, or domain type, or may reference the type of a table column. Depending on the implementation language it may also be allowed to specify pseudotypes such as `cstring`. If the function is not supposed to return a value, specify `void` as the return type.

When there are `OUT` or `INOUT` parameters, the `RETURNS` clause may be omitted. If present, it must agree with the result type implied by the output parameters: `RECORD` if there are multiple output parameters, or the same type as the single output parameter.

The `SETOF` modifier indicates that the function will return a set of items, rather than a single item.

The type of a column is referenced by writing `tablename.columnname%TYPE`.

`column_name`

The name of an output column in the `RETURNS TABLE` syntax. This is effectively another way of declaring a named `OUT` parameter, except that `RETURNS TABLE` also implies `RETURNS SETOF`.

`column_type`

The data type of an output column in the `RETURNS TABLE` syntax.

`langname`

The name of the language that the function is implemented in. May be `SQL`, `C`, `internal`, or the name of a user-defined procedural language. See `CREATE LANGUAGE` for the procedural languages supported in Greenplum Database. For backward compatibility, the name may be enclosed by single quotes.

`WINDOW`

`WINDOW` indicates that the function is a window function rather than a plain function. This is currently only useful for functions written in C. The `WINDOW` attribute cannot be changed when replacing an existing function definition.

`IMMUTABLE`

`STABLE`

`VOLATILE`

`LEAKPROOF`

These attributes inform the query optimizer about the behavior of the function. At most one choice may be specified. If none of these appear, `VOLATILE` is the default assumption. Since Greenplum Database currently has limited use of `VOLATILE` functions, if a function is truly `IMMUTABLE`, you must declare it as so to be able to use it without restrictions.

`IMMUTABLE` indicates that the function cannot modify the database and always returns the same result when given the same argument values. It does not do database lookups or otherwise use information not directly present in its argument list. If this option is given, any call of the function with all-constant arguments can be immediately replaced with the function value.

`STABLE` indicates that the function cannot modify the database, and that within a single table scan it will consistently return the same result for the same argument values, but that its result could change across SQL statements. This is the appropriate selection for functions whose results depend on database lookups, parameter values (such as the current time zone), and so on. Also note that the `current_timestamp` family of functions qualify as stable, since their values do not change within a transaction.

**VOLATILE** indicates that the function value can change even within a single table scan, so no optimizations can be made. Relatively few database functions are volatile in this sense; some examples are `random()`, `timeofday()`. But note that any function that has side-effects must be classified volatile, even if its result is quite predictable, to prevent calls from being optimized away; an example is `setval()`.

**LEAKPROOF** indicates that the function has no side effects. It reveals no information about its arguments other than by its return value. For example, a function that throws an error message for some argument values but not others, or that includes the argument values in any error message, is not leakproof. The query planner may push leakproof functions (but not others) into views created with the `security_barrier` option. See [CREATE VIEW](#) and [CREATE RULE](#). This option can only be set by the superuser.

CALLED ON NULL INPUT

RETURNS NULL ON NULL INPUT

STRICT

**CALLLED ON NULL INPUT** (the default) indicates that the function will be called normally when some of its arguments are null. It is then the function author's responsibility to check for null values if necessary and respond appropriately. **RETURNS NULL ON NULL INPUT** or **STRICT** indicates that the function always returns null whenever any of its arguments are null. If this parameter is specified, the function is not run when there are null arguments; instead a null result is assumed automatically.

NO SQL

CONTAINS SQL

READS SQL DATA

MODIFIES SQL

These attributes inform the query optimizer about whether or not the function contains SQL statements and whether, if it does, those statements read and/or write data.

**NO SQL** indicates that the function does not contain SQL statements.

**CONTAINS SQL** indicates that the function contains SQL statements, none of which either read or write data.

**READS SQL DATA** indicates that the function contains SQL statements that read data but none that modify data.

**MODIFIES SQL** indicates that the function contains statements that may write data.

[EXTERNAL] SECURITY INVOKER

[EXTERNAL] SECURITY DEFINER

**SECURITY INVOKER** (the default) indicates that the function is to be run with the privileges of the user that calls it. **SECURITY DEFINER** specifies that the function is to be run with the privileges of the user that created it. The key word **EXTERNAL** is allowed for SQL conformance, but it is optional since, unlike in SQL, this feature applies to all functions not just external ones.

EXECUTE ON ANY

EXECUTE ON MASTER

EXECUTE ON ALL SEGMENTS

EXECUTE ON INITPLAN

The `EXECUTE ON` attributes specify where (master or segment instance) a function runs when it is invoked during the query execution process.

`EXECUTE ON ANY` (the default) indicates that the function can be run on the master, or any segment instance, and it returns the same result regardless of where it is run. Greenplum Database determines where the function runs.

`EXECUTE ON MASTER` indicates that the function must run only on the master instance.

`EXECUTE ON ALL SEGMENTS` indicates that the function must run on all primary segment instances, but not the master, for each invocation. The overall result of the function is the `UNION ALL` of the results from all segment instances.

`EXECUTE ON INITPLAN` indicates that the function contains an SQL command that dispatches queries to the segment instances and requires special processing on the master instance by Greenplum Database when possible.

**Note:** `EXECUTE ON INITPLAN` is only supported in functions that are used in the `FROM` clause of a `CREATE TABLE AS` or `INSERT` command such as the `get_data()` function in these commands.

```
CREATE TABLE t AS SELECT * FROM get_data();

INSERT INTO t1 SELECT * FROM get_data();
```

Greenplum Database does not support the `EXECUTE ON INITPLAN` attribute in a function that is used in the `WITH` clause of a query, a CTE (common table expression). For example, specifying `EXECUTE ON INITPLAN` in function `get_data()` in this CTE is not supported.

```
WITH tbl_a AS (SELECT * FROM get_data() )
  SELECT * from tbl_a
  UNION
  SELECT * FROM tbl_b;
```

For information about using `EXECUTE ON` attributes, see [Notes](#).

#### COST execution\_cost

A positive number identifying the estimated execution cost for the function, in `cpu_operator_cost` units. If the function returns a set, `execution_cost` identifies the cost per returned row. If the cost is not specified, C-language and internal functions default to 1 unit, while functions in other languages default to 100 units. The planner tries to evaluate the function less often when you specify larger `execution_cost` values.

#### configuration\_parameter value

The `SET` clause applies a value to a session configuration parameter when the function is entered. The configuration parameter is restored to its prior value when the function exits. `SET FROM CURRENT` saves the value of the parameter that is current when `CREATE FUNCTION` is run as the value to be applied when the function is entered.

#### definition

A string constant defining the function; the meaning depends on the language. It may be an internal function name, the path to an object file, an SQL command, or text in a procedural language.

#### obj\_file, link\_symbol

This form of the `AS` clause is used for dynamically loadable C language functions when the function name in the C language source code is not the same as the name of the SQL function. The string `obj_file` is the name of the file containing the dynamically loadable object, and `link_symbol` is the name of the function in the C language source code. If the link symbol is omitted, it is assumed to be the same as the name of the SQL function being defined. The C names of all functions must be different, so you must give overloaded SQL functions different C names (for example, use the argument types as part of the C names). It is recommended to locate shared libraries either relative to `$libdir` (which is located at `$GPHOME/lib`) or through the dynamic library path (set by the `dynamic_library_path` server configuration parameter). This simplifies version upgrades if the new installation is at a different location.

`describe_function`

The name of a callback function to run when a query that calls this function is parsed. The callback function returns a tuple descriptor that indicates the result type.

## Notes

Any compiled code (shared library files) for custom functions must be placed in the same location on every host in your Greenplum Database array (master and all segments). This location must also be in the `LD_LIBRARY_PATH` so that the server can locate the files. It is recommended to locate shared libraries either relative to `$libdir` (which is located at `$GPHOME/lib`) or through the dynamic library path (set by the `dynamic_library_path` server configuration parameter) on all master segment instances in the Greenplum array.

The full SQL type syntax is allowed for input arguments and return value. However, some details of the type specification (such as the precision field for type numeric) are the responsibility of the underlying function implementation and are not recognized or enforced by the `CREATE FUNCTION` command.

Greenplum Database allows function overloading. The same name can be used for several different functions so long as they have distinct input argument types. However, the C names of all functions must be different, so you must give overloaded C functions different C names (for example, use the argument types as part of the C names).

Two functions are considered the same if they have the same names and input argument types, ignoring any `OUT` parameters. Thus for example these declarations conflict:

```
CREATE FUNCTION foo(int) ...
CREATE FUNCTION foo(int, out text) ...
```

Functions that have different argument type lists are not considered to conflict at creation time, but if argument defaults are provided, they might conflict in use. For example, consider:

```
CREATE FUNCTION foo(int) ...
CREATE FUNCTION foo(int, int default 42) ...
```

The call `foo(10)`, will fail due to the ambiguity about which function should be called.

When repeated `CREATE FUNCTION` calls refer to the same object file, the file is only loaded once. To unload and reload the file, use the `LOAD` command.

You must have the `USAGE` privilege on a language to be able to define a function using that language.

It is often helpful to use dollar quoting to write the function definition string, rather than the normal single quote syntax. Without dollar quoting, any single quotes or backslashes in the function definition must be escaped by doubling them. A dollar-quoted string constant consists of a dollar sign (`$`), an optional tag of zero or more characters, another dollar sign, an arbitrary sequence of characters that makes up the string content, a dollar sign, the same tag that began this dollar quote, and a dollar sign. Inside the dollar-quoted string, single quotes, backslashes, or any character can be used without escaping. The string content is always written literally. For example, here are two different ways to specify the string "Dianne's horse" using dollar quoting:

```
$$Dianne's horse$$
$SomeTag$Dianne's horse$SomeTag$
```

If a `SET` clause is attached to a function, the effects of a `SET LOCAL` command run inside the function for the same variable are restricted to the function; the configuration parameter's prior value is still restored when the function exits. However, an ordinary `SET` command (without `LOCAL`) overrides the `CREATE FUNCTION SET` clause, much as it would for a previous `SET LOCAL` command. The effects of such a command will persist after the function exits, unless the current transaction is rolled back.

If a function with a `VARIADIC` argument is declared as `STRICT`, the strictness check tests that the variadic array as a whole is non-null. PL/pgSQL will still call the function if the array has null elements.

When replacing an existing function with `CREATE OR REPLACE FUNCTION`, there are restrictions on changing parameter names. You cannot change the name already assigned to any input parameter (although you can add names to parameters that had none before). If there is more than one output parameter, you cannot change the names of the output parameters, because that would change the column names of the anonymous composite type that describes the function's result. These restrictions are made to ensure that existing calls of the function do not stop working when it is replaced.

### Using Functions with Queries on Distributed Data

In some cases, Greenplum Database does not support using functions in a query where the data in a table specified in the `FROM` clause is distributed over Greenplum Database segments. As an example, this SQL query contains the function `func()`:

```
SELECT func(a) FROM table1;
```

The function is not supported for use in the query if all of the following conditions are met:

- The data of table `table1` is distributed over Greenplum Database segments.
- The function `func()` reads or modifies data from distributed tables.
- The function `func()` returns more than one row or takes an argument (`a`) that comes from `table1`.

If any of the conditions are not met, the function is supported. Specifically, the function is supported if any of the following conditions apply:

- The function `func()` does not access data from distributed tables, or accesses data that is only on the Greenplum Database master.
- The table `table1` is a master only table.
- The function `func()` returns only one row and only takes input arguments that are constant values. The function is supported if it can be changed to require no input arguments.

### Using EXECUTE ON attributes

Most functions that run queries to access tables can only run on the master. However, functions that run only `SELECT` queries on replicated tables can run on segments. If the function accesses a hash-distributed table or a randomly distributed table, the function should be defined with the `EXECUTE ON MASTER` attribute. Otherwise, the function might return incorrect results when the function is used in a complicated query. Without the attribute, planner optimization might determine it would be beneficial to push the function invocation to segment instances.

These are limitations for functions defined with the `EXECUTE ON MASTER` or `EXECUTE ON ALL SEGMENTS` attribute:

- The function must be a set-returning function.
- The function cannot be in the `FROM` clause of a query.
- The function cannot be in the `SELECT` list of a query with a `FROM` clause.
- A query that includes the function falls back from GPORCA to the Postgres Planner.

The attribute `EXECUTE ON INITPLAN` indicates that the function contains an SQL command that dispatches queries to the segment instances and requires special processing on the master instance by Greenplum Database. When possible, Greenplum Database handles the function on the master instance in the following manner.

1. First, Greenplum Database runs the function as part of an `InitPlan` node on the master instance and holds the function output temporarily.
2. Then, in the `MainPlan` of the query plan, the function is called in an `EntryDB` (a special query executor (QE) that runs on the master instance) and Greenplum Database returns the data that was captured when the function was run as part of the `InitPlan` node. The function is not run in the `MainPlan`.

This simple example uses the function `get_data()` in a `CTAS` command to create a table using data from the table `country`. The function contains a `SELECT` command that retrieves data from the table `country` and uses the `EXECUTE ON INITPLAN` attribute.

```
CREATE TABLE country(
  c_id integer, c_name text, region int)
DISTRIBUTED RANDOMLY;

INSERT INTO country VALUES (11,'INDIA', 1 ), (22,'CANADA', 2), (33,'USA', 3);

CREATE OR REPLACE FUNCTION get_data()
  RETURNS TABLE (
    c_id integer, c_name text
  )
AS $$
SELECT
  c.c_id, c.c_name
```

```

FROM
    country c;
$$
LANGUAGE SQL EXECUTE ON INITPLAN;

CREATE TABLE t AS SELECT * FROM get_data() DISTRIBUTED RANDOMLY;

```

If you view the query plan of the CTAS command with `EXPLAIN ANALYZE VERBOSE`, the plan shows that the function is run as part of an InitPlan node, and one of the listed slices is labeled as `entry db`. The query plan of a simple CTAS command without the function does not have an InitPlan node or an `entry db` slice.

If the function did not contain the `EXECUTE ON INITPLAN` attribute, the CTAS command returns the error `function cannot execute on a QE slice`.

When a function uses the `EXECUTE ON INITPLAN` attribute, a command that uses the function such as `CREATE TABLE t AS SELECT * FROM get_data()` gathers the results of the function onto the master segment and then redistributes the results to segment instances when inserting the data. If the function returns a large amount of data, the master might become a bottleneck when gathering and redistributing data. Performance might improve if you rewrite the function to run the CTAS command in the user defined function and use the table name as an input parameter. In this example, the function runs a CTAS command and does not require the `EXECUTE ON INITPLAN` attribute. Running the `SELECT` command creates the table `t1` using the function that runs the CTAS command.

```

CREATE OR REPLACE FUNCTION my_ctas(_tbl text) RETURNS VOID AS
$$
BEGIN
    EXECUTE format('CREATE TABLE %s AS SELECT c.c_id, c.c_name FROM country c DISTRIBUTE
D RANDOMLY', _tbl);
END
$$
LANGUAGE plpgsql;

SELECT my_ctas('t1');

```

## Examples

A very simple addition function:

```

CREATE FUNCTION add(integer, integer) RETURNS integer
AS 'select $1 + $2;'
LANGUAGE SQL
IMMUTABLE
RETURNS NULL ON NULL INPUT;

```

Increment an integer, making use of an argument name, in PL/pgSQL:

```

CREATE OR REPLACE FUNCTION increment(i integer) RETURNS
integer AS $$
BEGIN
    RETURN i + 1;

```

```

    END;
$$ LANGUAGE plpgsql;

```

Increase the default segment host memory per query for a PL/pgSQL function:

```

CREATE OR REPLACE FUNCTION function_with_query() RETURNS
SETOF text AS $$
    BEGIN
        RETURN QUERY
            EXPLAIN ANALYZE SELECT * FROM large_table;
    END;
$$ LANGUAGE plpgsql
SET statement_mem='256MB';

```

Use polymorphic types to return an [ENUM](#) array:

```

CREATE TYPE rainbow AS ENUM('red','orange','yellow','green','blue','indigo','violet');
CREATE FUNCTION return_enum_as_array( anyenum, anyelement, anyelement )
    RETURNS TABLE (ae anyenum, aa anyarray) AS $$
    SELECT $1, array[$2, $3]
$$ LANGUAGE SQL STABLE;

SELECT * FROM return_enum_as_array('red'::rainbow, 'green'::rainbow, 'blue'::rainbow);

```

Return a record containing multiple output parameters:

```

CREATE FUNCTION dup(in int, out f1 int, out f2 text)
    AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
    LANGUAGE SQL;

SELECT * FROM dup(42);

```

You can do the same thing more verbosely with an explicitly named composite type:

```

CREATE TYPE dup_result AS (f1 int, f2 text);
CREATE FUNCTION dup(int) RETURNS dup_result
    AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
    LANGUAGE SQL;

SELECT * FROM dup(42);

```

Another way to return multiple columns is to use a [TABLE](#) function:

```

CREATE FUNCTION dup(int) RETURNS TABLE(f1 int, f2 text)
    AS $$ SELECT $1, CAST($1 AS text) || ' is text' $$
    LANGUAGE SQL;

SELECT * FROM dup(4);

```

This function is defined with the [EXECUTE ON ALL SEGMENTS](#) to run on all primary segment instances. The [SELECT](#) command runs the function that returns the time it was run on each segment instance.

```

CREATE FUNCTION run_on_segs (text) returns setof text as $$
begin
    return next ($1 || ' - ' || now()::text );

```

```

end;
$$ language plpgsql VOLATILE EXECUTE ON ALL SEGMENTS;

SELECT run_on_segs('my test');

```

This function looks up a part name in the parts table. The parts table is replicated, so the function can run on the master or on the primary segments.

```

CREATE OR REPLACE FUNCTION get_part_name(partno int) RETURNS text AS
$$
DECLARE
    result text := ' ';
BEGIN
    SELECT part_name INTO result FROM parts WHERE part_id = partno;
    RETURN result;
END;
$$ LANGUAGE plpgsql;

```

If you run `SELECT get_part_name(100);` at the master the function runs on the master. (The master instance directs the query to a single primary segment.) If orders is a distributed table and you run the following query, the `get_part_name()` function runs on the primary segments.

```

`SELECT order_id, get_part_name(orders.part_no) FROM orders;`

```

## Compatibility

`CREATE FUNCTION` is defined in SQL:1999 and later. The Greenplum Database version is similar but not fully compatible. The attributes are not portable, neither are the different available languages.

For compatibility with some other database systems, argmode can be written either before or after argname. But only the first way is standard-compliant.

For parameter defaults, the SQL standard specifies only the syntax with the `DEFAULT` key word. The syntax with `=` is used in T-SQL and Firebird.

## CREATE GROUP

Defines a new database role.

## Synopsis

```

CREATE GROUP <name> [[WITH] <option> [ ... ]]

```

where option can be:

```

SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| CREATEUSER | NOCREATEUSER
| CREATEEXTTABLE | NOCREATEEXTTABLE
| ( ( <attribute>='<value>' [, ...] ) )
|   where <attributes> and <value> are:
|     type='readable'|'writable'
|     protocol='gpfdist' | 'http'
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| CONNECTION LIMIT <conlimit>
| [ ENCRYPTED | UNENCRYPTED ] PASSWORD '<password>'
| VALID UNTIL '<timestamp>'
| IN ROLE <rolename> [, ...]
| ROLE <rolename> [, ...]
| ADMIN <rolename> [, ...]
| RESOURCE QUEUE <queue_name>
| RESOURCE GROUP <group_name>
| [ DENY <deny_point> ]
| [ DENY BETWEEN <deny_point> AND <deny_point>]

```

## Description

`CREATE GROUP` is an alias for `CREATE ROLE`.

## Compatibility

There is no `CREATE GROUP` statement in the SQL standard.

## See Also

[CREATE ROLE](#)

## CREATE INDEX

Defines a new index.

## Synopsis

```

CREATE [UNIQUE] INDEX [<name>] ON <table_name> [USING <method>]
  ( {<column_name> | (<expression>)} [COLLATE <parameter>] [<opclass>] [ ASC | DE
SC ] [ NULLS { FIRST | LAST } ] [, ...] )
  [ WITH ( <storage_parameter> = <value> [, ... ] ) ]
  [ TABLESPACE <tablespace> ]
  [ WHERE <predicate> ]

```

## Description

`CREATE INDEX` constructs an index on the specified column(s) of the specified table or materialized view. Indexes are primarily used to enhance database performance (though inappropriate use can result in slower performance).

The key field(s) for the index are specified as column names, or alternatively as expressions written in parentheses. Multiple fields can be specified if the index method supports multicolumn indexes.

An index field can be an expression computed from the values of one or more columns of the table row. This feature can be used to obtain fast access to data based on some transformation of the basic data. For example, an index computed on `upper(col)` would allow the clause `WHERE upper(col) = 'JIM'` to use an index.

Greenplum Database provides the index methods B-tree, bitmap, GiST, SP-GiST, and GIN. Users can also define their own index methods, but that is fairly complicated.

When the `WHERE` clause is present, a partial index is created. A partial index is an index that contains entries for only a portion of a table, usually a portion that is more useful for indexing than the rest of the table. For example, if you have a table that contains both billed and unbilled orders where the unbilled orders take up a small fraction of the total table and yet is most often selected, you can improve performance by creating an index on just that portion.

The expression used in the `WHERE` clause may refer only to columns of the underlying table, but it can use all columns, not just the ones being indexed. Subqueries and aggregate expressions are also forbidden in `WHERE`. The same restrictions apply to index fields that are expressions.

All functions and operators used in an index definition must be immutable. Their results must depend only on their arguments and never on any outside influence (such as the contents of another table or a parameter value). This restriction ensures that the behavior of the index is well-defined. To use a user-defined function in an index expression or `WHERE` clause, remember to mark the function `IMMUTABLE` when you create it.

## Parameters

### UNIQUE

Checks for duplicate values in the table when the index is created and each time data is added. Duplicate entries will generate an error. Unique indexes only apply to B-tree indexes. In Greenplum Database, unique indexes are allowed only if the columns of the index key are the same as (or a superset of) the Greenplum distribution key. On partitioned tables, a unique index is only supported within an individual partition - not across all partitions.

### name

The name of the index to be created. The index is always created in the same schema as its parent table. If the name is omitted, Greenplum Database chooses a suitable name based on the parent table's name and the indexed column name(s).

### table\_name

The name (optionally schema-qualified) of the table to be indexed.

### method

The name of the index method to be used. Choices are `btree`, `bitmap`, `gist`, `spgist`, and `gin`. The default method is `btree`.

Currently, only the B-tree, GiST, and GIN index methods support multicolumn indexes. Up to 32 fields can be specified by default. Only B-tree currently supports unique indexes.

GPORCA supports only B-tree, bitmap, GiST, and GIN indexes. GPORCA ignores indexes created with unsupported indexing methods.

#### column\_name

The name of a column of the table on which to create the index. Only the B-tree, bitmap, GiST, and GIN index methods support multicolumn indexes.

#### expression

An expression based on one or more columns of the table. The expression usually must be written with surrounding parentheses, as shown in the syntax. However, the parentheses may be omitted if the expression has the form of a function call.

#### collation

The name of the collation to use for the index. By default, the index uses the collation declared for the column to be indexed or the result collation of the expression to be indexed. Indexes with non-default collations can be useful for queries that involve expressions using non-default collations.

#### opclass

The name of an operator class. The operator class identifies the operators to be used by the index for that column. For example, a B-tree index on four-byte integers would use the `int4_ops` class (this operator class includes comparison functions for four-byte integers). In practice the default operator class for the column's data type is usually sufficient. The main point of having operator classes is that for some data types, there could be more than one meaningful ordering. For example, a complex-number data type could be sorted by either absolute value or by real part. We could do this by defining two operator classes for the data type and then selecting the proper class when making an index.

#### ASC

Specifies ascending sort order (which is the default).

#### DESC

Specifies descending sort order.

#### NULLS FIRST

Specifies that nulls sort before non-nulls. This is the default when `DESC` is specified.

#### NULLS LAST

Specifies that nulls sort after non-nulls. This is the default when `DESC` is not specified.

#### storage\_parameter

The name of an index-method-specific storage parameter. Each index method has its own set of allowed storage parameters.

**FILLFACTOR** - B-tree, bitmap, GiST, and SP-GiST index methods all accept this parameter. The **FILLFACTOR** for an index is a percentage that determines how full the index method will try to pack index pages. For B-trees, leaf pages are filled to this percentage during initial index build, and also when extending the index at the right (adding new largest key values). If pages subsequently become completely full, they will be split, leading to gradual degradation in the index's efficiency. B-trees use a default fillfactor of 90, but any integer value from 10 to 100 can be selected. If the table is static then fillfactor 100 is best to minimize the index's physical size, but for heavily updated tables a smaller fillfactor is better to minimize the need for page splits. The other index methods use fillfactor in different but roughly analogous ways; the default fillfactor varies between methods.

**BUFFERING** - In addition to **FILLFACTOR**, GiST indexes additionally accept the **BUFFERING** parameter. **BUFFERING** determines whether Greenplum Database builds the index using the

buffering build technique described in [GiST buffering build](#) in the PostgreSQL documentation. With `OFF` it is deactivated, with `ON` it is enabled, and with `AUTO` it is initially deactivated, but turned on on-the-fly once the index size reaches `effective-cache-size`. The default is `AUTO`.

`FASTUPDATE` - The GIN index method accepts the `FASTUPDATE` storage parameter. `FASTUPDATE` is a Boolean parameter that deactivates or enables the GIN index fast update technique. A value of `ON` enables fast update (the default), and `OFF` deactivates it. See [GIN fast update technique](#) in the PostgreSQL documentation for more information.

**Note:** Turning `FASTUPDATE` off via `ALTER INDEX` prevents future insertions from going into the list of pending index entries, but does not in itself flush previous entries. You might want to `VACUUM` the table afterward to ensure the pending list is emptied.

tablespace\_name

The tablespace in which to create the index. If not specified, the default tablespace is used, or [temp\\_tablespaces](#) for indexes on temporary tables.

predicate

The constraint expression for a partial index.

## Notes

An *operator class* can be specified for each column of an index. The operator class identifies the operators to be used by the index for that column. For example, a B-tree index on four-byte integers would use the `int4_ops` class; this operator class includes comparison functions for four-byte integers. In practice the default operator class for the column's data type is usually sufficient. The main point of having operator classes is that for some data types, there could be more than one meaningful ordering. For example, we might want to sort a complex-number data type either by absolute value or by real part. We could do this by defining two operator classes for the data type and then selecting the proper class when making an index.

For index methods that support ordered scans (currently, only B-tree), the optional clauses `ASC`, `DESC`, `NULLS FIRST`, and/or `NULLS LAST` can be specified to modify the sort ordering of the index. Since an ordered index can be scanned either forward or backward, it is not normally useful to create a single-column `DESC` index — that sort ordering is already available with a regular index. The value of these options is that multicolumn indexes can be created that match the sort ordering requested by a mixed-ordering query, such as `SELECT ... ORDER BY x ASC, y DESC`. The `NULLS` options are useful if you need to support "nulls sort low" behavior, rather than the default "nulls sort high", in queries that depend on indexes to avoid sorting steps.

For most index methods, the speed of creating an index is dependent on the setting of `maintenance_work_mem`. Larger values will reduce the time needed for index creation, so long as you don't make it larger than the amount of memory really available, which would drive the machine into swapping.

When an index is created on a partitioned table, the index is propagated to all the child tables created by Greenplum Database. Creating an index on a table that is created by Greenplum Database for use by a partitioned table is not supported.

`UNIQUE` indexes are allowed only if the index columns are the same as (or a superset of) the Greenplum distribution key columns.

`UNIQUE` indexes are not allowed on append-optimized tables.

A `UNIQUE` index can be created on a partitioned table. However, uniqueness is enforced only within a partition; uniqueness is not enforced between partitions. For example, for a partitioned table with partitions that are based on year and a subpartitions that are based on quarter, uniqueness is enforced only on each individual quarter partition. Uniqueness is not enforced between quarter partitions

Indexes are not used for `IS NULL` clauses by default. The best way to use indexes in such cases is to create a partial index using an `IS NULL` predicate.

`bitmap` indexes perform best for columns that have between 100 and 100,000 distinct values. For a column with more than 100,000 distinct values, the performance and space efficiency of a bitmap index decline. The size of a bitmap index is proportional to the number of rows in the table times the number of distinct values in the indexed column.

Columns with fewer than 100 distinct values usually do not benefit much from any type of index. For example, a gender column with only two distinct values for male and female would not be a good candidate for an index.

Prior releases of Greenplum Database also had an R-tree index method. This method has been removed because it had no significant advantages over the GiST method. If `USING rtree` is specified, `CREATE INDEX` will interpret it as `USING gist`.

For more information on the GiST index type, refer to the [PostgreSQL documentation](#).

The use of hash indexes has been deactivated in Greenplum Database.

## Examples

To create a B-tree index on the column `title` in the table `films`:

```
CREATE UNIQUE INDEX title_idx ON films (title);
```

To create a bitmap index on the column `gender` in the table `employee`:

```
CREATE INDEX gender_bmp_idx ON employee USING bitmap
(gender);
```

To create an index on the expression `lower(title)`, allowing efficient case-insensitive searches:

```
CREATE INDEX ON films ((lower(title)));
```

(In this example we have chosen to omit the index name, so the system will choose a name, typically `films_lower_idx`.)

To create an index with non-default collation:

```
CREATE INDEX title_idx_german ON films (title COLLATE "de_DE");
```

To create an index with non-default fill factor:

```
CREATE UNIQUE INDEX title_idx ON films (title) WITH
(fillfactor = 70);
```

To create a GIN index with fast updates deactivated:

```
CREATE INDEX gin_idx ON documents_table USING gin (locations) WITH (fastupdate = off);
```

To create an index on the column `code` in the table `films` and have the index reside in the tablespace `indexspace`:

```
CREATE INDEX code_idx ON films(code) TABLESPACE indexspace;
```

To create a GiST index on a point attribute so that we can efficiently use box operators on the result of the conversion function:

```
CREATE INDEX pointloc ON points USING gist (box(location,location));
SELECT * FROM points WHERE box(location,location) && '(0,0),(1,1)::box;
```

## Compatibility

`CREATE INDEX` is a Greenplum Database language extension. There are no provisions for indexes in the SQL standard.

Greenplum Database does not support the concurrent creation of indexes (`CONCURRENTLY` keyword not supported).

## CREATE LANGUAGE

Defines a new procedural language.

## Synopsis

```
CREATE [ OR REPLACE ] [ PROCEDURAL ] LANGUAGE <name>

CREATE [ OR REPLACE ] [ TRUSTED ] [ PROCEDURAL ] LANGUAGE <name>
    HANDLER <call_handler> [ INLINE <inline_handler> ]
    [ VALIDATOR <valfunction> ]
```

## Description

`CREATE LANGUAGE` registers a new procedural language with a Greenplum database. Subsequently, functions and trigger procedures can be defined in this new language.

**Note:** Procedural languages for Greenplum Database have been made into "extensions," and should therefore be installed with `CREATE EXTENSION`, not `CREATE LANGUAGE`. Using `CREATE LANGUAGE` directly should be restricted to extension installation scripts. If you have a "bare" language

in your database, perhaps as a result of an upgrade, you can convert it to an extension using `CREATE EXTENSION langname FROM unpackaged`.

Superusers can register a new language with a Greenplum database. A database owner can also register within that database any language listed in the `pg_pltemplate` catalog in which the `tmpldbcreate` field is true. The default configuration allows only trusted languages to be registered by database owners. The creator of a language becomes its owner and can later drop it, rename it, or assign ownership to a new owner.

`CREATE OR REPLACE LANGUAGE` will either create a new language, or replace an existing definition. If the language already exists, its parameters are updated according to the values specified or taken from `pg_pltemplate`, but the language's ownership and permissions settings do not change, and any existing functions written in the language are assumed to still be valid. In addition to the normal privilege requirements for creating a language, the user must be superuser or owner of the existing language. The `REPLACE` case is mainly meant to be used to ensure that the language exists. If the language has a `pg_pltemplate` entry then `REPLACE` will not actually change anything about an existing definition, except in the unusual case where the `pg_pltemplate` entry has been modified since the language was created.

`CREATE LANGUAGE` effectively associates the language name with handler function(s) that are responsible for running functions written in that language. For a function written in a procedural language (a language other than C or SQL), the database server has no built-in knowledge about how to interpret the function's source code. The task is passed to a special handler that knows the details of the language. The handler could either do all the work of parsing, syntax analysis, execution, and so on or it could serve as a bridge between Greenplum Database and an existing implementation of a programming language. The handler itself is a C language function compiled into a shared object and loaded on demand, just like any other C function. These procedural language packages are included in the standard Greenplum Database distribution: PL/pgSQL, PL/Perl, and PL/Python. Language handlers have also been added for PL/Java and PL/R, but those languages are not pre-installed with Greenplum Database. See the topic on [Procedural Languages](#) in the PostgreSQL documentation for more information on developing functions using these procedural languages.

The PL/Perl, PL/Java, and PL/R libraries require the correct versions of Perl, Java, and R to be installed, respectively.

On RHEL and SUSE platforms, download the appropriate extensions from [VMware Tanzu Network](#), then install the extensions using the Greenplum Package Manager (`gppkg`) utility to ensure that all dependencies are installed as well as the extensions. See the Greenplum Database Utility Guide for details about `gppkg`.

There are two forms of the `CREATE LANGUAGE` command. In the first form, the user specifies the name of the desired language and the Greenplum Database server uses the `pg_pltemplate` system catalog to determine the correct parameters. In the second form, the user specifies the language parameters as well as the language name. You can use the second form to create a language that is not defined in `pg_pltemplate`.

When the server finds an entry in the `pg_pltemplate` catalog for the given language name, it will use the catalog data even if the command includes language parameters. This behavior simplifies loading of old dump files, which are likely to contain out-of-date information about language support functions.

## Parameters

### TRUSTED

`TRUSTED` specifies that the language does not grant access to data that the user would not otherwise have. If this key word is omitted when registering the language, only users with the Greenplum Database superuser privilege can use this language to create new functions.

### PROCEDURAL

This is a noise word.

### name

The name of the new procedural language. The name must be unique among the languages in the database. Built-in support is included for `plpgsql`, `plperl`, and `plpythonu`. The languages `plpgsql` (PL/pgSQL) and `plpythonu` (PL/Python) are installed by default in Greenplum Database.

### HANDLER call\_handler

Ignored if the server has an entry for the specified language name in `pg_pltemplate`. The name of a previously registered function that will be called to run the procedural language functions. The call handler for a procedural language must be written in a compiled language such as C with version 1 call convention and registered with Greenplum Database as a function taking no arguments and returning the `language_handler` type, a placeholder type that is simply used to identify the function as a call handler.

### INLINE inline\_handler

The name of a previously registered function that is called to run an anonymous code block in this language that is created with the `DO` command. If an `inline_handler` function is not specified, the language does not support anonymous code blocks. The handler function must take one argument of type `internal`, which is the `DO` command internal representation. The function typically return `void`. The return value of the handler is ignored.

### VALIDATOR valfunction

Ignored if the server has an entry for the specified language name in `pg_pltemplate`. The name of a previously registered function that will be called to run the procedural language functions. The call handler for a procedural language must be written in a compiled language such as C with version 1 call convention and registered with Greenplum Database as a function taking no arguments and returning the `language_handler` type, a placeholder type that is simply used to identify the function as a call handler.

## Notes

The PL/pgSQL language is already registered in all databases by default. The PL/Python language extension is installed but not registered.

The system catalog `pg_language` records information about the currently installed languages.

To create functions in a procedural language, a user must have the `USAGE` privilege for the language. By default, `USAGE` is granted to `PUBLIC` (everyone) for trusted languages. This may be revoked if desired.

Procedural languages are local to individual databases. You create and drop languages for individual databases.

The call handler function and the validator function (if any) must already exist if the server does not have an entry for the language in `pg_pltemplate`. But when there is an entry, the functions need

not already exist; they will be automatically defined if not present in the database.

Any shared library that implements a language must be located in the same `LD_LIBRARY_PATH` location on all segment hosts in your Greenplum Database array.

## Examples

The preferred way of creating any of the standard procedural languages is to use `CREATE EXTENSION` instead of `CREATE LANGUAGE`. For example:

```
CREATE EXTENSION plperl;
```

For a language not known in the `pg_pltemplate` catalog:

```
CREATE FUNCTION plsample_call_handler() RETURNS
language_handler
AS '$libdir/plsample'
LANGUAGE C;
CREATE LANGUAGE plsample
HANDLER plsample_call_handler;
```

## Compatibility

`CREATE LANGUAGE` is a Greenplum Database extension.

## See Also

[ALTER LANGUAGE](#), [CREATE EXTENSION](#), [CREATE FUNCTION](#), [DROP EXTENSION](#), [DROP LANGUAGE](#), [GRANT DO](#)

Parent topic: [SQL Commands](#)

## CREATE MATERIALIZED VIEW

Defines a new materialized view.

## Synopsis

```
CREATE MATERIALIZED VIEW <table_name>
[ (<column_name> [, ...] ) ]
[ WITH ( <storage_parameter> [= <value>] [, ...] ) ]
[ TABLESPACE <tablespace_name> ]
AS <query>
[ WITH [ NO ] DATA ]
[ DISTRIBUTED { | BY <column> [<opclass>], [ ... ] | RANDOMLY | REPLICATED } ]
```

## Description

`CREATE MATERIALIZED VIEW` defines a materialized view of a query. The query is run and used to populate the view at the time the command is issued (unless `WITH NO DATA` is used) and can be

refreshed using `REFRESH MATERIALIZED VIEW`.

`CREATE MATERIALIZED VIEW` is similar to `CREATE TABLE AS`, except that it also remembers the query used to initialize the view, so that it can be refreshed later upon demand. To refresh materialized view data, use the `REFRESH MATERIALIZED VIEW` command. A materialized view has many of the same properties as a table, but there is no support for temporary materialized views or automatic generation of OIDs.

## Parameters

`table_name`

The name (optionally schema-qualified) of the materialized view to be created.

`column_name`

The name of a column in the materialized view. The column names are assigned based on position. The first column name is assigned to the first column of the query result, and so on. If a column name is not provided, it is taken from the output column names of the query.

`WITH ( storage_parameter [= value] [, ... ] )`

This clause specifies optional storage parameters for the materialized view. All parameters supported for `CREATE TABLE` are also supported for `CREATE MATERIALIZED VIEW` with the exception of OIDs. See `CREATE TABLE` for more information.

`TABLESPACE tablespace_name`

The `tablespace_name` is the name of the tablespace in which the new materialized view is to be created. If not specified, server configuration parameter `default_tablespace` is consulted.

`query`

A `SELECT` or `VALUES` command. This query will run within a security-restricted operation; in particular, calls to functions that themselves create temporary tables will fail.

`WITH [ NO ] DATA`

This clause specifies whether or not the materialized view should be populated with data at creation time. `WITH DATA` is the default, populate the materialized view. For `WITH NO DATA`, the materialized view is not populated with data, is flagged as unscannable, and cannot be queried until `REFRESH MATERIALIZED VIEW` is used to populate the materialized view. An error is returned if a query attempts to access an unscannable materialized view.

`DISTRIBUTED BY (column [opclass], [ ... ] )`

`DISTRIBUTED RANDOMLY`

`DISTRIBUTED REPLICATED`

Used to declare the Greenplum Database distribution policy for the materialized view data.

For information about a table distribution policy, see `CREATE TABLE`.

## Notes

Materialized views are read only. The system will not allow an `INSERT`, `UPDATE`, or `DELETE` on a materialized view. Use `REFRESH MATERIALIZED VIEW` to update the materialized view data.

If you want the data to be ordered upon generation, you must use an `ORDER BY` clause in the materialized view query. However, if a materialized view query contains an `ORDER BY` or `SORT` clause, the data is not guaranteed to be ordered or sorted if `SELECT` is performed on the materialized view.

## Examples

Create a view consisting of all comedy films:

```
CREATE MATERIALIZED VIEW comedies AS SELECT * FROM films
WHERE kind = 'comedy';
```

This will create a view containing the columns that are in the `film` table at the time of view creation. Though `*` was used to create the materialized view, columns added later to the table will not be part of the view.

Create a view that gets the top ten ranked baby names:

```
CREATE MATERIALIZED VIEW topten AS SELECT name, rank, gender, year FROM
names, rank WHERE rank < '11' AND names.id=rank.id;
```

## Compatibility

`CREATE MATERIALIZED VIEW` is a Greenplum Database extension of the SQL standard.

## CREATE OPERATOR

Defines a new operator.

## Synopsis

```
CREATE OPERATOR <name> (
    PROCEDURE = <funcname>
    [, LEFTARG = <lefttype>] [, RIGHTARG = <righttype>]
    [, COMMUTATOR = <com_op>] [, NEGATOR = <neg_op>]
    [, RESTRICT = <res_proc>] [, JOIN = <join_proc>]
    [, HASHES] [, MERGES] )
```

## Description

`CREATE OPERATOR` defines a new operator. The user who defines an operator becomes its owner.

The operator name is a sequence of up to `NAMEDATALEN-1` (63 by default) characters from the following list: `+ - * / < > = ~ ! @ # % ^ & | ` ?`

There are a few restrictions on your choice of name:

- `--` and `/*` cannot appear anywhere in an operator name, since they will be taken as the start of a comment.
- A multicharacter operator name cannot end in `+` or `-`, unless the name also contains at least one of these characters: `~ ! @ # % ^ & | ` ?`

For example, @- is an allowed operator name, but \*- is not. This restriction allows Greenplum Database to parse SQL-compliant commands without requiring spaces between tokens.

The use of => as an operator name is deprecated. It may be disallowed altogether in a future release.

The operator != is mapped to <> on input, so these two names are always equivalent.

At least one of `LEFTARG` and `RIGHTARG` must be defined. For binary operators, both must be defined. For right unary operators, only `LEFTARG` should be defined, while for left unary operators only `RIGHTARG` should be defined.

The funcname procedure must have been previously defined using `CREATE FUNCTION`, must be `IMMUTABLE`, and must be defined to accept the correct number of arguments (either one or two) of the indicated types.

The other clauses specify optional operator optimization clauses. These clauses should be provided whenever appropriate to speed up queries that use the operator. But if you provide them, you must be sure that they are correct. Incorrect use of an optimization clause can result in server process crashes, subtly wrong output, or other unexpected results. You can always leave out an optimization clause if you are not sure about it.

To be able to create an operator, you must have `USAGE` privilege on the argument types and the return type, as well as `EXECUTE` privilege on the underlying function. If a commutator or negator operator is specified, you must own these operators.

## Parameters

### name

The (optionally schema-qualified) name of the operator to be defined. Two operators in the same schema can have the same name if they operate on different data types.

### funcname

The function used to implement this operator (must be an `IMMUTABLE` function).

### lefttype

The data type of the operator's left operand, if any. This option would be omitted for a left-unary operator.

### righttype

The data type of the operator's right operand, if any. This option would be omitted for a right-unary operator.

### com\_op

The optional `COMMUTATOR` clause names an operator that is the commutator of the operator being defined. We say that operator A is the commutator of operator B if  $(x A y)$  equals  $(y B x)$  for all possible input values  $x, y$ . Notice that B is also the commutator of A. For example, operators `<` and `>` for a particular data type are usually each others commutators, and operator `+` is usually commutative with itself. But operator `-` is usually not commutative with anything. The left operand type of a commutable operator is the same as the right operand type of its commutator, and vice versa. So the name of the commutator operator is all that needs to be provided in the `COMMUTATOR` clause.

### neg\_op

The optional `NEGATOR` clause names an operator that is the negator of the operator being defined. We say that operator A is the negator of operator B if both return Boolean results

and  $(x A y)$  equals NOT  $(x B y)$  for all possible inputs  $x, y$ . Notice that  $B$  is also the negator of  $A$ . For example,  $<$  and  $>=$  are a negator pair for most data types. An operator's negator must have the same left and/or right operand types as the operator to be defined, so only the operator name need be given in the `NEGATOR` clause.

#### res\_proc

The optional `RESTRICT` names a restriction selectivity estimation function for the operator. Note that this is a function name, not an operator name. `RESTRICT` clauses only make sense for binary operators that return `boolean`. The idea behind a restriction selectivity estimator is to guess what fraction of the rows in a table will satisfy a `WHERE`-clause condition of the form:

```
column OP constant
```

for the current operator and a particular constant value. This assists the optimizer by giving it some idea of how many rows will be eliminated by `WHERE` clauses that have this form.

You can usually just use one of the following system standard estimator functions for many of your own operators:

```
`eqsel` for =
`neqsel` for <>
`scalarltsel` for < or <=
`scalargtsel` for \> or \>=
```

#### join\_proc

The optional `JOIN` clause names a join selectivity estimation function for the operator. Note that this is a function name, not an operator name. `JOIN` clauses only make sense for binary operators that return `boolean`. The idea behind a join selectivity estimator is to guess what fraction of the rows in a pair of tables will satisfy a `WHERE`-clause condition of the form

```
table1.column1 OP table2.column2
```

: for the current operator. This helps the optimizer by letting it figure out which of several possible join sequences is likely to take the least work.

You can usually just use one of the following system standard join selectivity estimator functions for many of your own operators:

```
eqjoinselect for =
neqjoinselect for <>
scalarltjoinselect for < or <=
scalargtjoinselect for > or >=
areajoinselect for 2D area-based comparisons
positionjoinselect for 2D position-based comparisons
contjoinselect for 2D containment-based comparisons
```

#### HASHES

The optional `HASHES` clause tells the system that it is permissible to use the hash join method for a join based on this operator. `HASHES` only makes sense for a binary operator that returns `boolean`. The hash join operator can only return true for pairs of left and right values that hash to the same hash code. If two values are put in different hash buckets, the join will never compare them, implicitly assuming that the result of the join operator must be false. Because of this, it never makes sense to specify `HASHES` for operators that do not represent equality.

In most cases, it is only practical to support hashing for operators that take the same data type on both sides. However, you can design compatible hash functions for two or more data types, which are functions that will generate the same hash codes for "equal" values, even if the values are differently represented.

To be marked `HASHES`, the join operator must appear in a hash index operator class. Attempts to use the operator in hash joins will fail at run time if no such operator class exists. The system needs the operator class to find the data-type-specific hash function for the operator's input data type. You must also supply a suitable hash function before you can create the operator class. Exercise care when preparing a hash function, as there are machine-dependent ways in which it could fail to function correctly. For example, on machines that meet the IEEE floating-point standard, negative zero and positive zero are different values (different bit patterns) but are defined to compare as equal. If a float value could contain a negative zero, define it to generate the same hash value as positive zero.

A hash-joinable operator must have a commutator (itself, if the two operand data types are the same, or a related equality operator if they are different) that appears in the same operator family. Otherwise, planner errors can occur when the operator is used. For better optimization, a hash operator family that supports multiple data types should provide equality operators for every combination of the data types.

**Note:** The function underlying a hash-joinable operator must be marked immutable or stable; an operator marked as volatile will not be used. If a hash-joinable operator has an underlying function that is marked strict, the function must also be complete, returning true or false, and not null, for any two non-null inputs.

## MERGES

The `MERGES` clause, if present, tells the system that it is permissible to use the merge-join method for a join based on this operator. `MERGES` only makes sense for a binary operator that returns `boolean`, and in practice the operator must represent equality for some data type or pair of data types.

Merge join is based on the idea of sorting the left- and right-hand tables into order and then scanning them in parallel. This means both data types must be capable of being fully ordered, and the join operator must be one that can only succeed for pairs of values that fall at equivalent places in the sort order. In practice, this means that the join operator must behave like an equality operator. However, you can merge-join two distinct data types so long as they are logically compatible. For example, the `smallint-versus-integer` equality operator is merge-joinable. Only sorting operators that bring both data types into a logically compatible sequence are needed.

To be marked `MERGES`, the join operator must appear as an equality member of a btree index operator family. This is not enforced when you create the operator, because the referencing

operator family does not exist until later. However, the operator will not actually be used for merge joins unless a matching operator family can be found. The `MERGE` flag thus acts as a suggestion to the planner to look for a matching operator family.

A merge-joinable operator must have a commutator that appears in the same operator family. This would be itself, if the two operand data types are the same, or a related equality operator if the data types are different. Without an appropriate commutator, planner errors can occur when the operator is used. Also, although not strictly required, a btree operator family that supports multiple data types should be able to provide equality operators for every combination of the data types; this allows better optimization.

**Note:** `SORT1`, `SORT2`, `LTCMP`, and `GTCMP` were formerly used to specify the names of sort operators associated with a merge-joinable operator. Information about associated operators is now found by looking at B-tree operator families; specifying any of these operators will be ignored, except that it will implicitly set `MERGES` to true.

## Notes

Any functions used to implement the operator must be defined as `IMMUTABLE`.

It is not possible to specify an operator's lexical precedence in `CREATE OPERATOR`, because the parser's precedence behavior is hard-wired. See [Operator Precedence](#) in the PostgreSQL documentation for precedence details.

Use `DROP OPERATOR` to delete user-defined operators from a database. Use `ALTER OPERATOR` to modify operators in a database.

## Examples

Here is an example of creating an operator for adding two complex numbers, assuming we have already created the definition of type `complex`. First define the function that does the work, then define the operator:

```
CREATE FUNCTION complex_add(complex, complex)
  RETURNS complex
  AS 'filename', 'complex_add'
  LANGUAGE C IMMUTABLE STRICT;
CREATE OPERATOR + (
  leftarg = complex,
  rightarg = complex,
  procedure = complex_add,
  commutator = +
);
```

To use this operator in a query:

```
SELECT (a + b) AS c FROM test_complex;
```

## Compatibility

`CREATE OPERATOR` is a Greenplum Database language extension. The SQL standard does not provide for user-defined operators.

## See Also

## CREATE OPERATOR CLASS

Defines a new operator class.

### Synopsis

```
CREATE OPERATOR CLASS <name> [DEFAULT] FOR TYPE <data_type>
  USING <index_method> [ FAMILY <family_name> ] AS
  { OPERATOR <strategy_number> <operator_name> [ ( <op_type>, <op_type> ) ] [ FOR SEAR
CH | FOR ORDER BY <sort_family_name> ]
  | FUNCTION <support_number> <funcname> (<argument_type> [, ...] )
  | STORAGE <storage_type>
  } [, ... ]
```

### Description

`CREATE OPERATOR CLASS` creates a new operator class. An operator class defines how a particular data type can be used with an index. The operator class specifies that certain operators will fill particular roles or strategies for this data type and this index method. The operator class also specifies the support procedures to be used by the index method when the operator class is selected for an index column. All the operators and functions used by an operator class must be defined before the operator class is created. Any functions used to implement the operator class must be defined as `IMMUTABLE`.

`CREATE OPERATOR CLASS` does not presently check whether the operator class definition includes all the operators and functions required by the index method, nor whether the operators and functions form a self-consistent set. It is the user's responsibility to define a valid operator class.

You must be a superuser to create an operator class.

### Parameters

name

The (optionally schema-qualified) name of the operator class to be defined. Two operator classes in the same schema can have the same name only if they are for different index methods.

DEFAULT

Makes the operator class the default operator class for its data type. At most one operator class can be the default for a specific data type and index method.

data\_type

The column data type that this operator class is for.

index\_method

The name of the index method this operator class is for. Choices are `btree`, `bitmap`, and `gist`.

family\_name

The name of the existing operator family to add this operator class to. If not specified, a family named the same as the operator class is used (creating it, if it doesn't already exist).

strategy\_number

The operators associated with an operator class are identified by *strategy numbers*, which serve to identify the semantics of each operator within the context of its operator class. For example, B-trees impose a strict ordering on keys, lesser to greater, and so operators like *less than* and *greater than or equal to* are interesting with respect to a B-tree. These strategies can be thought of as generalized operators. Each operator class specifies which actual operator corresponds to each strategy for a particular data type and interpretation of the index semantics. The corresponding strategy numbers for each index method are as follows:

| Operation             | Strategy Number |
|-----------------------|-----------------|
| less than             | 1               |
| less than or equal    | 2               |
| equal                 | 3               |
| greater than or equal | 4               |
| greater than          | 5               |

| Operation                   | Strategy Number |
|-----------------------------|-----------------|
| strictly left of            | 1               |
| does not extend to right of | 2               |
| overlaps                    | 3               |
| does not extend to left of  | 4               |
| strictly right of           | 5               |
| same                        | 6               |
| contains                    | 7               |
| contained by                | 8               |
| does not extend above       | 9               |
| strictly below              | 10              |
| strictly above              | 11              |
| does not extend below       | 12              |

sort\_family\_name

The name (optionally schema-qualified) of an existing *btree* operator family that describes the sort ordering associated with an ordering operator.

If neither `FOR SEARCH` nor `FOR ORDER BY` is specified, `FOR SEARCH` is the default.

operator\_name

The name (optionally schema-qualified) of an operator associated with the operator class.

op\_type

In an `OPERATOR` clause, the operand data type(s) of the operator, or `NONE` to signify a left-ary or right-ary operator. The operand data types can be omitted in the normal case where they are the same as the operator class's data type.

In a `FUNCTION` clause, the operand data type(s) the function is intended to support, if different from the input data type(s) of the function (for B-tree comparison functions and hash functions) or the class's data type (for B-tree sort support functions and all functions in GiST, SP-GiST, and GIN operator classes). These defaults are correct, and so `op_type` need not be specified in `FUNCTION` clauses, except for the case of a B-tree sort support function that is meant to support cross-data-type comparisons.

#### support\_number

Index methods require additional support routines in order to work. These operations are administrative routines used internally by the index methods. As with strategies, the operator class identifies which specific functions should play each of these roles for a given data type and semantic interpretation. The index method defines the set of functions it needs, and the operator class identifies the correct functions to use by assigning them to the *support function numbers* as follows:

| Function  | Support Number |
|---|----------------|
| Compare two keys and return an integer less than zero, zero, or greater than zero, indicating whether the first key is less than, equal to, or greater than the second. | 1              |
| Function  | Support Number |
| consistent - determine whether key satisfies the query qualifier.   | 1              |
| union - compute union of a set of keys.   | 2              |
| compress - compute a compressed representation of a key or value to be indexed.   | 3              |
| decompress - compute a decompressed representation of a compressed key.   | 4              |
| penalty - compute penalty for inserting new key into subtree with given subtree's key.  | 5              |
| picksplit - determine which entries of a page are to be moved to the new page and compute the union keys for resulting pages.   | 6              |
| equal - compare two keys and return true if they are equal.   | 7              |

#### funcname

The name (optionally schema-qualified) of a function that is an index method support procedure for the operator class.

#### argument\_types

The parameter data type(s) of the function.

#### storage\_type

The data type actually stored in the index. Normally this is the same as the column data type, but some index methods (currently GiST and GIN) allow it to be different. The `STORAGE` clause must be omitted unless the index method allows a different type to be used.

## Notes

Because the index machinery does not check access permissions on functions before using them, including a function or operator in an operator class is the same as granting public execute permission on it. This is usually not an issue for the sorts of functions that are useful in an operator class.

The operators should not be defined by SQL functions. A SQL function is likely to be inlined into the calling query, which will prevent the optimizer from recognizing that the query matches an index.

Any functions used to implement the operator class must be defined as `IMMUTABLE`.

Before Greenplum Database 6.0, the `OPERATOR` clause could include a `RECHECK` option. This option is no longer supported. Greenplum Database now determines whether an index operator is "lossy" on-the-fly at run time. This allows more efficient handling of cases where an operator might or might not be lossy.

## Examples

The following example command defines a GiST index operator class for the data type `_int4` (array of `int4`). See the `intarray` contrib module for the complete example.

```
CREATE OPERATOR CLASS gist__int_ops
  DEFAULT FOR TYPE _int4 USING gist AS
  OPERATOR 3 &&,
  OPERATOR 6 = (anyarray, anyarray),
  OPERATOR 7 @>,
  OPERATOR 8 <@,
  OPERATOR 20 @@ (_int4, query_int),
  FUNCTION 1 g_int_consistent (internal, _int4, int, oid, internal),
  FUNCTION 2 g_int_union (internal, internal),
  FUNCTION 3 g_int_compress (internal),
  FUNCTION 4 g_int_decompress (internal),
  FUNCTION 5 g_int_penalty (internal, internal, internal),
  FUNCTION 6 g_int_picksplit (internal, internal),
  FUNCTION 7 g_int_same (_int4, _int4, internal);
```

## Compatibility

`CREATE OPERATOR CLASS` is a Greenplum Database extension. There is no `CREATE OPERATOR CLASS` statement in the SQL standard.

## See Also

[ALTER OPERATOR CLASS](#), [DROP OPERATOR CLASS](#), [CREATE FUNCTION](#)

Parent topic: [SQL Commands](#)

## CREATE OPERATOR FAMILY

Defines a new operator family.

## Synopsis

```
CREATE OPERATOR FAMILY <name> USING <index_method>
```

## Description

`CREATE OPERATOR FAMILY` creates a new operator family. An operator family defines a collection of related operator classes, and perhaps some additional operators and support functions that are compatible with these operator classes but not essential for the functioning of any individual index. (Operators and functions that are essential to indexes should be grouped within the relevant operator class, rather than being "loose" in the operator family. Typically, single-data-type operators are bound to operator classes, while cross-data-type operators can be loose in an operator family containing operator classes for both data types.)

The new operator family is initially empty. It should be populated by issuing subsequent `CREATE OPERATOR CLASS` commands to add contained operator classes, and optionally `ALTER OPERATOR FAMILY` commands to add "loose" operators and their corresponding support functions.

If a schema name is given then the operator family is created in the specified schema. Otherwise it is created in the current schema. Two operator families in the same schema can have the same name only if they are for different index methods.

The user who defines an operator family becomes its owner. Presently, the creating user must be a superuser. (This restriction is made because an erroneous operator family definition could confuse or even crash the server.)

## Parameters

name

The (optionally schema-qualified) name of the operator family to be defined. The name can be schema-qualified.

index\_method

The name of the index method this operator family is for.

## Compatibility

`CREATE OPERATOR FAMILY` is a Greenplum Database extension. There is no `CREATE OPERATOR FAMILY` statement in the SQL standard.

## See Also

## CREATE PROTOCOL

Registers a custom data access protocol that can be specified when defining a Greenplum Database external table.

## Synopsis

```
CREATE [TRUSTED] PROTOCOL <name> (
  [readfunc='<read_call_handler>'] [, writefunc='<write_call_handler>']
  [, validatorfunc='<validate_handler>' ])
```

## Description

`CREATE PROTOCOL` associates a data access protocol name with call handlers that are responsible for reading from and writing data to an external data source. You must be a superuser to create a protocol.

The `CREATE PROTOCOL` command must specify either a read call handler or a write call handler. The call handlers specified in the `CREATE PROTOCOL` command must be defined in the database.

The protocol name can be specified in a `CREATE EXTERNAL TABLE` command.

For information about creating and enabling a custom data access protocol, see "Example Custom Data Access Protocol" in the *Greenplum Database Administrator Guide*.

## Parameters

### TRUSTED

If not specified, only superusers and the protocol owner can create external tables using the protocol. If specified, superusers and the protocol owner can `GRANT` permissions on the protocol to other database roles.

### name

The name of the data access protocol. The protocol name is case sensitive. The name must be unique among the protocols in the database.

### readfunc= 'read\_call\_handler'

The name of a previously registered function that Greenplum Database calls to read data from an external data source. The command must specify either a read call handler or a write call handler.

### writefunc= 'write\_call\_handler'

The name of a previously registered function that Greenplum Database calls to write data to an external data source. The command must specify either a read call handler or a write call handler.

### validatorfunc='validate\_handler'

An optional validator function that validates the URL specified in the `CREATE EXTERNAL TABLE` command.

## Notes

Greenplum Database handles external tables of type `file`, `gpfdist`, and `gpfdists` internally. See [s3:// Protocol](#) for information about enabling the `s3` protocol. Refer to [pxf:// Protocol](#) for information about using the `pxf` protocol.

Any shared library that implements a data access protocol must be located in the same location on all Greenplum Database segment hosts. For example, the shared library can be in a location

specified by the operating system environment variable `LD_LIBRARY_PATH` on all hosts. You can also specify the location when you define the handler function. For example, when you define the `s3` protocol in the `CREATE PROTOCOL` command, you specify `$libdir/gps3ext.so` as the location of the shared object, where `$libdir` is located at `$GPHOME/lib`.

## Compatibility

`CREATE PROTOCOL` is a Greenplum Database extension.

## See Also

[ALTER PROTOCOL](#), [CREATE EXTERNAL TABLE](#), [DROP PROTOCOL](#), [GRANT](#)

Parent topic: [SQL Commands](#)

## CREATE RESOURCE GROUP

Defines a new resource group.

## Synopsis

```
CREATE RESOURCE GROUP <name> WITH (<group_attribute>=<value> [, ... ])
```

where `group_attribute` is:

```
CPU_RATE_LIMIT=<integer> | CPuset=<tuple>
[ MEMORY_LIMIT=<integer> ]
[ CONCURRENCY=<integer> ]
[ MEMORY_SHARED_QUOTA=<integer> ]
[ MEMORY_SPILL_RATIO=<integer> ]
[ MEMORY_AUDITOR= {vmtracker | cgroup} ]
```

## Description

Creates a new resource group for Greenplum Database resource management. You can create resource groups to manage resources for roles or to manage the resources of a Greenplum Database external component such as PL/Container.

A resource group that you create to manage a user role identifies concurrent transaction, memory, and CPU limits for the role when resource groups are enabled. You may assign such resource groups to one or more roles.

A resource group that you create to manage the resources of a Greenplum Database external component such as PL/Container identifies the memory and CPU limits for the component when resource groups are enabled. These resource groups use cgroups for both CPU and memory management. Assignment of resource groups to external components is component-specific. For example, you assign a PL/Container resource group when you configure a PL/Container runtime. You cannot assign a resource group that you create for external components to a role, nor can you assign a resource group that you create for roles to an external component.

You must have `SUPERUSER` privileges to create a resource group. The maximum number of resource groups allowed in your Greenplum Database cluster is 100.

Greenplum Database pre-defines two default resource groups: `admin_group` and `default_group`. These group names, as well as the group name `none`, are reserved.

To set appropriate limits for resource groups, the Greenplum Database administrator must be familiar with the queries typically run on the system, as well as the users/roles running those queries and the external components they may be using, such as PL/Containers.

After creating a resource group for a role, assign the group to one or more roles using the `ALTER ROLE` or `CREATE ROLE` commands.

After you create a resource group to manage the CPU and memory resources of an external component, configure the external component to use the resource group. For example, configure the PL/Container runtime `resource_group_id`.

## Parameters

name

The name of the resource group.

CONCURRENCY integer

The maximum number of concurrent transactions, including active and idle transactions, that are permitted for this resource group. The `CONCURRENCY` value must be an integer in the range `[0 .. max_connections]`. The default `CONCURRENCY` value for resource groups defined for roles is 20.

You must set `CONCURRENCY` to zero (0) for resource groups that you create for external components.

**Note:** You cannot set the `CONCURRENCY` value for the `admin_group` to zero (0).

CPU\_RATE\_LIMIT integer

CPUSET tuple

Required. You must specify only one of `CPU_RATE_LIMIT` or `CPUSET` when you create a resource group.

`CPU_RATE_LIMIT` is the percentage of CPU resources to allocate to this resource group. The minimum CPU percentage you can specify for a resource group is 1. The maximum is 100. The sum of the `CPU_RATE_LIMIT` values specified for all resource groups defined in the Greenplum Database cluster must be less than or equal to 100.

`CPUSET` identifies the CPU cores to reserve for this resource group. The CPU cores that you specify in tuple must be available in the system and cannot overlap with any CPU cores that you specify for other resource groups.

tuple is a comma-separated list of single core numbers or core number intervals. You must enclose tuple in single quotes, for example, `'1,3-4'`.

**Note:** You can configure `CPUSET` for a resource group only after you have enabled resource group-based resource management for your Greenplum Database cluster.

MEMORY\_LIMIT integer

The total percentage of Greenplum Database memory resources to reserve for this resource group. The minimum memory percentage you can specify for a resource group is 0. The maximum is 100. The default value is 0.

When you specify a `MEMORY_LIMIT` of 0, Greenplum Database reserves no memory for the resource group, but uses global shared memory to fulfill all memory requests in the group. If `MEMORY_LIMIT` is 0, `MEMORY_SPILL_RATIO` must also be 0.

The sum of the `MEMORY_LIMIT` values specified for all resource groups defined in the Greenplum Database cluster must be less than or equal to 100.

#### `MEMORY_SHARED_QUOTA` integer

The quota of shared memory in the resource group. Resource groups with a `MEMORY_SHARED_QUOTA` threshold set aside a percentage of memory allotted to the resource group to share across transactions. This shared memory is allocated on a first-come, first-served basis as available. A transaction may use none, some, or all of this memory. The minimum memory shared quota percentage you can specify for a resource group is 0. The maximum is 100. The default `MEMORY_SHARED_QUOTA` value is 80.

#### `MEMORY_SPILL_RATIO` integer

The memory usage threshold for memory-intensive operators in a transaction. When this threshold is reached, a transaction spills to disk. You can specify an integer percentage value from 0 to 100 inclusive. The default `MEMORY_SPILL_RATIO` value is 0. When `MEMORY_SPILL_RATIO` is 0, Greenplum Database uses the `statement_mem` server configuration parameter value to control initial query operator memory.

#### `MEMORY_AUDITOR` {`vmtracker` | `cgroup`}

The memory auditor for the resource group. Greenplum Database employs virtual memory tracking for role resources and `cgroup` memory tracking for resources used by external components. The default `MEMORY_AUDITOR` is `vmtracker`. When you create a resource group with `vmtracker` memory auditing, Greenplum Database tracks that resource group's memory internally.

When you create a resource group specifying the `cgroup` `MEMORY_AUDITOR`, Greenplum Database defers the accounting of memory used by that resource group to `cgroups`. `CONCURRENCY` must be zero (0) for a resource group that you create for external components such as PL/Container. You cannot assign a resource group that you create for external components to a Greenplum Database role.

## Notes

You cannot submit a `CREATE RESOURCE GROUP` command in an explicit transaction or sub-transaction.

Use the `gp_toolkit.gp_resgroup_config` system view to display the limit settings of all resource groups:

```
SELECT * FROM gp_toolkit.gp_resgroup_config;
```

## Examples

Create a resource group with CPU and memory limit percentages of 35:

```
CREATE RESOURCE GROUP rgroup1 WITH (CPU_RATE_LIMIT=35, MEMORY_LIMIT=35);
```

Create a resource group with a concurrent transaction limit of 20, a memory limit of 15, and a CPU limit of 25:

```
CREATE RESOURCE GROUP rgroup2 WITH (CONCURRENCY=20,
MEMORY_LIMIT=15, CPU_RATE_LIMIT=25);
```

Create a resource group to manage PL/Container resources specifying a memory limit of 10, and a CPU limit of 10:

```
CREATE RESOURCE GROUP plc_run1 WITH (MEMORY_LIMIT=10, CPU_RATE_LIMIT=10,
CONCURRENCY=0, MEMORY_AUDITOR=cgroup);
```

Create a resource group with a memory limit percentage of 11 to which you assign CPU cores 1 to 3:

```
CREATE RESOURCE GROUP rgroup3 WITH (CPUSET='1-3', MEMORY_LIMIT=11);
```

## Compatibility

`CREATE RESOURCE GROUP` is a Greenplum Database extension. There is no provision for resource groups or resource management in the SQL standard.

## CREATE RESOURCE QUEUE

Defines a new resource queue.

## Synopsis

```
CREATE RESOURCE QUEUE <name> WITH (<queue_attribute>=<value> [, ... ])
```

where `queue_attribute` is:

```
ACTIVE_STATEMENTS=<integer>
  [ MAX_COST=<float > [ COST_OVERCOMMIT={TRUE|FALSE} ] ]
  [ MIN_COST=<float > ]
  [ PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX} ]
  [ MEMORY_LIMIT='<memory_units>' ]

| MAX_COST=float [ COST_OVERCOMMIT={TRUE|FALSE} ]
  [ ACTIVE_STATEMENTS=<integer > ]
  [ MIN_COST=<float > ]
```

```
[ PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX} ]
[ MEMORY_LIMIT='<memory_units>' ]
```

## Description

Creates a new resource queue for Greenplum Database resource management. A resource queue must have either an `ACTIVE_STATEMENTS` or a `MAX_COST` value (or it can have both). Only a superuser can create a resource queue.

Resource queues with an `ACTIVE_STATEMENTS` threshold set a maximum limit on the number of queries that can be run by roles assigned to that queue. It controls the number of active queries that are allowed to run at the same time. The value for `ACTIVE_STATEMENTS` should be an integer greater than 0.

Resource queues with a `MAX_COST` threshold set a maximum limit on the total cost of queries that can be run by roles assigned to that queue. Cost is measured in the *estimated total cost* for the query as determined by the query planner (as shown in the `EXPLAIN` output for a query). Therefore, an administrator must be familiar with the queries typically run on the system in order to set an appropriate cost threshold for a queue. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for `MAX_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2). If a resource queue is limited based on a cost threshold, then the administrator can allow `COST_OVERCOMMIT=TRUE` (the default). This means that a query that exceeds the allowed cost threshold will be allowed to run but only when the system is idle. If `COST_OVERCOMMIT=FALSE` is specified, queries that exceed the cost limit will always be rejected and never allowed to run. Specifying a value for `MIN_COST` allows the administrator to define a cost for small queries that will be exempt from resource queueing.

**Note:** GPORCA and the Postgres Planner utilize different query costing models and may compute different costs for the same query. The Greenplum Database resource queue resource management scheme neither differentiates nor aligns costs between GPORCA and the Postgres Planner; it uses the literal cost value returned from the optimizer to throttle queries.

When resource queue-based resource management is active, use the `MEMORY_LIMIT` and `ACTIVE_STATEMENTS` limits for resource queues rather than configuring cost-based limits. Even when using GPORCA, Greenplum Database may fall back to using the Postgres Planner for certain queries, so using cost-based limits can lead to unexpected results.

If a value is not defined for `ACTIVE_STATEMENTS` or `MAX_COST`, it is set to `-1` by default (meaning no limit). After defining a resource queue, you must assign roles to the queue using the `ALTER ROLE` or `CREATE ROLE` command.

You can optionally assign a `PRIORITY` to a resource queue to control the relative share of available CPU resources used by queries associated with the queue in relation to other resource queues. If a value is not defined for `PRIORITY`, queries associated with the queue have a default priority of `MEDIUM`.

Resource queues with an optional `MEMORY_LIMIT` threshold set a maximum limit on the amount of memory that all queries submitted through a resource queue can consume on a segment host. This determines the total amount of memory that all worker processes of a query can consume on a segment host during query execution. Greenplum recommends that `MEMORY_LIMIT` be used in conjunction with `ACTIVE_STATEMENTS` rather than with `MAX_COST`. The default amount of memory

allotted per query on statement-based queues is: `MEMORY_LIMIT / ACTIVE_STATEMENTS`. The default amount of memory allotted per query on cost-based queues is: `MEMORY_LIMIT * (query_cost / MAX_COST)`.

The default memory allotment can be overridden on a per-query basis using the `statement_mem` server configuration parameter, provided that `MEMORY_LIMIT` or `max_statement_mem` is not exceeded. For example, to allocate more memory to a particular query:

```
=> SET statement_mem='2GB';
=> SELECT * FROM my_big_table WHERE column='value' ORDER BY id;
=> RESET statement_mem;
```

The `MEMORY_LIMIT` value for all of your resource queues should not exceed the amount of physical memory of a segment host. If workloads are staggered over multiple queues, memory allocations can be oversubscribed. However, queries can be cancelled during execution if the segment host memory limit specified in `gp_vmem_protect_limit` is exceeded.

For information about `statement_mem`, `max_statement`, and `gp_vmem_protect_limit`, see [Server Configuration Parameters](#).

## Parameters

name

The name of the resource queue.

`ACTIVE_STATEMENTS` integer

Resource queues with an `ACTIVE_STATEMENTS` threshold limit the number of queries that can be run by roles assigned to that queue. It controls the number of active queries that are allowed to run at the same time. The value for `ACTIVE_STATEMENTS` should be an integer greater than 0.

`MEMORY_LIMIT` 'memory\_units'

Sets the total memory quota for all statements submitted from users in this resource queue. Memory units can be specified in kB, MB or GB. The minimum memory quota for a resource queue is 10MB. There is no maximum, however the upper boundary at query execution time is limited by the physical memory of a segment host. The default is no limit (-1).

`MAX_COST` float

Resource queues with a `MAX_COST` threshold set a maximum limit on the total cost of queries that can be run by roles assigned to that queue. Cost is measured in the *estimated total cost* for the query as determined by the Greenplum Database query optimizer (as shown in the `EXPLAIN` output for a query). Therefore, an administrator must be familiar with the queries typically run on the system in order to set an appropriate cost threshold for a queue. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for `MAX_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2).

`COST_OVERCOMMIT` boolean

If a resource queue is limited based on `MAX_COST`, then the administrator can allow `COST_OVERCOMMIT` (the default). This means that a query that exceeds the allowed cost threshold will be allowed to run but only when the system is idle. If `COST_OVERCOMMIT=FALSE` is specified, queries that exceed the cost limit will always be rejected and never allowed to run.

`MIN_COST` float

The minimum query cost limit of what is considered a small query. Queries with a cost under this limit will not be queued and run immediately. Cost is measured in the *estimated total cost* for the query as determined by the query planner (as shown in the `EXPLAIN` output for a query). Therefore, an administrator must be familiar with the queries typically run on the system in order to set an appropriate cost for what is considered a small query. Cost is measured in units of disk page fetches; 1.0 equals one sequential disk page read. The value for `MIN_COST` is specified as a floating point number (for example 100.0) or can also be specified as an exponent (for example 1e+2).

`PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX}`

Sets the priority of queries associated with a resource queue. Queries or statements in queues with higher priority levels will receive a larger share of available CPU resources in case of contention. Queries in low-priority queues may be delayed while higher priority queries are run. If no priority is specified, queries associated with the queue have a priority of `MEDIUM`.

## Notes

Use the `gp_toolkit.gp_resqueue_status` system view to see the limit settings and current status of a resource queue:

```
SELECT * from gp_toolkit.gp_resqueue_status WHERE
    rsqname='queue_name';
```

There is also another system view named `pg_stat_resqueues` which shows statistical metrics for a resource queue over time. To use this view, however, you must enable the `stats_queue_level` server configuration parameter. See "Managing Workload and Resources" in the *Greenplum Database Administrator Guide* for more information about using resource queues.

`CREATE RESOURCE QUEUE` cannot be run within a transaction.

Also, an SQL statement that is run during the execution time of an `EXPLAIN ANALYZE` command is excluded from resource queues.

## Examples

Create a resource queue with an active query limit of 20:

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20);
```

Create a resource queue with an active query limit of 20 and a total memory limit of 2000MB (each query will be allocated 100MB of segment host memory at execution time):

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=20,
    MEMORY_LIMIT='2000MB');
```

Create a resource queue with a query cost limit of 3000.0:

```
CREATE RESOURCE QUEUE myqueue WITH (MAX_COST=3000.0);
```

Create a resource queue with a query cost limit of 310 (or 30000000000.0) and do not allow overcommit. Allow small queries with a cost under 500 to run immediately:

```
CREATE RESOURCE QUEUE myqueue WITH (MAX_COST=3e+10,
  COST_OVERCOMMIT=FALSE, MIN_COST=500.0);
```

Create a resource queue with both an active query limit and a query cost limit:

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=30,
  MAX_COST=5000.00);
```

Create a resource queue with an active query limit of 5 and a maximum priority setting:

```
CREATE RESOURCE QUEUE myqueue WITH (ACTIVE_STATEMENTS=5,
  PRIORITY=MAX);
```

## Compatibility

`CREATE RESOURCE QUEUE` is a Greenplum Database extension. There is no provision for resource queues or resource management in the SQL standard.

| RESOURCE GROUP <group_name>
| [ DENY <deny_point> ]
| [ DENY BETWEEN <deny_point> AND <deny_point>]

```

## Description

**CREATE ROLE** adds a new role to a Greenplum Database system. A role is an entity that can own database objects and have database privileges. A role can be considered a user, a group, or both depending on how it is used. You must have **CREATEROLE** privilege or be a database superuser to use this command.

Note that roles are defined at the system-level and are valid for all databases in your Greenplum Database system.

## Parameters

name

The name of the new role.

**SUPERUSER**

**NOSUPERUSER**

If **SUPERUSER** is specified, the role being defined will be a superuser, who can override all access restrictions within the database. Superuser status is dangerous and should be used only when really needed. You must yourself be a superuser to create a new superuser.

**NOSUPERUSER** is the default.

**CREATEDB**

**NOCREATEDB**

If **CREATEDB** is specified, the role being defined will be allowed to create new databases.

**NOCREATEDB** (the default) will deny a role the ability to create databases.

**CREATEROLE**

**NOCREATEROLE**

If **CREATEROLE** is specified, the role being defined will be allowed to create new roles, alter other roles, and drop other roles. **NOCREATEROLE** (the default) will deny a role the ability to create roles or modify roles other than their own.

**CREATEUSER**

**NOCREATEUSER**

These clauses are obsolete, but still accepted, spellings of **SUPERUSER** and **NOSUPERUSER**. Note that they are not equivalent to the **CREATEROLE** and **NOCREATEROLE** clauses.

**CREATEEXTTABLE**

**NOCREATEEXTTABLE**

If **CREATEEXTTABLE** is specified, the role being defined is allowed to create external tables. The default **type** is **readable** and the default **protocol** is **gpfdist**, if not specified. Valid types are **gpfdist**, **gpfdists**, **http**, and **https**. **NOCREATEEXTTABLE** (the default type) denies the role the

ability to create external tables. Note that external tables that use the `file` or `execute` protocols can only be created by superusers.

Use the `GRANT...ON PROTOCOL` command to allow users to create and use external tables with a custom protocol type, including the `s3` and `pxf` protocols included with Greenplum Database.

#### INHERIT

#### NOINHERIT

If specified, `INHERIT` (the default) allows the role to use whatever database privileges have been granted to all roles it is directly or indirectly a member of. With `NOINHERIT`, membership in another role only grants the ability to `SET ROLE` to that other role.

#### LOGIN

#### NOLOGIN

If specified, `LOGIN` allows a role to log in to a database. A role having the `LOGIN` attribute can be thought of as a user. Roles with `NOLOGIN` are useful for managing database privileges, and can be thought of as groups. If not specified, `NOLOGIN` is the default, except when `CREATE ROLE` is invoked through its alternative spelling `CREATE USER`.

#### REPLICATION

#### NOREPLICATION

These clauses determine whether a role is allowed to initiate streaming replication or put the system in and out of backup mode. A role having the `REPLICATION` attribute is a very highly privileged role, and should only be used on roles actually used for replication. If not specified, `NOREPLICATION` is the default.

#### CONNECTION LIMIT `connlimit`

The number maximum of concurrent connections this role can make. The default of -1 means there is no limitation.

#### PASSWORD `password`

Sets the user password for roles with the `LOGIN` attribute. If you do not plan to use password authentication you can omit this option. If no password is specified, the password will be set to null and password authentication will always fail for that user. A null password can optionally be written explicitly as `PASSWORD NULL`. Specifying an empty string will also set the password to null, but that was not the case before Greenplum Database version 6.21. In earlier versions, an empty string could be used, or not, depending on the authentication method and the exact version, and libpq would refuse to use it in any case. To avoid the ambiguity, specifying an empty string should be avoided.

The `ENCRYPTED` and `UNENCRYPTED` key words control whether the password is stored encrypted in the system catalogs. (If neither is specified, the default behavior is determined by the configuration parameter `password_encryption`.) If the presented password string is already in MD5-encrypted or SCRAM-encrypted format, then it is stored encrypted as-is, regardless of whether `ENCRYPTED` or `UNENCRYPTED` is specified (since the system cannot decrypt the specified encrypted password string). This allows reloading of encrypted passwords during dump/restore. Note that older clients might lack support for the SCRAM authentication mechanism.

#### VALID UNTIL '`timestamp`'

The `VALID UNTIL` clause sets a date and time after which the role's password is no longer valid. If this clause is omitted the password will never expire.

#### IN ROLE `rolename`

Adds the new role as a member of the named roles. Note that there is no option to add the new role as an administrator; use a separate `GRANT` command to do that.

`ROLE rolename`

Adds the named roles as members of this role, making this new role a group.

`ADMIN rolename`

The `ADMIN` clause is like `ROLE`, but the named roles are added to the new role `WITH ADMIN OPTION`, giving them the right to grant membership in this role to others.

`RESOURCE GROUP group_name`

The name of the resource group to assign to the new role. The role will be subject to the concurrent transaction, memory, and CPU limits configured for the resource group. You can assign a single resource group to one or more roles.

If you do not specify a resource group for a new role, the role is automatically assigned the default resource group for the role's capability, `admin_group` for `SUPERUSER` roles, `default_group` for non-admin roles.

You can assign the `admin_group` resource group to any role having the `SUPERUSER` attribute.

You can assign the `default_group` resource group to any role.

You cannot assign a resource group that you create for an external component to a role.

`RESOURCE QUEUE queue_name`

The name of the resource queue to which the new user-level role is to be assigned. Only roles with `LOGIN` privilege can be assigned to a resource queue. The special keyword `NONE` means that the role is assigned to the default resource queue. A role can only belong to one resource queue.

Roles with the `SUPERUSER` attribute are exempt from resource queue limits. For a superuser role, queries always run immediately regardless of limits imposed by an assigned resource queue.

`DENY deny_point`

`DENY BETWEEN deny_point AND deny_point`

The `DENY` and `DENY BETWEEN` keywords set time-based constraints that are enforced at login. `DENY` sets a day or a day and time to deny access. `DENY BETWEEN` sets an interval during which access is denied. Both use the parameter `deny_point` that has the following format:

```
DAY day [ TIME 'time' ]
```

The two parts of the `deny_point` parameter use the following formats:

For `day`:

```
{ 'Sunday' | 'Monday' | 'Tuesday' | 'Wednesday' | 'Thursday' | 'Friday' |  
'Saturday' | 0-6 }
```

For `time`:

```
{ 00-23 : 00-59 | 01-12 : 00-59 { AM | PM } }
```

The `DENY BETWEEN` clause uses two `deny_point` parameters:

```
DENY BETWEEN <deny_point> AND <deny_point>
```

For more information and examples about time-based constraints, see "Managing Roles and Privileges" in the *Greenplum Database Administrator Guide*.

## Notes

The preferred way to add and remove role members (manage groups) is to use [GRANT](#) and [REVOKE](#).

The [VALID UNTIL](#) clause defines an expiration time for a password only, not for the role. The expiration time is not enforced when logging in using a non-password-based authentication method.

The [INHERIT](#) attribute governs inheritance of grantable privileges (access privileges for database objects and role memberships). It does not apply to the special role attributes set by [CREATE ROLE](#) and [ALTER ROLE](#). For example, being a member of a role with [CREATEDB](#) privilege does not immediately grant the ability to create databases, even if [INHERIT](#) is set. These privileges/attributes are never inherited: [SUPERUSER](#), [CREATEDB](#), [CREATEROLE](#), [CREATEEXTTABLE](#), [LOGIN](#), [RESOURCE GROUP](#), and [RESOURCE QUEUE](#). The attributes must be set on each user-level role.

The [INHERIT](#) attribute is the default for reasons of backwards compatibility. In prior releases of Greenplum Database, users always had access to all privileges of groups they were members of. However, [NOINHERIT](#) provides a closer match to the semantics specified in the SQL standard.

Be careful with the [CREATEROLE](#) privilege. There is no concept of inheritance for the privileges of a [CREATEROLE](#)-role. That means that even if a role does not have a certain privilege but is allowed to create other roles, it can easily create another role with different privileges than its own (except for creating roles with superuser privileges). For example, if a role has the [CREATEROLE](#) privilege but not the [CREATEDB](#) privilege, it can create a new role with the [CREATEDB](#) privilege. Therefore, regard roles that have the [CREATEROLE](#) privilege as almost-superuser-roles.

The [CONNECTION LIMIT](#) option is never enforced for superusers.

Caution must be exercised when specifying an unencrypted password with this command. The password will be transmitted to the server in clear-text, and it might also be logged in the client's command history or the server log. The client program `createuser`, however, transmits the password encrypted. Also, `psql` contains a command `\password` that can be used to safely change the password later.

## Examples

Create a role that can log in, but don't give it a password:

```
CREATE ROLE jonathan LOGIN;
```

Create a role that belongs to a resource queue:

```
CREATE ROLE jonathan LOGIN RESOURCE QUEUE poweruser;
```

Create a role with a password that is valid until the end of 2016 (`CREATE USER` is the same as `CREATE ROLE` except that it implies `LOGIN`):

```
CREATE USER joelle WITH PASSWORD 'jw8s0F4' VALID UNTIL '2017-01-01';
```

Create a role that can create databases and manage other roles:

```
CREATE ROLE admin WITH CREATEDB CREATEROLE;
```

Create a role that does not allow login access on Sundays:

```
CREATE ROLE user3 DENY DAY 'Sunday';
```

Create a role that can create readable and writable external tables of type 'gpfdist':

```
CREATE ROLE jan WITH CREATEEXTTABLE(type='readable', protocol='gpfdist')
CREATEEXTTABLE(type='writable', protocol='gpfdist');
```

Create a role, assigning a resource group:

```
CREATE ROLE bill RESOURCE GROUP rg_light;
```

## Compatibility

The SQL standard defines the concepts of users and roles, but it regards them as distinct concepts and leaves all commands defining users to be specified by the database implementation. In Greenplum Database users and roles are unified into a single type of object. Roles therefore have many more optional attributes than they do in the standard.

`CREATE ROLE` is in the SQL standard, but the standard only requires the syntax:

```
CREATE ROLE <name> [WITH ADMIN <rolename>]
```

Allowing multiple initial administrators, and all the other options of `CREATE ROLE`, are Greenplum Database extensions.

The behavior specified by the SQL standard is most closely approximated by giving users the `NOINHERIT` attribute, while roles are given the `INHERIT` attribute.

Parent topic: [SQL Commands](#)

## CREATE RULE

Defines a new rewrite rule.

## Synopsis

```
CREATE [OR REPLACE] RULE <name> AS ON <event>
TO <table_name> [WHERE <condition>]
DO [ALSO | INSTEAD] { NOTHING | <command> | (<command>; <command>
... ) }
```

where `<event>` can be one of:

```
SELECT | INSERT | UPDATE | DELETE
```

## Description

`CREATE RULE` defines a new rule applying to a specified table or view. `CREATE OR REPLACE RULE` will either create a new rule, or replace an existing rule of the same name for the same table.

The Greenplum Database rule system allows one to define an alternate action to be performed on insertions, updates, or deletions in database tables. A rule causes additional or alternate commands to be run when a given command on a given table is run. An `INSTEAD` rule can replace a given command by another, or cause a command to not be run at all. Rules can be used to implement SQL views as well. It is important to realize that a rule is really a command transformation mechanism, or command macro. The transformation happens before the execution of the command starts. It does not operate independently for each physical row as does a trigger.

`ON SELECT` rules must be unconditional `INSTEAD` rules and must have actions that consist of a single `SELECT` command. Thus, an `ON SELECT` rule effectively turns the table into a view, whose visible contents are the rows returned by the rule's `SELECT` command rather than whatever had been stored in the table (if anything). It is considered better style to write a `CREATE VIEW` command than to create a real table and define an `ON SELECT` rule for it.

You can create the illusion of an updatable view by defining `ON INSERT`, `ON UPDATE`, and `ON DELETE` rules (or any subset of those that is sufficient for your purposes) to replace update actions on the view with appropriate updates on other tables. If you want to support `INSERT RETURNING` and so on, be sure to put a suitable `RETURNING` clause into each of these rules.

There is a catch if you try to use conditional rules for complex view updates: there *must* be an unconditional `INSTEAD` rule for each action you wish to allow on the view. If the rule is conditional, or is not `INSTEAD`, then the system will still reject attempts to perform the update action, because it thinks it might end up trying to perform the action on the dummy table of the view in some cases. If you want to handle all of the useful cases in conditional rules, add an unconditional `DO INSTEAD NOTHING` rule to ensure that the system understands it will never be called on to update the dummy table. Then make the conditional rules non-`INSTEAD`; in the cases where they are applied, they add to the default `INSTEAD NOTHING` action. (This method does not currently work to support `RETURNING` queries, however.)

**Note:** A view that is simple enough to be automatically updatable (see [CREATE VIEW](#)) does not require a user-created rule in order to be updatable. While you can create an explicit rule anyway, the automatic update transformation will generally outperform an explicit rule.

## Parameters

name

The name of a rule to create. This must be distinct from the name of any other rule for the same table. Multiple rules on the same table and same event type are applied in alphabetical name order.

event

The event is one of `SELECT`, `INSERT`, `UPDATE`, or `DELETE`. Note that an `INSERT` containing an `ON CONFLICT` clause cannot be used on tables that have either `INSERT` or `UPDATE` rules. Consider using an updatable view instead.

table\_name

The name (optionally schema-qualified) of the table or view the rule applies to.

condition

Any SQL conditional expression (returning `boolean`). The condition expression can not refer to any tables except `NEW` and `OLD`, and can not contain aggregate functions.

INSTEAD

`INSTEAD NOTHING` indicates that the commands should be run *instead of* the original command.

ALSO

`ALSO` indicates that the commands should be run *in addition* to the original command. If neither `ALSO` nor `INSTEAD` is specified, `ALSO` is the default.

command

The command or commands that make up the rule action. Valid commands are `SELECT`, `INSERT`, `UPDATE`, `DELETE`, or `NOTIFY`.

## Notes

You must be the owner of a table to create or change rules for it.

In a rule for `INSERT`, `UPDATE`, or `DELETE` on a view, you can add a `RETURNING` clause that emits the view's columns. This clause will be used to compute the outputs if the rule is triggered by an `INSERT RETURNING`, `UPDATE RETURNING`, or `DELETE RETURNING` command respectively. When the rule is triggered by a command without `RETURNING`, the rule's `RETURNING` clause will be ignored. The current implementation allows only unconditional `INSTEAD` rules to contain `RETURNING`; furthermore there can be at most one `RETURNING` clause among all the rules for the same event. (This ensures that there is only one candidate `RETURNING` clause to be used to compute the results.) `RETURNING` queries on the view will be rejected if there is no `RETURNING` clause in any available rule.

It is very important to take care to avoid circular rules. For example, though each of the following two rule definitions are accepted by Greenplum Database, the `SELECT` command would cause Greenplum to report an error because of recursive expansion of a rule:

```
CREATE RULE "_RETURN" AS
  ON SELECT TO t1
  DO INSTEAD
    SELECT * FROM t2;

CREATE RULE "_RETURN" AS
  ON SELECT TO t2
  DO INSTEAD
    SELECT * FROM t1;

SELECT * FROM t1;
```

Presently, if a rule action contains a `NOTIFY` command, the `NOTIFY` command will be executed unconditionally, that is, the `NOTIFY` will be issued even if there are not any rows that the rule should apply to. For example, in:

```
CREATE RULE notify_me AS ON UPDATE TO mytable DO ALSO NOTIFY mytable;

UPDATE mytable SET name = 'foo' WHERE id = 42;
```

one `NOTIFY` event will be sent during the `UPDATE`, whether or not there are any rows that match the condition `id = 42`. This is an implementation restriction that might be fixed in future releases.

## Compatibility

`CREATE RULE` is a Greenplum Database language extension, as is the entire query rewrite system.

## CREATE SCHEMA

Defines a new schema.

## Synopsis

```
CREATE SCHEMA <schema_name> [AUTHORIZATION <username>]
    [<schema_element> [ ... ]]

CREATE SCHEMA AUTHORIZATION <rolename> [<schema_element> [ ... ]]

CREATE SCHEMA IF NOT EXISTS <schema_name> [ AUTHORIZATION <user_name> ]

CREATE SCHEMA IF NOT EXISTS AUTHORIZATION <user_name>
```

## Description

`CREATE SCHEMA` enters a new schema into the current database. The schema name must be distinct from the name of any existing schema in the current database.

A schema is essentially a namespace: it contains named objects (tables, data types, functions, and operators) whose names may duplicate those of other objects existing in other schemas. Named objects are accessed either by qualifying their names with the schema name as a prefix, or by setting a search path that includes the desired schema(s). A `CREATE` command specifying an unqualified object name creates the object in the current schema (the one at the front of the search path, which can be determined with the function `current_schema`).

Optionally, `CREATE SCHEMA` can include subcommands to create objects within the new schema. The subcommands are treated essentially the same as separate commands issued after creating the

schema, except that if the `AUTHORIZATION` clause is used, all the created objects will be owned by that role.

## Parameters

### schema\_name

The name of a schema to be created. If this is omitted, the user name is used as the schema name. The name cannot begin with `pg_`, as such names are reserved for system catalog schemas.

### user\_name

The name of the role who will own the schema. If omitted, defaults to the role running the command. Only superusers may create schemas owned by roles other than themselves.

### schema\_element

An SQL statement defining an object to be created within the schema. Currently, only `CREATE TABLE`, `CREATE VIEW`, `CREATE INDEX`, `CREATE SEQUENCE`, `CREATE TRIGGER` and `GRANT` are accepted as clauses within `CREATE SCHEMA`. Other kinds of objects may be created in separate commands after the schema is created.

**Note:** Greenplum Database does not support triggers.

### IF NOT EXISTS

Do nothing (except issuing a notice) if a schema with the same name already exists. `schema_element` subcommands cannot be included when this option is used.

## Notes

To create a schema, the invoking user must have the `CREATE` privilege for the current database or be a superuser.

## Examples

Create a schema:

```
CREATE SCHEMA myschema;
```

Create a schema for role `joe` (the schema will also be named `joe`):

```
CREATE SCHEMA AUTHORIZATION joe;
```

Create a schema named `test` that will be owned by user `joe`, unless there already is a schema named `test`. (It does not matter whether `joe` owns the pre-existing schema.)

```
CREATE SCHEMA IF NOT EXISTS test AUTHORIZATION joe;
```

## Compatibility

The SQL standard allows a `DEFAULT CHARACTER SET` clause in `CREATE SCHEMA`, as well as more subcommand types than are presently accepted by Greenplum Database.

The SQL standard specifies that the subcommands in `CREATE SCHEMA` may appear in any order. The present Greenplum Database implementation does not handle all cases of forward references in subcommands; it may sometimes be necessary to reorder the subcommands in order to avoid forward references.

According to the SQL standard, the owner of a schema always owns all objects within it. Greenplum Database allows schemas to contain objects owned by users other than the schema owner. This can happen only if the schema owner grants the `CREATE` privilege on the schema to someone else, or a superuser chooses to create objects in it.

The `IF NOT EXISTS` option is a Greenplum Database extension.

## CREATE SEQUENCE

Defines a new sequence generator.

### Synopsis

```
CREATE [TEMPORARY | TEMP] SEQUENCE <name>
    [INCREMENT [BY] <value>]
    [MINVALUE <minvalue> | NO MINVALUE]
    [MAXVALUE <maxvalue> | NO MAXVALUE]
    [START [ WITH ] <start>]
    [CACHE <cache>]
    [[NO] CYCLE]
    [OWNED BY { <table>.<column> | NONE }]
```

### Description

`CREATE SEQUENCE` creates a new sequence number generator. This involves creating and initializing a new special single-row table. The generator will be owned by the user issuing the command.

If a schema name is given, then the sequence is created in the specified schema. Otherwise it is created in the current schema. Temporary sequences exist in a special schema, so a schema name may not be given when creating a temporary sequence. The sequence name must be distinct from the name of any other sequence, table, index, view, or foreign table in the same schema.

After a sequence is created, you use the `nextval()` function to operate on the sequence. For example, to insert a row into a table that gets the next value of a sequence:

```
INSERT INTO distributors VALUES (nextval('myserial'), 'acme');
```

You can also use the function `setval()` to operate on a sequence, but only for queries that do not operate on distributed data. For example, the following query is allowed because it resets the sequence counter value for the sequence generator process on the master:

```
SELECT setval('myserial', 201);
```

But the following query will be rejected in Greenplum Database because it operates on distributed data:

```
INSERT INTO product VALUES (setval('myserial', 201), 'gizmo');
```

In a regular (non-distributed) database, functions that operate on the sequence go to the local sequence table to get values as they are needed. In Greenplum Database, however, keep in mind that each segment is its own distinct database process. Therefore the segments need a single point of truth to go for sequence values so that all segments get incremented correctly and the sequence moves forward in the right order. A sequence server process runs on the master and is the point-of-truth for a sequence in a Greenplum distributed database. Segments get sequence values at runtime from the master.

Because of this distributed sequence design, there are some limitations on the functions that operate on a sequence in Greenplum Database:

- `lastval()` and `currval()` functions are not supported.
- `setval()` can only be used to set the value of the sequence generator on the master, it cannot be used in subqueries to update records on distributed table data.
- `nextval()` sometimes grabs a block of values from the master for a segment to use, depending on the query. So values may sometimes be skipped in the sequence if all of the block turns out not to be needed at the segment level. Note that a regular PostgreSQL database does this too, so this is not something unique to Greenplum Database.

Although you cannot update a sequence directly, you can use a query like:

```
SELECT * FROM <sequence_name>;
```

to examine the parameters and current state of a sequence. In particular, the `last_value` field of the sequence shows the last value allocated by any session.

## Parameters

### TEMPORARY | TEMP

If specified, the sequence object is created only for this session, and is automatically dropped on session exit. Existing permanent sequences with the same name are not visible (in this session) while the temporary sequence exists, unless they are referenced with schema-qualified names.

### name

The name (optionally schema-qualified) of the sequence to be created.

### increment

Specifies which value is added to the current sequence value to create a new value. A positive value will make an ascending sequence, a negative one a descending sequence. The default value is 1.

### minvalue

NO MINVALUE

Determines the minimum value a sequence can generate. If this clause is not supplied or **NO MINVALUE** is specified, then defaults will be used. The defaults are 1 and -263-1 for ascending and descending sequences, respectively.

maxvalue

**NO MAXVALUE**

Determines the maximum value for the sequence. If this clause is not supplied or **NO MAXVALUE** is specified, then default values will be used. The defaults are 263-1 and -1 for ascending and descending sequences, respectively.

start

Allows the sequence to begin anywhere. The default starting value is minvalue for ascending sequences and maxvalue for descending ones.

cache

Specifies how many sequence numbers are to be preallocated and stored in memory for faster access. The minimum (and default) value is 1 (no cache).

**CYCLE**

**NO CYCLE**

Allows the sequence to wrap around when the maxvalue (for ascending) or minvalue (for descending) has been reached. If the limit is reached, the next number generated will be the minvalue (for ascending) or maxvalue (for descending). If **NO CYCLE** is specified, any calls to `nextval()` after the sequence has reached its maximum value will return an error. If not specified, **NO CYCLE** is the default.

**OWNED BY table.column**

**OWNED BY NONE**

Causes the sequence to be associated with a specific table column, such that if that column (or its whole table) is dropped, the sequence will be automatically dropped as well. The specified table must have the same owner and be in the same schema as the sequence.

**OWNED BY NONE**, the default, specifies that there is no such association.

## Notes

Sequences are based on bigint arithmetic, so the range cannot exceed the range of an eight-byte integer (-9223372036854775808 to 9223372036854775807).

Although multiple sessions are guaranteed to allocate distinct sequence values, the values may be generated out of sequence when all the sessions are considered. For example, session A might reserve values 1..10 and return `nextval=1`, then session B might reserve values 11..20 and return `nextval=11` before session A has generated `nextval=2`. Thus, you should only assume that the `nextval()` values are all distinct, not that they are generated purely sequentially. Also, `last_value` will reflect the latest value reserved by any session, whether or not it has yet been returned by `nextval()`.

## Examples

Create a sequence named myseq:

```
CREATE SEQUENCE myseq START 101;
```

Insert a row into a table that gets the next value of the sequence named idseq:

```
INSERT INTO distributors VALUES (nextval('idseq'), 'acme');
```

Reset the sequence counter value on the master:

```
SELECT setval('myseq', 201);
```

Illegal use of `setval()` in Greenplum Database (setting sequence values on distributed data):

```
INSERT INTO product VALUES (setval('myseq', 201), 'gizmo');
```

## Compatibility

`CREATE SEQUENCE` conforms to the SQL standard, with the following exceptions:

- The `AS data\_type` expression specified in the SQL standard is not supported.
- Obtaining the next value is done using the `nextval()` function instead of the `NEXT VALUE FOR` expression specified in the SQL standard.
- The `OWNED BY` clause is a Greenplum Database extension.

## CREATE SERVER

Defines a new foreign server.

## Synopsis

```
CREATE SERVER <server_name> [ TYPE '<server_type>' ] [ VERSION '<server_version>' ]
  FOREIGN DATA WRAPPER <fdw_name>
  [ OPTIONS ( [ mpp_execute { 'master' | 'any' | 'all segments' } [, ] ]
              [ num_segments '<num>' [, ] ]
              [ <option> '<value>' [, ... ] ] ) ]
```

## Description

`CREATE SERVER` defines a new foreign server. The user who defines the server becomes its owner.

A foreign server typically encapsulates connection information that a foreign-data wrapper uses to access an external data source. Additional user-specific connection information may be specified by means of user mappings.

Creating a server requires the `USAGE` privilege on the foreign-data wrapper specified.

## Parameters

`server_name`

The name of the foreign server to create. The server name must be unique within the database.

`server_type`

Optional server type, potentially useful to foreign-data wrappers.

`server_version`

Optional server version, potentially useful to foreign-data wrappers.

`fdw_name`

Name of the foreign-data wrapper that manages the server.

`OPTIONS ( option 'value' [, ... ] )`

The options for the new foreign server. The options typically define the connection details of the server, but the actual names and values are dependent upon the server's foreign-data wrapper.

`mpp_execute { 'master' | 'any' | 'all segments' }`

A Greenplum Database-specific option that identifies the host from which the foreign-data wrapper reads or writes data:

- `master` (the default)—Read or write data from the master host.
- `any`—Read data from either the master host or any one segment, depending on which path costs less.
- `all segments`—Read or write data from all segments. To support this option value, the foreign-data wrapper should have a policy that matches the segments to data.

**Note:** Greenplum Database supports parallel writes to foreign tables only when you set `mpp_execute 'all segments'`.

Support for the foreign server `mpp_execute` option, and the specific modes, is foreign-data wrapper-specific.

The `mpp_execute` option can be specified in multiple commands: `CREATE FOREIGN TABLE`, `CREATE SERVER`, and `CREATE FOREIGN DATA WRAPPER`. The foreign table setting takes precedence over the foreign server setting, followed by the foreign-data wrapper setting.

`num_segments 'num'`

When `mpp_execute` is set to `'all segments'`, the Greenplum Database-specific `num_segments` option identifies the number of query executors that Greenplum Database spawns on the source Greenplum Database cluster. If you do not provide a value, `num` defaults to the number of segments in the source cluster.

Support for the foreign server `num_segments` option is foreign-data wrapper-specific.

## Notes

When using the `dblink` module (see [dblink](#)), you can use the foreign server name as an argument of the `dblink_connect()` function to provide the connection parameters. You must have the `USAGE` privilege on the foreign server to use it in this manner.

## Examples

Create a foreign server named `myserver` that uses the foreign-data wrapper named `pgsql` and includes connection options:

```
CREATE SERVER myserver FOREIGN DATA WRAPPER pgsql
  OPTIONS (host 'foo', dbname 'foodb', port '5432');
```

## Compatibility

`CREATE SERVER` conforms to ISO/IEC 9075-9 (SQL/MED).

    [...] }
  ( <partition_spec> ) ]
} |

{ -- partitioned table without SUBPARTITION TEMPLATE
[ PARTITION BY <partition_type> (<column>)
  [ SUBPARTITION BY <partition_type> (<column1>) ]
```

```

    [ SUBPARTITION BY <partition_type> (<column2>) ]
    [...]
  ( <partition_spec>
    [ ( <subpartition_spec_column1>
      [ ( <subpartition_spec_column2>
        [...] ) ] ) ],
    [ <partition_spec>
      [ ( <subpartition_spec_column1>
        [ ( <subpartition_spec_column2>
          [...] ) ] ) ], ]
    [...]
  ) ]
}

CREATE [ [GLOBAL | LOCAL] {TEMPORARY | TEMP} | UNLOGGED ] TABLE [IF NOT EXISTS]
  <table_name>
  OF <type_name> [ (
  { <column_name> WITH OPTIONS [ <column_constraint> [ ... ] ]
  | <table_constraint> }
  [, ... ]
  ) ]
[ WITH ( <storage_parameter> [=<value>] [, ... ] ) ]
[ ON COMMIT { PRESERVE ROWS | DELETE ROWS | DROP } ]
[ TABLESPACE <tablespace_name> ]

```

where `column_constraint` is:

```

[ CONSTRAINT <constraint_name>]
{ NOT NULL
  | NULL
  | CHECK ( <expression> ) [ NO INHERIT ]
  | DEFAULT <default_expr>
  | UNIQUE <index_parameters>
  | PRIMARY KEY <index_parameters>
  | REFERENCES <reftable> [ ( refcolumn ) ]
    [ MATCH FULL | MATCH PARTIAL | MATCH SIMPLE ]
    [ ON DELETE <key_action> ] [ ON UPDATE <key_action> ] }
[ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]

```

and `table_constraint` is:

```

[ CONSTRAINT <constraint_name> ]
{ CHECK ( <expression> ) [ NO INHERIT ]
  | UNIQUE ( <column_name> [, ... ] ) <index_parameters>
  | PRIMARY KEY ( <column_name> [, ... ] ) <index_parameters>
  | FOREIGN KEY ( <column_name> [, ... ] )
    REFERENCES <reftable> [ ( <refcolumn> [, ... ] ) ]
    [ MATCH FULL | MATCH PARTIAL | MATCH SIMPLE ]
    [ ON DELETE <key_action> ] [ ON UPDATE <key_action> ] }
[ DEFERRABLE | NOT DEFERRABLE ] [ INITIALLY DEFERRED | INITIALLY IMMEDIATE ]

```

and `like_option` is:

```
{INCLUDING|EXCLUDING} {DEFAULTS|CONSTRAINTS|INDEXES|STORAGE|COMMENTS|ALL}
```

and `index_parameters` in **UNIQUE** and **PRIMARY KEY** constraints are:

```
[ WITH ( <storage_parameter> [=<value>] [, ... ] ) ]
[ USING INDEX TABLESPACE <tablespace_name> ]
```

and `storage_directive` for a column is:

```
compressstype={ZLIB|ZSTD|QUICKLZ|RLE_TYPE|NONE}
[compresslevel={0-9}]
[blocksize={8192-2097152} ]
```

and `storage_parameter` for the table is:

```
appendoptimized={TRUE|FALSE}
blocksize={8192-2097152}
orientation={COLUMN|ROW}
checksum={TRUE|FALSE}
compressstype={ZLIB|ZSTD|QUICKLZ|RLE_TYPE|NONE}
compresslevel={0-9}
fillfactor={10-100}
[oids=FALSE]
```

and `key_action` is:

```
ON DELETE
| ON UPDATE
| NO ACTION
| RESTRICT
| CASCADE
| SET NULL
| SET DEFAULT
```

and `partition_type` is:

```
LIST | RANGE
```

and `partition_specification` is:

```
<partition_element> [, ...]
```

and `partition_element` is:

```
DEFAULT PARTITION <name>
| [PARTITION <name>] VALUES (<list_value> [,... ] )
| [PARTITION <name>]
  START ([[datatype]] '<start_value>') [INCLUSIVE | EXCLUSIVE]
  [ END ([[datatype]] '<end_value>') [INCLUSIVE | EXCLUSIVE] ]
  [ EVERY ([[datatype]] [<number | >INTERVAL] '<interval_value>') ]
| [PARTITION <name>]
  END ([[datatype]] '<end_value>') [INCLUSIVE | EXCLUSIVE]
  [ EVERY ([[datatype]] [<number | >INTERVAL] '<interval_value>') ]
[ WITH ( <partition_storage_parameter>=<value> [, ... ] ) ]
[ <column_reference_storage_directive> [, ... ] ]
[ TABLESPACE <tablespace> ]
```

where `subpartition_spec` or `template_spec` is:

```
<subpartition_element> [, ...]
```

and `subpartition_element` is:

```

DEFAULT SUBPARTITION <name>
| [SUBPARTITION <name>] VALUES (<list_value> [,... ] )
| [SUBPARTITION <name>]
|   START ([<datatype>] '<start_value>') [INCLUSIVE | EXCLUSIVE]
|   [ END ([<datatype>] '<end_value>') [INCLUSIVE | EXCLUSIVE] ]
|   [ EVERY ([<datatype>] [<number | >INTERVAL] '<interval_value>') ]
| [SUBPARTITION <name>]
|   END ([<datatype>] '<end_value>') [INCLUSIVE | EXCLUSIVE]

[ WITH ( <partition_storage_parameter>=<value> [, ... ] ) ]
[ <column_reference_storage_directive> [, ... ] ]
[ TABLESPACE <tablespace> ]

```

where `storage_parameter` for a partition is:

```

appendoptimized={TRUE|FALSE}
blocksize={8192-2097152}
orientation={COLUMN|ROW}
checksum={TRUE|FALSE}
compresstype={ZLIB|ZSTD|QUICKLZ|RLE_TYPE|NONE}
compresslevel={1-19}
fillfactor={10-100}
[oids=FALSE]

```

## Description

**CREATE TABLE** creates an initially empty table in the current database. The user who issues the command owns the table.

To be able to create a table, you must have **USAGE** privilege on all column types or the type in the **OF** clause, respectively.

If you specify a schema name, Greenplum creates the table in the specified schema. Otherwise Greenplum creates the table in the current schema. Temporary tables exist in a special schema, so you cannot specify a schema name when creating a temporary table. Table names must be distinct from the name of any other table, external table, sequence, index, view, or foreign table in the same schema.

**CREATE TABLE** also automatically creates a data type that represents the composite type corresponding to one row of the table. Therefore, tables cannot have the same name as any existing data type in the same schema.

The optional constraint clauses specify conditions that new or updated rows must satisfy for an insert or update operation to succeed. A constraint is an SQL object that helps define the set of valid values in the table in various ways. Constraints apply to tables, not to partitions. You cannot add a constraint to a partition or subpartition.

Referential integrity constraints (foreign keys) are accepted but not enforced. The information is kept in the system catalogs but is otherwise ignored.

There are two ways to define constraints: table constraints and column constraints. A column constraint is defined as part of a column definition. A table constraint definition is not tied to a particular column, and it can encompass more than one column. Every column constraint can also be written as a table constraint; a column constraint is only a notational convenience for use when the constraint only affects one column.

When creating a table, there is an additional clause to declare the Greenplum Database distribution policy. If a `DISTRIBUTED BY`, `DISTRIBUTED RANDOMLY`, or `DISTRIBUTED REPLICATED` clause is not supplied, then Greenplum Database assigns a hash distribution policy to the table using either the `PRIMARY KEY` (if the table has one) or the first column of the table as the distribution key. Columns of geometric or user-defined data types are not eligible as Greenplum distribution key columns. If a table does not have a column of an eligible data type, the rows are distributed based on a round-robin or random distribution. To ensure an even distribution of data in your Greenplum Database system, you want to choose a distribution key that is unique for each record, or if that is not possible, then choose `DISTRIBUTED RANDOMLY`.

If the `DISTRIBUTED REPLICATED` clause is supplied, Greenplum Database distributes all rows of the table to all segments in the Greenplum Database system. This option can be used in cases where user-defined functions must run on the segments, and the functions require access to all rows of the table. Replicated functions can also be used to improve query performance by preventing broadcast motions for the table. The `DISTRIBUTED REPLICATED` clause cannot be used with the `PARTITION BY` clause or the `INHERITS` clause. A replicated table also cannot be inherited by another table. The hidden system columns (`ctid`, `cmin`, `cmax`, `xmin`, `xmax`, and `gp_segment_id`) cannot be referenced in user queries on replicated tables because they have no single, unambiguous value. Greenplum Database returns a `column does not exist` error for the query.

The `PARTITION BY` clause allows you to divide the table into multiple sub-tables (or parts) that, taken together, make up the parent table and share its schema. Though the sub-tables exist as independent tables, the Greenplum Database restricts their use in important ways. Internally, partitioning is implemented as a special form of inheritance. Each child table partition is created with a distinct `CHECK` constraint which limits the data the table can contain, based on some defining criteria. The `CHECK` constraints are also used by the query optimizer to determine which table partitions to scan in order to satisfy a given query predicate. These partition constraints are managed automatically by the Greenplum Database.

## Parameters

### GLOBAL | LOCAL

These keywords are present for SQL standard compatibility, but have no effect in Greenplum Database and are deprecated.

### TEMPORARY | TEMP

If specified, the table is created as a temporary table. Temporary tables are automatically dropped at the end of a session, or optionally at the end of the current transaction (see `ON COMMIT`). Existing permanent tables with the same name are not visible to the current session while the temporary table exists, unless they are referenced with schema-qualified names. Any indexes created on a temporary table are automatically temporary as well.

### UNLOGGED

If specified, the table is created as an unlogged table. Data written to unlogged tables is not written to the write-ahead (WAL) log, which makes them considerably faster than ordinary

tables. However, the contents of an unlogged table are not replicated to mirror segment instances. Also an unlogged table is not crash-safe. After a segment instance crash or unclean shutdown, the data for the unlogged table on that segment is truncated. Any indexes created on an unlogged table are automatically unlogged as well.

`table_name`

The name (optionally schema-qualified) of the table to be created.

`OF type_name`

Creates a typed table, which takes its structure from the specified composite type (name optionally schema-qualified). A typed table is tied to its type; for example the table will be dropped if the type is dropped (with `DROP TYPE ... CASCADE`).

When a typed table is created, the data types of the columns are determined by the underlying composite type and are not specified by the `CREATE TABLE` command. But the `CREATE TABLE` command can add defaults and constraints to the table and can specify storage parameters.

`column_name`

The name of a column to be created in the new table.

`data_type`

The data type of the column. This may include array specifiers.

For table columns that contain textual data, Specify the data type `VARCHAR` or `TEXT`. Specifying the data type `CHAR` is not recommended. In Greenplum Database, the data types `VARCHAR` or `TEXT` handles padding added to the data (space characters added after the last non-space character) as significant characters, the data type `CHAR` does not. See [Notes](#).

`COLLATE collation`

The `COLLATE` clause assigns a collation to the column (which must be of a collatable data type). If not specified, the column data type's default collation is used.

**Note:** GPORCA supports collation only when all columns in the query use the same collation. If columns in the query use different collations, then Greenplum uses the Postgres Planner.

`DEFAULT default_expr`

The `DEFAULT` clause assigns a default data value for the column whose column definition it appears within. The value is any variable-free expression (subqueries and cross-references to other columns in the current table are not allowed). The data type of the default expression must match the data type of the column. The default expression will be used in any insert operation that does not specify a value for the column. If there is no default for a column, then the default is null.

`ENCODING ( storage_directive [, ...] )`

For a column, the optional `ENCODING` clause specifies the type of compression and block size for the column data. See [storage\\_options](#) for `compress_type`, `compress_level`, and `blocksize` values.

The clause is valid only for append-optimized, column-oriented tables.

Column compression settings are inherited from the table level to the partition level to the subpartition level. The lowest-level settings have priority.

`INHERITS ( parent_table [, ...] )`

The optional `INHERITS` clause specifies a list of tables from which the new table automatically inherits all columns. Use of `INHERITS` creates a persistent relationship between the new child table and its parent table(s). Schema modifications to the parent(s) normally propagate to children as well, and by default the data of the child table is included in scans of the parent(s).

In Greenplum Database, the `INHERITS` clause is not used when creating partitioned tables. Although the concept of inheritance is used in partition hierarchies, the inheritance structure of a partitioned table is created using the `PARTITION BY` clause.

If the same column name exists in more than one parent table, an error is reported unless the data types of the columns match in each of the parent tables. If there is no conflict, then the duplicate columns are merged to form a single column in the new table. If the column name list of the new table contains a column name that is also inherited, the data type must likewise match the inherited column(s), and the column definitions are merged into one. If the new table explicitly specifies a default value for the column, this default overrides any defaults from inherited declarations of the column. Otherwise, any parents that specify default values for the column must all specify the same default, or an error will be reported.

`CHECK` constraints are merged in essentially the same way as columns: if multiple parent tables or the new table definition contain identically-named `constraints`, these constraints must all have the same check expression, or an error will be reported. Constraints having the same name and expression will be merged into one copy. A constraint marked `NO INHERIT` in a parent will not be considered. Notice that an unnamed `CHECK` constraint in the new table will never be merged, since a unique name will always be chosen for it.

Column `STORAGE` settings are also copied from parent tables.

LIKE source\_table like\_option ...]

The `LIKE` clause specifies a table from which the new table automatically copies all column names, their data types, not-null constraints, and distribution policy. Unlike `INHERITS`, the new table and original table are completely decoupled after creation is complete.

**Note:** Storage properties like append-optimized or partition structure are not copied.

Default expressions for the copied column definitions will only be copied if `INCLUDING DEFAULTS` is specified. The default behavior is to exclude default expressions, resulting in the copied columns in the new table having null defaults.

Not-null constraints are always copied to the new table. `CHECK` constraints will be copied only if `INCLUDING CONSTRAINTS` is specified. No distinction is made between column constraints and table constraints.

Indexes, `PRIMARY KEY`, and `UNIQUE` constraints on the original table will be created on the new table only if the `INCLUDING INDEXES` clause is specified. Names for the new indexes and constraints are chosen according to the default rules, regardless of how the originals were named. (This behavior avoids possible duplicate-name failures for the new indexes.)

Any indexes on the original table will not be created on the new table, unless the `INCLUDING INDEXES` clause is specified.

`STORAGE` settings for the copied column definitions will be copied only if `INCLUDING STORAGE` is specified. The default behavior is to exclude `STORAGE` settings, resulting in the copied columns in the new table having type-specific default settings.

Comments for the copied columns, constraints, and indexes will be copied only if `INCLUDING COMMENTS` is specified. The default behavior is to exclude comments, resulting in the copied columns and constraints in the new table having no comments.

`INCLUDING ALL` is an abbreviated form of `INCLUDING DEFAULTS INCLUDING CONSTRAINTS INCLUDING INDEXES INCLUDING STORAGE INCLUDING COMMENTS`.

Note that unlike `INHERITS`, columns and constraints copied by `LIKE` are not merged with similarly named columns and constraints. If the same name is specified explicitly or in another `LIKE` clause, an error is signaled.

The `LIKE` clause can also be used to copy columns from views, foreign tables, or composite types. Inapplicable options (e.g., `INCLUDING INDEXES` from a view) are ignored.

`CONSTRAINT constraint_name`

An optional name for a column or table constraint. If the constraint is violated, the constraint name is present in error messages, so constraint names like column must be positive can be used to communicate helpful constraint information to client applications. (Double-quotes are needed to specify constraint names that contain spaces.) If a constraint name is not specified, the system generates a name.

**Note:** The specified `constraint_name` is used for the constraint, but a system-generated unique name is used for the index name. In some prior releases, the provided name was used for both the constraint name and the index name.

`NULL | NOT NULL`

Specifies if the column is or is not allowed to contain null values. `NULL` is the default.

`CHECK (expression) [ NO INHERIT ]`

The `CHECK` clause specifies an expression producing a Boolean result which new or updated rows must satisfy for an insert or update operation to succeed. Expressions evaluating to `TRUE` or `UNKNOWN` succeed. Should any row of an insert or update operation produce a `FALSE` result an error exception is raised and the insert or update does not alter the database. A check constraint specified as a column constraint should reference that column's value only, while an expression appearing in a table constraint can reference multiple columns.

A constraint marked with `NO INHERIT` will not propagate to child tables.

Currently, `CHECK` expressions cannot contain subqueries nor refer to variables other than columns of the current row.

`UNIQUE ( column_constraint )`

`UNIQUE ( column_name [, ... ] ) ( table_constraint )`

The `UNIQUE` constraint specifies that a group of one or more columns of a table may contain only unique values. The behavior of the unique table constraint is the same as that for column constraints, with the additional capability to span multiple columns. For the purpose of a unique constraint, null values are not considered equal. The column(s) that are unique must contain all the columns of the Greenplum distribution key. In addition, the `<key>` must contain all the columns in the partition key if the table is partitioned. Note that a `<key>` constraint in a partitioned table is not the same as a simple `UNIQUE INDEX`.

For information about unique constraint management and limitations, see [Notes](#).

`PRIMARY KEY ( column_constraint )`

`PRIMARY KEY ( column_name [, ... ] ) ( table_constraint )`

The **PRIMARY KEY** constraint specifies that a column or columns of a table may contain only unique (non-duplicate), non-null values. Only one primary key can be specified for a table, whether as a column constraint or a table constraint.

For a table to have a primary key, it must be hash distributed (not randomly distributed), and the primary key, the column(s) that are unique, must contain all the columns of the Greenplum distribution key. In addition, the `<key>` must contain all the columns in the partition key if the table is partitioned. Note that a `<key>` constraint in a partitioned table is not the same as a simple **UNIQUE INDEX**.

**PRIMARY KEY** enforces the same data constraints as a combination of **UNIQUE** and **NOT NULL**, but identifying a set of columns as the primary key also provides metadata about the design of the schema, since a primary key implies that other tables can rely on this set of columns as a unique identifier for rows.

For information about primary key management and limitations, see [Notes](#).

REFERENCES reftable [ ( refcolumn ) ]

[ MATCH FULL | MATCH PARTIAL | MATCH SIMPLE ]

[ON DELETE | ON UPDATE] [key\_action]

FOREIGN KEY (column\_name [, ...])

The **REFERENCES** and **FOREIGN KEY** clauses specify referential integrity constraints (foreign key constraints). Greenplum accepts referential integrity constraints as specified in PostgreSQL syntax but does not enforce them. See the PostgreSQL documentation for information about referential integrity constraints.

DEFERRABLE

NOT DEFERRABLE

The `[NOT] DEFERRABLE` clause controls whether the constraint can be deferred. A constraint that is not deferrable will be checked immediately after every command. Checking of constraints that are deferrable can be postponed until the end of the transaction (using the **SET CONSTRAINTS** command). **NOT DEFERRABLE** is the default. Currently, only **UNIQUE** and **PRIMARY KEY** constraints are deferrable. **NOT NULL** and **CHECK** constraints are not deferrable. **REFERENCES** (foreign key) constraints accept this clause but are not enforced.

INITIALLY IMMEDIATE

INITIALLY DEFERRED

If a constraint is deferrable, this clause specifies the default time to check the constraint. If the constraint is **INITIALLY IMMEDIATE**, it is checked after each statement. This is the default. If the constraint is **INITIALLY DEFERRED**, it is checked only at the end of the transaction. The constraint check time can be altered with the **SET CONSTRAINTS** command.

WITH ( storage\_parameter=value )

The **WITH** clause can specify storage parameters for tables, and for indexes associated with a **UNIQUE** or **PRIMARY** constraint. Note that you can also set storage parameters on a particular partition or subpartition by declaring the **WITH** clause in the partition specification. The lowest-level settings have priority.

The defaults for some of the table storage options can be specified with the server configuration parameter `gp_default_storage_options`. For information about setting default storage options, see [Notes](#).

The following storage options are available:

**appendoptimized** — Set to `TRUE` to create the table as an append-optimized table. If `FALSE` or not declared, the table will be created as a regular heap-storage table.

**blocksize** — Set to the size, in bytes, for each block in a table. The `blocksize` must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default is 32768. The `blocksize` option is valid only if `appendoptimized=TRUE`.

**orientation** — Set to `column` for column-oriented storage, or `row` (the default) for row-oriented storage. This option is only valid if `appendoptimized=TRUE`. Heap-storage tables can only be row-oriented.

**checksum** — This option is valid only for append-optimized tables (`appendoptimized=TRUE`). The value `TRUE` is the default and enables CRC checksum validation for append-optimized tables. The checksum is calculated during block creation and is stored on disk. Checksum validation is performed during block reads. If the checksum calculated during the read does not match the stored checksum, the transaction is cancelled. If you set the value to `FALSE` to deactivate checksum validation, checking the table data for on-disk corruption will not be performed.

**compressstype** — Set to `ZLIB` (the default), `ZSTD`, `RLE_TYPE`, or `QUICKLZ1` to specify the type of compression used. The value `NONE` deactivates compression. Zstd provides for both speed or a good compression ratio, tunable with the `compresslevel` option. QuickLZ and zlib are provided for backwards-compatibility. Zstd outperforms these compression types on usual workloads. The `compressstype` option is only valid if `appendoptimized=TRUE`.

**Note:** QuickLZ compression is available only in the commercial release of Tanzu Greenplum.

The value `RLE_TYPE`, which is supported only if `orientation=column` is specified, enables the run-length encoding (RLE) compression algorithm. RLE compresses data better than the Zstd, zlib, or QuickLZ compression algorithms when the same data value occurs in many consecutive rows.

For columns of type `BIGINT`, `INTEGER`, `DATE`, `TIME`, or `TIMESTAMP`, delta compression is also applied if the `compressstype` option is set to `RLE_TYPE` compression. The delta compression algorithm is based on the delta between column values in consecutive rows and is designed to improve compression when data is loaded in sorted order or the compression is applied to column data that is in sorted order.

For information about using table compression, see [Choosing the Table Storage Model](#) in the *Greenplum Database Administrator Guide*.

**compresslevel** — For Zstd compression of append-optimized tables, set to an integer value from 1 (fastest compression) to 19 (highest compression ratio). For zlib compression, the valid range is from 1 to 9. QuickLZ compression level can only be set to 1. If not declared, the default is 1. For `RLE_TYPE`, the compression level can be an integer value from 1 (fastest compression) to 4 (highest compression ratio).

The `compresslevel` option is valid only if `appendoptimized=TRUE`.

**fillfactor** — The fillfactor for a table is a percentage between 10 and 100. 100 (complete packing) is the default. When a smaller fillfactor is specified, `INSERT` operations pack table pages only to the indicated percentage; the remaining space on each page is reserved for updating rows on that page. This gives `UPDATE` a chance to place the updated copy of a row on the same page as the original, which is more efficient than placing it on a different page.

For a table whose entries are never updated, complete packing is the best choice, but in heavily updated tables smaller fillfactors are appropriate. This parameter cannot be set for TOAST tables.

**oids=FALSE** — This setting is the default, and it ensures that rows do not have object identifiers assigned to them. VMware does not support using `WITH OIDS` or `oids=TRUE` to assign an OID system column. On large tables, such as those in a typical Greenplum Database system, using OIDs for table rows can cause wrap-around of the 32-bit OID counter. Once the counter wraps around, OIDs can no longer be assumed to be unique, which not only makes them useless to user applications, but can also cause problems in the Greenplum Database system catalog tables. In addition, excluding OIDs from a table reduces the space required to store the table on disk by 4 bytes per row, slightly improving performance. You cannot create OIDs on a partitioned or column-oriented table (an error is displayed). This syntax is deprecated and will be removed in a future Greenplum release.

#### ON COMMIT

The behavior of temporary tables at the end of a transaction block can be controlled using `ON COMMIT`. The three options are:

**PRESERVE ROWS** - No special action is taken at the ends of transactions for temporary tables. This is the default behavior.

**DELETE ROWS** - All rows in the temporary table will be deleted at the end of each transaction block. Essentially, an automatic `TRUNCATE` is done at each commit.

**DROP** - The temporary table will be dropped at the end of the current transaction block.

#### TABLESPACE tablespace

The name of the tablespace in which the new table is to be created. If not specified, the database's default tablespace is used, or `temp_tablespaces` if the table is temporary.

#### USING INDEX TABLESPACE tablespace

This clause allows selection of the tablespace in which the index associated with a `UNIQUE` or `PRIMARY KEY` constraint will be created. If not specified, the database's default tablespace is used, or `temp_tablespaces` if the table is temporary.

#### DISTRIBUTED BY (column [opclass], [ ... ] )

#### DISTRIBUTED RANDOMLY

#### DISTRIBUTED REPLICATED

Used to declare the Greenplum Database distribution policy for the table. `DISTRIBUTED BY` uses hash distribution with one or more columns declared as the distribution key. For the most even data distribution, the distribution key should be the primary key of the table or a unique column (or set of columns). If that is not possible, then you may choose `DISTRIBUTED RANDOMLY`, which will send the data round-robin to the segment instances. Additionally, an operator class, `opclass`, can be specified, to use a non-default hash function.

The Greenplum Database server configuration parameter

`gp_create_table_random_default_distribution` controls the default table distribution policy if the `DISTRIBUTED BY` clause is not specified when you create a table. Greenplum Database follows these rules to create a table if a distribution policy is not specified.

If the value of the parameter is `off` (the default), Greenplum Database chooses the table distribution key based on the command:

- If a `LIKE` or `INHERITS` clause is specified, then Greenplum copies the distribution key from the source or parent table.
- If a `PRIMARY KEY` or `UNIQUE` constraints are specified, then Greenplum chooses the largest subset of all the key columns as the distribution key.
- If neither constraints nor a `LIKE` or `INHERITS` clause is specified, then Greenplum chooses the first suitable column as the distribution key. (Columns with geometric or user-defined data types are not eligible as Greenplum distribution key columns.)

If the value of the parameter is set to `on`, Greenplum Database follows these rules:

- If `PRIMARY KEY` or `UNIQUE` columns are not specified, the distribution of the table is random (`DISTRIBUTED RANDOMLY`). Table distribution is random even if the table creation command contains the `LIKE` or `INHERITS` clause.
- If `PRIMARY KEY` or `UNIQUE` columns are specified, a `DISTRIBUTED BY` clause must also be specified. If a `DISTRIBUTED BY` clause is not specified as part of the table creation command, the command fails.

For more information about setting the default table distribution policy, see `gp_create_table_random_default_distribution`.

The `DISTRIBUTED REPLICATED` clause replicates the entire table to all Greenplum Database segment instances. It can be used when it is necessary to run user-defined functions on segments when the functions require access to all rows in the table, or to improve query performance by preventing broadcast motions.

## PARTITION BY

Declares one or more columns by which to partition the table.

When creating a partitioned table, Greenplum Database creates the root partitioned table (the root partition) with the specified table name. Greenplum Database also creates a hierarchy of tables, child tables, that are the subpartitions based on the partitioning options that you specify. The Greenplum Database `pg_partition*` system views contain information about the subpartition tables.

For each partition level (each hierarchy level of tables), a partitioned table can have a maximum of 32,767 partitions.

**Note:** Greenplum Database stores partitioned table data in the leaf child tables, the lowest-level tables in the hierarchy of child tables for use by the partitioned table.

`partition_type`

Declares partition type: `LIST` (list of values) or `RANGE` (a numeric or date range).

`partition_specification`

Declares the individual partitions to create. Each partition can be defined individually or, for range partitions, you can use the `EVERY` clause (with a `START` and optional `END` clause) to define an increment pattern to use to create the individual partitions.

`DEFAULT PARTITION name` — Declares a default partition. When data does not match to an existing partition, it is inserted into the default partition. Partition designs that do not have a default partition will reject incoming rows that do not match to an existing partition.

**PARTITION name** — Declares a name to use for the partition. Partitions are created using the following naming convention: `parentname_level\#_prt_givename`.

**VALUES** — For list partitions, defines the value(s) that the partition will contain.

**START** — For range partitions, defines the starting range value for the partition. By default, start values are **INCLUSIVE**. For example, if you declared a start date of '2016-01-01', then the partition would contain all dates greater than or equal to '2016-01-01'. Typically the data type of the **START** expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

**END** — For range partitions, defines the ending range value for the partition. By default, end values are **EXCLUSIVE**. For example, if you declared an end date of '2016-02-01', then the partition would contain all dates less than but not equal to '2016-02-01'. Typically the data type of the **END** expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

**EVERY** — For range partitions, defines how to increment the values from **START** to **END** to create individual partitions. Typically the data type of the **EVERY** expression is the same type as the partition key column. If that is not the case, then you must explicitly cast to the intended data type.

**WITH**— Sets the table storage options for a partition. For example, you may want older partitions to be append-optimized tables and newer partitions to be regular heap tables.

**TABLESPACE** — The name of the tablespace in which the partition is to be created.

#### SUBPARTITION BY

Declares one or more columns by which to subpartition the first-level partitions of the table. The format of the subpartition specification is similar to that of a partition specification described above.

#### SUBPARTITION TEMPLATE

Instead of declaring each subpartition definition individually for each partition, you can optionally declare a subpartition template to be used to create the subpartitions (lower level child tables). This subpartition specification would then apply to all parent partitions.

## Notes

- In Greenplum Database (a Postgres-based system) the data types **VARCHAR** or **TEXT** handle padding added to the textual data (space characters added after the last non-space character) as significant characters; the data type **CHAR** does not.

In Greenplum Database, values of type **CHAR(n)** are padded with trailing spaces to the specified width *n*. The values are stored and displayed with the spaces. However, the padding spaces are treated as semantically insignificant. When the values are distributed, the trailing spaces are disregarded. The trailing spaces are also treated as semantically insignificant when comparing two values of data type **CHAR**, and the trailing spaces are removed when converting a character value to one of the other string types.

- VMware does not support using **WITH OIDS** or **oids=TRUE** to assign an OID system column. Using OIDs in new applications is not recommended. This syntax is deprecated and will be removed in a future Greenplum release. As an alternative, use a **SERIAL** or other sequence generator as the table's primary key. However, if your application does make use

of OIDs to identify specific rows of a table, it is recommended to create a unique constraint on the OID column of that table, to ensure that OIDs in the table will indeed uniquely identify rows even after counter wrap-around. Avoid assuming that OIDs are unique across tables; if you need a database-wide unique identifier, use the combination of table OID and row OID for that purpose.

- Greenplum Database has some special conditions for primary key and unique constraints with regards to columns that are the *distribution key* in a Greenplum table. For a unique constraint to be enforced in Greenplum Database, the table must be hash-distributed (not `DISTRIBUTED RANDOMLY`), and the constraint columns must be the same as (or a superset of) the table's distribution key columns.

Replicated tables (`DISTRIBUTED REPLICATED`) can have both `PRIMARY KEY` and `UNIQUE` column constraints.

A primary key constraint is simply a combination of a unique constraint and a not-null constraint.

Greenplum Database automatically creates a `UNIQUE` index for each `UNIQUE` or `PRIMARY KEY` constraint to enforce uniqueness. Thus, it is not necessary to create an index explicitly for primary key columns. `UNIQUE` and `PRIMARY KEY` constraints are not allowed on append-optimized tables because the `UNIQUE` indexes that are created by the constraints are not allowed on append-optimized tables.

Foreign key constraints are not supported in Greenplum Database.

For inherited tables, unique constraints, primary key constraints, indexes and table privileges are *not* inherited in the current implementation.

- For append-optimized tables, `UPDATE` and `DELETE` are not allowed in a repeatable read or serializable transaction and will cause the transaction to end prematurely. `DECLARE...FOR UPDATE`, and triggers are not supported with append-optimized tables. `CLUSTER` on append-optimized tables is only supported over B-tree indexes.
- To insert data into a partitioned table, you specify the root partitioned table, the table created with the `CREATE TABLE` command. You also can specify a leaf child table of the partitioned table in an `INSERT` command. An error is returned if the data is not valid for the specified leaf child table. Specifying a child table that is not a leaf child table in the `INSERT` command is not supported. Execution of other DML commands such as `UPDATE` and `DELETE` on any child table of a partitioned table is not supported. These commands must be run on the root partitioned table, the table created with the `CREATE TABLE` command.
- The default values for these table storage options can be specified with the server configuration parameter `gp_default_storage_option`.
  - `appendoptimized`
  - `blocksize`
  - `checksum`
  - `compressstype`
  - `compresslevel`

- orientation The defaults can be set for the system, a database, or a user. For information about setting storage options, see the server configuration parameter [gp\\_default\\_storage\\_options](#).

**Important:** The current Postgres Planner allows list partitions with multi-column (composite) partition keys. GPORCA does not support composite keys, so using composite partition keys is not recommended.

## Examples

Create a table named `rank` in the schema named `baby` and distribute the data using the columns `rank`, `gender`, and `year`:

```
CREATE TABLE baby.rank (id int, rank int, year smallint,
gender char(1), count int ) DISTRIBUTED BY (rank, gender,
year);
```

Create table `films` and table `distributors` (the primary key will be used as the Greenplum distribution key by default):

```
CREATE TABLE films (
code          char(5) CONSTRAINT firstkey PRIMARY KEY,
title         varchar(40) NOT NULL,
did           integer NOT NULL,
date_prod    date,
kind          varchar(10),
len           interval hour to minute
);

CREATE TABLE distributors (
did           integer PRIMARY KEY DEFAULT nextval('serial'),
name          varchar(40) NOT NULL CHECK (name <> '')
);
```

Create a gzip-compressed, append-optimized table:

```
CREATE TABLE sales (txn_id int, qty int, date date)
WITH (appendoptimized=true, compresslevel=5)
DISTRIBUTED BY (txn_id);
```

Create a simple, single level partitioned table:

```
CREATE TABLE sales (id int, year int, qtr int, c_rank int, code char(1), region text)
DISTRIBUTED BY (id)
PARTITION BY LIST (code)
( PARTITION sales VALUES ('S'),
  PARTITION returns VALUES ('R')
);
```

Create a three level partitioned table that defines subpartitions without the `SUBPARTITION TEMPLATE` clause:

```
CREATE TABLE sales (id int, year int, qtr int, c_rank int, code char(1), region text)
DISTRIBUTED BY (id)
```

```

PARTITION BY LIST (code)
  SUBPARTITION BY RANGE (c_rank)
    SUBPARTITION by LIST (region)

( PARTITION sales VALUES ('S')
  ( SUBPARTITION cr1 START (1) END (2)
    ( SUBPARTITION ca VALUES ('CA') ),
    SUBPARTITION cr2 START (3) END (4)
      ( SUBPARTITION ca VALUES ('CA') ) ),

PARTITION returns VALUES ('R')
  ( SUBPARTITION cr1 START (1) END (2)
    ( SUBPARTITION ca VALUES ('CA') ),
    SUBPARTITION cr2 START (3) END (4)
      ( SUBPARTITION ca VALUES ('CA') ) )
);

```

Create the same partitioned table as the previous table using the `SUBPARTITION TEMPLATE` clause:

```

CREATE TABLE sales1 (id int, year int, qtr int, c_rank int, code char(1), region text)
DISTRIBUTED BY (id)
PARTITION BY LIST (code)

  SUBPARTITION BY RANGE (c_rank)
    SUBPARTITION TEMPLATE (
      SUBPARTITION cr1 START (1) END (2),
      SUBPARTITION cr2 START (3) END (4) )

  SUBPARTITION BY LIST (region)
    SUBPARTITION TEMPLATE (
      SUBPARTITION ca VALUES ('CA') )

( PARTITION sales VALUES ('S'),
  PARTITION returns VALUES ('R')
);

```

Create a three level partitioned table using subpartition templates and default partitions at each level:

```

CREATE TABLE sales (id int, year int, qtr int, c_rank int, code char(1), region text)
DISTRIBUTED BY (id)
PARTITION BY RANGE (year)

  SUBPARTITION BY RANGE (qtr)
    SUBPARTITION TEMPLATE (
      START (1) END (5) EVERY (1),
      DEFAULT SUBPARTITION bad_qtr )

  SUBPARTITION BY LIST (region)
    SUBPARTITION TEMPLATE (
      SUBPARTITION usa VALUES ('usa'),
      SUBPARTITION europe VALUES ('europe'),
      SUBPARTITION asia VALUES ('asia'),
      DEFAULT SUBPARTITION other_regions)

( START (2009) END (2011) EVERY (1),
  DEFAULT PARTITION outlying_years);

```

# Compatibility

`CREATE TABLE` command conforms to the SQL standard, with the following exceptions:

- **Temporary Tables** — In the SQL standard, temporary tables are defined just once and automatically exist (starting with empty contents) in every session that needs them. Greenplum Database instead requires each session to issue its own `CREATE TEMPORARY TABLE` command for each temporary table to be used. This allows different sessions to use the same temporary table name for different purposes, whereas the standard's approach constrains all instances of a given temporary table name to have the same table structure. The standard's distinction between global and local temporary tables is not in Greenplum Database. Greenplum Database will accept the `GLOBAL` and `LOCAL` keywords in a temporary table declaration, but they have no effect and are deprecated.

If the `ON COMMIT` clause is omitted, the SQL standard specifies that the default behavior is `ON COMMIT DELETE ROWS`. However, the default behavior in Greenplum Database is `ON COMMIT PRESERVE ROWS`. The `ON COMMIT DROP` option does not exist in the SQL standard.

- **Column Check Constraints** — The SQL standard says that `CHECK` column constraints may only refer to the column they apply to; only `CHECK` table constraints may refer to multiple columns. Greenplum Database does not enforce this restriction; it treats column and table check constraints alike.
- **NULL Constraint** — The `NULL` constraint is a Greenplum Database extension to the SQL standard that is included for compatibility with some other database systems (and for symmetry with the `NOT NULL` constraint). Since it is the default for any column, its presence is not required.
- **Inheritance** — Multiple inheritance via the `INHERITS` clause is a Greenplum Database language extension. SQL:1999 and later define single inheritance using a different syntax and different semantics. SQL:1999-style inheritance is not yet supported by Greenplum Database.
- **Partitioning** — Table partitioning via the `PARTITION BY` clause is a Greenplum Database language extension.
- **Zero-column tables** — Greenplum Database allows a table of no columns to be created (for example, `CREATE TABLE foo();`). This is an extension from the SQL standard, which does not allow zero-column tables. Zero-column tables are not in themselves very useful, but disallowing them creates odd special cases for `ALTER TABLE DROP COLUMN`, so Greenplum decided to ignore this spec restriction.
- **LIKE** — While a `LIKE` clause exists in the SQL standard, many of the options that Greenplum Database accepts for it are not in the standard, and some of the standard's options are not implemented by Greenplum Database.
- **WITH clause** — The `WITH` clause is a Greenplum Database extension; neither storage parameters nor OIDs are in the standard.
- **Tablespaces** — The Greenplum Database concept of tablespaces is not part of the SQL standard. The clauses `TABLESPACE` and `USING INDEX TABLESPACE` are extensions.
- **Data Distribution** — The Greenplum Database concept of a parallel or distributed database is not part of the SQL standard. The `DISTRIBUTED` clauses are extensions.

Parent topic: [SQL Commands](#)

## CREATE TABLE AS

Defines a new table from the results of a query.

### Synopsis

```
CREATE [ [ GLOBAL | LOCAL ] { TEMPORARY | TEMP } | UNLOGGED ] TABLE <table_name>
  [ (<column_name> [, ...] ) ]
  [ WITH ( <storage_parameter> [= <value>] [, ...] ) | WITHOUT OIDS ]
  [ ON COMMIT { PRESERVE ROWS | DELETE ROWS | DROP } ]
  [ TABLESPACE <tablespace_name> ]
AS <query>
  [ WITH [ NO ] DATA ]
  [ DISTRIBUTED BY (column [, ...] ) | DISTRIBUTED RANDOMLY | DISTRIBUTED REPLICATED ]
```

where `storage_parameter` is:

```
appendoptimized={TRUE|FALSE}
blocksize={8192-2097152}
orientation={COLUMN|ROW}
compressstype={ZLIB|ZSTD|QUICKLZ|RLE_TYPE|NONE}
compresslevel={1-19 | 1}
fillfactor={10-100}
[oids=FALSE]
```

### Description

`CREATE TABLE AS` creates a table and fills it with data computed by a `SELECT` command. The table columns have the names and data types associated with the output columns of the `SELECT`, however you can override the column names by giving an explicit list of new column names.

`CREATE TABLE AS` creates a new table and evaluates the query just once to fill the new table initially. The new table will not track subsequent changes to the source tables of the query.

### Parameters

GLOBAL | LOCAL

Ignored for compatibility. These keywords are deprecated; refer to [CREATE TABLE](#) for details.

TEMPORARY | TEMP

If specified, the new table is created as a temporary table. Temporary tables are automatically dropped at the end of a session, or optionally at the end of the current transaction (see [ON COMMIT](#)). Existing permanent tables with the same name are not visible to

the current session while the temporary table exists, unless they are referenced with schema-qualified names. Any indexes created on a temporary table are automatically temporary as well.

#### UNLOGGED

If specified, the table is created as an unlogged table. Data written to unlogged tables is not written to the write-ahead (WAL) log, which makes them considerably faster than ordinary tables. However, the contents of an unlogged table are not replicated to mirror segment instances. Also an unlogged table is not crash-safe. After a segment instance crash or unclean shutdown, the data for the unlogged table on that segment is truncated. Any indexes created on an unlogged table are automatically unlogged as well.

#### table\_name

The name (optionally schema-qualified) of the new table to be created.

#### column\_name

The name of a column in the new table. If column names are not provided, they are taken from the output column names of the query.

#### WITH ( storage\_parameter=value )

The **WITH** clause can be used to set storage options for the table or its indexes. Note that you can also set different storage parameters on a particular partition or subpartition by declaring the **WITH** clause in the partition specification. The following storage options are available:

**appendoptimized** — Set to **TRUE** to create the table as an append-optimized table. If **FALSE** or not declared, the table will be created as a regular heap-storage table.

**blocksize** — Set to the size, in bytes for each block in a table. The **blocksize** must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default is 32768. The **blocksize** option is valid only if **appendoptimized=TRUE**.

**orientation** — Set to **column** for column-oriented storage, or **row** (the default) for row-oriented storage. This option is only valid if **appendoptimized=TRUE**. Heap-storage tables can only be row-oriented.

**compresstype** — Set to **ZLIB** (the default), **ZSTD**, **RLE\_TYPE**, or **QUICKLZ**<sup>1</sup> to specify the type of compression used. The value **NONE** deactivates compression. Zstd provides for both speed or a good compression ratio, tunable with the **compresslevel** option. QuickLZ and zlib are provided for backwards-compatibility. Zstd outperforms these compression types on usual workloads. The **compresstype** option is valid only if **appendoptimized=TRUE**.

**Note:** <sup>1</sup>QuickLZ compression is available only in the commercial release of Tanzu Greenplum.

The value **RLE\_TYPE**, which is supported only if **orientation=column** is specified, enables the run-length encoding (RLE) compression algorithm. RLE compresses data better than the Zstd, zlib, or QuickLZ compression algorithms when the same data value occurs in many consecutive rows.

For columns of type **BIGINT**, **INTEGER**, **DATE**, **TIME**, or **TIMESTAMP**, delta compression is also applied if the **compresstype** option is set to **RLE\_TYPE** compression. The delta compression algorithm is based on the delta between column values in consecutive rows and is designed to improve compression when data is loaded in sorted order or the compression is applied to column data that is in sorted order.

For information about using table compression, see [Choosing the Table Storage Model](#) in the *Greenplum Database Administrator Guide*.

**compresslevel** — For Zstd compression of append-optimized tables, set to an integer value from 1 (fastest compression) to 19 (highest compression ratio). For zlib compression, the valid range is from 1 to 9. QuickLZ compression level can only be set to 1. If not declared, the default is 1. The `compresslevel` option is valid only if `appendoptimized=TRUE`.

**fillfactor** — See [CREATE INDEX](#) for more information about this index storage parameter.

**oids=FALSE** — This setting is the default, and it ensures that rows do not have object identifiers assigned to them. VMware does not support using `WITH OIDS` or `oids=TRUE` to assign an OID system column. On large tables, such as those in a typical Greenplum Database system, using OIDs for table rows can cause wrap-around of the 32-bit OID counter. Once the counter wraps around, OIDs can no longer be assumed to be unique, which not only makes them useless to user applications, but can also cause problems in the Greenplum Database system catalog tables. In addition, excluding OIDs from a table reduces the space required to store the table on disk by 4 bytes per row, slightly improving performance. You cannot create OIDs on a partitioned or column-oriented table (an error is displayed). This syntax is deprecated and will be removed in a future Greenplum release.

## ON COMMIT

The behavior of temporary tables at the end of a transaction block can be controlled using `ON COMMIT`. The three options are:

**PRESERVE ROWS** — No special action is taken at the ends of transactions for temporary tables. This is the default behavior.

**DELETE ROWS** — All rows in the temporary table will be deleted at the end of each transaction block. Essentially, an automatic `TRUNCATE` is done at each commit.

**DROP** — The temporary table will be dropped at the end of the current transaction block.

## TABLESPACE tablespace\_name

The `tablespace_name` parameter is the name of the tablespace in which the new table is to be created. If not specified, the database's default tablespace is used, or `temp_tablespaces` if the table is temporary.

## AS query

A `SELECT`, `TABLE`, or `VALUES` command, or an `EXECUTE` command that runs a prepared `SELECT` or `VALUES` query.

`DISTRIBUTED BY` ({column [opclass]}, [ ... ])

`DISTRIBUTED RANDOMLY`

`DISTRIBUTED REPLICATED`

Used to declare the Greenplum Database distribution policy for the table. `DISTRIBUTED BY` uses hash distribution with one or more columns declared as the distribution key. For the most even data distribution, the distribution key should be the primary key of the table or a unique column (or set of columns). If that is not possible, then you may choose `DISTRIBUTED RANDOMLY`, which will send the data round-robin to the segment instances.

`DISTRIBUTED REPLICATED` replicates all rows in the table to all Greenplum Database segments. It cannot be used with partitioned tables or with tables that inherit from other tables.

The Greenplum Database server configuration parameter

`gp_create_table_random_default_distribution` controls the default table distribution policy if the `DISTRIBUTED BY` clause is not specified when you create a table. Greenplum Database follows these rules to create a table if a distribution policy is not specified.

- If the Postgres Planner creates the table, and the value of the parameter is `off`, the table distribution policy is determined based on the command.
- If the Postgres Planner creates the table, and the value of the parameter is `on`, the table distribution policy is random.
- If GPORCA creates the table, the table distribution policy is random. The parameter value has no effect.

For more information about setting the default table distribution policy, see

`gp_create_table_random_default_distribution`. For information about the Postgres Planner and GPORCA, see [Querying Data](#) in the *Greenplum Database Administrator Guide*.

## Notes

This command is functionally similar to `SELECT INTO`, but it is preferred since it is less likely to be confused with other uses of the `SELECT INTO` syntax. Furthermore, `CREATE TABLE AS` offers a superset of the functionality offered by `SELECT INTO`.

`CREATE TABLE AS` can be used for fast data loading from external table data sources. See [CREATE EXTERNAL TABLE](#).

## Examples

Create a new table `films_recent` consisting of only recent entries from the table `films`:

```
CREATE TABLE films_recent AS SELECT * FROM films WHERE
date_prod >= '2007-01-01';
```

Create a new temporary table `films_recent`, consisting of only recent entries from the table `films`, using a prepared statement. The new table will be dropped at commit:

```
PREPARE recentfilms(date) AS SELECT * FROM films WHERE
date_prod > $1;
CREATE TEMP TABLE films_recent ON COMMIT DROP AS
EXECUTE recentfilms('2007-01-01');
```

## Compatibility

`CREATE TABLE AS` conforms to the SQL standard, with the following exceptions:

- The standard requires parentheses around the subquery clause; in Greenplum Database, these parentheses are optional.
- The standard defines a `WITH [NO] DATA` clause; this is not currently implemented by Greenplum Database. The behavior provided by Greenplum Database is equivalent to the

standard's `WITH DATA` case. `WITH NO DATA` can be simulated by appending `LIMIT 0` to the query.

- Greenplum Database handles temporary tables differently from the standard; see `CREATE TABLE` for details.
- The `WITH` clause is a Greenplum Database extension; neither storage parameters nor `OIDs` are in the standard. The syntax for creating OID system columns is deprecated and will be removed in a future Greenplum release.
- The Greenplum Database concept of tablespaces is not part of the standard. The `TABLESPACE` clause is an extension.

## CREATE TABLESPACE

Defines a new tablespace.

## Synopsis

```
CREATE TABLESPACE <tablespace_name> [OWNER <username>] LOCATION '</path/to/dir>'
    [WITH (content<ID_1>='</path/to/dir1>' [, content<ID_2>='</path/to/dir2>' ... ])]
```

## Description

`CREATE TABLESPACE` registers and configures a new tablespace for your Greenplum Database system. The tablespace name must be distinct from the name of any existing tablespace in the system. A tablespace is a Greenplum Database system object (a global object), you can use a tablespace from any database if you have appropriate privileges.

A tablespace allows superusers to define an alternative host file system location where the data files containing database objects (such as tables and indexes) reside.

A user with appropriate privileges can pass a tablespace name to `CREATE DATABASE`, `CREATE TABLE`, or `CREATE INDEX` to have the data files for these objects stored within the specified tablespace.

In Greenplum Database, the file system location must exist on all hosts including the hosts running the master, standby mirror, each primary segment, and each mirror segment.

## Parameters

tablespacename

The name of a tablespace to be created. The name cannot begin with `pg_` or `gp_`, as such names are reserved for system tablespaces.

**OWNER** username

The name of the user who will own the tablespace. If omitted, defaults to the user running the command. Only superusers can create tablespaces, but they can assign ownership of tablespaces to non-superusers.

**LOCATION** '/path/to/dir'

The absolute path to the directory (host system file location) that will be the root directory for the tablespace. When registering a tablespace, the directory should be empty and must be owned by the Greenplum Database system user. The directory must be specified by an absolute path name of no more than 100 characters. (The location is used to create a symlink target in the `pg_tblspc` directory, and symlink targets are truncated to 100 characters when sending to `tar` from utilities such as `pg_basebackup`.)

For each segment instance, you can specify a different directory for the tablespace in the `WITH` clause.

## contentID\_i='/path/to/dir\_i'

The value `ID_i` is the content ID for the segment instance. `/path/to/dir_i` is the absolute path to the host system file location that the segment instance uses as the root directory for the tablespace. You cannot specify the content ID of the master instance (`-1`). You can specify the same directory for multiple segments.

If a segment instance is not listed in the `WITH` clause, Greenplum Database uses the directory specified in the `LOCATION` clause.

When registering a tablespace, the directories should be empty and must be owned by the Greenplum Database system user. Each directory must be specified by an absolute path name of no more than 100 characters.

## Notes

Tablespaces are only supported on systems that support symbolic links.

`CREATE TABLESPACE` cannot be run inside a transaction block.

When creating tablespaces, ensure that file system locations have sufficient I/O speed and available disk space.

`CREATE TABLESPACE` creates symbolic links from the `pg_tblspc` directory in the master and segment instance data directory to the directories specified in the command.

The system catalog table `pg_tablespace` stores tablespace information. This command displays the tablespace OID values, names, and owner.

```
SELECT oid, spcname, spcowner FROM pg_tablespace;
```

The Greenplum Database built-in function `gp_tablespace_location(tablespace\_oid)` displays the tablespace host system file locations for all segment instances. This command lists the segment database IDs and host system file locations for the tablespace with OID `16385`.

```
SELECT * FROM gp_tablespace_location(16385)
```

**Note:** Greenplum Database does not support different tablespace locations for a primary-mirror pair with the same content ID. It is only possible to configure different locations for different content IDs. Do not modify symbolic links under the `pg_tblspc` directory so that primary-mirror pairs point to different file locations; this will lead to erroneous behavior.

## Examples

Create a new tablespace and specify the file system location for the master and all segment instances:

```
CREATE TABLESPACE mytblspace LOCATION '/gpdbtspc/mytestspace';
```

Create a new tablespace and specify a location for segment instances with content ID 0 and 1. For the master and segment instances not listed in the `WITH` clause, the file system location for the tablespace is specified in the `LOCATION` clause.

```
CREATE TABLESPACE mytblspace LOCATION '/gpdbtspc/mytestspace' WITH (content0='/temp/mytest', content1='/temp/mytest');
```

The example specifies the same location for the two segment instances. You can specify a different location for each segment.

## Compatibility

`CREATE TABLESPACE` is a Greenplum Database extension.

## CREATE TEXT SEARCH CONFIGURATION

Defines a new text search configuration.

## Synopsis

```
CREATE TEXT SEARCH CONFIGURATION <name> (
    PARSER = <parser_name> |
    COPY = <source_config>
)
```

## Description

`CREATE TEXT SEARCH CONFIGURATION` creates a new text search configuration. A text search configuration specifies a text search parser that can divide a string into tokens, plus dictionaries that can be used to determine which tokens are of interest for searching.

If only the parser is specified, then the new text search configuration initially has no mappings from token types to dictionaries, and therefore will ignore all words. Subsequent `ALTER TEXT SEARCH CONFIGURATION` commands must be used to create mappings to make the configuration useful. Alternatively, an existing text search configuration can be copied.

If a schema name is given then the text search configuration is created in the specified schema. Otherwise it is created in the current schema.

The user who defines a text search configuration becomes its owner.

Refer to [Using Full Text Search](#) for further information.

## Parameters

name

The name of the text search configuration to be created. The name can be schema-qualified.

parser\_name

The name of the text search parser to use for this configuration.

source\_config

The name of an existing text search configuration to copy.

## Notes

The `PARSER` and `COPY` options are mutually exclusive, because when an existing configuration is copied, its parser selection is copied too.

## Compatibility

There is no `CREATE TEXT SEARCH CONFIGURATION` statement in the SQL standard.

## See Also

[ALTER TEXT SEARCH CONFIGURATION](#), [DROP TEXT SEARCH CONFIGURATION](#)

Parent topic: [SQL Commands](#)

## CREATE TEXT SEARCH DICTIONARY

Defines a new text search dictionary.

## Synopsis

```
CREATE TEXT SEARCH DICTIONARY <name> (
    TEMPLATE = <template>
    [, <option> = <value> [, ... ]]
)
```

## Description

`CREATE TEXT SEARCH DICTIONARY` creates a new text search dictionary. A text search dictionary specifies a way of recognizing interesting or uninteresting words for searching. A dictionary depends on a text search template, which specifies the functions that actually perform the work. Typically the dictionary provides some options that control the detailed behavior of the template's functions.

If a schema name is given then the text search dictionary is created in the specified schema. Otherwise it is created in the current schema.

The user who defines a text search dictionary becomes its owner.

Refer to [Using Full Text Search](#) for further information.

## Parameters

### `name`

The name of the text search dictionary to be created. The name can be schema-qualified.

### `template`

The name of the text search template that will define the basic behavior of this dictionary.

### `option`

The name of a template-specific option to be set for this dictionary.

### `value`

The value to use for a template-specific option. If the value is not a simple identifier or number, it must be quoted (but you can always quote it, if you wish).

The options can appear in any order.

## Examples

The following example command creates a Snowball-based dictionary with a nonstandard list of stop words.

```
CREATE TEXT SEARCH DICTIONARY my_russian (
    template = snowball,
    language = russian,
    stopwords = myrussian
);
```

## Compatibility

There is no `CREATE TEXT SEARCH DICTIONARY` statement in the SQL standard.

## See Also

[ALTER TEXT SEARCH DICTIONARY](#), [DROP TEXT SEARCH DICTIONARY](#)

Parent topic: [SQL Commands](#)

## CREATE TEXT SEARCH PARSER

## Description

Defines a new text search parser.

## Synopsis

```
CREATE TEXT SEARCH_PARSER name (
    START = start_function ,
    GETTOKEN = gettoken_function ,
    END = end_function ,
    LEXTYPES = lextypes_function
    [, HEADLINE = headline_function ]
)
```

## Description

`CREATE TEXT SEARCH_PARSER` creates a new text search parser. A text search parser defines a method for splitting a text string into tokens and assigning types (categories) to the tokens. A parser is not particularly useful by itself, but must be bound into a text search configuration along with some text search dictionaries to be used for searching.

If a schema name is given then the text search parser is created in the specified schema. Otherwise it is created in the current schema.

You must be a superuser to use `CREATE TEXT SEARCH_PARSER`. (This restriction is made because an erroneous text search parser definition could confuse or even crash the server.)

Refer to [Using Full Text Search](#) for further information.

## Parameters

`name`

The name of the text search parser to be created. The name can be schema-qualified.

`start\_function`

The name of the start function for the parser.

`gettoken\_function`

The name of the get-next-token function for the parser.

`end\_function`

The name of the end function for the parser.

`lextypes\_function`

The name of the lextypes function for the parser (a function that returns information about the set of token types it produces).

`headline\_function`

The name of the headline function for the parser (a function that summarizes a set of tokens).

The function names can be schema-qualified if necessary. Argument types are not given, since the argument list for each type of function is predetermined. All except the headline function are required.

The arguments can appear in any order, not only the one shown above.

## Compatibility

There is no `CREATE TEXT SEARCH PARSER` statement in the SQL standard.

## See Also

[ALTER TEXT SEARCH PARSER](#), [DROP TEXT SEARCH PARSER](#)

Parent topic: [SQL Commands](#)

## CREATE TEXT SEARCH TEMPLATE

### Description

Defines a new text search template.

### Synopsis

```
CREATE TEXT SEARCH TEMPLATE <name> (
    [ INIT = <init_function> , ]
    LEXIZE = <lexize_function>
)
```

### Description

`CREATE TEXT SEARCH TEMPLATE` creates a new text search template. Text search templates define the functions that implement text search dictionaries. A template is not useful by itself, but must be instantiated as a dictionary to be used. The dictionary typically specifies parameters to be given to the template functions.

If a schema name is given then the text search template is created in the specified schema. Otherwise it is created in the current schema.

You must be a superuser to use `CREATE TEXT SEARCH TEMPLATE`. This restriction is made because an erroneous text search template definition could confuse or even crash the server. The reason for separating templates from dictionaries is that a template encapsulates the "unsafe" aspects of defining a dictionary. The parameters that can be set when defining a dictionary are safe for unprivileged users to set, and so creating a dictionary need not be a privileged operation.

Refer to [Using Full Text Search](#) for further information.

### Parameters

`name`

The name of the text search template to be created. The name can be schema-qualified.

`init\_function`

The name of the init function for the template.

`lexize\_function`

The name of the lexize function for the template.

The function names can be schema-qualified if necessary. Argument types are not given, since the argument list for each type of function is predetermined. The lexize function is required, but the init function is optional.

The arguments can appear in any order, not only the order shown above.

## Compatibility

There is no `CREATE TEXT SEARCH TEMPLATE` statement in the SQL standard.

## See Also

[DROP TEXT SEARCH TEMPLATE](#), [ALTER TEXT SEARCH TEMPLATE](#)

Parent topic: [SQL Commands](#)

## CREATE TYPE

Defines a new data type.

## Synopsis

```
CREATE TYPE <name> AS
    ( <attribute_name> <data_type> [ COLLATE <collation> ] [, ... ] )

CREATE TYPE <name> AS ENUM
    ( [ '<label>' [, ... ] ] )

CREATE TYPE <name> AS RANGE (
    SUBTYPE = <subtype>
    [ , SUBTYPE_OPCLASS = <subtype_operator_class> ]
    [ , COLLATION = <collation> ]
    [ , CANONICAL = <canonical_function> ]
    [ , SUBTYPE_DIFF = <subtype_diff_function> ]
)

CREATE TYPE <name> (
    INPUT = <input_function>,
    OUTPUT = <output_function>
    [, RECEIVE = <receive_function>]
    [, SEND = <send_function>]
    [, TYPMOD_IN = <type_modifier_input_function> ]
    [, TYPMOD_OUT = <type_modifier_output_function> ]
    [, INTERNALLENGTH = {<internallength> | VARIABLE}]
    [, PASSEDBYVALUE]
    [, ALIGNMENT = <alignment>]
    [, STORAGE = <storage>]
    [, LIKE = <like_type>
    [, CATEGORY = <category>]
    [, PREFERRED = <preferred>]
    [, DEFAULT = <default>]
    [, ELEMENT = <element>]
    [, DELIMITER = <delimiter>]
    [, COLLATABLE = <collatable>]
    [, COMPRESSTYPE = <compression_type>]
```

```
[, COMPRESSLEVEL = <compression_level>]
[, BLOCKSIZE = <blocksize>] )

CREATE TYPE <name>
```

## Description

`CREATE TYPE` registers a new data type for use in the current database. The user who defines a type becomes its owner.

If a schema name is given then the type is created in the specified schema. Otherwise it is created in the current schema. The type name must be distinct from the name of any existing type or domain in the same schema. The type name must also be distinct from the name of any existing table in the same schema.

There are five forms of `CREATE TYPE`, as shown in the syntax synopsis above. They respectively create a *composite type*, an *enum type*, a *range type*, a *base type*, or a *shell type*. The first four of these are discussed in turn below. A shell type is simply a placeholder for a type to be defined later; it is created by issuing `CREATE TYPE` with no parameters except for the type name. Shell types are needed as forward references when creating range types and base types, as discussed in those sections.

### Composite Types

The first form of `CREATE TYPE` creates a composite type. The composite type is specified by a list of attribute names and data types. An attribute's collation can be specified too, if its data type is collatable. A composite type is essentially the same as the row type of a table, but using `CREATE TYPE` avoids the need to create an actual table when all that is wanted is to define a type. A stand-alone composite type is useful, for example, as the argument or return type of a function.

To be able to create a composite type, you must have `USAGE` privilege on all attribute types.

### Enumerated Types

The second form of `CREATE TYPE` creates an enumerated (`ENUM`) type, as described in [Enumerated Types](#) in the PostgreSQL documentation. `ENUM` types take a list of quoted labels, each of which must be less than `NAMEDATALEN` bytes long (64 in a standard build).

It is possible to create an enumerated type with zero labels, but such a type cannot be used to hold values before at least one label is added using `ALTER TYPE`.

### Range Types

The third form of `CREATE TYPE` creates a new range type, as described in [Range Types](#).

The range type's subtype can be any type with an associated b-tree operator class (to determine the ordering of values for the range type). Normally the subtype's default b-tree operator class is used to determine ordering; to use a non-default operator class, specify its name with `subtype_opclass`. If the subtype is collatable, and you want to use a non-default collation in the range's ordering, specify the desired collation with the `collation` option.

The optional canonical function must take one argument of the range type being defined, and return a value of the same type. This is used to convert range values to a canonical form, when applicable. See Section [Defining New Range Types](#) for more information. Creating a canonical function is a bit tricky, since it must be defined before the range type can be declared. To do this,

you must first create a shell type, which is a placeholder type that has no properties except a name and an owner. This is done by issuing the command `CREATE TYPE name`, with no additional parameters. Then the function can be declared using the shell type as argument and result, and finally the range type can be declared using the same name. This automatically replaces the shell type entry with a valid range type.

The optional `<subtype_diff>` function must take two values of the subtype type as argument, and return a double precision value representing the difference between the two given values. While this is optional, providing it allows much greater efficiency of GiST indexes on columns of the range type. See [Defining New Range Types](#) for more information.

## Base Types

The fourth form of `CREATE TYPE` creates a new base type (scalar type). You must be a superuser to create a new base type. The parameters may appear in any order, not only that shown in the syntax, and most are optional. You must register two or more functions (using `CREATE FUNCTION`) before defining the type. The support functions `input_function` and `output_function` are required, while the functions `receive_function`, `send_function`, `type_modifier_input_function`, `type_modifier_output_function`, and `analyze_function` are optional. Generally these functions have to be coded in C or another low-level language. In Greenplum Database, any function used to implement a data type must be defined as `IMMUTABLE`.

The `input_function` converts the type's external textual representation to the internal representation used by the operators and functions defined for the type. `output_function` performs the reverse transformation. The input function may be declared as taking one argument of type `cstring`, or as taking three arguments of types `cstring`, `oid`, `integer`. The first argument is the input text as a C string, the second argument is the type's own OID (except for array types, which instead receive their element type's OID), and the third is the `typmod` of the destination column, if known (`-1` will be passed if not). The input function must return a value of the data type itself. Usually, an input function should be declared `STRICT`; if it is not, it will be called with a `NULL` first parameter when reading a `NULL` input value. The function must still return `NULL` in this case, unless it raises an error. (This case is mainly meant to support domain input functions, which may need to reject `NULL` inputs.) The output function must be declared as taking one argument of the new data type. The output function must return type `cstring`. Output functions are not invoked for `NULL` values.

The optional `receive_function` converts the type's external binary representation to the internal representation. If this function is not supplied, the type cannot participate in binary input. The binary representation should be chosen to be cheap to convert to internal form, while being reasonably portable. (For example, the standard integer data types use network byte order as the external binary representation, while the internal representation is in the machine's native byte order.) The receive function should perform adequate checking to ensure that the value is valid. The receive function may be declared as taking one argument of type `internal`, or as taking three arguments of types `internal`, `oid`, `integer`. The first argument is a pointer to a `StringInfo` buffer holding the received byte string; the optional arguments are the same as for the text input function. The receive function must return a value of the data type itself. Usually, a receive function should be declared `STRICT`; if it is not, it will be called with a `NULL` first parameter when reading a `NULL` input value. The function must still return `NULL` in this case, unless it raises an error. (This case is mainly meant to support domain receive functions, which may need to reject `NULL` inputs.) Similarly, the optional `send_function` converts from the internal representation to the external

binary representation. If this function is not supplied, the type cannot participate in binary output. The send function must be declared as taking one argument of the new data type. The send function must return type `bytea`. Send functions are not invoked for `NULL` values.

The optional `type_modifier_input_function` and `type_modifier_output_function` are required if the type supports modifiers. Modifiers are optional constraints attached to a type declaration, such as `char(5)` or `numeric(30,2)`. While Greenplum Database allows user-defined types to take one or more simple constants or identifiers as modifiers, this information must fit into a single non-negative integer value for storage in the system catalogs. Greenplum Database passes the declared modifier(s) to the `type_modifier_input_function` in the form of a `cstring` array. The modifier input function must check the values for validity, throwing an error if they are incorrect. If the values are correct, the modifier input function returns a single non-negative integer value that Greenplum Database stores as the column `typmod`. Type modifiers are rejected if the type was not defined with a `type_modifier_input_function`. The `type_modifier_output_function` converts the internal integer `typmod` value back to the correct form for user display. The modifier output function must return a `cstring` value that is the exact string to append to the type name. For example, `numeric`'s function might return `(30,2)`. The `type_modifier_output_function` is optional. When not specified, the default display format is the stored `typmod` integer value enclosed in parentheses.

You should at this point be wondering how the input and output functions can be declared to have results or arguments of the new type, when they have to be created before the new type can be created. The answer is that the type should first be defined as a shell type, which is a placeholder type that has no properties except a name and an owner. This is done by issuing the command `CREATE TYPE name`, with no additional parameters. Then the I/O functions can be defined referencing the shell type. Finally, `CREATE TYPE` with a full definition replaces the shell entry with a complete, valid type definition, after which the new type can be used normally.

The `like_type` parameter provides an alternative method for specifying the basic representation properties of a data type: copy them from some existing type. The values `internallength`, `passedbyvalue`, `alignment`, and `storage` are copied from the named type. (It is possible, though usually undesirable, to override some of these values by specifying them along with the `LIKE` clause.) Specifying representation this way is especially useful when the low-level implementation of the new type "piggybacks" on an existing type in some fashion.

While the details of the new type's internal representation are only known to the I/O functions and other functions you create to work with the type, there are several properties of the internal representation that must be declared to Greenplum Database. Foremost of these is `internallength`. Base data types can be fixed-length, in which case `internallength` is a positive integer, or variable length, indicated by setting `internallength` to `VARIABLE`. (Internally, this is represented by setting `typplen` to `-1`.) The internal representation of all variable-length types must start with a 4-byte integer giving the total length of this value of the type.

The optional flag `PASSEDBYVALUE` indicates that values of this data type are passed by value, rather than by reference. You may not pass by value types whose internal representation is larger than the size of the `Datum` type (4 bytes on most machines, 8 bytes on a few).

The `alignment` parameter specifies the storage alignment required for the data type. The allowed values equate to alignment on 1, 2, 4, or 8 byte boundaries. Note that variable-length types must have an alignment of at least 4, since they necessarily contain an `int4` as their first component.

The storage parameter allows selection of storage strategies for variable-length data types. (Only `plain` is allowed for fixed-length types.) `plain` specifies that data of the type will always be stored in-line and not compressed. `extended` specifies that the system will first try to compress a long data value, and will move the value out of the main table row if it's still too long. `external` allows the value to be moved out of the main table, but the system will not try to compress it. `main` allows compression, but discourages moving the value out of the main table. (Data items with this storage strategy may still be moved out of the main table if there is no other way to make a row fit, but they will be kept in the main table preferentially over `extended` and `external` items.)

A default value may be specified, in case a user wants columns of the data type to default to something other than the null value. Specify the default with the `DEFAULT` key word. (Such a default may be overridden by an explicit `DEFAULT` clause attached to a particular column.)

To indicate that a type is an array, specify the type of the array elements using the `ELEMENT` key word. For example, to define an array of 4-byte integers (`int4`), specify `ELEMENT = int4`. More details about array types appear below.

The `category` and `preferred` parameters can be used to help control which implicit cast Greenplum Database applies in ambiguous situations. Each data type belongs to a category named by a single ASCII character, and each type is either "preferred" or not within its category. The parser will prefer casting to preferred types (but only from other types within the same category) when this rule helps resolve overloaded functions or operators. For types that have no implicit casts to or from any other types, it is sufficient to retain the default settings. However, for a group of related types that have implicit casts, it is often helpful to mark them all as belonging to a category and select one or two of the "most general" types as being preferred within the category. The `category` parameter is especially useful when you add a user-defined type to an existing built-in category, such as the numeric or string types. It is also possible to create new entirely-user-defined type categories. Select any ASCII character other than an upper-case letter to name such a category.

To indicate the delimiter to be used between values in the external representation of arrays of this type, `delimiter` can be set to a specific character. The default delimiter is the comma (,). Note that the delimiter is associated with the array element type, not the array type itself.

If the optional Boolean parameter `collatable` is true, column definitions and expressions of the type may carry collation information through use of the `COLLATE` clause. It is up to the implementations of the functions operating on the type to actually make use of the collation information; this does not happen automatically merely by marking the type collatable.

## Array Types

Whenever a user-defined type is created, Greenplum Database automatically creates an associated array type, whose name consists of the element type's name prepended with an underscore, and truncated if necessary to keep it less than `NAMEDATALEN` bytes long. (If the name so generated collides with an existing type name, the process is repeated until a non-colliding name is found.) This implicitly-created array type is variable length and uses the built-in input and output functions `array_in` and `array_out`. The array type tracks any changes in its element type's owner or schema, and is dropped if the element type is.

You might reasonably ask why there is an `ELEMENT` option, if the system makes the correct array type automatically. The only case where it's useful to use `ELEMENT` is when you are making a fixed-length type that happens to be internally an array of a number of identical things, and you want to allow these things to be accessed directly by subscripting, in addition to whatever operations you

plan to provide for the type as a whole. For example, type `point` is represented as just two floating-point numbers, each can be accessed using `point[0]` and `point[1]`. Note that this facility only works for fixed-length types whose internal form is exactly a sequence of identical fixed-length fields. A subscriptable variable-length type must have the generalized internal representation used by `array_in` and `array_out`. For historical reasons (i.e., this is clearly wrong but it's far too late to change it), subscripting of fixed-length array types starts from zero, rather than from one as for variable-length arrays.

## Parameters

`name`

The name (optionally schema-qualified) of a type to be created.

`attribute_name`

The name of an attribute (column) for the composite type.

`data_type`

The name of an existing data type to become a column of the composite type.

`collation`

The name of an existing collation to be associated with a column of a composite type, or with a range type.

`label`

A string literal representing the textual label associated with one value of an enum type.

`subtype`

The name of the element type that the range type will represent ranges of.

`subtype_operator_class`

The name of a b-tree operator class for the subtype.

`canonical_function`

The name of the canonicalization function for the range type.

`subtype_diff_function`

The name of a difference function for the subtype.

`input_function`

The name of a function that converts data from the type's external textual form to its internal form.

`output_function`

The name of a function that converts data from the type's internal form to its external textual form.

`receive_function`

The name of a function that converts data from the type's external binary form to its internal form.

`send_function`

The name of a function that converts data from the type's internal form to its external binary form.

`type_modifier_input_function`

The name of a function that converts an array of modifier(s) for the type to internal form.

`type_modifier_output_function`

The name of a function that converts the internal form of the type's modifier(s) to external textual form.

`internallength`

A numeric constant that specifies the length in bytes of the new type's internal representation. The default assumption is that it is variable-length.

#### alignment

The storage alignment requirement of the data type. Must be one of `char`, `int2`, `int4`, or `double`. The default is `int4`.

#### storage

The storage strategy for the data type. Must be one of `plain`, `external`, `extended`, or `main`. The default is `plain`.

#### like\_type

The name of an existing data type that the new type will have the same representation as. The values `internallength`, `passedbyvalue`, `alignment`, and `storage`, are copied from that type, unless overridden by explicit specification elsewhere in this `CREATE TYPE` command.

#### category

The category code (a single ASCII character) for this type. The default is `'u'`, signifying a user-defined type. You can find the other standard category codes in [pg\\_type Category Codes](#). You may also assign unused ASCII characters to custom categories that you create.

#### preferred

`true` if this type is a preferred type within its type category, else `false`. The default value is `false`. Be careful when you create a new preferred type within an existing type category; this could cause surprising behaviour changes.

#### default

The default value for the data type. If this is omitted, the default is null.

#### element

The type being created is an array; this specifies the type of the array elements.

#### delimiter

The delimiter character to be used between values in arrays made of this type.

#### collatable

True if this type's operations can use collation information. The default is false.

#### compression\_type

Set to `ZLIB` (the default), `ZSTD`, `RLE_TYPE`, or `QUICKLZ`<sup>1</sup> to specify the type of compression used in columns of this type.

**Note:** <sup>1</sup>QuickLZ compression is available only in the commercial release of Tanzu Greenplum.

#### compression\_level

For Zstd compression, set to an integer value from 1 (fastest compression) to 19 (highest compression ratio). For zlib compression, the valid range is from 1 to 9. The QuickLZ compression level can only be set to 1. For `RLE_TYPE`, the compression level can be set to an integer value from 1 (fastest compression) to 4 (highest compression ratio). The default compression level is 1.

#### blocksize

Set to the size, in bytes, for each block in the column. The `BLOCKSIZE` must be between 8192 and 2097152 bytes, and be a multiple of 8192. The default block size is 32768.

## Notes

User-defined type names cannot begin with the underscore character (`_`) and can only be 62 characters long (or in general `NAMEDATALEN - 2`, rather than the `NAMEDATALEN - 1` characters allowed

for other names). Type names beginning with underscore are reserved for internally-created array type names.

Greenplum Database does not support adding storage options for row or composite types.

Storage options defined at the table- and column- level override the default storage options defined for a scalar type.

Because there are no restrictions on use of a data type once it's been created, creating a base type or range type is tantamount to granting public execute permission on the functions mentioned in the type definition. (The creator of the type is therefore required to own these functions.) This is usually not an issue for the sorts of functions that are useful in a type definition. But you might want to think twice before designing a type in a way that would require 'secret' information to be used while converting it to or from external form.

## Examples

This example creates a composite type and uses it in a function definition:

```
CREATE TYPE compfoo AS (f1 int, f2 text);

CREATE FUNCTION getfoo() RETURNS SETOF compfoo AS $$
    SELECT foid, fooname FROM foo
$$ LANGUAGE SQL;
```

This example creates the enumerated type `mood` and uses it in a table definition.

```
CREATE TYPE mood AS ENUM ('sad', 'ok', 'happy');
CREATE TABLE person (
    name text,
    current_mood mood
);
INSERT INTO person VALUES ('Moe', 'happy');
SELECT * FROM person WHERE current_mood = 'happy';
 name | current_mood
-----+-----
 Moe  | happy
(1 row)
```

This example creates a range type:

```
CREATE TYPE float8_range AS RANGE (subtype = float8, subtype_diff = float8mi);
```

This example creates the base data type `box` and then uses the type in a table definition:

```
CREATE TYPE box;

CREATE FUNCTION my_box_in_function(cstring) RETURNS box AS
... ;

CREATE FUNCTION my_box_out_function(box) RETURNS cstring AS
... ;

CREATE TYPE box (
```

```

INTERNALLENGTH = 16,
INPUT = my_box_in_function,
OUTPUT = my_box_out_function
);

CREATE TABLE myboxes (
  id integer,
  description box
);

```

If the internal structure of `box` were an array of four `float4` elements, we might instead use:

```

CREATE TYPE box (
  INTERNALLENGTH = 16,
  INPUT = my_box_in_function,
  OUTPUT = my_box_out_function,
  ELEMENT = float4
);

```

which would allow a `box` value's component numbers to be accessed by subscripting. Otherwise the type behaves the same as before.

This example creates a large object type and uses it in a table definition:

```

CREATE TYPE bigobj (
  INPUT = lo_filein, OUTPUT = lo_fileout,
  INTERNALLENGTH = VARIABLE
);

CREATE TABLE big_objs (
  id integer,
  obj bigobj
);

```

## Compatibility

The first form of the `CREATE TYPE` command, which creates a composite type, conforms to the SQL standard. The other forms are Greenplum Database extensions. The `CREATE TYPE` statement in the SQL standard also defines other forms that are not implemented in Greenplum Database.

The ability to create a composite type with zero attributes is a Greenplum Database-specific deviation from the standard (analogous to the same case in `CREATE TABLE`).

## See Also

[ALTER TYPE](#), [CREATE DOMAIN](#), [CREATE FUNCTION](#), [DROP TYPE](#)

Parent topic: [SQL Commands](#)

## CREATE USER

Defines a new database role with the `LOGIN` privilege by default.

## Synopsis

```
CREATE USER <name> [[WITH] <option> [ ... ]]
```

where option can be:

```

SUPERUSER | NOSUPERUSER
| CREATEDB | NOCREATEDB
| CREATEROLE | NOCREATEROLE
| CREATEUSER | NOCREATEUSER
| CREATEEXTTABLE | NOCREATEEXTTABLE
| ( ( <attribute>='<value>' [, ...] ) )
| where <attributes> and <value> are:
| type='readable'|'writable'
| protocol='gpfdist'|'http'
| INHERIT | NOINHERIT
| LOGIN | NOLOGIN
| REPLICATION | NOREPLICATION
| CONNECTION LIMIT <connlimit>
| [ ENCRYPTED | UNENCRYPTED ] PASSWORD '<password>'
| VALID UNTIL '<timestamp>'
| IN ROLE <role_name> [, ...]
| IN GROUP <role_name>
| ROLE <role_name> [, ...]
| ADMIN <role_name> [, ...]
| USER <role_name> [, ...]
| SYSID <uid>
| RESOURCE QUEUE <queue_name>
| RESOURCE GROUP <group_name>
| [ DENY <deny_point> ]
| [ DENY BETWEEN <deny_point> AND <deny_point>]
```

## Description

`CREATE USER` is an alias for `CREATE ROLE`.

The only difference between `CREATE ROLE` and `CREATE USER` is that `LOGIN` is assumed by default with `CREATE USER`, whereas `NOLOGIN` is assumed by default with `CREATE ROLE`.

## Compatibility

There is no `CREATE USER` statement in the SQL standard.

## See Also

[CREATE ROLE](#)

## CREATE USER MAPPING

Defines a new mapping of a user to a foreign server.

## Synopsis

```
CREATE USER MAPPING FOR { <username> | USER | CURRENT_USER | PUBLIC }
    SERVER <servername>
    [ OPTIONS ( <option> '<value>' [, ... ] ) ]
```

## Description

`CREATE USER MAPPING` defines a mapping of a user to a foreign server. You must be the owner of the server to define user mappings for it.

## Parameters

username

The name of an existing user that is mapped to the foreign server. `CURRENT_USER` and `USER` match the name of the current user. `PUBLIC` is used to match all present and future user names in the system.

servername

The name of an existing server for which Greenplum Database is to create the user mapping.

OPTIONS ( option 'value' [, ... ] )

The options for the new user mapping. The options typically define the actual user name and password of the mapping. Option names must be unique. The option names and values are specific to the server's foreign-data wrapper.

## Examples

Create a user mapping for user `bob`, server `foo`:

```
CREATE USER MAPPING FOR bob SERVER foo OPTIONS (user 'bob', password 'secret');
```

## Compatibility

`CREATE USER MAPPING` conforms to ISO/IEC 9075-9 (SQL/MED).

## See Also

[ALTER USER MAPPING](#), [DROP USER MAPPING](#), [DROP USER MAPPING](#), [CREATE FOREIGN DATA WRAPPER](#), [CREATE SERVER](#)

## CREATE VIEW

Defines a new view.

## Synopsis

```
CREATE [OR REPLACE] [TEMP | TEMPORARY] [RECURSIVE] VIEW <name> [ ( <column_name> [,
... ] ) ]
    [ WITH ( view_option_name [= view_option_value] [, ... ] ) ]
AS <query>
    [ WITH [ CASCADED | LOCAL ] CHECK OPTION ]
```

## Description

**CREATE VIEW** defines a view of a query. The view is not physically materialized. Instead, the query is run every time the view is referenced in a query.

**CREATE OR REPLACE VIEW** is similar, but if a view of the same name already exists, it is replaced. The new query must generate the same columns that were generated by the existing view query (that is, the same column names in the same order, and with the same data types), but it may add additional columns to the end of the list. The calculations giving rise to the output columns may be completely different.

If a schema name is given then the view is created in the specified schema. Otherwise it is created in the current schema. Temporary views exist in a special schema, so a schema name may not be given when creating a temporary view. The name of the view must be distinct from the name of any other view, table, sequence, index or foreign table in the same schema.

## Parameters

### TEMPORARY | TEMP

If specified, the view is created as a temporary view. Temporary views are automatically dropped at the end of the current session. Existing permanent relations with the same name are not visible to the current session while the temporary view exists, unless they are referenced with schema-qualified names. If any of the tables referenced by the view are temporary, the view is created as a temporary view (whether **TEMPORARY** is specified or not).

### RECURSIVE

Creates a recursive view. The syntax

```
CREATE RECURSIVE VIEW [ <schema> . ] <view_name> (<column_names>) AS SELECT <...>;
```

is equivalent to

```
CREATE VIEW [ <schema> . ] <view_name> AS WITH RECURSIVE <view_name> (<column_names>) AS (SELECT <...>) SELECT <column_names> FROM <view_name>;
```

A view column name list must be specified for a recursive view.

### name

The name (optionally schema-qualified) of a view to be created.

### column\_name

An optional list of names to be used for columns of the view. If not given, the column names are deduced from the query.

WITH ( *view\_option\_name* [= *view\_option\_value*] [, ... ] )

This clause specifies optional parameters for a view; the following parameters are supported:

*check\_option* (string)

This parameter may be either `local` or `cascaded`, and is equivalent to specifying `WITH [ CASCADED | LOCAL ] CHECK OPTION` (see below). This option can be changed on existing views using `ALTER VIEW`.

*security\_barrier* (boolean)

This should be used if the view is intended to provide row-level security.

query

A `SELECT` or `VALUES` command which will provide the columns and rows of the view.

## Notes

Views in Greenplum Database are read only. The system will not allow an insert, update, or delete on a view. You can get the effect of an updatable view by creating rewrite rules on the view into appropriate actions on other tables. For more information see `CREATE RULE`.

Be careful that the names and data types of the view's columns will be assigned the way you want. For example:

```
CREATE VIEW vista AS SELECT 'Hello World';
```

is bad form in two ways: the column name defaults to `?column?`, and the column data type defaults to `unknown`. If you want a string literal in a view's result, use something like:

```
CREATE VIEW vista AS SELECT text 'Hello World' AS hello;
```

Access to tables referenced in the view is determined by permissions of the view owner not the current user (even if the current user is a superuser). This can be confusing in the case of superusers, since superusers typically have access to all objects. In the case of a view, even superusers must be explicitly granted access to tables referenced in the view if they are not the owner of the view.

However, functions called in the view are treated the same as if they had been called directly from the query using the view. Therefore the user of a view must have permissions to call any functions used by the view.

If you create a view with an `ORDER BY` clause, the `ORDER BY` clause is ignored when you do a `SELECT` from the view.

When `CREATE OR REPLACE VIEW` is used on an existing view, only the view's defining `SELECT` rule is changed. Other view properties, including ownership, permissions, and non-`SELECT` rules, remain unchanged. You must own the view to replace it (this includes being a member of the owning role).

## Examples

Create a view consisting of all comedy films:

```
CREATE VIEW comedies AS SELECT * FROM films
WHERE kind = 'comedy';
```

This will create a view containing the columns that are in the `film` table at the time of view creation. Though `*` was used to create the view, columns added later to the table will not be part of the view.

Create a view that gets the top ten ranked baby names:

```
CREATE VIEW topten AS SELECT name, rank, gender, year FROM
names, rank WHERE rank < '11' AND names.id=rank.id;
```

Create a recursive view consisting of the numbers from 1 to 100:

```
CREATE RECURSIVE VIEW public.nums_1_100 (n) AS
VALUES (1)
UNION ALL
SELECT n+1 FROM nums_1_100 WHERE n < 100;
```

Notice that although the recursive view's name is schema-qualified in this `CREATE VIEW` command, its internal self-reference is not schema-qualified. This is because the implicitly-created CTE's name cannot be schema-qualified.

## Compatibility

The SQL standard specifies some additional capabilities for the `CREATE VIEW` statement that are not in Greenplum Database. The optional clauses for the full SQL command in the standard are:

- **CHECK OPTION** — This option has to do with updatable views. All `INSERT` and `UPDATE` commands on the view will be checked to ensure data satisfy the view-defining condition (that is, the new data would be visible through the view). If they do not, the update will be rejected.
- **LOCAL** — Check for integrity on this view.
- **CASCADED** — Check for integrity on this view and on any dependent view. `CASCADED` is assumed if neither `CASCADED` nor `LOCAL` is specified.

`CREATE OR REPLACE VIEW` is a Greenplum Database language extension. So is the concept of a temporary view.

## DEALLOCATE

Deallocates a prepared statement.

## Synopsis

```
DEALLOCATE [PREPARE] <name>
```

## Description

`DEALLOCATE` is used to deallocate a previously prepared SQL statement. If you do not explicitly deallocate a prepared statement, it is deallocated when the session ends.

For more information on prepared statements, see [PREPARE](#).

## Parameters

`PREPARE`

Optional key word which is ignored.

`name`

The name of the prepared statement to deallocate.

## Examples

Deallocated the previously prepared statement named `insert_names`:

```
DEALLOCATE insert_names;
```

## Compatibility

The SQL standard includes a `DEALLOCATE` statement, but it is only for use in embedded SQL.

## See Also

[EXECUTE](#), [PREPARE](#)

Parent topic: [SQL Commands](#)

## DECLARE

Defines a cursor.

## Synopsis

```
DECLARE <name> [BINARY] [INSENSITIVE] [NO SCROLL] [PARALLEL RETRIEVE] CURSOR
    [{WITH | WITHOUT} HOLD]
    FOR <query> [FOR READ ONLY]
```

## Description

**DECLARE** allows a user to create a cursor, which can be used to retrieve a small number of rows at a time out of a larger query. Cursors can return data either in text or in binary format using **FETCH**.

**Note:** This page describes usage of cursors at the SQL command level. If you are trying to use cursors inside a PL/pgSQL function, the rules are different, see [PL/pgSQL](#).

Normal cursors return data in text format, the same as a **SELECT** would produce. Since data is stored natively in binary format, the system must do a conversion to produce the text format. Once the information comes back in text form, the client application may need to convert it to a binary format to manipulate it. In addition, data in the text format is often larger in size than in the binary format. Binary cursors return the data in a binary representation that may be more easily manipulated. Nevertheless, if you intend to display the data as text anyway, retrieving it in text form will save you some effort on the client side.

As an example, if a query returns a value of one from an integer column, you would get a string of 1 with a default cursor whereas with a binary cursor you would get a 4-byte field containing the internal representation of the value (in big-endian byte order).

Binary cursors should be used carefully. Many applications, including psql, are not prepared to handle binary cursors and expect data to come back in the text format.

**Note:** When the client application uses the 'extended query' protocol to issue a **FETCH** command, the Bind protocol message specifies whether data is to be retrieved in text or binary format. This choice overrides the way that the cursor is defined. The concept of a binary cursor as such is thus obsolete when using extended query protocol — any cursor can be treated as either text or binary.

A cursor can be specified in the **WHERE CURRENT OF** clause of the **UPDATE** or **DELETE** statement to update or delete table data. The **UPDATE** or **DELETE** statement can only be run on the server, for example in an interactive psql session or a script. Language extensions such as PL/pgSQL do not have support for updatable cursors.

### Parallel Retrieve Cursors

Greenplum Database supports a special type of cursor, a parallel retrieve cursor. You can use a parallel retrieve cursor to retrieve query results, in parallel, directly from the Greenplum Database segments, bypassing the Greenplum coordinator.

Parallel retrieve cursors do not support the **WITH HOLD** clause. Greenplum Database ignores the **BINARY** clause when you declare a parallel retrieve cursor.

You open a special retrieve session to each parallel retrieve cursor endpoint, and use the **RETRIEVE** command to retrieve the query results from a parallel retrieve cursor.

## Parameters

name

The name of the cursor to be created.

**BINARY**

Causes the cursor to return data in binary rather than in text format.

**Note:** Greenplum Database ignores the **BINARY** clause when you declare a **PARALLEL RETRIEVE** cursor.

**INSENSITIVE**

Indicates that data retrieved from the cursor should be unaffected by updates to the tables underlying the cursor while the cursor exists. In Greenplum Database, all cursors are insensitive. This key word currently has no effect and is present for compatibility with the SQL standard.

#### NO SCROLL

A cursor cannot be used to retrieve rows in a nonsequential fashion. This is the default behavior in Greenplum Database, since scrollable cursors (`SCROLL`) are not supported.

#### PARALLEL RETRIEVE

Declare a parallel retrieve cursor. A parallel retrieve cursor is a special type of cursor that you can use to retrieve results directly from Greenplum Database segments, in parallel.

#### WITH HOLD

#### WITHOUT HOLD

`WITH HOLD` specifies that the cursor may continue to be used after the transaction that created it successfully commits. `WITHOUT HOLD` specifies that the cursor cannot be used outside of the transaction that created it. `WITHOUT HOLD` is the default.

**Note:** Greenplum Database does not support declaring a `PARALLEL RETRIEVE` cursor with the `WITH HOLD` clause. `WITH HOLD` also cannot not be specified when the `query` includes a `FOR UPDATE` or `FOR SHARE` clause.

#### query

A `SELECT` or `VALUES` command which will provide the rows to be returned by the cursor.

If the cursor is used in the `WHERE CURRENT OF` clause of the `UPDATE` or `DELETE` command, the `SELECT` command must satisfy the following conditions:

- Cannot reference a view or external table.
- References only one table.

The table must be updatable. For example, the following are not updatable: table functions, set-returning functions, append-only tables, columnar tables.

- Cannot contain any of the following:
  - A grouping clause
  - A set operation such as `UNION ALL` or `UNION DISTINCT`
  - A sorting clause
  - A windowing clause
  - A join or a self-join

Specifying the `FOR UPDATE` clause in the `SELECT` command prevents other sessions from changing the rows between the time they are fetched and the time they are updated. Without the `FOR UPDATE` clause, a subsequent use of the `UPDATE` or `DELETE` command with the `WHERE CURRENT OF` clause has no effect if the row was changed since the cursor was created.

**Note:** Specifying the `FOR UPDATE` clause in the `SELECT` command locks the entire table, not just the selected rows.

## FOR READ ONLY

`FOR READ ONLY` indicates that the cursor is used in a read-only mode.

## Notes

Unless `WITH HOLD` is specified, the cursor created by this command can only be used within the current transaction. Thus, `DECLARE` without `WITH HOLD` is useless outside a transaction block: the cursor would survive only to the completion of the statement. Therefore Greenplum Database reports an error if this command is used outside a transaction block. Use `BEGIN` and `COMMIT` (or `ROLLBACK`) to define a transaction block.

If `WITH HOLD` is specified and the transaction that created the cursor successfully commits, the cursor can continue to be accessed by subsequent transactions in the same session. (But if the creating transaction ends prematurely, the cursor is removed.) A cursor created with `WITH HOLD` is closed when an explicit `CLOSE` command is issued on it, or the session ends. In the current implementation, the rows represented by a held cursor are copied into a temporary file or memory area so that they remain available for subsequent transactions.

If you create a cursor with the `DECLARE` command in a transaction, you cannot use the `SET` command in the transaction until you close the cursor with the `CLOSE` command.

Scrollable cursors are not currently supported in Greenplum Database. You can only use `FETCH` or `RETRIEVE` to move the cursor position forward, not backwards.

`DECLARE...FOR UPDATE` is not supported with append-optimized tables.

You can see all available cursors by querying the `pg_cursors` system view.

## Examples

Declare a cursor:

```
DECLARE mycursor CURSOR FOR SELECT * FROM mytable;
```

Declare a parallel retrieve cursor for the same query:

```
DECLARE myprcursor PARALLEL RETRIEVE CURSOR FOR SELECT * FROM mytable;
```

## Compatibility

SQL standard allows cursors only in embedded SQL and in modules. Greenplum Database permits cursors to be used interactively.

Greenplum Database does not implement an `OPEN` statement for cursors. A cursor is considered to be open when it is declared.

The SQL standard allows cursors to move both forward and backward. All Greenplum Database cursors are forward moving only (not scrollable).

Binary cursors are a Greenplum Database extension.

The SQL standard makes no provisions for parallel retrieve cursors.

## See Also

[CLOSE](#), [DELETE](#), [FETCH](#), [MOVE](#), [RETRIEVE](#), [SELECT](#), [UPDATE](#)

Parent topic: [SQL Commands](#)

## DELETE

Deletes rows from a table.

## Synopsis

```
[ WITH [ RECURSIVE ] <with_query> [, ...] ]
DELETE FROM [ONLY] <table> [[AS] <alias>]
    [USING <usinglist>]
    [WHERE <condition> | WHERE CURRENT OF <cursor_name>]
    [RETURNING * | <output_expression> [[AS] <output_name>] [, ...]]
```

## Description

**DELETE** deletes rows that satisfy the **WHERE** clause from the specified table. If the **WHERE** clause is absent, the effect is to delete all rows in the table. The result is a valid, but empty table.

By default, **DELETE** will delete rows in the specified table and all its child tables. If you wish to delete only from the specific table mentioned, you must use the **ONLY** clause.

There are two ways to delete rows in a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the **USING** clause. Which technique is more appropriate depends on the specific circumstances.

If the **WHERE CURRENT OF** clause is specified, the row that is deleted is the one most recently fetched from the specified cursor.

The **WHERE CURRENT OF** clause is not supported with replicated tables.

The optional **RETURNING** clause causes **DELETE** to compute and return value(s) based on each row actually deleted. Any expression using the table's columns, and/or columns of other tables mentioned in **USING**, can be computed. The syntax of the **RETURNING** list is identical to that of the output list of **SELECT**.

**Note:** The **RETURNING** clause is not supported when deleting from append-optimized tables.

You must have the **DELETE** privilege on the table to delete from it.

**Note:** As the default, Greenplum Database acquires an **EXCLUSIVE** lock on tables for **DELETE** operations on heap tables. When the Global Deadlock Detector is enabled, the lock mode for **DELETE** operations on heap tables is **ROW EXCLUSIVE**. See [Global Deadlock Detector](#).

### Outputs

On successful completion, a **DELETE** command returns a command tag of the form

```
DELETE <count>
```

The count is the number of rows deleted. If count is 0, no rows were deleted by the query (this is not considered an error).

If the `DELETE` command contains a `RETURNING` clause, the result will be similar to that of a `SELECT` statement containing the columns and values defined in the `RETURNING` list, computed over the row(s) deleted by the command.

## Parameters

`with_query`

The `WITH` clause allows you to specify one or more subqueries that can be referenced by name in the `DELETE` query.

For a `DELETE` command that includes a `WITH` clause, the clause can only contain `SELECT` statements, the `WITH` clause cannot contain a data-modifying command (`INSERT`, `UPDATE`, or `DELETE`).

See [WITH Queries \(Common Table Expressions\)](#) and `SELECT` for details.

`ONLY`

If specified, delete rows from the named table only. When not specified, any tables inheriting from the named table are also processed.

`table`

The name (optionally schema-qualified) of an existing table.

`alias`

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given `DELETE FROM foo AS f`, the remainder of the `DELETE` statement must refer to this table as `f` not `foo`.

`usinglist`

A list of table expressions, allowing columns from other tables to appear in the `WHERE` condition. This is similar to the list of tables that can be specified in the `FROM` Clause of a `SELECT` statement; for example, an alias for the table name can be specified. Do not repeat the target table in the `usinglist`, unless you wish to set up a self-join.

`condition`

An expression returning a value of type `boolean`, which determines the rows that are to be deleted.

`cursor_name`

The name of the cursor to use in a `WHERE CURRENT OF` condition. The row to be deleted is the one most recently fetched from this cursor. The cursor must be a simple non-grouping query on the `DELETE` target table.

`WHERE CURRENT OF` cannot be specified together with a Boolean condition.

The `DELETE...WHERE CURRENT OF` cursor statement can only be run on the server, for example in an interactive `psql` session or a script. Language extensions such as PL/pgSQL do not have support for updatable cursors.

See `DECLARE` for more information about creating cursors.

`output_expression`

An expression to be computed and returned by the `DELETE` command after each row is deleted. The expression can use any column names of the table or table(s) listed in `USING`.

Write `*` to return all columns.

`output_name`

A name to use for a returned column.

## Notes

Greenplum Database lets you reference columns of other tables in the `WHERE` condition by specifying the other tables in the `USING` clause. For example, to the name `Hannah` from the `rank` table, one might do:

```
DELETE FROM rank USING names WHERE names.id = rank.id AND
name = 'Hannah';
```

What is essentially happening here is a join between `rank` and `names`, with all successfully joined rows being marked for deletion. This syntax is not standard. However, this join style is usually easier to write and faster to run than a more standard sub-select style, such as:

```
DELETE FROM rank WHERE id IN (SELECT id FROM names WHERE name
= 'Hannah');
```

Execution of `UPDATE` and `DELETE` commands directly on a specific partition (child table) of a partitioned table is not supported. Instead, these commands must be run on the root partitioned table, the table created with the `CREATE TABLE` command.

For a partitioned table, all the child tables are locked during the `DELETE` operation when the Global Deadlock Detector is not enabled (the default). Only some of the leaf child tables are locked when the Global Deadlock Detector is enabled. For information about the Global Deadlock Detector, see [Global Deadlock Detector](#).

## Examples

Delete all films but musicals:

```
DELETE FROM films WHERE kind <> 'Musical';
```

Clear the table films:

```
DELETE FROM films;
```

Delete completed tasks, returning full details of the deleted rows:

```
DELETE FROM tasks WHERE status = 'DONE' RETURNING *;
```

Delete using a join:

```
DELETE FROM rank USING names WHERE names.id = rank.id AND
name = 'Hannah';
```

## Compatibility

This command conforms to the SQL standard, except that the `USING` and `RETURNING` clauses are Greenplum Database extensions, as is the ability to use `WITH` with `DELETE`.

## See Also

[DECLARE](#), [TRUNCATE](#)

Parent topic: [SQL Commands](#)

## DISCARD

Discards the session state.

## Synopsis

```
DISCARD { ALL | PLANS | TEMPORARY | TEMP }
```

## Description

`DISCARD` releases internal resources associated with a database session. This command is useful for partially or fully resetting the session's state. There are several subcommands to release different types of resources. `DISCARD ALL` is not supported by Greenplum Database.

## Parameters

### PLANS

Releases all cached query plans, forcing re-planning to occur the next time the associated prepared statement is used.

### SEQUENCES

Discards all cached sequence-related state, including any preallocated sequence values that have not yet been returned by `nextval()`. (See `CREATE SEQUENCE` for a description of preallocated sequence values.)

### TEMPORARY/TEMP

Drops all temporary tables created in the current session.

### ALL

Releases all temporary resources associated with the current session and resets the session to its initial state.

**Note:** Greenplum Database does not support `DISCARD ALL` and returns a notice message if you attempt to run the command.

As an alternative, you can run the following commands to release temporary session resources:

```
SET SESSION AUTHORIZATION DEFAULT;
RESET ALL;
DEALLOCATE ALL;
CLOSE ALL;
SELECT pg_advisory_unlock_all();
```

```
DISCARD PLANS;
DISCARD SEQUENCES;
DISCARD TEMP;
```

## Compatibility

`DISCARD` is a Greenplum Database extension.

Parent topic: [SQL Commands](#)

## DO

Runs anonymous code block as a transient anonymous function.

## Synopsis

```
DO [ LANGUAGE <lang_name> ] <code>
```

## Description

`DO` Runs an anonymous code block, or in other words a transient anonymous function in a procedural language.

The code block is treated as though it were the body of a function with no parameters, returning void. It is parsed and run a single time.

The optional `LANGUAGE` clause can appear either before or after the code block.

Anonymous blocks are procedural language structures that provide the capability to create and run procedural code on the fly without persistently storing the code as database objects in the system catalogs. The concept of anonymous blocks is similar to UNIX shell scripts, which enable several manually entered commands to be grouped and run as one step. As the name implies, anonymous blocks do not have a name, and for this reason they cannot be referenced from other objects. Although built dynamically, anonymous blocks can be easily stored as scripts in the operating system files for repetitive execution.

Anonymous blocks are standard procedural language blocks. They carry the syntax and obey the rules that apply to the procedural language, including declaration and scope of variables, execution, exception handling, and language usage.

The compilation and execution of anonymous blocks are combined in one step, while a user-defined function needs to be re-defined before use each time its definition changes.

## Parameters

code

The procedural language code to be run. This must be specified as a string literal, just as with the `CREATE FUNCTION` command. Use of a dollar-quoted literal is recommended. Optional keywords have no effect. These procedural languages are supported: PL/pgSQL (`plpgsql`), PL/Python (`plpythonu`), and PL/Perl (`plperl` and `plperlu`).

## lang\_name

The name of the procedural language that the code is written in. The default is `plpgsql`. The language must be installed on the Greenplum Database system and registered in the database.

## Notes

The PL/pgSQL language is installed on the Greenplum Database system and is registered in a user created database. The PL/Python and PL/Perl languages are installed by default, but not registered. Other languages are not installed or registered. The system catalog `pg_language` contains information about the registered languages in a database.

The user must have `USAGE` privilege for the procedural language, or must be a superuser if the language is untrusted. This is the same privilege requirement as for creating a function in the language.

Anonymous blocks do not support function volatility or `EXECUTE ON` attributes.

## Examples

This PL/pgSQL example grants all privileges on all views in schema `public` to role `webuser`:

```
DO $$DECLARE r record;
BEGIN
    FOR r IN SELECT table_schema, table_name FROM information_schema.tables
            WHERE table_type = 'VIEW' AND table_schema = 'public'
    LOOP
        EXECUTE 'GRANT ALL ON ' || quote_ident(r.table_schema) || '.' || quote_ident
(r.table_name) || ' TO webuser';
    END LOOP;
END$$;
```

This PL/pgSQL example determines if a Greenplum Database user is a superuser. In the example, the anonymous block retrieves the input value from a temporary table.

```
CREATE TEMP TABLE list AS VALUES ('gpadmin') DISTRIBUTED RANDOMLY;

DO $$
DECLARE
    name TEXT := 'gpadmin' ;
    superuser TEXT := '' ;
    t1_row pg_authid%ROWTYPE;
BEGIN
    SELECT * INTO t1_row FROM pg_authid, list
        WHERE pg_authid.rolname = name ;
    IF t1_row.rolsuper = 'f' THEN
        superuser := 'not ' ;
    END IF ;
    RAISE NOTICE 'user % is %a superuser', t1_row.rolname, superuser ;
END $$ LANGUAGE plpgsql ;
```

**Note:** The example PL/pgSQL uses `SELECT` with the `INTO` clause. It is different from the SQL command `SELECT INTO`.

## Compatibility

There is no `DO` statement in the SQL standard.

## See Also

[CREATE LANGUAGE](#)

Parent topic: [SQL Commands](#)

## DROP AGGREGATE

Removes an aggregate function.

## Synopsis

```
DROP AGGREGATE [IF EXISTS] <name> ( <aggregate_signature> ) [CASCADE | RESTRICT]
```

where `aggregate_signature` is:

```
* |
[ <argmode> ] [ <argname> ] <argtype> [ , ... ] |
[ [ <argmode> ] [ <argname> ] <argtype> [ , ... ] ] ORDER BY [ <argmode> ] [ <argname> ]
] <argtype> [ , ... ]
```

## Description

`DROP AGGREGATE` will delete an existing aggregate function. To run this command the current user must be the owner of the aggregate function.

## Parameters

### IF EXISTS

Do not throw an error if the aggregate does not exist. A notice is issued in this case.

### name

The name (optionally schema-qualified) of an existing aggregate function.

### argmode

The mode of an argument: `IN` or `VARIADIC`. If omitted, the default is `IN`.

### argname

The name of an argument. Note that `DROP AGGREGATE` does not actually pay any attention to argument names, since only the argument data types are needed to determine the aggregate function's identity.

### argtype

An input data type on which the aggregate function operates. To reference a zero-argument aggregate function, write `*` in place of the list of input data types. To reference an ordered-set aggregate function, write `ORDER BY` between the direct and aggregated argument specifications.

### CASCADE

Automatically drop objects that depend on the aggregate function.

**RESTRICT**

Refuse to drop the aggregate function if any objects depend on it. This is the default.

## Notes

Alternative syntaxes for referencing ordered-set aggregates are described under [ALTER AGGREGATE](#).

## Examples

To remove the aggregate function `myavg` for type `integer`:

```
DROP AGGREGATE myavg(integer);
```

To remove the hypothetical-set aggregate function `myrank`, which takes an arbitrary list of ordering columns and a matching list of direct arguments:

```
DROP AGGREGATE myrank(VARIADIC "any" ORDER BY VARIADIC "any");
```

## Compatibility

There is no `DROP AGGREGATE` statement in the SQL standard.

## See Also

[ALTER AGGREGATE](#), [CREATE AGGREGATE](#)

Parent topic: [SQL Commands](#)

## DROP CAST

Removes a cast.

## Synopsis

```
DROP CAST [IF EXISTS] (<sourcetype> AS <targettype>) [CASCADE | RESTRICT]
```

## Description

`DROP CAST` will delete a previously defined cast. To be able to drop a cast, you must own the source or the target data type. These are the same privileges that are required to create a cast.

## Parameters

**IF EXISTS**

Do not throw an error if the cast does not exist. A notice is issued in this case.

`sourcetype`

The name of the source data type of the cast.

targettype

The name of the target data type of the cast.

CASCADE

RESTRICT

These keywords have no effect since there are no dependencies on casts.

## Examples

To drop the cast from type `text` to type `int`:

```
DROP CAST (text AS int);
```

## Compatibility

There `DROP CAST` command conforms to the SQL standard.

## See Also

[CREATE CAST](#)

Parent topic: [SQL Commands](#)

## DROP COLLATION

Removes a previously defined collation.

## Synopsis

```
DROP COLLATION [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

## Parameters

`IF EXISTS`

Do not throw an error if the collation does not exist. A notice is issued in this case.

name

The name of the collation. The collation name can be schema-qualified.

`CASCADE`

Automatically drop objects that depend on the collation.

`RESTRICT`

Refuse to drop the collation if any objects depend on it. This is the default.

## Notes

`DROP COLLATION` removes a previously defined collation. To be able to drop a collation, you must own the collation.

## Examples

To drop the collation named `german`:

```
DROP COLLATION german;
```

## Compatibility

The `DROP COLLATION` command conforms to the SQL standard, apart from the `IF EXISTS` option, which is a Greenplum Database extension.

## See Also

[ALTER COLLATION](#), [CREATE COLLATION](#)

Parent topic: [SQL Commands](#)

## DROP CONVERSION

Removes a conversion.

## Synopsis

```
DROP CONVERSION [IF EXISTS] <name> [CASCADE | RESTRICT]
```

## Description

`DROP CONVERSION` removes a previously defined conversion. To be able to drop a conversion, you must own the conversion.

## Parameters

`IF EXISTS`

Do not throw an error if the conversion does not exist. A notice is issued in this case.

`name`

The name of the conversion. The conversion name may be schema-qualified.

`CASCADE`

`RESTRICT`

These keywords have no effect since there are no dependencies on conversions.

## Examples

Drop the conversion named `myname`:

```
DROP CONVERSION myname;
```

## Compatibility

There is no `DROP CONVERSION` statement in the SQL standard. The standard has `CREATE TRANSLATION` and `DROP TRANSLATION` statements that are similar to the Greenplum Database `CREATE CONVERSION` and `DROP CONVERSION` statements.

## See Also

[ALTER CONVERSION](#), [CREATE CONVERSION](#)

Parent topic: [SQL Commands](#)

## DROP DATABASE

Removes a database.

## Synopsis

```
DROP DATABASE [IF EXISTS] <name>
```

## Description

`DROP DATABASE` drops a database. It removes the catalog entries for the database and deletes the directory containing the data. It can only be run by the database owner. Also, it cannot be run while you or anyone else are connected to the target database. (Connect to `postgres` or any other database to issue this command.)

**Warning:** `DROP DATABASE` cannot be undone. Use it with care!

## Parameters

`IF EXISTS`

Do not throw an error if the database does not exist. A notice is issued in this case.

`name`

The name of the database to remove.

## Notes

`DROP DATABASE` cannot be run inside a transaction block.

This command cannot be run while connected to the target database. Thus, it might be more convenient to use the program `dropdb` instead, which is a wrapper around this command.

## Examples

Drop the database named `testdb`:

```
DROP DATABASE testdb;
```

## Compatibility

There is no `DROP DATABASE` statement in the SQL standard.

## See Also

[ALTER DATABASE](#), [CREATE DATABASE](#)

Parent topic: [SQL Commands](#)

## DROP DOMAIN

Removes a domain.

## Synopsis

```
DROP DOMAIN [IF EXISTS] <name> [, ...] [CASCADE | RESTRICT]
```

## Description

`DROP DOMAIN` removes a previously defined domain. You must be the owner of a domain to drop it.

## Parameters

`IF EXISTS`

Do not throw an error if the domain does not exist. A notice is issued in this case.

`name`

The name (optionally schema-qualified) of an existing domain.

`CASCADE`

Automatically drop objects that depend on the domain (such as table columns).

`RESTRICT`

Refuse to drop the domain if any objects depend on it. This is the default.

## Examples

Drop the domain named `zipcode`:

```
DROP DOMAIN zipcode;
```

## Compatibility

This command conforms to the SQL standard, except for the `IF EXISTS` option, which is a Greenplum Database extension.

## See Also

[ALTER DOMAIN](#), [CREATE DOMAIN](#)

Parent topic: [SQL Commands](#)

## DROP EXTENSION

Removes an extension from a Greenplum database.

### Synopsis

```
DROP EXTENSION [ IF EXISTS ] <name> [, ...] [ CASCADE | RESTRICT ]
```

### Description

`DROP EXTENSION` removes extensions from the database. Dropping an extension causes its component objects to be dropped as well.

**Note:** The required supporting extension files what were installed to create the extension are not deleted. The files must be manually removed from the Greenplum Database hosts.

You must own the extension to use `DROP EXTENSION`.

This command fails if any of the extension objects are in use in the database. For example, if a table is defined with columns of the extension type. Add the `CASCADE` option to forcibly remove those dependent objects.

**Important:** Before issuing a `DROP EXTENSION` with the `CASCADE` keyword, you should be aware of all object that depend on the extension to avoid unintended consequences.

### Parameters

#### IF EXISTS

Do not throw an error if the extension does not exist. A notice is issued.

#### name

The name of an installed extension.

#### CASCADE

Automatically drop objects that depend on the extension, and in turn all objects that depend on those objects. See the PostgreSQL information about [Dependency Tracking](#).

#### RESTRICT

Refuse to drop an extension if any objects depend on it, other than the extension member objects. This is the default.

### Compatibility

`DROP EXTENSION` is a Greenplum Database extension.

### See Also

[CREATE EXTENSION](#), [ALTER EXTENSION](#)

Parent topic: [SQL Commands](#)

# DROP EXTERNAL TABLE

Removes an external table definition.

## Synopsis

```
DROP EXTERNAL [WEB] TABLE [IF EXISTS] <name> [CASCADE | RESTRICT]
```

## Description

`DROP EXTERNAL TABLE` drops an existing external table definition from the database system. The external data sources or files are not deleted. To run this command you must be the owner of the external table.

## Parameters

WEB

Optional keyword for dropping external web tables.

IF EXISTS

Do not throw an error if the external table does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of an existing external table.

CASCADE

Automatically drop objects that depend on the external table (such as views).

RESTRICT

Refuse to drop the external table if any objects depend on it. This is the default.

## Examples

Remove the external table named `staging` if it exists:

```
DROP EXTERNAL TABLE IF EXISTS staging;
```

## Compatibility

There is no `DROP EXTERNAL TABLE` statement in the SQL standard.

## See Also

[CREATE EXTERNAL TABLE](#), [ALTER EXTERNAL TABLE](#)

Parent topic: [SQL Commands](#)

## DROP FOREIGN DATA WRAPPER

Removes a foreign-data wrapper.

## Synopsis

```
DROP FOREIGN DATA WRAPPER [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

## Description

`DROP FOREIGN DATA WRAPPER` removes an existing foreign-data wrapper from the current database. A foreign-data wrapper may be removed only by its owner.

## Parameters

### IF EXISTS

Do not throw an error if the foreign-data wrapper does not exist. Greenplum Database issues a notice in this case.

### name

The name of an existing foreign-data wrapper.

### CASCADE

Automatically drop objects that depend on the foreign-data wrapper (such as servers).

### RESTRICT

Refuse to drop the foreign-data wrapper if any object depends on it. This is the default.

## Examples

Drop the foreign-data wrapper named `dbi`:

```
DROP FOREIGN DATA WRAPPER dbi;
```

## Compatibility

`DROP FOREIGN DATA WRAPPER` conforms to ISO/IEC 9075-9 (SQL/MED). The `IF EXISTS` clause is a Greenplum Database extension.

## See Also

[CREATE FOREIGN DATA WRAPPER](#), [ALTER FOREIGN DATA WRAPPER](#)

Parent topic: [SQL Commands](#)

## DROP FOREIGN TABLE

Removes a foreign table.

## Synopsis

```
DROP FOREIGN TABLE [ IF EXISTS ] <name> [, ...] [ CASCADE | RESTRICT ]
```

## Description

`DROP FOREIGN TABLE` removes an existing foreign table. Only the owner of a foreign table can remove it.

## Parameters

### IF EXISTS

Do not throw an error if the foreign table does not exist. Greenplum Database issues a notice in this case.

### name

The name (optionally schema-qualified) of the foreign table to drop.

### CASCADE

Automatically drop objects that depend on the foreign table (such as views).

### RESTRICT

Refuse to drop the foreign table if any objects depend on it. This is the default.

## Examples

Drop the foreign tables named `films` and `distributors`:

```
DROP FOREIGN TABLE films, distributors;
```

## Compatibility

`DROP FOREIGN TABLE` conforms to ISO/IEC 9075-9 (SQL/MED), except that the standard only allows one foreign table to be dropped per command. The `IF EXISTS` clause is a Greenplum Database extension.

## See Also

[ALTER FOREIGN TABLE](#), [CREATE FOREIGN TABLE](#)

Parent topic: [SQL Commands](#)

## DROP FUNCTION

Removes a function.

## Synopsis

```
DROP FUNCTION [IF EXISTS] name ( [ [argmode] [argname] argtype
    [, ...] ] ) [CASCADE | RESTRICT]
```

## Description

`DROP FUNCTION` removes the definition of an existing function. To run this command the user must be the owner of the function. The argument types to the function must be specified, since several different functions may exist with the same name and different argument lists.

## Parameters

### IF EXISTS

Do not throw an error if the function does not exist. A notice is issued in this case.

### name

The name (optionally schema-qualified) of an existing function.

### argmode

The mode of an argument: either `IN`, `OUT`, `INOUT`, or `VARIADIC`. If omitted, the default is `IN`.

Note that `DROP FUNCTION` does not actually pay any attention to `OUT` arguments, since only the input arguments are needed to determine the function's identity. So it is sufficient to list the `IN`, `INOUT`, and `VARIADIC` arguments.

### argname

The name of an argument. Note that `DROP FUNCTION` does not actually pay any attention to argument names, since only the argument data types are needed to determine the function's identity.

### argtype

The data type(s) of the function's arguments (optionally schema-qualified), if any.

### CASCADE

Automatically drop objects that depend on the function such as operators.

### RESTRICT

Refuse to drop the function if any objects depend on it. This is the default.

## Examples

Drop the square root function:

```
DROP FUNCTION sqrt(integer);
```

## Compatibility

A `DROP FUNCTION` statement is defined in the SQL standard, but it is not compatible with this command.

## See Also

[CREATE FUNCTION](#), [ALTER FUNCTION](#)

Parent topic: [SQL Commands](#)

## DROP GROUP

Removes a database role.

## Synopsis

```
DROP GROUP [IF EXISTS] <name> [, ...]
```

## Description

`DROP GROUP` is an alias for `DROP ROLE`. See [DROP ROLE](#) for more information.

## Compatibility

There is no `DROP GROUP` statement in the SQL standard.

## See Also

[DROP ROLE](#)

Parent topic: [SQL Commands](#)

## DROP INDEX

Removes an index.

## Synopsis

```
DROP INDEX [ CONCURRENTLY ] [ IF EXISTS ] <name> [, ...] [ CASCADE | RESTRICT ]
```

## Description

`DROP INDEX` drops an existing index from the database system. To run this command you must be the owner of the index.

## Parameters

### CONCURRENTLY

Drop the index without locking out concurrent selects, inserts, updates, and deletes on the index's table. A normal `DROP INDEX` acquires an exclusive lock on the table, blocking other accesses until the index drop can be completed. With this option, the command instead waits until conflicting transactions have completed.

There are several caveats to be aware of when using this option. Only one index name can be specified, and the `CASCADE` option is not supported. (Thus, an index that supports a `UNIQUE` or `PRIMARY KEY` constraint cannot be dropped this way.) Also, regular `DROP INDEX` commands can be performed within a transaction block, but `DROP INDEX CONCURRENTLY` cannot.

### IF EXISTS

Do not throw an error if the index does not exist. A notice is issued in this case.

### name

The name (optionally schema-qualified) of an existing index.

**CASCADE**

Automatically drop objects that depend on the index.

**RESTRICT**

Refuse to drop the index if any objects depend on it. This is the default.

## Examples

Remove the index `title_idx`:

```
DROP INDEX title_idx;
```

## Compatibility

`DROP INDEX` is a Greenplum Database language extension. There are no provisions for indexes in the SQL standard.

## See Also

[ALTER INDEX](#), [CREATE INDEX](#), [REINDEX](#)

Parent topic: [SQL Commands](#)

## DROP LANGUAGE

Removes a procedural language.

## Synopsis

```
DROP [PROCEDURAL] LANGUAGE [IF EXISTS] <name> [CASCADE | RESTRICT]
```

## Description

`DROP LANGUAGE` will remove the definition of the previously registered procedural language. You must be a superuser or owner of the language to drop a language.

## Parameters

**PROCEDURAL**

Optional keyword - has no effect.

**IF EXISTS**

Do not throw an error if the language does not exist. A notice is issued in this case.

**name**

The name of an existing procedural language. For backward compatibility, the name may be enclosed by single quotes.

**CASCADE**

Automatically drop objects that depend on the language (such as functions written in that language).

**RESTRICT**

Refuse to drop the language if any objects depend on it. This is the default.

## Examples

Remove the procedural language `plsample`:

```
DROP LANGUAGE plsample;
```

## Compatibility

There is no `DROP LANGUAGE` statement in the SQL standard.

## See Also

[ALTER LANGUAGE](#), [CREATE LANGUAGE](#)

Parent topic: [SQL Commands](#)

## DROP MATERIALIZED VIEW

Removes a materialized view.

## Synopsis

```
DROP MATERIALIZED VIEW [ IF EXISTS ] <name> [, ...] [ CASCADE | RESTRICT ]
```

## Description

`DROP MATERIALIZED VIEW` drops an existing materialized view. To run this command, you must be the owner of the materialized view.

## Parameters

**IF EXISTS**

Do not throw an error if the materialized view does not exist. A notice is issued in this case.

**name**

The name (optionally schema-qualified) of a materialized view to be dropped.

**CASCADE**

Automatically drop objects that depend on the materialized view (such as other materialized views, or regular views).

**RESTRICT**

Refuse to drop the materialized view if any objects depend on it. This is the default.

## Examples

This command removes the materialized view called `order_summary`.

```
DROP MATERIALIZED VIEW order_summary;
```

## Compatibility

`DROP MATERIALIZED VIEW` is a Greenplum Database extension of the SQL standard.

## See Also

[ALTER MATERIALIZED VIEW](#), [CREATE MATERIALIZED VIEW](#), [REFRESH MATERIALIZED VIEW](#)

Parent topic: [SQL Commands](#)

## DROP OPERATOR

Removes an operator.

## Synopsis

```
DROP OPERATOR [IF EXISTS] <name> ( {<lefttype> | NONE} ,
    {<righttype> | NONE} ) [CASCADE | RESTRICT]
```

## Description

`DROP OPERATOR` drops an existing operator from the database system. To run this command you must be the owner of the operator.

## Parameters

### IF EXISTS

Do not throw an error if the operator does not exist. A notice is issued in this case.

### name

The name (optionally schema-qualified) of an existing operator.

### lefttype

The data type of the operator's left operand; write `NONE` if the operator has no left operand.

### righttype

The data type of the operator's right operand; write `NONE` if the operator has no right operand.

### CASCADE

Automatically drop objects that depend on the operator.

### RESTRICT

Refuse to drop the operator if any objects depend on it. This is the default.

## Examples

Remove the power operator `a^b` for type `integer`:

```
DROP OPERATOR ^ (integer, integer);
```

Remove the left unary bitwise complement operator `~b` for type `bit`:

```
DROP OPERATOR ~ (none, bit);
```

Remove the right unary factorial operator `x!` for type `bigint`:

```
DROP OPERATOR ! (bigint, none);
```

## Compatibility

There is no `DROP OPERATOR` statement in the SQL standard.

## See Also

[ALTER OPERATOR](#), [CREATE OPERATOR](#)

Parent topic: [SQL Commands](#)

## DROP OPERATOR CLASS

Removes an operator class.

## Synopsis

```
DROP OPERATOR CLASS [IF EXISTS] <name> USING <index_method> [CASCADE | RESTRICT]
```

## Description

`DROP OPERATOR` drops an existing operator class. To run this command you must be the owner of the operator class.

## Parameters

`IF EXISTS`

Do not throw an error if the operator class does not exist. A notice is issued in this case.

`name`

The name (optionally schema-qualified) of an existing operator class.

`index_method`

The name of the index access method the operator class is for.

`CASCADE`

Automatically drop objects that depend on the operator class.

`RESTRICT`

Refuse to drop the operator class if any objects depend on it. This is the default.

## Examples

Remove the B-tree operator class `widget_ops`:

```
DROP OPERATOR CLASS widget_ops USING btree;
```

This command will not succeed if there are any existing indexes that use the operator class. Add `CASCADE` to drop such indexes along with the operator class.

## Compatibility

There is no `DROP OPERATOR CLASS` statement in the SQL standard.

## See Also

[ALTER OPERATOR CLASS, CREATE OPERATOR CLASS](#)

Parent topic: [SQL Commands](#)

## DROP OPERATOR FAMILY

Removes an operator family.

## Synopsis

```
DROP OPERATOR FAMILY [IF EXISTS] <name> USING <index_method> [CASCADE | RESTRICT]
```

## Description

`DROP OPERATOR FAMILY` drops an existing operator family. To run this command you must be the owner of the operator family.

`DROP OPERATOR FAMILY` includes dropping any operator classes contained in the family, but it does not drop any of the operators or functions referenced by the family. If there are any indexes depending on operator classes within the family, you will need to specify `CASCADE` for the drop to complete.

## Parameters

### IF EXISTS

Do not throw an error if the operator family does not exist. A notice is issued in this case.

### name

The name (optionally schema-qualified) of an existing operator family.

### index\_method

The name of the index access method the operator family is for.

### CASCADE

Automatically drop objects that depend on the operator family.

### RESTRICT

Refuse to drop the operator family if any objects depend on it. This is the default.

## Examples

Remove the B-tree operator family `float_ops`:

```
DROP OPERATOR FAMILY float_ops USING btree;
```

This command will not succeed if there are any existing indexes that use the operator family. Add `CASCADE` to drop such indexes along with the operator family.

## Compatibility

There is no `DROP OPERATOR FAMILY` statement in the SQL standard.

## See Also

[ALTER OPERATOR FAMILY](#), [CREATE OPERATOR FAMILY](#), [ALTER OPERATOR CLASS](#), [CREATE OPERATOR CLASS](#), [DROP OPERATOR CLASS](#)

Parent topic: [SQL Commands](#)

## DROP OWNED

Removes database objects owned by a database role.

## Synopsis

```
DROP OWNED BY <name> [, ...] [CASCADE | RESTRICT]
```

## Description

`DROP OWNED` drops all the objects in the current database that are owned by one of the specified roles. Any privileges granted to the given roles on objects in the current database or on shared objects (databases, tablespaces) will also be revoked.

## Parameters

`name`

The name of a role whose objects will be dropped, and whose privileges will be revoked.

`CASCADE`

Automatically drop objects that depend on the affected objects.

`RESTRICT`

Refuse to drop the objects owned by a role if any other database objects depend on one of the affected objects. This is the default.

## Notes

`DROP OWNED` is often used to prepare for the removal of one or more roles. Because `DROP OWNED` only affects the objects in the current database, it is usually necessary to run this command in each

database that contains objects owned by a role that is to be removed.

Using the `CASCADE` option may make the command recurse to objects owned by other users.

The `REASSIGN OWNED` command is an alternative that reassigns the ownership of all the database objects owned by one or more roles. However, `REASSIGN OWNED` does not deal with privileges for other objects.

## Examples

Remove any database objects owned by the role named `sally`:

```
DROP OWNED BY sally;
```

## Compatibility

The `DROP OWNED` command is a Greenplum Database extension.

## See Also

[REASSIGN OWNED](#), [DROP ROLE](#)

Parent topic: [SQL Commands](#)

## DROP PROTOCOL

Removes an external table data access protocol from a database.

## Synopsis

```
DROP PROTOCOL [IF EXISTS] <name>
```

## Description

`DROP PROTOCOL` removes the specified protocol from a database. A protocol name can be specified in the `CREATE EXTERNAL TABLE` command to read data from or write data to an external data source.

You must be a superuser or the protocol owner to drop a protocol.

**Warning:** If you drop a data access protocol, external tables that have been defined with the protocol will no longer be able to access the external data source.

## Parameters

`IF EXISTS`

Do not throw an error if the protocol does not exist. A notice is issued in this case.

`name`

The name of an existing data access protocol.

## Notes

If you drop a data access protocol, the call handlers that defined in the database that are associated with the protocol are not dropped. You must drop the functions manually.

Shared libraries that were used by the protocol should also be removed from the Greenplum Database hosts.

## Compatibility

`DROP PROTOCOL` is a Greenplum Database extension.

## See Also

[CREATE EXTERNAL TABLE](#), [CREATE PROTOCOL](#)

Parent topic: [SQL Commands](#)

## DROP RESOURCE GROUP

Removes a resource group.

## Synopsis

```
DROP RESOURCE GROUP <group_name>
```

## Description

This command removes a resource group from Greenplum Database. Only a superuser can drop a resource group. When you drop a resource group, the memory and CPU resources reserved by the group are returned to Greenplum Database.

To drop a role resource group, the group cannot be assigned to any roles, nor can it have any statements pending or running in the group. If you drop a resource group that you created for an external component, the behavior is determined by the external component. For example, dropping a resource group that you assigned to a PL/Container runtime stops running containers in the group.

You cannot drop the pre-defined `admin_group` and `default_group` resource groups.

## Parameters

`group_name`

The name of the resource group to remove.

## Notes

You cannot submit a `DROP RESOURCE GROUP` command in an explicit transaction or sub-transaction.

Use [ALTER ROLE](#) to remove a resource group assigned to a specific user/role.

Perform the following query to view all of the currently active queries for all resource groups:

```
SELECT username, query, waiting, pid,
       rsgid, rsgname, rsgqueueduration
FROM pg_stat_activity;
```

To view the resource group assignments, perform the following query on the `pg_roles` and `pg_resgroup` system catalog tables:

```
SELECT rolname, rsgname
FROM pg_roles, pg_resgroup
WHERE pg_roles.rolresgroup=pg_resgroup.oid;
```

## Examples

Remove the resource group assigned to a role. This operation then assigns the default resource group `default_group` to the role:

```
ALTER ROLE bob RESOURCE GROUP NONE;
```

Remove the resource group named `adhoc`:

```
DROP RESOURCE GROUP adhoc;
```

## Compatibility

The `DROP RESOURCE GROUP` statement is a Greenplum Database extension.

## See Also

[ALTER RESOURCE GROUP](#), [CREATE RESOURCE GROUP](#), [ALTER ROLE](#)

Parent topic: [SQL Commands](#)

## DROP RESOURCE QUEUE

Removes a resource queue.

## Synopsis

```
DROP RESOURCE QUEUE <queue_name>
```

## Description

This command removes a resource queue from Greenplum Database. To drop a resource queue, the queue cannot have any roles assigned to it, nor can it have any statements waiting in the queue. Only a superuser can drop a resource queue.

## Parameters

`queue_name`

The name of a resource queue to remove.

## Notes

Use [ALTER ROLE](#) to remove a user from a resource queue.

To see all the currently active queries for all resource queues, perform the following query of the `pg_locks` table joined with the `pg_roles` and `pg_resqueue` tables:

```
SELECT rolname, rsqname, locktype, objid, pid,
mode, granted FROM pg_roles, pg_resqueue, pg_locks WHERE
pg_roles.rolresqueue=pg_locks.objid AND
pg_locks.objid=pg_resqueue.oid;
```

To see the roles assigned to a resource queue, perform the following query of the `pg_roles` and `pg_resqueue` system catalog tables:

```
SELECT rolname, rsqname FROM pg_roles, pg_resqueue WHERE
pg_roles.rolresqueue=pg_resqueue.oid;
```

## Examples

Remove a role from a resource queue (and move the role to the default resource queue, `pg_default`):

```
ALTER ROLE bob RESOURCE QUEUE NONE;
```

Remove the resource queue named `adhoc`:

```
DROP RESOURCE QUEUE adhoc;
```

## Compatibility

The `DROP RESOURCE QUEUE` statement is a Greenplum Database extension.

## See Also

[ALTER RESOURCE QUEUE](#), [CREATE RESOURCE QUEUE](#), [ALTER ROLE](#)

Parent topic: [SQL Commands](#)

## DROP ROLE

Removes a database role.

## Synopsis

```
DROP ROLE [IF EXISTS] <name> [, ...]
```

## Description

`DROP ROLE` removes the specified role(s). To drop a superuser role, you must be a superuser yourself. To drop non-superuser roles, you must have `CREATEROLE` privilege.

A role cannot be removed if it is still referenced in any database; an error will be raised if so. Before dropping the role, you must drop all the objects it owns (or reassign their ownership) and revoke any privileges the role has been granted on other objects. The `REASSIGN OWNED` and `DROP OWNED` commands can be useful for this purpose.

However, it is not necessary to remove role memberships involving the role; `DROP ROLE` automatically revokes any memberships of the target role in other roles, and of other roles in the target role. The other roles are not dropped nor otherwise affected.

## Parameters

`IF EXISTS`

Do not throw an error if the role does not exist. A notice is issued in this case.

`name`

The name of the role to remove.

## Examples

Remove the roles named `sally` and `bob`:

```
DROP ROLE sally, bob;
```

## Compatibility

The SQL standard defines `DROP ROLE`, but it allows only one role to be dropped at a time, and it specifies different privilege requirements than Greenplum Database uses.

## See Also

[REASSIGN OWNED](#), [DROP OWNED](#), [CREATE ROLE](#), [ALTER ROLE](#), [SET ROLE](#)

Parent topic: [SQL Commands](#)

## DROP RULE

Removes a rewrite rule.

## Synopsis

```
DROP RULE [IF EXISTS] <name> ON <table_name> [CASCADE | RESTRICT]
```

## Description

`DROP RULE` drops a rewrite rule from a table or view.

## Parameters

### IF EXISTS

Do not throw an error if the rule does not exist. A notice is issued in this case.

### name

The name of the rule to remove.

### table\_name

The name (optionally schema-qualified) of the table or view that the rule applies to.

### CASCADE

Automatically drop objects that depend on the rule.

### RESTRICT

Refuse to drop the rule if any objects depend on it. This is the default.

## Examples

Remove the rewrite rule `sales_2006` on the table `sales`:

```
DROP RULE sales_2006 ON sales;
```

## Compatibility

`DROP RULE` is a Greenplum Database language extension, as is the entire query rewrite system.

## See Also

[ALTER RULE](#), [CREATE RULE](#)

Parent topic: [SQL Commands](#)

## DROP SCHEMA

Removes a schema.

## Synopsis

```
DROP SCHEMA [IF EXISTS] <name> [, ...] [CASCADE | RESTRICT]
```

## Description

`DROP SCHEMA` removes schemas from the database. A schema can only be dropped by its owner or a superuser. Note that the owner can drop the schema (and thereby all contained objects) even if they do not own some of the objects within the schema.

## Parameters

### IF EXISTS

Do not throw an error if the schema does not exist. A notice is issued in this case.

### name

The name of the schema to remove.

### CASCADE

Automatically drops any objects contained in the schema (tables, functions, etc.).

### RESTRICT

Refuse to drop the schema if it contains any objects. This is the default.

## Examples

Remove the schema `mystuff` from the database, along with everything it contains:

```
DROP SCHEMA mystuff CASCADE;
```

## Compatibility

`DROP SCHEMA` is fully conforming with the SQL standard, except that the standard only allows one schema to be dropped per command. Also, the `IF EXISTS` option is a Greenplum Database extension.

## See Also

[CREATE SCHEMA](#), [ALTER SCHEMA](#)

Parent topic: [SQL Commands](#)

## DROP SEQUENCE

Removes a sequence.

## Synopsis

```
DROP SEQUENCE [IF EXISTS] <name> [, ...] [CASCADE | RESTRICT]
```

## Description

`DROP SEQUENCE` removes a sequence generator table. You must own the sequence to drop it (or be a superuser).

## Parameters

### IF EXISTS

Do not throw an error if the sequence does not exist. A notice is issued in this case.

### name

The name (optionally schema-qualified) of the sequence to remove.

CASCADE

Automatically drop objects that depend on the sequence.

RESTRICT

Refuse to drop the sequence if any objects depend on it. This is the default.

## Examples

Remove the sequence `myserial`:

```
DROP SEQUENCE myserial;
```

## Compatibility

`DROP SEQUENCE` is fully conforming with the SQL standard, except that the standard only allows one sequence to be dropped per command. Also, the `IF EXISTS` option is a Greenplum Database extension.

## See Also

[ALTER SEQUENCE](#), [CREATE SEQUENCE](#)

Parent topic: [SQL Commands](#)

## DROP SERVER

Removes a foreign server descriptor.

## Synopsis

```
DROP SERVER [ IF EXISTS ] <servername> [ CASCADE | RESTRICT ]
```

## Description

`DROP SERVER` removes an existing foreign server descriptor. The user running this command must be the owner of the server.

## Parameters

IF EXISTS

Do not throw an error if the server does not exist. Greenplum Database issues a notice in this case.

servername

The name of an existing server.

CASCADE

Automatically drop objects that depend on the server (such as user mappings).

RESTRICT

Refuse to drop the server if any object depends on it. This is the default.

## Examples

Drop the server named `foo` if it exists:

```
DROP SERVER IF EXISTS foo;
```

## Compatibility

`DROP SERVER` conforms to ISO/IEC 9075-9 (SQL/MED). The `IF EXISTS` clause is a Greenplum Database extension.

## See Also

[CREATE SERVER](#), [ALTER SERVER](#)

Parent topic: [SQL Commands](#)

## DROP TABLE

Removes a table.

## Synopsis

```
DROP TABLE [IF EXISTS] <name> [, ...] [CASCADE | RESTRICT]
```

## Description

`DROP TABLE` removes tables from the database. Only the table owner, the schema owner, and superuser can drop a table. To empty a table of rows without removing the table definition, use `DELETE` or `TRUNCATE`.

`DROP TABLE` always removes any indexes, rules, triggers, and constraints that exist for the target table. However, to drop a table that is referenced by a view, `CASCADE` must be specified. `CASCADE` will remove a dependent view entirely.

## Parameters

### IF EXISTS

Do not throw an error if the table does not exist. A notice is issued in this case.

### name

The name (optionally schema-qualified) of the table to remove.

### CASCADE

Automatically drop objects that depend on the table (such as views).

### RESTRICT

Refuse to drop the table if any objects depend on it. This is the default.

## Examples

Remove the table `mytable`:

```
DROP TABLE mytable;
```

## Compatibility

`DROP TABLE` is fully conforming with the SQL standard, except that the standard only allows one table to be dropped per command. Also, the `IF EXISTS` option is a Greenplum Database extension.

## See Also

[CREATE TABLE](#), [ALTER TABLE](#), [TRUNCATE](#)

Parent topic: [SQL Commands](#)

## DROP TABLESPACE

Removes a tablespace.

## Synopsis

```
DROP TABLESPACE [IF EXISTS] <tablespacename>
```

## Description

`DROP TABLESPACE` removes a tablespace from the system.

A tablespace can only be dropped by its owner or a superuser. The tablespace must be empty of all database objects before it can be dropped. It is possible that objects in other databases may still reside in the tablespace even if no objects in the current database are using the tablespace. Also, if the tablespace is listed in the `temp_tablespaces` setting of any active session, `DROP TABLESPACE` might fail due to temporary files residing in the tablespace.

## Parameters

`IF EXISTS`

Do not throw an error if the tablespace does not exist. A notice is issued in this case.

`tablespacename`

The name of the tablespace to remove.

## Notes

Run `DROP TABLESPACE` during a period of low activity to avoid issues due to concurrent creation of tables and temporary objects. When a tablespace is dropped, there is a small window in which a table could be created in the tablespace that is currently being dropped. If this occurs, Greenplum Database returns a warning. This is an example of the `DROP TABLESPACE` warning.

```
testdb=# DROP TABLESPACE mytest;
WARNING: tablespace with oid "16415" is not empty (seg1 192.168.8.145:25433 pid=2902
3)
WARNING: tablespace with oid "16415" is not empty (seg0 192.168.8.145:25432 pid=2902
2)
WARNING: tablespace with oid "16415" is not empty
DROP TABLESPACE
```

The table data in the tablespace directory is not dropped. You can use the [ALTER TABLE](#) command to change the tablespace defined for the table and move the data to an existing tablespace.

## Examples

Remove the tablespace `mystuff`:

```
DROP TABLESPACE mystuff;
```

## Compatibility

`DROP TABLESPACE` is a Greenplum Database extension.

## See Also

[CREATE TABLESPACE](#), [ALTER TABLESPACE](#)

Parent topic: [SQL Commands](#)

## DROP TEXT SEARCH CONFIGURATION

Removes a text search configuration.

## Synopsis

```
DROP TEXT SEARCH CONFIGURATION [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

## Description

`DROP TEXT SEARCH CONFIGURATION` drops an existing text search configuration. To run this command you must be the owner of the configuration.

## Parameters

### `IF EXISTS`

Do not throw an error if the text search configuration does not exist. A notice is issued in this case.

### `name`

The name (optionally schema-qualified) of an existing text search configuration.

**CASCADE**

Automatically drop objects that depend on the text search configuration.

**RESTRICT**

Refuse to drop the text search configuration if any objects depend on it. This is the default.

## Examples

Remove the text search configuration `my_english`:

```
DROP TEXT SEARCH CONFIGURATION my_english;
```

This command will not succeed if there are any existing indexes that reference the configuration in `to_tsvector` calls. Add **CASCADE** to drop such indexes along with the text search configuration.

## Compatibility

There is no **DROP TEXT SEARCH CONFIGURATION** statement in the SQL standard.

## See Also

[ALTER TEXT SEARCH CONFIGURATION](#), [CREATE TEXT SEARCH CONFIGURATION](#)

Parent topic: [SQL Commands](#)

## DROP TEXT SEARCH DICTIONARY

Removes a text search dictionary.

## Synopsis

```
DROP TEXT SEARCH DICTIONARY [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

## Description

**DROP TEXT SEARCH DICTIONARY** drops an existing text search dictionary. To run this command you must be the owner of the dictionary.

## Parameters

**IF EXISTS**

Do not throw an error if the text search dictionary does not exist. A notice is issued in this case.

**name**

The name (optionally schema-qualified) of an existing text search dictionary.

**CASCADE**

Automatically drop objects that depend on the text search dictionary.

**RESTRICT**

Refuse to drop the text search dictionary if any objects depend on it. This is the default.

## Examples

Remove the text search dictionary `english`:

```
DROP TEXT SEARCH DICTIONARY english;
```

This command will not succeed if there are any existing text search configurations that use the dictionary. Add `CASCADE` to drop such configurations along with the dictionary.

## Compatibility

There is no `CREATE TEXT SEARCH DICTIONARY` statement in the SQL standard.

## See Also

[ALTER TEXT SEARCH DICTIONARY](#), [CREATE TEXT SEARCH DICTIONARY](#)

Parent topic: [SQL Commands](#)

## DROP TEXT SEARCH PARSER

### Description

Remove a text search parser.

### Synopsis

```
DROP TEXT SEARCH PARSER [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

### Description

`DROP TEXT SEARCH PARSER` drops an existing text search parser. You must be a superuser to use this command.

### Parameters

**IF EXISTS**

Do not throw an error if the text search parser does not exist. A notice is issued in this case.

**name**

The name (optionally schema-qualified) of an existing text search parser.

**CASCADE**

Automatically drop objects that depend on the text search parser.

**RESTRICT**

Refuse to drop the text search parser if any objects depend on it. This is the default.

## Examples

Remove the text search parser `my_parser`:

```
DROP TEXT SEARCH PARSER my_parser;
```

This command will not succeed if there are any existing text search configurations that use the parser. Add `CASCADE` to drop such configurations along with the parser.

## Compatibility

There is no `DROP TEXT SEARCH PARSER` statement in the SQL standard.

## See Also

[ALTER TEXT SEARCH PARSER](#), [CREATE TEXT SEARCH PARSER](#)

Parent topic: [SQL Commands](#)

# DROP TEXT SEARCH TEMPLATE

## Description

Removes a text search template.

## Synopsis

```
DROP TEXT SEARCH TEMPLATE [ IF EXISTS ] <name> [ CASCADE | RESTRICT ]
```

## Description

`DROP TEXT SEARCH TEMPLATE` drops an existing text search template. You must be a superuser to use this command.

You must be a superuser to use `ALTER TEXT SEARCH TEMPLATE`.

## Parameters

### `IF EXISTS`

Do not throw an error if the text search template does not exist. A notice is issued in this case.

### `name`

The name (optionally schema-qualified) of an existing text search template.

### `CASCADE`

Automatically drop objects that depend on the text search template.

### `RESTRICT`

Refuse to drop the text search template if any objects depend on it. This is the default.

## Compatibility

There is no `DROP TEXT SEARCH TEMPLATE` statement in the SQL standard.

## See Also

[ALTER TEXT SEARCH TEMPLATE](#), [CREATE TEXT SEARCH TEMPLATE](#)

Parent topic: [SQL Commands](#)

## DROP TYPE

Removes a data type.

## Synopsis

```
DROP TYPE [IF EXISTS] <name> [, ...] [CASCADE | RESTRICT]
```

## Description

`DROP TYPE` will remove a user-defined data type. Only the owner of a type can remove it.

## Parameters

### IF EXISTS

Do not throw an error if the type does not exist. A notice is issued in this case.

### name

The name (optionally schema-qualified) of the data type to remove.

### CASCADE

Automatically drop objects that depend on the type (such as table columns, functions, operators).

### RESTRICT

Refuse to drop the type if any objects depend on it. This is the default.

## Examples

Remove the data type `box`;

```
DROP TYPE box;
```

## Compatibility

This command is similar to the corresponding command in the SQL standard, apart from the `IF EXISTS` option, which is a Greenplum Database extension. But note that much of the `CREATE TYPE` command and the data type extension mechanisms in Greenplum Database differ from the SQL standard.

## See Also

[ALTER TYPE, CREATE TYPE](#)Parent topic: [SQL Commands](#)

## DROP USER

Removes a database role.

### Synopsis

```
DROP USER [IF EXISTS] <name> [, ...]
```

### Description

`DROP USER` is an alias for `DROP ROLE`. See [DROP ROLE](#) for more information.

### Compatibility

There is no `DROP USER` statement in the SQL standard. The SQL standard leaves the definition of users to the implementation.

### See Also

[DROP ROLE, CREATE USER](#)Parent topic: [SQL Commands](#)

## DROP USER MAPPING

Removes a user mapping for a foreign server.

### Synopsis

```
DROP USER MAPPING [ IF EXISTS ] { <username> | USER | CURRENT_USER | PUBLIC }  
SERVER <servername>
```

### Description

`DROP USER MAPPING` removes an existing user mapping from a foreign server. To run this command, the current user must be the owner of the server containing the mapping.

### Parameters

**IF EXISTS**

Do not throw an error if the user mapping does not exist. Greenplum Database issues a notice in this case.

**username**

User name of the mapping. `CURRENT_USER` and `USER` match the name of the current user.

`PUBLIC` is used to match all present and future user names in the system.

servername

Server name of the user mapping.

## Examples

Drop the user mapping named `bob`, server `foo` if it exists:

```
DROP USER MAPPING IF EXISTS FOR bob SERVER foo;
```

## Compatibility

`DROP SERVER` conforms to ISO/IEC 9075-9 (SQL/MED). The `IF EXISTS` clause is a Greenplum Database extension.

## See Also

[CREATE USER MAPPING](#), [ALTER USER MAPPING](#)

Parent topic: [SQL Commands](#)

## DROP VIEW

Removes a view.

## Synopsis

```
DROP VIEW [IF EXISTS] <name> [, ...] [CASCADE | RESTRICT]
```

## Description

`DROP VIEW` will remove an existing view. Only the owner of a view can remove it.

## Parameters

`IF EXISTS`

Do not throw an error if the view does not exist. A notice is issued in this case.

name

The name (optionally schema-qualified) of the view to remove.

`CASCADE`

Automatically drop objects that depend on the view (such as other views).

`RESTRICT`

Refuse to drop the view if any objects depend on it. This is the default.

## Examples

Remove the view `topten`:

```
DROP VIEW topten;
```

## Compatibility

`DROP VIEW` is fully conforming with the SQL standard, except that the standard only allows one view to be dropped per command. Also, the `IF EXISTS` option is a Greenplum Database extension.

## See Also

[CREATE VIEW](#), [ALTER VIEW](#)

Parent topic: [SQL Commands](#)

## END

Commits the current transaction.

## Synopsis

```
END [WORK | TRANSACTION]
```

## Description

`END` commits the current transaction. All changes made by the transaction become visible to others and are guaranteed to be durable if a crash occurs. This command is a Greenplum Database extension that is equivalent to [COMMIT](#).

## Parameters

WORK

TRANSACTION

Optional keywords. They have no effect.

## Examples

Commit the current transaction:

```
END;
```

## Compatibility

`END` is a Greenplum Database extension that provides functionality equivalent to [COMMIT](#), which is specified in the SQL standard.

## See Also

[BEGIN](#), [ROLLBACK](#), [COMMIT](#)

Parent topic: [SQL Commands](#)

## EXECUTE

Runs a prepared SQL statement.

## Synopsis

```
EXECUTE <name> [ (<parameter> [, ...] ) ]
```

## Description

**EXECUTE** is used to run a previously prepared statement. Since prepared statements only exist for the duration of a session, the prepared statement must have been created by a **PREPARE** statement run earlier in the current session.

If the **PREPARE** statement that created the statement specified some parameters, a compatible set of parameters must be passed to the **EXECUTE** statement, or else an error is raised. Note that (unlike functions) prepared statements are not overloaded based on the type or number of their parameters; the name of a prepared statement must be unique within a database session.

For more information on the creation and usage of prepared statements, see [PREPARE](#).

## Parameters

name

The name of the prepared statement to run.

parameter

The actual value of a parameter to the prepared statement. This must be an expression yielding a value that is compatible with the data type of this parameter, as was determined when the prepared statement was created.

## Examples

Create a prepared statement for an **INSERT** statement, and then run it:

```
PREPARE fooplan (int, text, bool, numeric) AS INSERT INTO
foo VALUES($1, $2, $3, $4);
EXECUTE fooplan(1, 'Hunter Valley', 't', 200.00);
```

## Compatibility

The SQL standard includes an **EXECUTE** statement, but it is only for use in embedded SQL. This version of the **EXECUTE** statement also uses a somewhat different syntax.

## See Also

[DEALLOCATE](#), [PREPARE](#)

Parent topic: [SQL Commands](#)

## EXPLAIN

Shows the query plan of a statement.

## Synopsis

```
EXPLAIN [ ( <option> [, ...] ) ] <statement>
EXPLAIN [ANALYZE] [VERBOSE] <statement>
```

where option can be one of:

```
ANALYZE [ <boolean> ]
VERBOSE [ <boolean> ]
COSTS [ <boolean> ]
BUFFERS [ <boolean> ]
TIMING [ <boolean> ]
FORMAT { TEXT | XML | JSON | YAML }
```

## Description

**EXPLAIN** displays the query plan that the Greenplum or Postgres Planner generates for the supplied statement. Query plans are a tree plan of nodes. Each node in the plan represents a single operation, such as table scan, join, aggregation or a sort.

Plans should be read from the bottom up as each node feeds rows into the node directly above it. The bottom nodes of a plan are usually table scan operations (sequential, index or bitmap index scans). If the query requires joins, aggregations, or sorts (or other operations on the raw rows) then there will be additional nodes above the scan nodes to perform these operations. The topmost plan nodes are usually the Greenplum Database motion nodes (redistribute, explicit redistribute, broadcast, or gather motions). These are the operations responsible for moving rows between the segment instances during query processing.

The output of **EXPLAIN** has one line for each node in the plan tree, showing the basic node type plus the following cost estimates that the planner made for the execution of that plan node:

- **cost** — the planner's guess at how long it will take to run the statement (measured in cost units that are arbitrary, but conventionally mean disk page fetches). Two cost numbers are shown: the start-up cost before the first row can be returned, and the total cost to return all the rows. Note that the total cost assumes that all rows will be retrieved, which may not always be the case (if using **LIMIT** for example).
- **rows** — the total number of rows output by this plan node. This is usually less than the actual number of rows processed or scanned by the plan node, reflecting the estimated selectivity of any **WHERE** clause conditions. Ideally the top-level nodes estimate will approximate the number of rows actually returned, updated, or deleted by the query.

- **width** — total bytes of all the rows output by this plan node.

It is important to note that the cost of an upper-level node includes the cost of all its child nodes. The topmost node of the plan has the estimated total execution cost for the plan. This is this number that the planner seeks to minimize. It is also important to realize that the cost only reflects things that the query optimizer cares about. In particular, the cost does not consider the time spent transmitting result rows to the client.

**EXPLAIN ANALYZE** causes the statement to be actually run, not only planned. The **EXPLAIN ANALYZE** plan shows the actual results along with the planner's estimates. This is useful for seeing whether the planner's estimates are close to reality. In addition to the information shown in the **EXPLAIN** plan, **EXPLAIN ANALYZE** will show the following additional information:

- The total elapsed time (in milliseconds) that it took to run the query.
- The number of *workers* (segments) involved in a plan node operation. Only segments that return rows are counted.
- The maximum number of rows returned by the segment that produced the most rows for an operation. If multiple segments produce an equal number of rows, the one with the longest *time to end* is the one chosen.
- The segment id number of the segment that produced the most rows for an operation.
- For relevant operations, the `work_mem` used by the operation. If `work_mem` was not sufficient to perform the operation in memory, the plan will show how much data was spilled to disk and how many passes over the data were required for the lowest performing segment. For example:

```
Work_mem used: 64K bytes avg, 64K bytes max (seg0).
Work_mem wanted: 90K bytes avg, 90K bytes max (seg0) to abate workfile
I/O affecting 2 workers.
[seg0] pass 0: 488 groups made from 488 rows; 263 rows written to
workfile
[seg0] pass 1: 263 groups made from 263 rows
```

- The time (in milliseconds) it took to retrieve the first row from the segment that produced the most rows, and the total time taken to retrieve all rows from that segment. The *<time> to first row* may be omitted if it is the same as the *<time> to end*.

**Important:** Keep in mind that the statement is actually run when **ANALYZE** is used. Although **EXPLAIN ANALYZE** will discard any output that a **SELECT** would return, other side effects of the statement will happen as usual. If you wish to use **EXPLAIN ANALYZE** on a DML statement without letting the command affect your data, use this approach:

```
BEGIN;
EXPLAIN ANALYZE ...;
ROLLBACK;
```

Only the **ANALYZE** and **VERBOSE** options can be specified, and only in that order, without surrounding the option list in parentheses.

## Parameters

**ANALYZE**

Carry out the command and show the actual run times and other statistics. This parameter defaults to `FALSE` if you omit it; specify `ANALYZE true` to enable it.

**VERBOSE**

Display additional information regarding the plan. Specifically, include the output column list for each node in the plan tree, schema-qualify table and function names, always label variables in expressions with their range table alias, and always print the name of each trigger for which statistics are displayed. This parameter defaults to `FALSE` if you omit it; specify `VERBOSE true` to enable it.

**COSTS**

Include information on the estimated startup and total cost of each plan node, as well as the estimated number of rows and the estimated width of each row. This parameter defaults to `TRUE` if you omit it; specify `COSTS false` to deactivate it.

**BUFFERS**

Include information on buffer usage. Specifically, include the number of shared blocks hit, read, dirtied, and written, the number of local blocks hit, read, dirtied, and written, and the number of temp blocks read and written. A *hit* means that a read was avoided because the block was found already in cache when needed. Shared blocks contain data from regular tables and indexes; local blocks contain data from temporary tables and indexes; while temp blocks contain short-term working data used in sorts, hashes, Materialize plan nodes, and similar cases. The number of blocks *dirtied* indicates the number of previously unmodified blocks that were changed by this query; while the number of blocks *written* indicates the number of previously-dirtied blocks evicted from cache by this backend during query processing. The number of blocks shown for an upper-level node includes those used by all its child nodes. In text format, only non-zero values are printed. This parameter may only be used when `ANALYZE` is also enabled. This parameter defaults to `FALSE` if you omit it; specify `BUFFERS true` to enable it.

**TIMING**

Include actual startup time and time spent in each node in the output. The overhead of repeatedly reading the system clock can slow down the query significantly on some systems, so it may be useful to set this parameter to `FALSE` when only actual row counts, and not exact times, are needed. Run time of the entire statement is always measured, even when node-level timing is turned off with this option. This parameter may only be used when `ANALYZE` is also enabled. It defaults to `TRUE`.

**FORMAT**

Specify the output format, which can be `TEXT`, `XML`, `JSON`, or `YAML`. Non-text output contains the same information as the text output format, but is easier for programs to parse. This parameter defaults to `TEXT`.

**boolean**

Specifies whether the selected option should be turned on or off. You can write `TRUE`, `ON`, or `1` to enable the option, and `FALSE`, `OFF`, or `0` to deactivate it. The boolean value can also be omitted, in which case `TRUE` is assumed.

**statement**

Any `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `VALUES`, `EXECUTE`, `DECLARE`, or `CREATE TABLE AS` statement, whose execution plan you wish to see.

## Notes

In order to allow the query optimizer to make reasonably informed decisions when optimizing queries, the `ANALYZE` statement should be run to record statistics about the distribution of data within the table. If you have not done this (or if the statistical distribution of the data in the table has changed significantly since the last time `ANALYZE` was run), the estimated costs are unlikely to conform to the real properties of the query, and consequently an inferior query plan may be chosen.

An SQL statement that is run during the execution of an `EXPLAIN ANALYZE` command is excluded from Greenplum Database resource queues.

For more information about query profiling, see "Query Profiling" in the *Greenplum Database Administrator Guide*. For more information about resource queues, see "Resource Management with Resource Queues" in the *Greenplum Database Administrator Guide*.

## Examples

To illustrate how to read an `EXPLAIN` query plan, consider the following example for a very simple query:

```
EXPLAIN SELECT * FROM names WHERE name = 'Joelle';
          QUERY PLAN
-----
 Gather Motion 3:1  (slice1; segments: 3)  (cost=0.00..431.27 rows=1 width=58)
   ->  Seq Scan on names  (cost=0.00..431.27 rows=1 width=58)
        Filter: (name = 'Joelle'::text)
Optimizer: Pivotal Optimizer (GPORCA) version 3.23.0
(4 rows)
```

If we read the plan from the bottom up, the query optimizer starts by doing a sequential scan of the `names` table. Notice that the `WHERE` clause is being applied as a *filter* condition. This means that the scan operation checks the condition for each row it scans, and outputs only the ones that pass the condition.

The results of the scan operation are passed up to a *gather motion* operation. In Greenplum Database, a gather motion is when segments send rows up to the master. In this case we have 3 segment instances sending to 1 master instance (3:1). This operation is working on `slice1` of the parallel query execution plan. In Greenplum Database a query plan is divided into *slices* so that portions of the query plan can be worked on in parallel by the segments.

The estimated startup cost for this plan is `00.00` (no cost) and a total cost of `431.27`. The planner is estimating that this query will return one row.

Here is the same query, with cost estimates suppressed:

```
EXPLAIN (COSTS FALSE) SELECT * FROM names WHERE name = 'Joelle';
          QUERY PLAN
-----
 Gather Motion 3:1  (slice1; segments: 3)
   ->  Seq Scan on names
        Filter: (name = 'Joelle'::text)
Optimizer: Pivotal Optimizer (GPORCA) version 3.23.0
(4 rows)
```

Here is the same query, with JSON formatting:

```

EXPLAIN (FORMAT JSON) SELECT * FROM names WHERE name = 'Joelle';
      QUERY PLAN
-----
[
  {
    "Plan": {
      "Node Type": "Gather Motion",
      "Senders": 3,
      "Receivers": 1,
      "Slice": 1,
      "Segments": 3,
      "Gang Type": "primary reader",
      "Startup Cost": 0.00,
      "Total Cost": 431.27,
      "Plan Rows": 1,
      "Plan Width": 58,
      "Plans": [
        {
          "Node Type": "Seq Scan",
          "Parent Relationship": "Outer",
          "Slice": 1,
          "Segments": 3,
          "Gang Type": "primary reader",
          "Relation Name": "names",
          "Alias": "names",
          "Startup Cost": 0.00,
          "Total Cost": 431.27,
          "Plan Rows": 1,
          "Plan Width": 58,
          "Filter": "(name = 'Joelle'::text)"
        }
      ]
    },
    "Settings": {
      "Optimizer": "Pivotal Optimizer (GPORCA) version 3.23.0"
    }
  }
]
(1 row)

```

If there is an index and we use a query with an indexable `WHERE` condition, `EXPLAIN` might show a different plan. This query generates a plan with an index scan, with YAML formatting:

```

EXPLAIN (FORMAT YAML) SELECT * FROM NAMES WHERE LOCATION='Sydney, Australia';
      QUERY PLAN
-----
- Plan:
  Node Type: "Gather Motion"
  Senders: 3
  Receivers: 1
  Slice: 1
  Segments: 3
  Gang Type: "primary reader"
  Startup Cost: 0.00
  Total Cost: 10.81
  Plan Rows: 10000
  Plan Width: 70
  Plans:

```

```

- Node Type: "Index Scan" +
  Parent Relationship: "Outer" +
  Slice: 1 +
  Segments: 3 +
  Gang Type: "primary reader" +
  Scan Direction: "Forward" +
  Index Name: "names_idx_loc" +
  Relation Name: "names" +
  Alias: "names" +
  Startup Cost: 0.00 +
  Total Cost: 7.77 +
  Plan Rows: 10000 +
  Plan Width: 70 +
  Index Cond: "(location = 'Sydney, Australia'::text)"+
Settings: +
  Optimizer: "Pivotal Optimizer (GPORCA) version 3.23.0"
(1 row)

```

## Compatibility

There is no `EXPLAIN` statement defined in the SQL standard.

## See Also

[ANALYZE](#)

Parent topic: [SQL Commands](#)

## FETCH

Retrieves rows from a query using a cursor.

## Synopsis

```
FETCH [ <forward_direction> { FROM | IN } ] <cursor_name>
```

where `forward_direction` can be empty or one of:

```

NEXT
FIRST
ABSOLUTE <count>
RELATIVE <count>
<count>
ALL
FORWARD
FORWARD <count>
FORWARD ALL

```

## Description

`FETCH` retrieves rows using a previously-created cursor.

**Note:** You cannot `FETCH` from a `PARALLEL RETRIEVE CURSOR`, you must `RETRIEVE` the rows from it.

**Note:** This page describes usage of cursors at the SQL command level. If you are trying to use cursors inside a PL/pgSQL function, the rules are different. See [PL/pgSQL function](#).

A cursor has an associated position, which is used by `FETCH`. The cursor position can be before the first row of the query result, on any particular row of the result, or after the last row of the result. When created, a cursor is positioned before the first row. After fetching some rows, the cursor is positioned on the row most recently retrieved. If `FETCH` runs off the end of the available rows then the cursor is left positioned after the last row. `FETCH ALL` will always leave the cursor positioned after the last row.

The forms `NEXT`, `FIRST`, `ABSOLUTE`, `RELATIVE` fetch a single row after moving the cursor appropriately. If there is no such row, an empty result is returned, and the cursor is left positioned before the first row or after the last row as appropriate.

The forms using `FORWARD` retrieve the indicated number of rows moving in the forward direction, leaving the cursor positioned on the last-returned row (or after all rows, if the count exceeds the number of rows available). Note that it is not possible to move a cursor position backwards in Greenplum Database, since scrollable cursors are not supported. You can only move a cursor forward in position using `FETCH`.

`RELATIVE 0` and `FORWARD 0` request fetching the current row without moving the cursor, that is, re-fetching the most recently fetched row. This will succeed unless the cursor is positioned before the first row or after the last row, in which case no row is returned.

## Outputs

On successful completion, a `FETCH` command returns a command tag of the form

```
FETCH <count>
```

The count is the number of rows fetched (possibly zero). Note that in `psql`, the command tag will not actually be displayed, since `psql` displays the fetched rows instead.

## Parameters

`forward_direction`

Defines the fetch direction and number of rows to fetch. Only forward fetches are allowed in Greenplum Database. It can be one of the following:

`NEXT`

Fetch the next row. This is the default if direction is omitted.

`FIRST`

Fetch the first row of the query (same as `ABSOLUTE 1`). Only allowed if it is the first `FETCH` operation using this cursor.

`ABSOLUTE count`

Fetch the specified row of the query. Position after last row if count is out of range. Only allowed if the row specified by count moves the cursor position forward.

`RELATIVE count`

Fetch the specified row of the query count rows ahead of the current cursor position. `RELATIVE 0` re-fetches the current row, if any. Only allowed if count moves the cursor position forward.

`count`

Fetch the next count number of rows (same as `FORWARD count`).

`ALL`

Fetch all remaining rows (same as `FORWARD ALL`).

`FORWARD`

Fetch the next row (same as `NEXT`).

`FORWARD count`

Fetch the next count number of rows. `FORWARD 0` re-fetches the current row.

`FORWARD ALL`

Fetch all remaining rows.

`cursor_name`

The name of an open cursor.

## Notes

Greenplum Database does not support scrollable cursors, so you can only use `FETCH` to move the cursor position forward.

`ABSOLUTE` fetches are not any faster than navigating to the desired row with a relative move: the underlying implementation must traverse all the intermediate rows anyway.

`DECLARE` is used to define a cursor. Use `MOVE` to change cursor position without retrieving data.

## Examples

-- Start the transaction:

```
BEGIN;
```

-- Set up a cursor:

```
DECLARE mycursor CURSOR FOR SELECT * FROM films;
```

-- Fetch the first 5 rows in the cursor `mycursor`:

```
FETCH FORWARD 5 FROM mycursor;
code |          title          | did | date_prod | kind   | len
-----+-----+-----+-----+-----+-----
BL101 | The Third Man           | 101 | 1949-12-23 | Drama  | 01:44
BL102 | The African Queen      | 101 | 1951-08-11 | Romantic | 01:43
JL201 | Une Femme est une Femme | 102 | 1961-03-12 | Romantic | 01:25
P_301 | Vertigo                 | 103 | 1958-11-14 | Action  | 02:08
P_302 | Becket                  | 103 | 1964-02-03 | Drama   | 02:28
```

-- Close the cursor and end the transaction:

```
CLOSE mycursor;
COMMIT;
```

Change the `kind` column of the table `films` in the row at the `c_films` cursor's current position:

```
UPDATE films SET kind = 'Dramatic' WHERE CURRENT OF c_films;
```

## Compatibility

SQL standard allows cursors only in embedded SQL and in modules. Greenplum Database permits cursors to be used interactively.

The variant of `FETCH` described here returns the data as if it were a `SELECT` result rather than placing it in host variables. Other than this point, `FETCH` is fully upward-compatible with the SQL standard.

The `FETCH` forms involving `FORWARD`, as well as the forms `FETCH count` and `FETCH ALL`, in which `FORWARD` is implicit, are Greenplum Database extensions. `BACKWARD` is not supported.

The SQL standard allows only `FROM` preceding the cursor name; the option to use `IN`, or to leave them out altogether, is an extension.

## Description

Greenplum Database unifies the concepts of users and groups into a single kind of entity called a role. It is therefore not necessary to use the keyword `GROUP` to identify whether a grantee is a user or a group. `GROUP` is still allowed in the command, but it is a noise word.

The `GRANT` command has two basic variants: one that grants privileges on a database object (table, column, view, foreign table, sequence, database, foreign-data wrapper, foreign server, function, procedural language, schema, or tablespace), and one that grants membership in a role.

### GRANT on Database Objects

This variant of the `GRANT` command gives specific privileges on a database object to one or more roles. These privileges are added to those already granted, if any.

There is also an option to grant privileges on all objects of the same type within one or more schemas. This functionality is currently supported only for tables, sequences, and functions (but note that `ALL TABLES` is considered to include views and foreign tables).

The keyword `PUBLIC` indicates that the privileges are to be granted to all roles, including those that may be created later. `PUBLIC` may be thought of as an implicitly defined group-level role that always includes all roles. Any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to `PUBLIC`.

If `WITH GRANT OPTION` is specified, the recipient of the privilege may in turn grant it to others. Without a grant option, the recipient cannot do that. Grant options cannot be granted to `PUBLIC`.

There is no need to grant privileges to the owner of an object (usually the role that created it), as the owner has all privileges by default. (The owner could, however, choose to revoke some of their own privileges for safety.)

The right to drop an object, or to alter its definition in any way is not treated as a grantable privilege; it is inherent in the owner, and cannot be granted or revoked. (However, a similar effect can be obtained by granting or revoking membership in the role that owns the object; see below.) The owner implicitly has all grant options for the object, too.

Greenplum Database grants default privileges on some types of objects to `PUBLIC`. No privileges are granted to `PUBLIC` by default on tables, table columns, sequences, foreign-data wrappers, foreign servers, large objects, schemas, or tablespaces. For other types of objects, the default privileges granted to `PUBLIC` are as follows:

- `CONNECT` and `TEMPORARY` (create temporary tables) privileges for databases,
- `EXECUTE` privilege for functions, and
- `USAGE` privilege for languages and data types (including domains).

The object owner can, of course, `REVOKE` both default and expressly granted privileges. (For maximum security, issue the `REVOKE` in the same transaction that creates the object; then there is no window in which another user can use the object.)

### GRANT on Roles

This variant of the `GRANT` command grants membership in a role to one or more other roles. Membership in a role is significant because it conveys the privileges granted to a role to each of its members.

If `WITH ADMIN OPTION` is specified, the member may in turn grant membership in the role to others, and revoke membership in the role as well. Without the admin option, ordinary users cannot do that. A role is not considered to hold `WITH ADMIN OPTION` on itself, but it may grant or revoke membership in itself from a database session where the session user matches the role. Database superusers can grant or revoke membership in any role to anyone. Roles having `CREATEROLE` privilege can grant or revoke membership in any role that is not a superuser.

Unlike the case with privileges, membership in a role cannot be granted to `PUBLIC`.

### GRANT on Protocols

You can also use the `GRANT` command to specify which users can access a trusted protocol. (If the protocol is not trusted, you cannot give any other user permission to use it to read or write data.)

- To allow a user to create a readable external table with a trusted protocol:

```
GRANT SELECT ON PROTOCOL <protocolname> TO <username>
```

- To allow a user to create a writable external table with a trusted protocol:

```
GRANT INSERT ON PROTOCOL <protocolname> TO <username>
```

- To allow a user to create both readable and writable external table with a trusted protocol:

```
GRANT ALL ON PROTOCOL <protocolname> TO <username>
```

You can also use this command to grant users permissions to create and use `s3` and `pxf` external tables. However, external tables of type `http`, `https`, `gpfdist`, and `gpfdists`, are implemented internally in Greenplum Database instead of as custom protocols. For these types, use the `CREATE ROLE` or `ALTER ROLE` command to set the `CREATEEXTTABLE` or `NOCREATEEXTTABLE` attribute for each user. See [CREATE ROLE](#) for syntax and examples.

## Parameters

### SELECT

Allows `SELECT` from any column, or the specific columns listed, of the specified table, view, or sequence. Also allows the use of `COPY TO`. This privilege is also needed to reference existing column values in `UPDATE` or `DELETE`.

### INSERT

Allows `INSERT` of a new row into the specified table. If specific columns are listed, only those columns may be assigned to in the `INSERT` command (other columns will receive default values). Also allows `COPY FROM`.

### UPDATE

Allows `UPDATE` of any column, or the specific columns listed, of the specified table. `SELECT ... FOR UPDATE` and `SELECT ... FOR SHARE` also require this privilege on at least one column, (as well as the `SELECT` privilege). For sequences, this privilege allows the use of the `nextval()` and `setval()` functions.

### DELETE

Allows `DELETE` of a row from the specified table.

### REFERENCES

This keyword is accepted, although foreign key constraints are currently not supported in Greenplum Database. To create a foreign key constraint, it is necessary to have this privilege on both the referencing and referenced columns. The privilege may be granted for all columns of a table, or just specific columns.

### TRIGGER

Allows the creation of a trigger on the specified table.

**Note:** Greenplum Database does not support triggers.

### TRUNCATE

Allows `TRUNCATE` of all rows from the specified table.

### CREATE

For databases, allows new schemas to be created within the database.

For schemas, allows new objects to be created within the schema. To rename an existing object, you must own the object and have this privilege for the containing schema.

For tablespaces, allows tables and indexes to be created within the tablespace, and allows databases to be created that have the tablespace as their default tablespace. (Note that revoking this privilege will not alter the placement of existing objects.)

### CONNECT

Allows the user to connect to the specified database. This privilege is checked at connection startup (in addition to checking any restrictions imposed by `pg_hba.conf`).

**TEMPORARY****TEMP**

Allows temporary tables to be created while using the database.

**EXECUTE**

Allows the use of the specified function and the use of any operators that are implemented on top of the function. This is the only type of privilege that is applicable to functions. (This syntax works for aggregate functions, as well.)

**USAGE**

For procedural languages, allows the use of the specified language for the creation of functions in that language. This is the only type of privilege that is applicable to procedural languages.

For schemas, allows access to objects contained in the specified schema (assuming that the objects' own privilege requirements are also met). Essentially this allows the grantee to look up objects within the schema.

For sequences, this privilege allows the use of the `currval()` and `nextval()` function.

For types and domains, this privilege allows the use of the type or domain in the creation of tables, functions, and other schema objects. (Note that it does not control general "usage" of the type, such as values of the type appearing in queries. It only prevents objects from being created that depend on the type. The main purpose of the privilege is controlling which users create dependencies on a type, which could prevent the owner from changing the type later.)

For foreign-data wrappers, this privilege enables the grantee to create new servers using that foreign-data wrapper.

For servers, this privilege enables the grantee to create foreign tables using the server, and also to create, alter, or drop their own user's user mappings associated with that server.

**ALL PRIVILEGES**

Grant all of the available privileges at once. The `PRIVILEGES` key word is optional in Greenplum Database, though it is required by strict SQL.

**PUBLIC**

A special group-level role that denotes that the privileges are to be granted to all roles, including those that may be created later.

**WITH GRANT OPTION**

The recipient of the privilege may in turn grant it to others.

**WITH ADMIN OPTION**

The member of a role may in turn grant membership in the role to others.

## Notes

A user may perform `SELECT`, `INSERT`, and so forth, on a column if they hold that privilege for either the specific column or the whole table. Granting the privilege at the table level and then revoking it for one column does not do what you might wish: the table-level grant is unaffected by a column-level operation.

Database superusers can access all objects regardless of object privilege settings. One exception to this rule is view objects. Access to tables referenced in the view is determined by permissions of

the view owner not the current user (even if the current user is a superuser).

If a superuser chooses to issue a `GRANT` or `REVOKE` command, the command is performed as though it were issued by the owner of the affected object. In particular, privileges granted via such a command will appear to have been granted by the object owner. For role membership, the membership appears to have been granted by the containing role itself.

`GRANT` and `REVOKE` can also be done by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges `WITH GRANT OPTION` on the object. In this case the privileges will be recorded as having been granted by the role that actually owns the object or holds the privileges `WITH GRANT OPTION`.

Granting permission on a table does not automatically extend permissions to any sequences used by the table, including sequences tied to `SERIAL` columns. Permissions on a sequence must be set separately.

The `GRANT` command cannot be used to set privileges for the protocols `file`, `gpfdist`, or `gpfdists`. These protocols are implemented internally in Greenplum Database. Instead, use the `CREATE ROLE` or `ALTER ROLE` command to set the `CREATEEXTTABLE` attribute for the role.

Use `psql`'s `\dp` meta-command to obtain information about existing privileges for tables and columns. There are other `\d` meta-commands that you can use to display the privileges of non-table objects.

## Examples

Grant insert privilege to all roles on table `mytable`:

```
GRANT INSERT ON mytable TO PUBLIC;
```

Grant all available privileges to role `sally` on the view `topten`. Note that while the above will indeed grant all privileges if run by a superuser or the owner of `topten`, when run by someone else it will only grant those permissions for which the granting role has grant options.

```
GRANT ALL PRIVILEGES ON topten TO sally;
```

Grant membership in role `admins` to user `joe`:

```
GRANT admins TO joe;
```

## Compatibility

The `PRIVILEGES` key word is required in the SQL standard, but optional in Greenplum Database. The SQL standard does not support setting the privileges on more than one object per command.

Greenplum Database allows an object owner to revoke their own ordinary privileges: for example, a table owner can make the table read-only to themselves by revoking their own `INSERT`, `UPDATE`, `DELETE`, and `TRUNCATE` privileges. This is not possible according to the SQL standard. Greenplum Database treats the owner's privileges as having been granted by the owner to the owner; therefore they can revoke them too. In the SQL standard, the owner's privileges are granted by an assumed *system* entity.

The SQL standard provides for a **USAGE** privilege on other kinds of objects: character sets, collations, translations.

In the SQL standard, sequences only have a **USAGE** privilege, which controls the use of the **NEXT VALUE FOR** expression, which is equivalent to the function `nextval` in Greenplum Database. The sequence privileges **SELECT** and **UPDATE** are Greenplum Database extensions. The application of the sequence **USAGE** privilege to the `currval` function is also a Greenplum Database extension (as is the function itself).

Privileges on databases, tablespaces, schemas, and languages are Greenplum Database extensions.

## INSERT

Creates new rows in a table.

## Synopsis

```
[ WITH [ RECURSIVE ] <with_query> [, ...] ]
INSERT INTO <table> [( <column> [, ...] )]
    {DEFAULT VALUES | VALUES ( {<expression> | DEFAULT} [, ...] ) [, ...] | <query>}
    [RETURNING * | <output_expression> [[AS] <output_name>] [, ...]]
```

## Description

**INSERT** inserts new rows into a table. One can insert one or more rows specified by value expressions, or zero or more rows resulting from a query.

The target column names may be listed in any order. If no list of column names is given at all, the default is the columns of the table in their declared order. The values supplied by the **VALUES** clause or query are associated with the explicit or implicit column list left-to-right.

Each column not present in the explicit or implicit column list will be filled with a default value, either its declared default value or null if there is no default.

If the expression for any column is not of the correct data type, automatic type conversion will be attempted.

The optional **RETURNING** clause causes **INSERT** to compute and return value(s) based on each row actually inserted. This is primarily useful for obtaining values that were supplied by defaults, such as a serial sequence number. However, any expression using the table's columns is allowed. The syntax of the **RETURNING** list is identical to that of the output list of **SELECT**.

You must have **INSERT** privilege on a table in order to insert into it. When a column list is specified, you need **INSERT** privilege only on the listed columns. Use of the **RETURNING** clause requires **SELECT** privilege on all columns mentioned in **RETURNING**. If you provide a query to insert rows from a query, you must have **SELECT** privilege on any table or column referenced in the query.

## Outputs

On successful completion, an `INSERT` command returns a command tag of the form:

```
INSERT <oid> <count>
```

The count is the number of rows inserted. If count is exactly one, and the target table has OIDs, then oid is the OID assigned to the inserted row. Otherwise OID is zero.

## Parameters

### with\_query

The `WITH` clause allows you to specify one or more subqueries that can be referenced by name in the `INSERT` query.

For an `INSERT` command that includes a `WITH` clause, the clause can only contain `SELECT` statements, the `WITH` clause cannot contain a data-modifying command (`INSERT`, `UPDATE`, or `DELETE`).

It is possible for the query (`SELECT` statement) to also contain a `WITH` clause. In such a case both sets of `with_query` can be referenced within the `INSERT` query, but the second one takes precedence since it is more closely nested.

See [WITH Queries \(Common Table Expressions\)](#) and [SELECT](#) for details.

### table

The name (optionally schema-qualified) of an existing table.

### column

The name of a column in table. The column name can be qualified with a subfield name or array subscript, if needed. (Inserting into only some fields of a composite column leaves the other fields null.)

### DEFAULT VALUES

All columns will be filled with their default values.

### expression

An expression or value to assign to the corresponding column.

### DEFAULT

The corresponding column will be filled with its default value.

### query

A query (`SELECT` statement) that supplies the rows to be inserted. Refer to the `SELECT` statement for a description of the syntax.

### output\_expression

An expression to be computed and returned by the `INSERT` command after each row is inserted. The expression can use any column names of the table. Write `*` to return all columns of the inserted row(s).

### output\_name

A name to use for a returned column.

## Notes

To insert data into a partitioned table, you specify the root partitioned table, the table created with the `CREATE TABLE` command. You also can specify a leaf child table of the partitioned table in an

`INSERT` command. An error is returned if the data is not valid for the specified leaf child table. Specifying a child table that is not a leaf child table in the `INSERT` command is not supported. Execution of other DML commands such as `UPDATE` and `DELETE` on any child table of a partitioned table is not supported. These commands must be run on the root partitioned table, the table created with the `CREATE TABLE` command.

For a partitioned table, all the child tables are locked during the `INSERT` operation when the Global Deadlock Detector is not enabled (the default). Only some of the leaf child tables are locked when the Global Deadlock Detector is enabled. For information about the Global Deadlock Detector, see [Global Deadlock Detector](#).

For append-optimized tables, Greenplum Database supports a maximum of 127 concurrent `INSERT` transactions into a single append-optimized table.

For writable S3 external tables, the `INSERT` operation uploads to one or more files in the configured S3 bucket, as described in [s3:// Protocol](#). Pressing `Ctrl-C` cancels the `INSERT` and stops uploading to S3.

## Examples

Insert a single row into table `films`:

```
INSERT INTO films VALUES ('UA502', 'Bananas', 105,
'1971-07-13', 'Comedy', '82 minutes');
```

In this example, the `length` column is omitted and therefore it will have the default value:

```
INSERT INTO films (code, title, did, date_prod, kind) VALUES
('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

This example uses the `DEFAULT` clause for the `date_prod` column rather than specifying a value:

```
INSERT INTO films VALUES ('UA502', 'Bananas', 105, DEFAULT,
'Comedy', '82 minutes');
```

To insert a row consisting entirely of default values:

```
INSERT INTO films DEFAULT VALUES;
```

To insert multiple rows using the multirow `VALUES` syntax:

```
INSERT INTO films (code, title, did, date_prod, kind) VALUES
('B6717', 'Tampopo', 110, '1985-02-10', 'Comedy'),
('HG120', 'The Dinner Game', 140, DEFAULT, 'Comedy');
```

This example inserts some rows into table `films` from a table `tmp_films` with the same column layout as `films`:

```
INSERT INTO films SELECT * FROM tmp_films WHERE date_prod <
'2004-05-07';
```

Insert a single row into table distributors, returning the sequence number generated by the DEFAULT clause:

```
INSERT INTO distributors (did, dname) VALUES (DEFAULT, 'XYZ Widgets')
RETURNING did;
```

## Compatibility

`INSERT` conforms to the SQL standard. The case in which a column name list is omitted, but not all the columns are filled from the `VALUES` clause or query, is disallowed by the standard.

Possible limitations of the query clause are documented under `SELECT`.

Parent topic: [SQL Commands](#)

## LISTEN

Listens for a notification.

## Synopsis

```
LISTEN <channel>
```

## Description

`LISTEN` registers the current session as a listener on the notification channel named `<channel>`. If the current session is already registered as a listener for this notification channel, nothing is done.

Whenever the command `NOTIFY <channel>` is invoked, either by this session or another one connected to the same database, all the sessions currently listening on that notification channel are notified, and each will in turn notify its connected client application.

A session can be unregistered for a given notification channel with the `UNLISTEN` command. A session's listen registrations are automatically cleared when the session ends.

The method a client application must use to detect notification events depends on which PostgreSQL application programming interface it uses. With the `libpq` library, the application issues `LISTEN` as an ordinary SQL command, and then must periodically call the function `PQnotifies()` to find out whether any notification events have been received. Other interfaces such as `libpqtc1` provide higher-level methods for handling notify events; indeed, with `libpqtc1` the application programmer should not even issue `LISTEN` or `UNLISTEN` directly. See the documentation for the interface you are using for more details.

[NOTIFY](#) contains a more extensive discussion of the use of `LISTEN` and `NOTIFY`.

## Parameters

channel

The name of a notification channel (any identifier).

## Notes

`LISTEN` takes effect at transaction commit. If `LISTEN` or `UNLISTEN` is executed within a transaction that later rolls back, the set of notification channels being listened to is unchanged.

A transaction that has executed `LISTEN` cannot be prepared for two-phase commit.

## Examples

Configure and execute a listen/notify sequence from `psql`:

```
LISTEN virtual;
NOTIFY virtual;
Asynchronous notification "virtual" received from server process with PID 8448.
```

## Compatibility

There is no `LISTEN` statement in the SQL standard.

## See Also

[NOTIFY](#), [UNLISTEN](#)

Parent topic: [SQL Commands](#)

## LOAD

Loads or reloads a shared library file.

## Synopsis

```
LOAD '<filename>'
```

## Description

This command loads a shared library file into the Greenplum Database server address space. If the file had been loaded previously, it is first unloaded. This command is primarily useful to unload and reload a shared library file that has been changed since the server first loaded it. To make use of the shared library, function(s) in it need to be declared using the `CREATE FUNCTION` command.

The file name is specified in the same way as for shared library names in `CREATE FUNCTION`; in particular, one may rely on a search path and automatic addition of the system's standard shared library file name extension.

Note that in Greenplum Database the shared library file (`.so` file) must reside in the same path location on every host in the Greenplum Database array (masters, segments, and mirrors).

Only database superusers can load shared library files.

## Parameters

filename

The path and file name of a shared library file. This file must exist in the same location on all hosts in your Greenplum Database array.

## Examples

Load a shared library file:

```
LOAD '/usr/local/greenplum-db/lib/myfuncs.so';
```

## Compatibility

`LOAD` is a Greenplum Database extension.

## See Also

[CREATE FUNCTION](#)

## LOCK

Locks a table.

## Synopsis

```
LOCK [TABLE] [ONLY] name [ * ] [, ...] [IN <lockmode> MODE] [NOWAIT] [MASTER ONLY]
```

where lockmode is one of:

```
ACCESS SHARE | ROW SHARE | ROW EXCLUSIVE | SHARE UPDATE EXCLUSIVE
| SHARE | SHARE ROW EXCLUSIVE | EXCLUSIVE | ACCESS EXCLUSIVE
```

## Description

`LOCK TABLE` obtains a table-level lock, waiting if necessary for any conflicting locks to be released. If `NOWAIT` is specified, `LOCK TABLE` does not wait to acquire the desired lock: if it cannot be acquired immediately, the command is stopped and an error is emitted. Once obtained, the lock is held for the remainder of the current transaction. There is no `UNLOCK TABLE` command; locks are always released at transaction end.

When acquiring locks automatically for commands that reference tables, Greenplum Database always uses the least restrictive lock mode possible. `LOCK TABLE` provides for cases when you might need more restrictive locking. For example, suppose an application runs a transaction at the *Read*

*Committed* isolation level and needs to ensure that data in a table remains stable for the duration of the transaction. To achieve this you could obtain `SHARE` lock mode over the table before querying. This will prevent concurrent data changes and ensure subsequent reads of the table see a stable view of committed data, because `SHARE` lock mode conflicts with the `ROW EXCLUSIVE` lock acquired by writers, and your `LOCK TABLE name IN SHARE MODE` statement will wait until any concurrent holders of `ROW EXCLUSIVE` mode locks commit or roll back. Thus, once you obtain the lock, there are no uncommitted writes outstanding; furthermore none can begin until you release the lock.

To achieve a similar effect when running a transaction at the `REPEATABLE READ` or `SERIALIZABLE` isolation level, you have to run the `LOCK TABLE` statement before running any `SELECT` or data modification statement. A `REPEATABLE READ` or `SERIALIZABLE` transaction's view of data will be frozen when its first `SELECT` or data modification statement begins. A `LOCK TABLE` later in the transaction will still prevent concurrent writes — but it won't ensure that what the transaction reads corresponds to the latest committed values.

If a transaction of this sort is going to change the data in the table, then it should use `SHARE ROW EXCLUSIVE` lock mode instead of `SHARE` mode. This ensures that only one transaction of this type runs at a time. Without this, a deadlock is possible: two transactions might both acquire `SHARE` mode, and then be unable to also acquire `ROW EXCLUSIVE` mode to actually perform their updates. Note that a transaction's own locks never conflict, so a transaction can acquire `ROW EXCLUSIVE` mode when it holds `SHARE` mode — but not if anyone else holds `SHARE` mode. To avoid deadlocks, make sure all transactions acquire locks on the same objects in the same order, and if multiple lock modes are involved for a single object, then transactions should always acquire the most restrictive mode first.

## Parameters

### name

The name (optionally schema-qualified) of an existing table to lock. If `ONLY` is specified, only that table is locked. If `ONLY` is not specified, the table and all its descendant tables (if any) are locked. Optionally, `*` can be specified after the table name to explicitly indicate that descendant tables are included.

If multiple tables are given, tables are locked one-by-one in the order specified in the `LOCK TABLE` command.

### lockmode

The lock mode specifies which locks this lock conflicts with. If no lock mode is specified, then `ACCESS EXCLUSIVE`, the most restrictive mode, is used. Lock modes are as follows:

- `ACCESS SHARE` — Conflicts with the `ACCESS EXCLUSIVE` lock mode only. The `SELECT` command acquires a lock of this mode on referenced tables. In general, any query that only reads a table and does not modify it will acquire this lock mode.
- `ROW SHARE` — Conflicts with the `EXCLUSIVE` and `ACCESS EXCLUSIVE` lock modes. The `SELECT FOR SHARE` command automatically acquires a lock of this mode on the target table(s) (in addition to `ACCESS SHARE` locks on any other tables that are referenced but not selected `FOR SHARE`).
- `ROW EXCLUSIVE` — Conflicts with the `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes. The commands `INSERT` and `COPY` automatically acquire

this lock mode on the target table (in addition to `ACCESS SHARE` locks on any other referenced tables) See [Note](#).

- `SHARE UPDATE EXCLUSIVE` — Conflicts with the `SHARE UPDATE EXCLUSIVE`, `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes. This mode protects a table against concurrent schema changes and `VACUUM` runs. Acquired by `VACUUM` (without `FULL`) on heap tables and `ANALYZE`.
- `SHARE` — Conflicts with the `ROW EXCLUSIVE`, `SHARE UPDATE EXCLUSIVE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes. This mode protects a table against concurrent data changes. Acquired automatically by `CREATE INDEX`.
- `SHARE ROW EXCLUSIVE` — Conflicts with the `ROW EXCLUSIVE`, `SHARE UPDATE EXCLUSIVE`, `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes. This lock mode is not automatically acquired by any Greenplum Database command.
- `EXCLUSIVE` — Conflicts with the `ROW SHARE`, `ROW EXCLUSIVE`, `SHARE UPDATE EXCLUSIVE`, `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE` lock modes. This mode allows only concurrent `ACCESS SHARE` locks, i.e., only reads from the table can proceed in parallel with a transaction holding this lock mode. This lock mode is automatically acquired for `UPDATE`, `SELECT FOR UPDATE`, and `DELETE` in Greenplum Database (which is more restrictive locking than in regular PostgreSQL). See [Note](#).
- `ACCESS EXCLUSIVE` — Conflicts with locks of all modes (`ACCESS SHARE`, `ROW SHARE`, `ROW EXCLUSIVE`, `SHARE UPDATE EXCLUSIVE`, `SHARE`, `SHARE ROW EXCLUSIVE`, `EXCLUSIVE`, and `ACCESS EXCLUSIVE`). This mode guarantees that the holder is the only transaction accessing the table in any way. Acquired automatically by the `ALTER TABLE`, `DROP TABLE`, `TRUNCATE`, `REINDEX`, `CLUSTER`, and `VACUUM FULL` commands. This is the default lock mode for `LOCK TABLE` statements that do not specify a mode explicitly. This lock is also briefly acquired by `VACUUM` (without `FULL`) on append-optimized tables during processing.

**Note:** By default Greenplum Database acquires the more restrictive `EXCLUSIVE` lock (rather than `ROW EXCLUSIVE` in PostgreSQL) for `UPDATE`, `DELETE`, and `SELECT...FOR UPDATE` operations on heap tables. When the Global Deadlock Detector is enabled the lock mode for `UPDATE` and `DELETE` operations on heap tables is `ROW EXCLUSIVE`. See [Global Deadlock Detector](#).

Greenplum always holds a table-level lock with `SELECT...FOR UPDATE` statements.

#### NOWAIT

Specifies that `LOCK TABLE` should not wait for any conflicting locks to be released: if the specified lock(s) cannot be acquired immediately without waiting, the transaction is cancelled.

#### MASTER ONLY

Specifies that when a `LOCK TABLE` command is issued, Greenplum Database will lock tables on the master only, rather than on the master and all of the segments. This is particularly useful for metadata-only operations.

**Note:** This option is only supported in `ACCESS SHARE MODE`.

## Notes

`LOCK TABLE ... IN ACCESS SHARE MODE` requires `SELECT` privileges on the target table. All other forms of `LOCK` require table-level `UPDATE`, `DELETE`, or `TRUNCATE` privileges.

`LOCK TABLE` is useless outside of a transaction block: the lock would be held only to the completion of the `LOCK` statement. Therefore, Greenplum Database reports an error if `LOCK` is used outside of a transaction block. Use `BEGIN` and `END` to define a transaction block.

`LOCK TABLE` only deals with table-level locks, and so the mode names involving `ROW` are all misnomers. These mode names should generally be read as indicating the intention of the user to acquire row-level locks within the locked table. Also, `ROW EXCLUSIVE` mode is a shareable table lock. Keep in mind that all the lock modes have identical semantics so far as `LOCK TABLE` is concerned, differing only in the rules about which modes conflict with which. For information on how to acquire an actual row-level lock, see the `FOR UPDATE/FOR SHARE` clause in the `SELECT` reference documentation.

## Examples

Obtain a `SHARE` lock on the `films` table when going to perform inserts into the `films_user_comments` table:

```
BEGIN WORK;
LOCK TABLE films IN SHARE MODE;
SELECT id FROM films
    WHERE name = 'Star Wars: Episode I - The Phantom Menace';
-- Do ROLLBACK if record was not returned
INSERT INTO films_user_comments VALUES
    (_id_, 'GREAT! I was waiting for it for so long!');
COMMIT WORK;
```

Take a `SHARE ROW EXCLUSIVE` lock on a table when performing a delete operation:

```
BEGIN WORK;
LOCK TABLE films IN SHARE ROW EXCLUSIVE MODE;
DELETE FROM films_user_comments WHERE id IN
    (SELECT id FROM films WHERE rating < 5);
DELETE FROM films WHERE rating < 5;
COMMIT WORK;
```

## Compatibility

There is no `LOCK TABLE` in the SQL standard, which instead uses `SET TRANSACTION` to specify concurrency levels on transactions. Greenplum Database supports that too.

Except for `ACCESS SHARE`, `ACCESS EXCLUSIVE`, and `SHARE UPDATE EXCLUSIVE` lock modes, the Greenplum Database lock modes and the `LOCK TABLE` syntax are compatible with those present in Oracle.

## See Also

[BEGIN, SET TRANSACTION, SELECT](#)

**Parent topic:** [SQL Commands](#)

# MOVE

Positions a cursor.

## Synopsis

```
MOVE [ <forward_direction> [ FROM | IN ] ] <cursor_name>
```

where `forward_direction` can be empty or one of:

```
NEXT
FIRST
LAST
ABSOLUTE <count>
RELATIVE <count>
<count>
ALL
FORWARD
FORWARD <count>
FORWARD ALL
```

## Description

`MOVE` repositions a cursor without retrieving any data. `MOVE` works exactly like the `FETCH` command, except it only positions the cursor and does not return rows.

**Note:** You cannot `MOVE` a `PARALLEL RETRIEVE CURSOR`.

It is not possible to move a cursor position backwards in Greenplum Database, since scrollable cursors are not supported. You can only move a cursor forward in position using `MOVE`.

### Outputs

On successful completion, a `MOVE` command returns a command tag of the form

```
MOVE <count>
```

The count is the number of rows that a `FETCH` command with the same parameters would have returned (possibly zero).

## Parameters

`forward_direction`

The parameters for the `MOVE` command are identical to those of the `FETCH` command; refer to `FETCH` for details on syntax and usage.

`cursor_name`

The name of an open cursor.

## Examples

-- Start the transaction:

```
BEGIN;
```

-- Set up a cursor:

```
DECLARE mycursor CURSOR FOR SELECT * FROM films;
```

-- Move forward 5 rows in the cursor `mycursor`:

```
MOVE FORWARD 5 IN mycursor;
MOVE 5
```

-- Fetch the next row after that (row 6):

```
FETCH 1 FROM mycursor;
 code | title | did | date_prod | kind | len
-----+-----+-----+-----+-----+-----
 P_303 | 48 Hrs | 103 | 1982-10-22 | Action | 01:37
(1 row)
```

-- Close the cursor and end the transaction:

```
CLOSE mycursor;
COMMIT;
```

## Compatibility

There is no `MOVE` statement in the SQL standard.

## See Also

[DECLARE](#), [FETCH](#), [CLOSE](#)

**Parent topic:** [SQL Commands](#)

## NOTIFY

Generates a notification.

## Synopsis

```
NOTIFY <channel> [ , <payload> ]
```

## Description

The `NOTIFY` command sends a notification event together with an optional “payload” string to each client application that has previously executed `LISTEN <channel>` for the specified channel name in the current database. Notifications are visible to all users.

`NOTIFY` provides a simple interprocess communication mechanism for a collection of processes accessing the same Greenplum database. A payload string can be sent along with the notification,

and higher-level mechanisms for passing structured data can be built by using tables in the database to pass additional data from notifier to listener(s).

The information passed to the client for a notification event includes the notification channel name, the notifying session's server process PID, and the payload string, which is an empty string if it has not been specified.

It is up to the database designer to define the channel names that will be used in a given database and what each one means. Commonly, the channel name is the same as the name of some table in the database, and the notify event essentially means, “I changed this table, take a look at it to see what's new”. But no such association is enforced by the `NOTIFY` and `LISTEN` commands. For example, a database designer could use several different channel names to signal different sorts of changes to a single table. Alternatively, the payload string could be used to differentiate various cases.

When `NOTIFY` is used to signal the occurrence of changes to a particular table, a useful programming technique is to put the `NOTIFY` in a statement trigger that is triggered by table updates. In this way, notification happens automatically when the table is changed, and the application programmer cannot accidentally forget to do it.

`NOTIFY` interacts with SQL transactions in some important ways. Firstly, if a `NOTIFY` is executed inside a transaction, the notify events are not delivered until and unless the transaction is committed. This is appropriate, since if the transaction is aborted, all the commands within it have had no effect, including `NOTIFY`. But it can be disconcerting if one is expecting the notification events to be delivered immediately. Secondly, if a listening session receives a notification signal while it is within a transaction, the notification event will not be delivered to its connected client until just after the transaction is completed (either committed or aborted). Again, the reasoning is that if a notification were delivered within a transaction that was later aborted, one would want the notification to be undone somehow — but the server cannot “take back” a notification once it has sent it to the client. So notification events are only delivered between transactions. The upshot of this is that applications using `NOTIFY` for real-time signaling should try to keep their transactions short.

If the same channel name is signaled multiple times from the same transaction with identical payload strings, the database server can decide to deliver a single notification only. On the other hand, notifications with distinct payload strings will always be delivered as distinct notifications. Similarly, notifications from different transactions will never get folded into one notification. Except for dropping later instances of duplicate notifications, `NOTIFY` guarantees that notifications from the same transaction get delivered in the order they were sent. It is also guaranteed that messages from different transactions are delivered in the order in which the transactions committed.

It is common for a client that executes `NOTIFY` to be listening on the same notification channel itself. In that case it will get back a notification event, just like all the other listening sessions. Depending on the application logic, this could result in useless work, for example, reading a database table to find the same updates that that session just wrote out. It is possible to avoid such extra work by noticing whether the notifying session's server process PID (supplied in the notification event message) is the same as one's own session's PID (available from `libpq`). When they are the same, the notification event is one's own work bouncing back, and can be ignored.

## Parameters

**channel**

The name of a notification channel (any identifier).

**payload**

The “payload” string to be communicated along with the notification. This must be specified as a simple string literal. In the default configuration it must be shorter than 8000 bytes. (If binary data or large amounts of information need to be communicated, it's best to put it in a database table and send the key of the record.)

## Notes

There is a queue that holds notifications that have been sent but not yet processed by all listening sessions. If this queue becomes full, transactions calling `NOTIFY` will fail at commit. The queue is quite large (8GB in a standard installation) and should be sufficiently sized for almost every use case. However, no cleanup can take place if a session executes `LISTEN` and then enters a transaction for a very long time. Once the queue is half full you will see warnings in the log file pointing you to the session that is preventing cleanup. In this case you should make sure that this session ends its current transaction so that cleanup can proceed.

The function `pg_notification_queue_usage()` returns the fraction of the queue that is currently occupied by pending notifications.

A transaction that has executed `NOTIFY` cannot be prepared for two-phase commit.

## pg\_notify

To send a notification you can also use the function `pg_notify(text, text)`. The function takes the channel name as the first argument and the payload as the second. The function is much easier to use than the `NOTIFY` command if you need to work with non-constant channel names and payloads.

## Examples

Configure and execute a listen/notify sequence from `psql`:

```
LISTEN virtual;
NOTIFY virtual;
Asynchronous notification "virtual" received from server process with PID 8448.

LISTEN foo;
SELECT pg_notify('fo' || 'o', 'pay' || 'load');
Asynchronous notification "foo" with payload "payload" received from server process with PID 14728.
```

## Compatibility

There is no `NOTIFY` statement in the SQL standard.

## See Also

[LISTEN, UNLISTEN](#)

**Parent topic:** [SQL Commands](#)

# PREPARE

Prepare a statement for execution.

## Synopsis

```
PREPARE <name> [ (<datatype> [, ...] ) ] AS <statement>
```

## Description

**PREPARE** creates a prepared statement. A prepared statement is a server-side object that can be used to optimize performance. When the **PREPARE** statement is run, the specified statement is parsed, analyzed, and rewritten. When an **EXECUTE** command is subsequently issued, the prepared statement is planned and run. This division of labor avoids repetitive parse analysis work, while allowing the execution plan to depend on the specific parameter values supplied.

Prepared statements can take parameters, values that are substituted into the statement when it is run. When creating the prepared statement, refer to parameters by position, using **\$1**, **\$2**, etc. A corresponding list of parameter data types can optionally be specified. When a parameter's data type is not specified or is declared as unknown, the type is inferred from the context in which the parameter is first used (if possible). When running the statement, specify the actual values for these parameters in the **EXECUTE** statement.

Prepared statements only last for the duration of the current database session. When the session ends, the prepared statement is forgotten, so it must be recreated before being used again. This also means that a single prepared statement cannot be used by multiple simultaneous database clients; however, each client can create their own prepared statement to use. Prepared statements can be manually cleaned up using the **DEALLOCATE** command.

Prepared statements have the largest performance advantage when a single session is being used to run a large number of similar statements. The performance difference will be particularly significant if the statements are complex to plan or rewrite, for example, if the query involves a join of many tables or requires the application of several rules. If the statement is relatively simple to plan and rewrite but relatively expensive to run, the performance advantage of prepared statements will be less noticeable.

## Parameters

name

An arbitrary name given to this particular prepared statement. It must be unique within a single session and is subsequently used to run or deallocate a previously prepared statement.

datatype

The data type of a parameter to the prepared statement. If the data type of a particular parameter is unspecified or is specified as unknown, it will be inferred from the context in which the parameter is first used. To refer to the parameters in the prepared statement itself, use **\$1**, **\$2**, etc.

statement

Any **SELECT**, **INSERT**, **UPDATE**, **DELETE**, or **VALUES** statement.

## Notes

A prepared statement can be run with either a *generic plan* or a *custom plan*. A generic plan is the same across all executions, while a custom plan is generated for a specific execution using the parameter values given in that call. Use of a generic plan avoids planning overhead, but in some situations a custom plan will be much more efficient to run because the planner can make use of knowledge of the parameter values. If the prepared statement has no parameters, a generic plan is always used.

By default (with the default value, `auto`, for the server configuration parameter `plan_cache_mode`), the server automatically chooses whether to use a generic or custom plan for a prepared statement that has parameters. The current rule for this is that the first five executions are done with custom plans and the average estimated cost of those plans is calculated. Then a generic plan is created and its estimated cost is compared to the average custom-plan cost. Subsequent executions use the generic plan if its cost is not so much higher than the average custom-plan cost as to make repeated replanning seem preferable.

This heuristic can be overridden, forcing the server to use either generic or custom plans, by setting `plan_cache_mode` to `force_generic_plan` or `force_custom_plan` respectively. This setting is primarily useful if the generic plan's cost estimate is badly off for some reason, allowing it to be chosen even though its actual cost is much more than that of a custom plan.

To examine the query plan Greenplum Database is using for a prepared statement, use `EXPLAIN`, for example:

```
EXPLAIN EXECUTE <name>(<parameter_values>);
```

If a generic plan is in use, it will contain parameter symbols `$n`, while a custom plan will have the supplied parameter values substituted into it.

For more information on query planning and the statistics collected by Greenplum Database for that purpose, see the `ANALYZE` documentation.

Although the main point of a prepared statement is to avoid repeated parse analysis and planning of the statement, Greenplum will force re-analysis and re-planning of the statement before using it whenever database objects used in the statement have undergone definitional (DDL) changes since the previous use of the prepared statement. Also, if the value of `search_path` changes from one use to the next, the statement will be re-parsed using the new `search_path`. (This latter behavior is new as of Greenplum 6.) These rules make use of a prepared statement semantically almost equivalent to re-submitting the same query text over and over, but with a performance benefit if no object definitions are changed, especially if the best plan remains the same across uses. An example of a case where the semantic equivalence is not perfect is that if the statement refers to a table by an unqualified name, and then a new table of the same name is created in a schema appearing earlier in the `search_path`, no automatic re-parse will occur since no object used in the statement changed. However, if some other change forces a re-parse, the new table will be referenced in subsequent uses.

You can see all prepared statements available in the session by querying the `pg_prepared_statements` system view.

## Examples

Create a prepared statement for an `INSERT` statement, and then run it:

```
PREPARE fooplan (int, text, bool, numeric) AS INSERT INTO
foo VALUES($1, $2, $3, $4);
EXECUTE fooplan(1, 'Hunter Valley', 't', 200.00);
```

Create a prepared statement for a `SELECT` statement, and then run it. Note that the data type of the second parameter is not specified, so it is inferred from the context in which `$2` is used:

```
PREPARE usrrptplan (int) AS SELECT * FROM users u, logs l
WHERE u.usrid=$1 AND u.usrid=l.usrid AND l.date = $2;
EXECUTE usrrptplan(1, current_date);
```

## Compatibility

The SQL standard includes a `PREPARE` statement, but it can only be used in embedded SQL, and it uses a different syntax.

## See Also

[EXECUTE](#), [DEALLOCATE](#)

Parent topic: [SQL Commands](#)

## REASSIGN OWNED

Changes the ownership of database objects owned by a database role.

## Synopsis

```
REASSIGN OWNED BY <old_role> [, ...] TO <new_role>
```

## Description

`REASSIGN OWNED` changes the ownership of database objects owned by any of the `old_roles` to `new_role`.

## Parameters

`old_role`

The name of a role. The ownership of all the objects in the current database, and of all shared objects (databases, tablespaces), owned by this role will be reassigned to `new_role`.

`new_role`

The name of the role that will be made the new owner of the affected objects.

## Notes

`REASSIGN OWNED` is often used to prepare for the removal of one or more roles. Because `REASSIGN OWNED` does not affect objects in other databases, it is usually necessary to run this command in each database that contains objects owned by a role that is to be removed.

`REASSIGN OWNED` requires privileges on both the source role(s) and the target role.

The `DROP OWNED` command is an alternative that simply drops all of the database objects owned by one or more roles. `DROP OWNED` requires privileges only on the source role(s).

The `REASSIGN OWNED` command does not affect any privileges granted to the old\_roles on objects that are not owned by them. Likewise, it does not affect default privileges created with `ALTER DEFAULT PRIVILEGES`. Use `DROP OWNED` to revoke such privileges.

## Examples

Reassign any database objects owned by the role named `sally` and `bob` to `admin`:

```
REASSIGN OWNED BY sally, bob TO admin;
```

## Compatibility

The `REASSIGN OWNED` command is a Greenplum Database extension.

## See Also

[DROP OWNED](#), [DROP ROLE](#), [ALTER DATABASE](#)

Parent topic: [SQL Commands](#)

## REFRESH MATERIALIZED VIEW

Replaces the contents of a materialized view.

## Synopsis

```
REFRESH MATERIALIZED VIEW [ CONCURRENTLY ] <name>
    [ WITH [ NO ] DATA ]
```

## Description

`REFRESH MATERIALIZED VIEW` completely replaces the contents of a materialized view. The old contents are discarded. To run this command you must be the owner of the materialized view. With the default, `WITH DATA`, the materialized view query is run to provide the new data, and the materialized view is left in a scannable state. If `WITH NO DATA` is specified, no new data is generated and the materialized view is left in an unscannable state. A query returns an error if the query attempts to access the materialized view.

## Parameters

## CONCURRENTLY

Refresh the materialized view without locking out concurrent selects on the materialized view. Without this option, a refresh that affects a lot of rows tends to use fewer resources and completes more quickly, but could block other connections which are trying to read from the materialized view. This option might be faster in cases where a small number of rows are affected.

This option is only allowed if there is at least one `UNIQUE` index on the materialized view which uses only column names and includes all rows; that is, it must not index on any expressions nor include a `WHERE` clause.

This option cannot be used when the materialized view is not already populated, and it cannot be used with the `WITH NO DATA` clause.

Even with this option, only one `REFRESH` at a time may run against any one materialized view.

name

The name (optionally schema-qualified) of the materialized view to refresh.

WITH [ NO ] DATA

`WITH DATA` is the default and specifies that the materialized view query is run to provide new data, and the materialized view is left in a scannable state. If `WITH NO DATA` is specified, no new data is generated and the materialized view is left in an unscannable state. An error is returned if a query attempts to access an unscannable materialized view.

`WITH NO DATA` cannot be used with `CONCURRENTLY`.

## Notes

While the default index for future `CLUSTER` operations is retained, `REFRESH MATERIALIZED VIEW` does not order the generated rows based on this property. If you want the data to be ordered upon generation, you must use an `ORDER BY` clause in the materialized view query. However, if a materialized view query contains an `ORDER BY` or `SORT` clause, the data is not guaranteed to be ordered or sorted if `SELECT` is performed on the materialized view.

## Examples

This command replaces the contents of the materialized view `order_summary` using the query from the materialized view's definition, and leaves it in a scannable state.

```
REFRESH MATERIALIZED VIEW order_summary;
```

This command frees storage associated with the materialized view `annual_statistics_basis` and leaves it in an unscannable state.

```
REFRESH MATERIALIZED VIEW annual_statistics_basis WITH NO DATA;
```

## Compatibility

`REFRESH MATERIALIZED VIEW` is a Greenplum Database extension of the SQL standard.

## See Also

[ALTER MATERIALIZED VIEW](#), [CREATE MATERIALIZED VIEW](#), [DROP MATERIALIZED VIEW](#)

Parent topic: [SQL Commands](#)

## REINDEX

Rebuilds indexes.

## Synopsis

```
REINDEX {INDEX | TABLE | DATABASE | SYSTEM} <name>
```

## Description

`REINDEX` rebuilds an index using the data stored in the index's table, replacing the old copy of the index. There are several scenarios in which to use `REINDEX`:

- An index has become bloated, that is, it contains many empty or nearly-empty pages. This can occur with B-tree indexes in Greenplum Database under certain uncommon access patterns. `REINDEX` provides a way to reduce the space consumption of the index by writing a new version of the index without the dead pages.
- You have altered the `FILLFACTOR` storage parameter for an index, and wish to ensure that the change has taken full effect.

## Parameters

### INDEX

Recreate the specified index.

### TABLE

Recreate all indexes of the specified table. If the table has a secondary TOAST table, that is reindexed as well.

### DATABASE

Recreate all indexes within the current database. Indexes on shared system catalogs are also processed. This form of `REINDEX` cannot be run inside a transaction block.

### SYSTEM

Recreate all indexes on system catalogs within the current database. Indexes on shared system catalogs are included. Indexes on user tables are not processed. This form of `REINDEX` cannot be run inside a transaction block.

### name

The name of the specific index, table, or database to be reindexed. Index and table names may be schema-qualified. Presently, `REINDEX DATABASE` and `REINDEX SYSTEM` can only reindex the current database, so their parameter must match the current database's name.

## Notes

`REINDEX` causes locking of system catalog tables, which could affect currently running queries. To avoid disrupting ongoing business operations, schedule the `REINDEX` operation during a period of low activity.

`REINDEX` is similar to a drop and recreate of the index in that the index contents are rebuilt from scratch. However, the locking considerations are rather different. `REINDEX` locks out writes but not reads of the index's parent table. It also takes an exclusive lock on the specific index being processed, which will block reads that attempt to use that index. In contrast, `DROP INDEX` momentarily takes an exclusive lock on the parent table, blocking both writes and reads. The subsequent `CREATE INDEX` locks out writes but not reads; since the index is not there, no read will attempt to use it, meaning that there will be no blocking but reads may be forced into expensive sequential scans.

Reindexing a single index or table requires being the owner of that index or table. Reindexing a database requires being the owner of the database (note that the owner can therefore rebuild indexes of tables owned by other users). Of course, superusers can always reindex anything.

`REINDEX` does not update the `reltuples` and `relpages` statistics for the index. To update those statistics, run `ANALYZE` on the table after reindexing.

If you suspect that shared global system catalog indexes are corrupted, they can only be reindexed in Greenplum utility mode. The typical symptom of a corrupt shared index is "index is not a btree" errors, or else the server crashes immediately at startup due to reliance on the corrupted indexes. Contact Greenplum Customer Support for assistance in this situation.

## Examples

Rebuild a single index:

```
REINDEX INDEX my_index;
```

Rebuild all the indexes on the table `my_table`:

```
REINDEX TABLE my_table;
```

## Compatibility

There is no `REINDEX` command in the SQL standard.

## See Also

## RELEASE SAVEPOINT

Destroys a previously defined savepoint.

## Synopsis

```
RELEASE [SAVEPOINT] <savepoint_name>
```

## Description

`RELEASE SAVEPOINT` destroys a savepoint previously defined in the current transaction.

Destroying a savepoint makes it unavailable as a rollback point, but it has no other user visible behavior. It does not undo the effects of commands run after the savepoint was established. (To do that, see [ROLLBACK TO SAVEPOINT](#).) Destroying a savepoint when it is no longer needed may allow the system to reclaim some resources earlier than transaction end.

`RELEASE SAVEPOINT` also destroys all savepoints that were established *after* the named savepoint was established.

## Parameters

savepoint\_name

The name of the savepoint to destroy.

## Examples

To establish and later destroy a savepoint:

```
BEGIN;
  INSERT INTO table1 VALUES (3);
  SAVEPOINT my_savepoint;
  INSERT INTO table1 VALUES (4);
  RELEASE SAVEPOINT my_savepoint;
COMMIT;
```

The above transaction will insert both 3 and 4.

## Compatibility

This command conforms to the SQL standard. The standard specifies that the key word `SAVEPOINT` is mandatory, but Greenplum Database allows it to be omitted.

## See Also

[BEGIN](#), [SAVEPOINT](#), [ROLLBACK TO SAVEPOINT](#), [COMMIT](#)

Parent topic: [SQL Commands](#)

## RESET

Restores the value of a system configuration parameter to the default value.

## Synopsis

```
RESET <configuration_parameter>

RESET ALL
```

## Description

`RESET` restores system configuration parameters to their default values. `RESET` is an alternative spelling for `SET configuration\_parameter TO DEFAULT`.

The default value is defined as the value that the parameter would have had, had no `SET` ever been issued for it in the current session. The actual source of this value might be a compiled-in default, the master `postgresql.conf` configuration file, command-line options, or per-database or per-user default settings. See [Server Configuration Parameters](#) for more information.

## Parameters

`configuration\_parameter`

The name of a system configuration parameter. See [Server Configuration Parameters](#) for details.

`ALL`

Resets all settable configuration parameters to their default values.

## Examples

Set the `statement\_mem` configuration parameter to its default value:

```
RESET statement_mem;
```

## Compatibility

`RESET` is a Greenplum Database extension.

## See Also

[SET](#)

Parent topic: [SQL Commands](#)

## RETRIEVE

Retrieves rows from a query using a parallel retrieve cursor.

## Synopsis

```
RETRIEVE { <count> | ALL } FROM ENDPOINT <endpoint_name>
```

## Description

`RETRIEVE` retrieves rows using a previously-created parallel retrieve cursor. You retrieve the rows in individual retrieve sessions, separate direct connections to individual segment endpoints that will serve the results for each individual segment. When you initiate a retrieve session, you must specify `gp_retrieve_conn=true` on the connection request. Because a retrieve session is independent of the parallel retrieve cursors or their corresponding endpoints, you can `RETRIEVE` from multiple endpoints in the same retrieve session.

A parallel retrieve cursor has an associated position, which is used by `RETRIEVE`. The cursor position can be before the first row of the query result, on any particular row of the result, or after the last row of the result.

When it is created, a parallel retrieve cursor is positioned before the first row. After retrieving some rows, the cursor is positioned on the row most recently retrieved.

If `RETRIEVE` runs off the end of the available rows then the cursor is left positioned after the last row.

`RETRIEVE ALL` always leaves the parallel retrieve cursor positioned after the last row.

**Note:** Greenplum Database does not support scrollable cursors; you can only move a cursor forward in position using the `RETRIEVE` command.

### Outputs

On successful completion, a `RETRIEVE` command returns the fetched rows (possibly empty) and a count of the number of rows fetched (possibly zero).

## Parameters

count

Retrieve the next count number of rows. count must be a positive number.

ALL

Retrieve all remaining rows.

endpoint\_name

The name of the endpoint from which to retrieve the rows.

## Notes

Use `DECLARE ... PARALLEL RETRIEVE CURSOR` to define a parallel retrieve cursor.

Parallel retrieve cursors do not support `FETCH` or `MOVE` operations.

## Examples

-- Start the transaction:

```
BEGIN;
```

-- Create a parallel retrieve cursor:

```
DECLARE mycursor PARALLEL RETRIEVE CURSOR FOR SELECT * FROM films;
```

-- List the cursor endpoints:

```
SELECT * FROM gp_endpoints WHERE cursorname='mycursor';
```

-- Note the hostname, port, auth\_token, and name associated with each endpoint.

-- In another terminal window, initiate a retrieve session using a hostname, port, and auth\_token returned from the previous query. For example:

```
PGPASSWORD=d3825fc07e56bee5fcd2b1d0b600c85e PGOPTIONS='-c gp_retrieve_conn=true' psql
-d testdb -h sdw3 -p 6001;
```

-- Fetch all rows from an endpoint (for example, the endpoint named `prc10000001100000005`):

```
RETRIEVE ALL FROM ENDPOINT prc10000001100000005;
```

-- Exit the retrieve session

-- Back in the original session, close the cursor and end the transaction:

```
CLOSE mycursor;
COMMIT;
```

## Compatibility

`RETRIEVE` is a Greenplum Database extension. The SQL standard makes no provisions for parallel retrieve cursors.

ON TYPE <type_name> [, ...]

```

```

FROM { [ GROUP ] <role_name> | PUBLIC } [, ...]
[ CASCADE | RESTRICT ]

REVOKE [ADMIN OPTION FOR] <parent_role> [, ...]
FROM [ GROUP ] <member_role> [, ...]
[CASCADE | RESTRICT]

```

## Description

**REVOKE** command revokes previously granted privileges from one or more roles. The key word **PUBLIC** refers to the implicitly defined group of all roles.

See the description of the **GRANT** command for the meaning of the privilege types.

Note that any particular role will have the sum of privileges granted directly to it, privileges granted to any role it is presently a member of, and privileges granted to **PUBLIC**. Thus, for example, revoking **SELECT** privilege from **PUBLIC** does not necessarily mean that all roles have lost **SELECT** privilege on the object: those who have it granted directly or via another role will still have it. Similarly, revoking **SELECT** from a user might not prevent that user from using **SELECT** if **PUBLIC** or another membership role still has **SELECT** rights.

If **GRANT OPTION FOR** is specified, only the grant option for the privilege is revoked, not the privilege itself. Otherwise, both the privilege and the grant option are revoked.

If a role holds a privilege with grant option and has granted it to other roles then the privileges held by those other roles are called dependent privileges. If the privilege or the grant option held by the first role is being revoked and dependent privileges exist, those dependent privileges are also revoked if **CASCADE** is specified, else the revoke action will fail. This recursive revocation only affects privileges that were granted through a chain of roles that is traceable to the role that is the subject of this **REVOKE** command. Thus, the affected roles may effectively keep the privilege if it was also granted through other roles.

When you revoke privileges on a table, Greenplum Database revokes the corresponding column privileges (if any) on each column of the table, as well. On the other hand, if a role has been granted privileges on a table, then revoking the same privileges from individual columns will have no effect.

When revoking membership in a role, **GRANT OPTION** is instead called **ADMIN OPTION**, but the behavior is similar.

## Parameters

See **GRANT**.

## Notes

A user may revoke only those privileges directly granted by that user. If, for example, user A grants a privilege with grant option to user B, and user B has in turn granted it to user C, then user A cannot revoke the privilege directly from C. Instead, user A could revoke the grant option from user B and use the **CASCADE** option so that the privilege is in turn revoked from user C. For another example, if both A and B grant the same privilege to C, A can revoke their own grant but not B's grant, so C effectively still has the privilege.

When a non-owner of an object attempts to **REVOKE** privileges on the object, the command fails outright if the user has no privileges whatsoever on the object. As long as some privilege is available, the command proceeds, but it will revoke only those privileges for which the user has grant options. The **REVOKE ALL PRIVILEGES** forms issue a warning message if no grant options are held, while the other forms issue a warning if grant options for any of the privileges specifically named in the command are not held. (In principle these statements apply to the object owner as well, but since Greenplum Database always treats the owner as holding all grant options, the cases can never occur.)

If a superuser chooses to issue a **GRANT** or **REVOKE** command, Greenplum Database performs the command as though it were issued by the owner of the affected object. Since all privileges ultimately come from the object owner (possibly indirectly via chains of grant options), it is possible for a superuser to revoke all privileges, but this might require use of **CASCADE** as stated above.

**REVOKE** may also be invoked by a role that is not the owner of the affected object, but is a member of the role that owns the object, or is a member of a role that holds privileges **WITH GRANT OPTION** on the object. In this case, Greenplum Database performs the command as though it were issued by the containing role that actually owns the object or holds the privileges **WITH GRANT OPTION**. For example, if table `t1` is owned by role `g1`, of which role `u1` is a member, then `u1` can revoke privileges on `t1` that are recorded as being granted by `g1`. This includes grants made by `u1` as well as by other members of role `g1`.

If the role that runs **REVOKE** holds privileges indirectly via more than one role membership path, it is unspecified which containing role will be used to perform the command. In such cases it is best practice to use **SET ROLE** to become the specific role as which you want to do the **REVOKE**. Failure to do so may lead to revoking privileges other than the ones you intended, or not revoking any privileges at all.

Use `psql`'s `\dp` meta-command to obtain information about existing privileges for tables and columns. There are other `\d` meta-commands that you can use to display the privileges of non-table objects.

## Examples

Revoke insert privilege for the public on table `films`:

```
REVOKE INSERT ON films FROM PUBLIC;
```

Revoke all privileges from role `sally` on view `topten`. Note that this actually means revoke all privileges that the current role granted (if not a superuser).

```
REVOKE ALL PRIVILEGES ON topten FROM sally;
```

Revoke membership in role `admins` from user `joe`:

```
REVOKE admins FROM joe;
```

## Compatibility

The compatibility notes of the **GRANT** command also apply to **REVOKE**.

Either `RESTRICT` or `CASCADE` is required according to the standard, but Greenplum Database assumes `RESTRICT` by default.

## See Also

[GRANT](#)

Parent topic: [SQL Commands](#)

## ROLLBACK

Stops the current transaction.

## Synopsis

```
ROLLBACK [WORK | TRANSACTION]
```

## Description

`ROLLBACK` rolls back the current transaction and causes all the updates made by the transaction to be discarded.

## Parameters

`WORK`

`TRANSACTION`

Optional key words. They have no effect.

## Notes

Use `COMMIT` to successfully end the current transaction.

Issuing `ROLLBACK` when not inside a transaction does no harm, but it will provoke a warning message.

## Examples

To discard all changes made in the current transaction:

```
ROLLBACK;
```

## Compatibility

The SQL standard only specifies the two forms `ROLLBACK` and `ROLLBACK WORK`. Otherwise, this command is fully conforming.

## See Also

[BEGIN](#), [COMMIT](#), [SAVEPOINT](#), [ROLLBACK TO SAVEPOINT](#)

Parent topic: [SQL Commands](#)

## ROLLBACK TO SAVEPOINT

Rolls back the current transaction to a savepoint.

### Synopsis

```
ROLLBACK [WORK | TRANSACTION] TO [SAVEPOINT] <savepoint_name>
```

### Description

This command will roll back all commands that were run after the savepoint was established. The savepoint remains valid and can be rolled back to again later, if needed.

`ROLLBACK TO SAVEPOINT` implicitly destroys all savepoints that were established after the named savepoint.

### Parameters

WORK

TRANSACTION

Optional key words. They have no effect.

savepoint\_name

The name of a savepoint to roll back to.

### Notes

Use `RELEASE SAVEPOINT` to destroy a savepoint without discarding the effects of commands run after it was established.

Specifying a savepoint name that has not been established is an error.

Cursors have somewhat non-transactional behavior with respect to savepoints. Any cursor that is opened inside a savepoint will be closed when the savepoint is rolled back. If a previously opened cursor is affected by a `FETCH` command inside a savepoint that is later rolled back, the cursor remains at the position that `FETCH` left it pointing to (that is, cursor motion caused by `FETCH` is not rolled back). Closing a cursor is not undone by rolling back, either. However, other side-effects caused by the cursor's query (such as side-effects of volatile functions called by the query) are rolled back if they occur during a savepoint that is later rolled back. A cursor whose execution causes a transaction to end prematurely is put in a cannot-execute state, so while the transaction can be restored using `ROLLBACK TO SAVEPOINT`, the cursor can no longer be used.

### Examples

To undo the effects of the commands run after `my_savepoint` was established:

```
ROLLBACK TO SAVEPOINT my_savepoint;
```

Cursor positions are not affected by a savepoint rollback:

```
BEGIN;
DECLARE foo CURSOR FOR SELECT 1 UNION SELECT 2;
SAVEPOINT foo;
FETCH 1 FROM foo;
column
-----
          1
ROLLBACK TO SAVEPOINT foo;
FETCH 1 FROM foo;
column
-----
          2
COMMIT;
```

## Compatibility

The SQL standard specifies that the key word `SAVEPOINT` is mandatory, but Greenplum Database (and Oracle) allow it to be omitted. SQL allows only `WORK`, not `TRANSACTION`, as a noise word after `ROLLBACK`. Also, SQL has an optional clause `AND [NO] CHAIN` which is not currently supported by Greenplum Database. Otherwise, this command conforms to the SQL standard.

## See Also

[BEGIN](#), [COMMIT](#), [SAVEPOINT](#), [RELEASE SAVEPOINT](#), [ROLLBACK](#)

Parent topic: [SQL Commands](#)

## SAVEPOINT

Defines a new savepoint within the current transaction.

## Synopsis

```
SAVEPOINT <savepoint_name>
```

## Description

`SAVEPOINT` establishes a new savepoint within the current transaction.

A savepoint is a special mark inside a transaction that allows all commands that are run after it was established to be rolled back, restoring the transaction state to what it was at the time of the savepoint.

## Parameters

savepoint\_name

The name of the new savepoint.

## Notes

Use [ROLLBACK TO SAVEPOINT](#) to rollback to a savepoint. Use [RELEASE SAVEPOINT](#) to destroy a savepoint, keeping the effects of commands run after it was established.

Savepoints can only be established when inside a transaction block. There can be multiple savepoints defined within a transaction.

## Examples

To establish a savepoint and later undo the effects of all commands run after it was established:

```
BEGIN;
  INSERT INTO table1 VALUES (1);
  SAVEPOINT my_savepoint;
  INSERT INTO table1 VALUES (2);
  ROLLBACK TO SAVEPOINT my_savepoint;
  INSERT INTO table1 VALUES (3);
COMMIT;
```

The above transaction will insert the values 1 and 3, but not 2.

To establish and later destroy a savepoint:

```
BEGIN;
  INSERT INTO table1 VALUES (3);
  SAVEPOINT my_savepoint;
  INSERT INTO table1 VALUES (4);
  RELEASE SAVEPOINT my_savepoint;
COMMIT;
```

The above transaction will insert both 3 and 4.

## Compatibility

SQL requires a savepoint to be destroyed automatically when another savepoint with the same name is established. In Greenplum Database, the old savepoint is kept, though only the more recent one will be used when rolling back or releasing. (Releasing the newer savepoint will cause the older one to again become accessible to [ROLLBACK TO SAVEPOINT](#) and [RELEASE SAVEPOINT](#).) Otherwise, [SAVEPOINT](#) is fully SQL conforming.

  [ ON <join_condition> | USING ( <join_column> [, ...] ) ]
```

where `grouping_element` can be one of:

```
()
<expression>
ROLLUP (<expression> [,...])
CUBE (<expression> [,...])
GROUPING SETS ((<grouping_element> [, ...]))
```

where `window_definition` is:

```
[<existing_window_name>]
[PARTITION BY <expression> [, ...]]
[ORDER BY <expression> [ASC | DESC | USING <operator>]
```

```
[NULLS {FIRST | LAST}] [, ...]
[ { RANGE | ROWS } <frame_start>
  | { RANGE | ROWS } BETWEEN <frame_start> AND <frame_end>
```

where `frame_start` and `frame_end` can be one of:

```
UNBOUNDED PRECEDING
<value> PRECEDING
CURRENT ROW
<value> FOLLOWING
UNBOUNDED FOLLOWING
```

<sup>2</sup>When a locking clause is specified (the `FOR` clause), the Global Deadlock Detector affects how table rows are locked. See item 12 in Description and see "The Locking Clause" later in this section.

## Description

`SELECT` retrieves rows from zero or more tables. The general processing of `SELECT` is as follows:

1. All queries in the `WITH` clause are computed. These effectively serve as temporary tables that can be referenced in the `FROM` list.
2. All elements in the `FROM` list are computed. (Each element in the `FROM` list is a real or virtual table.) If more than one element is specified in the `FROM` list, they are cross-joined together.
3. If the `WHERE` clause is specified, all rows that do not satisfy the condition are eliminated from the output.
4. If the `GROUP BY` clause is specified, or if there are aggregate function calls, the output is combined into groups of rows that match on one or more values, and the results of aggregate functions are computed. If the `HAVING` clause is present, it eliminates groups that do not satisfy the given condition.
5. The actual output rows are computed using the `SELECT` output expressions for each selected row or row group.
6. `SELECT DISTINCT` eliminates duplicate rows from the result. `SELECT DISTINCT ON` eliminates rows that match on all the specified expressions. `SELECT ALL` (the default) will return all candidate rows, including duplicates.
7. If a window expression is specified (and optional `WINDOW` clause), the output is organized according to the positional (row) or value-based (range) window frame.
8. The actual output rows are computed using the `SELECT` output expressions for each selected row.
9. Using the operators `UNION`, `INTERSECT`, and `EXCEPT`, the output of more than one `SELECT` statement can be combined to form a single result set. The `UNION` operator returns all rows that are in one or both of the result sets. The `INTERSECT` operator returns all rows that are strictly in both result sets. The `EXCEPT` operator returns the rows that are in the first result set but not in the second. In all three cases, duplicate rows are eliminated unless `ALL` is specified. The noise word `DISTINCT` can be added to explicitly specify eliminating duplicate

rows. Notice that `DISTINCT` is the default behavior here, even though `ALL` is the default for `SELECT` itself.

10. If the `ORDER BY` clause is specified, the returned rows are sorted in the specified order. If `ORDER BY` is not given, the rows are returned in whatever order the system finds fastest to produce.
11. If the `LIMIT` (or `FETCH FIRST`) or `OFFSET` clause is specified, the `SELECT` statement only returns a subset of the result rows.
12. If `FOR UPDATE`, `FOR NO KEY UPDATE`, `FOR SHARE`, or `FOR KEY SHARE` is specified, the `SELECT` statement locks the entire table against concurrent updates.

You must have `SELECT` privilege on each column used in a `SELECT` command. The use of `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, or `FOR KEY SHARE` requires `UPDATE` privilege as well (for at least one column of each table so selected).

## Parameters

### The WITH Clause

The optional `WITH` clause allows you to specify one or more subqueries that can be referenced by name in the primary query. The subqueries effectively act as temporary tables or views for the duration of the primary query. Each subquery can be a `SELECT`, `INSERT`, `UPDATE`, or `DELETE` statement. When writing a data-modifying statement (`INSERT`, `UPDATE`, or `DELETE`) in `WITH`, it is usual to include a `RETURNING` clause. It is the output of `RETURNING`, *not* the underlying table that the statement modifies, that forms the temporary table that is read by the primary query. If `RETURNING` is omitted, the statement is still run, but it produces no output so it cannot be referenced as a table by the primary query.

For a `SELECT` command that includes a `WITH` clause, the clause can contain at most a single clause that modifies table data (`INSERT`, `UPDATE` or `DELETE` command).

A `with_query_name` without schema qualification must be specified for each query in the `WITH` clause. Optionally, a list of column names can be specified; if the list of column names is omitted, the names are inferred from the subquery. The primary query and the `WITH` queries are all (notionally) run at the same time.

If `RECURSIVE` is specified, it allows a `SELECT` subquery to reference itself by name. Such a subquery has the general form

```
<non_recursive_term> UNION [ALL | DISTINCT] <recursive_term>
```

where the recursive self-reference appears on the right-hand side of the `UNION`. Only one recursive self-reference is permitted per query. Recursive data-modifying statements are not supported, but you can use the results of a recursive `SELECT` query in a data-modifying statement.

If the `RECURSIVE` keyword is specified, the `WITH` queries need not be ordered: a query can reference another query that is later in the list. However, circular references, or mutual recursion, are not supported.

Without the `RECURSIVE` keyword, `WITH` queries can only reference sibling `WITH` queries that are earlier in the `WITH` list.

**WITH RECURSIVE** limitations. These items are not supported:

- A recursive **WITH** clause that contains the following in the recursive\_term.
  - Subqueries with a self-reference
  - **DISTINCT** clause
  - **GROUP BY** clause
  - A window function
- A recursive **WITH** clause where the with\_query\_name is a part of a set operation.

Following is an example of the set operation limitation. This query returns an error because the set operation **UNION** contains a reference to the table `foo`.

```
WITH RECURSIVE foo(i) AS (
  SELECT 1
  UNION ALL
  SELECT i+1 FROM (SELECT * FROM foo UNION SELECT 0) bar
)
SELECT * FROM foo LIMIT 5;
```

This recursive CTE is allowed because the set operation **UNION** does not have a reference to the CTE `foo`.

```
WITH RECURSIVE foo(i) AS (
  SELECT 1
  UNION ALL
  SELECT i+1 FROM (SELECT * FROM bar UNION SELECT 0) bar, foo
  WHERE foo.i = bar.a
)
SELECT * FROM foo LIMIT 5;
```

A key property of **WITH** queries is that they are evaluated only once per execution of the primary query, even if the primary query refers to them more than once. In particular, data-modifying statements are guaranteed to be run once and only once, regardless of whether the primary query reads all or any of their output.

The primary query and the **WITH** queries are all (notionally) run at the same time. This implies that the effects of a data-modifying statement in **WITH** cannot be seen from other parts of the query, other than by reading its **RETURNING** output. If two such data-modifying statements attempt to modify the same row, the results are unspecified.

See [WITH Queries \(Common Table Expressions\)](#) in the *Greenplum Database Administrator Guide* for additional information.

## The SELECT List

The **SELECT** list (between the key words **SELECT** and **FROM**) specifies expressions that form the output rows of the **SELECT** statement. The expressions can (and usually do) refer to columns computed in the **FROM** clause.

An expression in the **SELECT** list can be a constant value, a column reference, an operator invocation, a function call, an aggregate expression, a window expression, a scalar subquery, and so on. A number of constructs can be classified as an expression but do not follow any general syntax rules. These generally have the semantics of a function or operator. For information about SQL

value expressions and function calls, see "Querying Data" in the *Greenplum Database Administrator Guide*.

Just as in a table, every output column of a `SELECT` has a name. In a simple `SELECT` this name is just used to label the column for display, but when the `SELECT` is a sub-query of a larger query, the name is seen by the larger query as the column name of the virtual table produced by the sub-query. To specify the name to use for an output column, write `AS output_name` after the column's expression. (You can omit `AS`, but only if the desired output name does not match any SQL keyword. For protection against possible future keyword additions, you can always either write `AS` or double-quote the output name.) If you do not specify a column name, Greenplum Database chooses a name automatically. If the column's expression is a simple column reference then the chosen name is the same as that column's name. In more complex cases, a function or type name may be used, or the system may fall back on a generated name such as `?column?` or `columnN`.

An output column's name can be used to refer to the column's value in `ORDER BY` and `GROUP BY` clauses, but not in the `WHERE` or `HAVING` clauses; there you must write out the expression instead.

Instead of an expression, `*` can be written in the output list as a shorthand for all the columns of the selected rows. Also, you can write `table_name.*` as a shorthand for the columns coming from just that table. In these cases it is not possible to specify new names with `AS`; the output column names will be the same as the table columns' names.

### The DISTINCT Clause

If `SELECT DISTINCT` is specified, all duplicate rows are removed from the result set (one row is kept from each group of duplicates). `SELECT ALL` specifies the opposite: all rows are kept; that is the default.

`SELECT DISTINCT ON ( expression [, ...] )` keeps only the first row of each set of rows where the given expressions evaluate to equal. The `DISTINCT ON` expressions are interpreted using the same rules as for `ORDER BY` (see above). Note that the "first row" of each set is unpredictable unless `ORDER BY` is used to ensure that the desired row appears first. For example:

```
SELECT DISTINCT ON (location) location, time, report
FROM weather_reports
ORDER BY location, time DESC;
```

retrieves the most recent weather report for each location. But if we had not used `ORDER BY` to force descending order of time values for each location, we'd have gotten a report from an unpredictable time for each location.

The `DISTINCT ON` expression(s) must match the leftmost `ORDER BY` expression(s). The `ORDER BY` clause will normally contain additional expression(s) that determine the desired precedence of rows within each `DISTINCT ON` group.

### The FROM Clause

The `FROM` clause specifies one or more source tables for the `SELECT`. If multiple sources are specified, the result is the Cartesian product (cross join) of all the sources. But usually qualification conditions are added (via `WHERE`) to restrict the returned rows to a small subset of the Cartesian product. The `FROM` clause can contain the following elements:

**table\_name**

The name (optionally schema-qualified) of an existing table or view. If **ONLY** is specified, only that table is scanned. If **ONLY** is not specified, the table and all its descendant tables (if any) are scanned.

**alias**

A substitute name for the **FROM** item containing the alias. An alias is used for brevity or to eliminate ambiguity for self-joins (where the same table is scanned multiple times). When an alias is provided, it completely hides the actual name of the table or function; for example given **FROM foo AS f**, the remainder of the **SELECT** must refer to this **FROM** item as **f** not **foo**. If an alias is written, a column alias list can also be written to provide substitute names for one or more columns of the table.

**select**

A sub-**SELECT** can appear in the **FROM** clause. This acts as though its output were created as a temporary table for the duration of this single **SELECT** command. Note that the sub-**SELECT** must be surrounded by parentheses, and an alias must be provided for it. A **VALUES** command can also be used here. See "Non-standard Clauses" in the [Compatibility](#) section for limitations of using correlated sub-selects in Greenplum Database.

**with\_query\_name**

A **with\_query** is referenced in the **FROM** clause by specifying its **with\_query\_name**, just as though the name were a table name. The **with\_query\_name** cannot contain a schema qualifier. An alias can be provided in the same way as for a table.

The **with\_query** hides a table of the same name for the purposes of the primary query. If necessary, you can refer to a table of the same name by qualifying the table name with the schema.

**function\_name**

Function calls can appear in the **FROM** clause. (This is especially useful for functions that return result sets, but any function can be used.) This acts as though its output were created as a temporary table for the duration of this single **SELECT** command. An alias may also be used. If an alias is written, a column alias list can also be written to provide substitute names for one or more attributes of the function's composite return type. If the function has been defined as returning the record data type, then an alias or the key word **AS** must be present, followed by a column definition list in the form ( **column\_name data\_type [, ... ]** ). The column definition list must match the actual number and types of columns returned by the function.

**join\_type**

One of:

- **[INNER] JOIN**
- **LEFT [OUTER] JOIN**
- **RIGHT [OUTER] JOIN**
- **FULL [OUTER] JOIN**
- **CROSS JOIN**

For the **INNER** and **OUTER** join types, a join condition must be specified, namely exactly one of **NATURAL**, **ON join\_condition**, or **USING ( join\_column [, ... ] )**. See below for the meaning. For **CROSS JOIN**, none of these clauses may appear.

A JOIN clause combines two FROM items, which for convenience we will refer to as "tables", though in reality they can be any type of FROM item. Use parentheses if necessary to determine the order of nesting. In the absence of parentheses, JOINS nest left-to-right. In any case JOIN binds more tightly than the commas separating FROM-list items.

CROSS JOIN and INNER JOIN produce a simple Cartesian product, the same result as you get from listing the two tables at the top level of FROM, but restricted by the join condition (if any). CROSS JOIN is equivalent to INNER JOIN ON `` (TRUE), that is, no rows are removed by qualification. These join types are just a notational convenience, since they do nothing you could not do with plain FROM and WHERE.

LEFT OUTER JOIN returns all rows in the qualified Cartesian product (i.e., all combined rows that pass its join condition), plus one copy of each row in the left-hand table for which there was no right-hand row that passed the join condition. This left-hand row is extended to the full width of the joined table by inserting null values for the right-hand columns. Note that only the JOIN clause's own condition is considered while deciding which rows have matches. Outer conditions are applied afterwards.

Conversely, RIGHT OUTER JOIN returns all the joined rows, plus one row for each unmatched right-hand row (extended with nulls on the left). This is just a notational convenience, since you could convert it to a LEFT OUTER JOIN by switching the left and right tables.

FULL OUTER JOIN returns all the joined rows, plus one row for each unmatched left-hand row (extended with nulls on the right), plus one row for each unmatched right-hand row (extended with nulls on the left).

ON join\_condition

join\_condition is an expression resulting in a value of type boolean (similar to a WHERE clause) that specifies which rows in a join are considered to match.

USING (join\_column [, ...])

A clause of the form USING ( a, b, ... ) is shorthand for ON left\_table.a = right\_table.a AND left\_table.b = right\_table.b .... Also, USING implies that only one of each pair of equivalent columns will be included in the join output, not both.

NATURAL

NATURAL is shorthand for a USING list that mentions all columns in the two tables that have the same names. If there are no common column names, NATURAL is equivalent to ON TRUE.

## The WHERE Clause

The optional WHERE clause has the general form:

```
WHERE <condition>
```

where condition is any expression that evaluates to a result of type boolean. Any row that does not satisfy this condition will be eliminated from the output. A row satisfies the condition if it returns true when the actual row values are substituted for any variable references.

## The GROUP BY Clause

The optional GROUP BY clause has the general form:

```
GROUP BY <grouping_element >[, ...]
```

where grouping\_element can be one of:

```
(
<expression>
ROLLUP (<expression> [,...])
CUBE (<expression> [,...])
GROUPING SETS ((<grouping_element> [, ...]))
```

**GROUP BY** will condense into a single row all selected rows that share the same values for the grouped expressions. **expression** can be an input column name, or the name or ordinal number of an output column (**SELECT** list item), or an arbitrary expression formed from input-column values. In case of ambiguity, a **GROUP BY** name will be interpreted as an input-column name rather than an output column name.

Aggregate functions, if any are used, are computed across all rows making up each group, producing a separate value for each group. (If there are aggregate functions but no **GROUP BY** clause, the query is treated as having a single group comprising all the selected rows.) The set of rows fed to each aggregate function can be further filtered by attaching a **FILTER** clause to the aggregate function call. When a **FILTER** clause is present, only those rows matching it are included in the input to that aggregate function. See [Aggregate Expressions](#).

When **GROUP BY** is present, or any aggregate functions are present, it is not valid for the **SELECT** list expressions to refer to ungrouped columns except within aggregate functions or when the ungrouped column is functionally dependent on the grouped columns, since there would otherwise be more than one possible value to return for an ungrouped column. A functional dependency exists if the grouped columns (or a subset thereof) are the primary key of the table containing the ungrouped column.

Keep in mind that all aggregate functions are evaluated before evaluating any "scalar" expressions in the **HAVING** clause or **SELECT** list. This means that, for example, a **CASE** expression cannot be used to skip evaluation of an aggregate function; see [Expression Evaluation Rules](#).

Greenplum Database has the following additional OLAP grouping extensions (often referred to as *supergroups*):

## ROLLUP

A **ROLLUP** grouping is an extension to the **GROUP BY** clause that creates aggregate subtotals that roll up from the most detailed level to a grand total, following a list of grouping columns (or expressions). **ROLLUP** takes an ordered list of grouping columns, calculates the standard aggregate values specified in the **GROUP BY** clause, then creates progressively higher-level subtotals, moving from right to left through the list. Finally, it creates a grand total. A **ROLLUP** grouping can be thought of as a series of grouping sets. For example:

```
GROUP BY ROLLUP (a,b,c)
```

is equivalent to:

```
GROUP BY GROUPING SETS( (a,b,c), (a,b), (a), () )
```

Notice that the  $n$  elements of a **ROLLUP** translate to  $n+1$  grouping sets. Also, the order in which the grouping expressions are specified is significant in a **ROLLUP**.

## CUBE

A **CUBE** grouping is an extension to the **GROUP BY** clause that creates subtotals for all of the possible combinations of the given list of grouping columns (or expressions). In terms of multidimensional analysis, **CUBE** generates all the subtotals that could be calculated for a data cube with the specified dimensions. For example:

```
GROUP BY CUBE (a,b,c)
```

is equivalent to:

```
GROUP BY GROUPING SETS( (a,b,c), (a,b), (a,c), (b,c), (a),
(b), (c), () )
```

Notice that  $n$  elements of a **CUBE** translate to  $2^n$  grouping sets. Consider using **CUBE** in any situation requiring cross-tabular reports. **CUBE** is typically most suitable in queries that use columns from multiple dimensions rather than columns representing different levels of a single dimension. For instance, a commonly requested cross-tabulation might need subtotals for all the combinations of month, state, and product.

## GROUPING SETS

You can selectively specify the set of groups that you want to create using a **GROUPING SETS** expression within a **GROUP BY** clause. This allows precise specification across multiple dimensions without computing a whole **ROLLUP** or **CUBE**. For example:

```
GROUP BY GROUPING SETS( (a,c), (a,b) )
```

If using the grouping extension clauses **ROLLUP**, **CUBE**, or **GROUPING SETS**, two challenges arise. First, how do you determine which result rows are subtotals, and then the exact level of aggregation for a given subtotal. Or, how do you differentiate between result rows that contain both stored **NULL** values and "NULL" values created by the **ROLLUP** or **CUBE**. Secondly, when duplicate grouping sets are specified in the **GROUP BY** clause, how do you determine which result rows are duplicates? There are two additional grouping functions you can use in the **SELECT** list to help with this:

- **grouping(column [, ...])** — The **grouping** function can be applied to one or more grouping attributes to distinguish super-aggregated rows from regular grouped rows. This can be helpful in distinguishing a "NULL" representing the set of all values in a super-aggregated row from a **NULL** value in a regular row. Each argument in this function produces a bit — either **1** or **0**, where **1** means the result row is super-aggregated, and **0** means the result row is from a regular grouping. The **grouping** function returns an integer by treating these bits as a binary number and then converting it to a base-10 integer.
- **group\_id()** — For grouping extension queries that contain duplicate grouping sets, the **group\_id** function is used to identify duplicate rows in the output. All *unique* grouping set output rows will have a **group\_id** value of **0**. For each duplicate grouping set detected, the **group\_id** function assigns a **group\_id** number greater than **0**. All output rows in a particular duplicate grouping set are identified by the same **group\_id** number.

## The WINDOW Clause

The optional **WINDOW** clause specifies the behavior of window functions appearing in the query's **SELECT** list or **ORDER BY** clause. These functions can reference the **WINDOW** clause entries by name in their **OVER** clauses. A **WINDOW** clause entry does not have to be referenced anywhere, however; if it

is not used in the query it is simply ignored. It is possible to use window functions without any `WINDOW` clause at all, since a window function call can specify its window definition directly in its `OVER` clause. However, the `WINDOW` clause saves typing when the same window definition is needed for more than one window function.

For example:

```
SELECT vendor, rank() OVER (mywindow) FROM sale
GROUP BY vendor
WINDOW mywindow AS (ORDER BY sum(prc*qty));
```

A `WINDOW` clause has this general form:

```
WINDOW <window_name> AS (<window_definition>)
```

where `window_name` is a name that can be referenced from `OVER` clauses or subsequent window definitions, and `window_definition` is:

```
[<existing_window_name>]
[PARTITION BY <expression> [, ...]]
[ORDER BY <expression> [ASC | DESC | USING <operator>] [NULLS {FIRST | LAST}] [, ...]
]
[<frame_clause>]
```

#### existing\_window\_name

If an `existing\_window\_name` is specified it must refer to an earlier entry in the `WINDOW` list; the new window copies its partitioning clause from that entry, as well as its ordering clause if any. The new window cannot specify its own `PARTITION BY` clause, and it can specify `ORDER BY` only if the copied window does not have one. The new window always uses its own frame clause; the copied window must not specify a frame clause.

#### PARTITION BY

The `PARTITION BY` clause organizes the result set into logical groups based on the unique values of the specified expression. The elements of the `PARTITION BY` clause are interpreted in much the same fashion as elements of a `GROUP BY` clause, except that they are always simple expressions and never the name or number of an output column. Another difference is that these expressions can contain aggregate function calls, which are not allowed in a regular `GROUP BY` clause. They are allowed here because windowing occurs after grouping and aggregation. When used with window functions, the functions are applied to each partition independently. For example, if you follow `PARTITION BY` with a column name, the result set is partitioned by the distinct values of that column. If omitted, the entire result set is considered one partition.

Similarly, the elements of the `ORDER BY` list are interpreted in much the same fashion as elements of an `ORDER BY` clause, except that the expressions are always taken as simple expressions and never the name or number of an output column.

#### ORDER BY

The elements of the `ORDER BY` clause define how to sort the rows in each partition of the result set. If omitted, rows are returned in whatever order is most efficient and may vary.

**Note:** Columns of data types that lack a coherent ordering, such as `time`, are not good candidates for use in the `ORDER BY` clause of a window specification. Time, with or without

time zone, lacks a coherent ordering because addition and subtraction do not have the expected effects. For example, the following is not generally true: `x::time < x::time + '2 hour'::interval`

#### frame\_clause

The optional `frame_clause` defines the *window frame* for window functions that depend on the frame (not all do). The window frame is a set of related rows for each row of the query (called the *current row*). The `frame_clause` can be one of

```
{ RANGE | ROWS } <frame_start>
{ RANGE | ROWS } BETWEEN <frame_start> AND <frame_end>
```

where `frame_start` and `frame_end` can be one of

- UNBOUNDED PRECEDING
- value PRECEDING
- CURRENT ROW
- value FOLLOWING
- UNBOUNDED FOLLOWING

If `frame_end` is omitted it defaults to `CURRENT ROW`. Restrictions are that `frame_start` cannot be `UNBOUNDED FOLLOWING`, `frame_end` cannot be `UNBOUNDED PRECEDING`, and the `frame_end` choice cannot appear earlier in the above list than the `frame_start` choice — for example `RANGE BETWEEN CURRENT ROW AND value PRECEDING` is not allowed.

The default framing option is `RANGE UNBOUNDED PRECEDING`, which is the same as `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`; it sets the frame to be all rows from the partition start up through the current row's last peer (a row that `ORDER BY` considers equivalent to the current row, or all rows if there is no `ORDER BY`). In general, `UNBOUNDED PRECEDING` means that the frame starts with the first row of the partition, and similarly `UNBOUNDED FOLLOWING` means that the frame ends with the last row of the partition (regardless of `RANGE` or `ROWS` mode). In `ROWS` mode, `CURRENT ROW` means that the frame starts or ends with the current row; but in `RANGE` mode it means that the frame starts or ends with the current row's first or last peer in the `ORDER BY` ordering. The value `PRECEDING` and value `FOLLOWING` cases are currently only allowed in `ROWS` mode. They indicate that the frame starts or ends with the row that many rows before or after the current row. value must be an integer expression not containing any variables, aggregate functions, or window functions. The value must not be null or negative; but it can be zero, which selects the current row itself.

Beware that the `ROWS` options can produce unpredictable results if the `ORDER BY` ordering does not order the rows uniquely. The `RANGE` options are designed to ensure that rows that are peers in the `ORDER BY` ordering are treated alike; all peer rows will be in the same frame.

Use either a `ROWS` or `RANGE` clause to express the bounds of the window. The window bound can be one, many, or all rows of a partition. You can express the bound of the window either in terms of a range of data values offset from the value in the current row (`RANGE`), or in terms of the number of rows offset from the current row (`ROWS`). When using the `RANGE` clause, you must also use an `ORDER BY` clause. This is because the calculation performed to produce the window requires that the values be sorted. Additionally, the `ORDER BY` clause cannot contain more than one expression, and the expression must result in either a date or a numeric

value. When using the `ROWS` or `RANGE` clauses, if you specify only a starting row, the current row is used as the last row in the window.

**PRECEDING** — The `PRECEDING` clause defines the first row of the window using the current row as a reference point. The starting row is expressed in terms of the number of rows preceding the current row. For example, in the case of `ROWS` framing, `5 PRECEDING` sets the window to start with the fifth row preceding the current row. In the case of `RANGE` framing, it sets the window to start with the first row whose ordering column value precedes that of the current row by 5 in the given order. If the specified order is ascending by date, this will be the first row within 5 days before the current row. `UNBOUNDED PRECEDING` sets the first row in the window to be the first row in the partition.

**BETWEEN** — The `BETWEEN` clause defines the first and last row of the window, using the current row as a reference point. First and last rows are expressed in terms of the number of rows preceding and following the current row, respectively. For example, `BETWEEN 3 PRECEDING AND 5 FOLLOWING` sets the window to start with the third row preceding the current row, and end with the fifth row following the current row. Use `BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING` to set the first and last rows in the window to be the first and last row in the partition, respectively. This is equivalent to the default behavior if no `ROW` or `RANGE` clause is specified.

**FOLLOWING** — The `FOLLOWING` clause defines the last row of the window using the current row as a reference point. The last row is expressed in terms of the number of rows following the current row. For example, in the case of `ROWS` framing, `5 FOLLOWING` sets the window to end with the fifth row following the current row. In the case of `RANGE` framing, it sets the window to end with the last row whose ordering column value follows that of the current row by 5 in the given order. If the specified order is ascending by date, this will be the last row within 5 days after the current row. Use `UNBOUNDED FOLLOWING` to set the last row in the window to be the last row in the partition.

If you do not specify a `ROW` or a `RANGE` clause, the window bound starts with the first row in the partition (`UNBOUNDED PRECEDING`) and ends with the current row (`CURRENT ROW`) if `ORDER BY` is used. If an `ORDER BY` is not specified, the window starts with the first row in the partition (`UNBOUNDED PRECEDING`) and ends with last row in the partition (`UNBOUNDED FOLLOWING`).

## The HAVING Clause

The optional `HAVING` clause has the general form:

```
HAVING <condition>
```

where condition is the same as specified for the `WHERE` clause. `HAVING` eliminates group rows that do not satisfy the condition. `HAVING` is different from `WHERE`: `WHERE` filters individual rows before the application of `GROUP BY`, while `HAVING` filters group rows created by `GROUP BY`. Each column referenced in condition must unambiguously reference a grouping column, unless the reference appears within an aggregate function or the ungrouped column is functionally dependent on the grouping columns.

The presence of `HAVING` turns a query into a grouped query even if there is no `GROUP BY` clause. This is the same as what happens when the query contains aggregate functions but no `GROUP BY` clause. All the selected rows are considered to form a single group, and the `SELECT` list and `HAVING` clause

can only reference table columns from within aggregate functions. Such a query will emit a single row if the `HAVING` condition is true, zero rows if it is not true.

## The UNION Clause

The `UNION` clause has this general form:

```
<select_statement> UNION [ALL | DISTINCT] <select_statement>
```

where `select_statement` is any `SELECT` statement without an `ORDER BY`, `LIMIT`, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, or `FOR KEY SHARE` clause. (`ORDER BY` and `LIMIT` can be attached to a subquery expression if it is enclosed in parentheses. Without parentheses, these clauses will be taken to apply to the result of the `UNION`, not to its right-hand input expression.)

The `UNION` operator computes the set union of the rows returned by the involved `SELECT` statements. A row is in the set union of two result sets if it appears in at least one of the result sets. The two `SELECT` statements that represent the direct operands of the `UNION` must produce the same number of columns, and corresponding columns must be of compatible data types.

The result of `UNION` does not contain any duplicate rows unless the `ALL` option is specified. `ALL` prevents elimination of duplicates. (Therefore, `UNION ALL` is usually significantly quicker than `UNION`; use `ALL` when you can.) `DISTINCT` can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple `UNION` operators in the same `SELECT` statement are evaluated left to right, unless otherwise indicated by parentheses.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, and `FOR KEY SHARE` cannot be specified either for a `UNION` result or for any input of a `UNION`.

## The INTERSECT Clause

The `INTERSECT` clause has this general form:

```
<select_statement> INTERSECT [ALL | DISTINCT] <select_statement>
```

where `select_statement` is any `SELECT` statement without an `ORDER BY`, `LIMIT`, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, or `FOR KEY SHARE` clause.

The `INTERSECT` operator computes the set intersection of the rows returned by the involved `SELECT` statements. A row is in the intersection of two result sets if it appears in both result sets.

The result of `INTERSECT` does not contain any duplicate rows unless the `ALL` option is specified. With `ALL`, a row that has  $m$  duplicates in the left table and  $n$  duplicates in the right table will appear  $\min(m, n)$  times in the result set. `DISTINCT` can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple `INTERSECT` operators in the same `SELECT` statement are evaluated left to right, unless parentheses dictate otherwise. `INTERSECT` binds more tightly than `UNION`. That is, `A UNION B INTERSECT C` will be read as `A UNION (B INTERSECT C)`.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, and `FOR KEY SHARE` cannot be specified either for an `INTERSECT` result or for any input of an `INTERSECT`.

## The EXCEPT Clause

The `EXCEPT` clause has this general form:

```
<select_statement> EXCEPT [ALL | DISTINCT] <select_statement>
```

where `select_statement` is any `SELECT` statement without an `ORDER BY`, `LIMIT`, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, or `FOR KEY SHARE` clause.

The `EXCEPT` operator computes the set of rows that are in the result of the left `SELECT` statement but not in the result of the right one.

The result of `EXCEPT` does not contain any duplicate rows unless the `ALL` option is specified. With `ALL`, a row that has  $m$  duplicates in the left table and  $n$  duplicates in the right table will appear  $\max(m-n, 0)$  times in the result set. `DISTINCT` can be written to explicitly specify the default behavior of eliminating duplicate rows.

Multiple `EXCEPT` operators in the same `SELECT` statement are evaluated left to right, unless parentheses dictate otherwise. `EXCEPT` binds at the same level as `UNION`.

Currently, `FOR NO KEY UPDATE`, `FOR UPDATE`, `FOR SHARE`, and `FOR KEY SHARE` cannot be specified either for an `EXCEPT` result or for any input of an `EXCEPT`.

### The `ORDER BY` Clause

The optional `ORDER BY` clause has this general form:

```
ORDER BY <expression> [ASC | DESC | USING <operator>] [NULLS {FIRST | LAST}] [, ...]
```

where `expression` can be the name or ordinal number of an output column (`SELECT` list item), or it can be an arbitrary expression formed from input-column values.

The `ORDER BY` clause causes the result rows to be sorted according to the specified expressions. If two rows are equal according to the left-most expression, they are compared according to the next expression and so on. If they are equal according to all specified expressions, they are returned in an implementation-dependent order.

The ordinal number refers to the ordinal (left-to-right) position of the output column. This feature makes it possible to define an ordering on the basis of a column that does not have a unique name. This is never absolutely necessary because it is always possible to assign a name to an output column using the `AS` clause.

It is also possible to use arbitrary expressions in the `ORDER BY` clause, including columns that do not appear in the `SELECT` output list. Thus the following statement is valid:

```
SELECT name FROM distributors ORDER BY code;
```

A limitation of this feature is that an `ORDER BY` clause applying to the result of a `UNION`, `INTERSECT`, or `EXCEPT` clause may only specify an output column name or number, not an expression.

If an `ORDER BY` expression is a simple name that matches both an output column name and an input column name, `ORDER BY` will interpret it as the output column name. This is the opposite of the choice that `GROUP BY` will make in the same situation. This inconsistency is made to be compatible with the SQL standard.

Optionally one may add the key word `ASC` (ascending) or `DESC` (descending) after any expression in the `ORDER BY` clause. If not specified, `ASC` is assumed by default. Alternatively, a specific ordering

operator name may be specified in the `USING` clause. `ASC` is usually equivalent to `USING <` and `DESC` is usually equivalent to `USING >`. (But the creator of a user-defined data type can define exactly what the default sort ordering is, and it might correspond to operators with other names.)

If `NULLS LAST` is specified, null values sort after all non-null values; if `NULLS FIRST` is specified, null values sort before all non-null values. If neither is specified, the default behavior is `NULLS LAST` when `ASC` is specified or implied, and `NULLS FIRST` when `DESC` is specified (thus, the default is to act as though nulls are larger than non-nulls). When `USING` is specified, the default nulls ordering depends upon whether the operator is a less-than or greater-than operator.

Note that ordering options apply only to the expression they follow; for example `ORDER BY x, y DESC` does not mean the same thing as `ORDER BY x DESC, y DESC`.

Character-string data is sorted according to the locale-specific collation order that was established when the database was created.

Character-string data is sorted according to the collation that applies to the column being sorted. That can be overridden as needed by including a `COLLATE` clause in the expression, for example `ORDER BY mycolumn COLLATE "en_US"`. For information about defining collations, see [CREATE COLLATION](#).

## The LIMIT Clause

The `LIMIT` clause consists of two independent sub-clauses:

```
LIMIT {<count> | ALL}
OFFSET <start>
```

where `count` specifies the maximum number of rows to return, while `start` specifies the number of rows to skip before starting to return rows. When both are specified, `start` rows are skipped before starting to count the `count` rows to be returned.

If the `count` expression evaluates to `NULL`, it is treated as `LIMIT ALL`, that is, no limit. If `start` evaluates to `NULL`, it is treated the same as `OFFSET 0`.

SQL:2008 introduced a different syntax to achieve the same result, which Greenplum Database also supports. It is:

```
OFFSET <start> [ ROW | ROWS ]
      FETCH { FIRST | NEXT } [ <count> ] { ROW | ROWS } ONLY
```

In this syntax, the `start` or `count` value is required by the standard to be a literal constant, a parameter, or a variable name; as a Greenplum Database extension, other expressions are allowed, but will generally need to be enclosed in parentheses to avoid ambiguity. If `count` is omitted in a `FETCH` clause, it defaults to 1. `ROW` and `ROWS` as well as `FIRST` and `NEXT` are noise words that don't influence the effects of these clauses. According to the standard, the `OFFSET` clause must come before the `FETCH` clause if both are present; but Greenplum Database allows either order.

When using `LIMIT`, it is a good idea to use an `ORDER BY` clause that constrains the result rows into a unique order. Otherwise you will get an unpredictable subset of the query's rows — you may be asking for the tenth through twentieth rows, but tenth through twentieth in what ordering? You don't know what ordering unless you specify `ORDER BY`.

The query optimizer takes `LIMIT` into account when generating a query plan, so you are very likely to get different plans (yielding different row orders) depending on what you use for `LIMIT` and `OFFSET`. Thus, using different `LIMIT/OFFSET` values to select different subsets of a query result will give inconsistent results unless you enforce a predictable result ordering with `ORDER BY`. This is not a defect; it is an inherent consequence of the fact that SQL does not promise to deliver the results of a query in any particular order unless `ORDER BY` is used to constrain the order.

## The Locking Clause

`FOR UPDATE`, `FOR NO KEY UPDATE`, `FOR SHARE` and `FOR KEY SHARE` are *locking clauses*; they affect how `SELECT` locks rows as they are obtained from the table.

The locking clause has the general form

```
FOR <lock_strength> [OF <table_name> [ , ... ] ] [ NOWAIT ]
```

where `lock_strength` can be one of

- `FOR UPDATE` - Locks the table with an `EXCLUSIVE` lock.
- `FOR NO KEY UPDATE` - Locks the table with an `EXCLUSIVE` lock.
- `FOR SHARE` - Locks the table with a `ROW SHARE` lock.
- `FOR KEY SHARE` - Locks the table with a `ROW SHARE` lock.

**Note:** By default Greenplum Database acquires the more restrictive `EXCLUSIVE` lock (rather than `ROW EXCLUSIVE` in PostgreSQL) for `UPDATE`, `DELETE`, and `SELECT...FOR UPDATE` operations on heap tables. When the Global Deadlock Detector is enabled the lock mode for `UPDATE` and `DELETE` operations on heap tables is `ROW EXCLUSIVE`. See [Global Deadlock Detector](#). Greenplum always holds a table-level lock with `SELECT...FOR UPDATE` statements.

For more information on each row-level lock mode, refer to [Explicit Locking](#) in the PostgreSQL documentation.

To prevent the operation from waiting for other transactions to commit, use the `NOWAIT` option. With `NOWAIT`, the statement reports an error, rather than waiting, if a selected row cannot be locked immediately. Note that `NOWAIT` only affects whether the `SELECT` statement waits to obtain row-level locks. A required table-level lock is always taken in the ordinary way. For example, a `SELECT FOR UPDATE NOWAIT` statement will always wait for the required table-level lock; it behaves as if `NOWAIT` was omitted. You can use `LOCK` with the `NOWAIT` option first, if you need to acquire the table-level lock without waiting.

If specific tables are named in a locking clause, then only rows coming from those tables are locked; any other tables used in the `SELECT` are simply read as usual. A locking clause without a table list affects all tables used in the statement. If a locking clause is applied to a view or sub-query, it affects all tables used in the view or sub-query. However, these clauses do not apply to `WITH` queries referenced by the primary query. If you want row locking to occur within a `WITH` query, specify a locking clause within the `WITH` query.

Multiple locking clauses can be written if it is necessary to specify different locking behavior for different tables. If the same table is mentioned (or implicitly affected) by both more than one locking clause, then it is processed as if it was only specified by the strongest one. Similarly, a table is processed as `NOWAIT` if that is specified in any of the clauses affecting it.

The locking clauses cannot be used in contexts where returned rows cannot be clearly identified with individual table rows; for example they cannot be used with aggregation.

When a locking clause appears at the top level of a `SELECT` query, the rows that are locked are exactly those that are returned by the query; in the case of a join query, the rows locked are those that contribute to returned join rows. In addition, rows that satisfied the query conditions as of the query snapshot will be locked, although they will not be returned if they were updated after the snapshot and no longer satisfy the query conditions. If a `LIMIT` is used, locking stops once enough rows have been returned to satisfy the limit (but note that rows skipped over by `OFFSET` will get locked). Similarly, if a locking clause is used in a cursor's query, only rows actually fetched or stepped past by the cursor will be locked.

When locking clause appears in a sub-`SELECT`, the rows locked are those returned to the outer query by the sub-query. This might involve fewer rows than inspection of the sub-query alone would suggest, since conditions from the outer query might be used to optimize execution of the sub-query. For example,

```
SELECT * FROM (SELECT * FROM mytable FOR UPDATE) ss WHERE col1 = 5;
```

will lock only rows having `col1 = 5`, even though that condition is not textually within the sub-query.

It is possible for a `SELECT` command running at the `READ COMMITTED` transaction isolation level and using `ORDER BY` and a locking clause to return rows out of order. This is because `ORDER BY` is applied first. The command sorts the result, but might then block trying to obtain a lock on one or more of the rows. Once the `SELECT` unblocks, some of the ordering column values might have been modified, leading to those rows appearing to be out of order (though they are in order in terms of the original column values). This can be worked around at need by placing the `FOR UPDATE/SHARE` clause in a sub-query, for example

```
SELECT * FROM (SELECT * FROM mytable FOR UPDATE) ss ORDER BY column1;
```

Note that this will result in locking all rows of `mytable`, whereas `FOR UPDATE` at the top level would lock only the actually returned rows. This can make for a significant performance difference, particularly if the `ORDER BY` is combined with `LIMIT` or other restrictions. So this technique is recommended only if concurrent updates of the ordering columns are expected and a strictly sorted result is required.

At the `REPEATABLE READ` or `SERIALIZABLE` transaction isolation level this would cause a serialization failure (with a `SQLSTATE` of `40001`), so there is no possibility of receiving rows out of order under these isolation levels.

## The TABLE Command

The command

```
TABLE <name>
```

is completely equivalent to

```
SELECT * FROM <name>
```

It can be used as a top-level command or as a space-saving syntax variant in parts of complex queries.

## Examples

To join the table `films` with the table `distributors`:

```
SELECT f.title, f.did, d.name, f.date_prod, f.kind FROM
distributors d, films f WHERE f.did = d.did
```

To sum the column `length` of all films and group the results by `kind`:

```
SELECT kind, sum(length) AS total FROM films GROUP BY kind;
```

To sum the column `length` of all films, group the results by `kind` and show those group totals that are less than 5 hours:

```
SELECT kind, sum(length) AS total FROM films GROUP BY kind
HAVING sum(length) < interval '5 hours';
```

Calculate the subtotals and grand totals of all sales for movie `kind` and `distributor`.

```
SELECT kind, distributor, sum(prc*qty) FROM sales
GROUP BY ROLLUP(kind, distributor)
ORDER BY 1,2,3;
```

Calculate the rank of movie distributors based on total sales:

```
SELECT distributor, sum(prc*qty),
       rank() OVER (ORDER BY sum(prc*qty) DESC)
FROM sale
GROUP BY distributor ORDER BY 2 DESC;
```

The following two examples are identical ways of sorting the individual results according to the contents of the second column (`name`):

```
SELECT * FROM distributors ORDER BY name;
SELECT * FROM distributors ORDER BY 2;
```

The next example shows how to obtain the union of the tables `distributors` and `actors`, restricting the results to those that begin with the letter `w` in each table. Only distinct rows are wanted, so the key word `ALL` is omitted:

```
SELECT distributors.name FROM distributors WHERE
distributors.name LIKE 'W%' UNION SELECT actors.name FROM
actors WHERE actors.name LIKE 'W%';
```

This example shows how to use a function in the `FROM` clause, both with and without a column definition list:

```
CREATE FUNCTION distributors(int) RETURNS SETOF distributors
AS $$ SELECT * FROM distributors WHERE did = $1; $$ LANGUAGE
```

```
SQL;
SELECT * FROM distributors(111);

CREATE FUNCTION distributors_2(int) RETURNS SETOF record AS
$$ SELECT * FROM distributors WHERE did = $1; $$ LANGUAGE
SQL;
SELECT * FROM distributors_2(111) AS (dist_id int, dist_name
text);
```

This example uses a simple **WITH** clause:

```
WITH test AS (
  SELECT random() as x FROM generate_series(1, 3)
)
SELECT * FROM test
UNION ALL
SELECT * FROM test;
```

This example uses the **WITH** clause to display per-product sales totals in only the top sales regions.

```
WITH regional_sales AS
  SELECT region, SUM(amount) AS total_sales
  FROM orders
  GROUP BY region
), top_regions AS (
  SELECT region
  FROM regional_sales
  WHERE total_sales > (SELECT SUM(total_sales) FROM
    regional_sales)
)
SELECT region, product, SUM(quantity) AS product_units,
  SUM(amount) AS product_sales
FROM orders
WHERE region IN (SELECT region FROM top_regions)
GROUP BY region, product;
```

The example could have been written without the **WITH** clause but would have required two levels of nested sub-**SELECT** statements.

This example uses the **WITH RECURSIVE** clause to find all subordinates (direct or indirect) of the employee Mary, and their level of indirectness, from a table that shows only direct subordinates:

```
WITH RECURSIVE employee_recursive(distance, employee_name, manager_name) AS (
  SELECT 1, employee_name, manager_name
  FROM employee
  WHERE manager_name = 'Mary'
  UNION ALL
  SELECT er.distance + 1, e.employee_name, e.manager_name
  FROM employee_recursive er, employee e
  WHERE er.employee_name = e.manager_name
)
SELECT distance, employee_name FROM employee_recursive;
```

The typical form of recursive queries: an initial condition, followed by **UNION [ALL]**, followed by the recursive part of the query. Be sure that the recursive part of the query will eventually return no

tuples, or else the query will loop indefinitely. See [WITH Queries \(Common Table Expressions\)](#) in the *Greenplum Database Administrator Guide* for more examples.

## Compatibility

The `SELECT` statement is compatible with the SQL standard, but there are some extensions and some missing features.

### Omitted FROM Clauses

Greenplum Database allows one to omit the `FROM` clause. It has a straightforward use to compute the results of simple expressions. For example:

```
SELECT 2+2;
```

Some other SQL databases cannot do this except by introducing a dummy one-row table from which to do the `SELECT`.

Note that if a `FROM` clause is not specified, the query cannot reference any database tables. For example, the following query is invalid:

```
SELECT distributors.* WHERE distributors.name = 'Westward';
```

In earlier releases, setting a server configuration parameter, `add_missing_from`, to true allowed Greenplum Database to add an implicit entry to the query's `FROM` clause for each table referenced by the query. This is no longer allowed.

### Omitting the AS Key Word

In the SQL standard, the optional key word `AS` can be omitted before an output column name whenever the new column name is a valid column name (that is, not the same as any reserved keyword). Greenplum Database is slightly more restrictive: `AS` is required if the new column name matches any keyword at all, reserved or not. Recommended practice is to use `AS` or double-quote output column names, to prevent any possible conflict against future keyword additions.

In `FROM` items, both the standard and Greenplum Database allow `AS` to be omitted before an alias that is an unreserved keyword. But this is impractical for output column names, because of syntactic ambiguities.

### ONLY and Inheritance

The SQL standard requires parentheses around the table name when writing `ONLY`, for example:

```
SELECT * FROM ONLY (tab1), ONLY (tab2) WHERE ...
```

Greenplum Database considers these parentheses to be optional.

Greenplum Database allows a trailing `*` to be written to explicitly specify the non-`ONLY` behavior of including child tables. The standard does not allow this.

(These points apply equally to all SQL commands supporting the `ONLY` option.)

### Namespace Available to GROUP BY and ORDER BY

In the SQL-92 standard, an `ORDER BY` clause may only use output column names or numbers, while a `GROUP BY` clause may only use expressions based on input column names. Greenplum Database

extends each of these clauses to allow the other choice as well (but it uses the standard's interpretation if there is ambiguity). Greenplum Database also allows both clauses to specify arbitrary expressions. Note that names appearing in an expression are always taken as input-column names, not as output column names.

SQL:1999 and later use a slightly different definition which is not entirely upward compatible with SQL-92. In most cases, however, Greenplum Database interprets an `ORDER BY` or `GROUP BY` expression the same way SQL:1999 does.

### Functional Dependencies

Greenplum Database recognizes functional dependency (allowing columns to be omitted from `GROUP BY`) only when a table's primary key is included in the `GROUP BY` list. The SQL standard specifies additional conditions that should be recognized.

### LIMIT and OFFSET

The clauses `LIMIT` and `OFFSET` are Greenplum Database-specific syntax, also used by MySQL. The SQL:2008 standard has introduced the clauses `OFFSET .. FETCH {FIRST|NEXT} ...` for the same functionality, as shown above. This syntax is also used by IBM DB2. (Applications for Oracle frequently use a workaround involving the automatically generated `rownum` column, which is not available in Greenplum Database, to implement the effects of these clauses.)

### FOR NO KEY UPDATE, FOR UPDATE, FOR SHARE, and FOR KEY SHARE

Although `FOR UPDATE` appears in the SQL standard, the standard allows it only as an option of `DECLARE CURSOR`. Greenplum Database allows it in any `SELECT` query as well as in sub-`SELECTs`, but this is an extension. The `FOR NO KEY UPDATE`, `FOR SHARE`, and `FOR KEY SHARE` variants, as well as the `NOWAIT` option, do not appear in the standard.

### Data-Modifying Statements in WITH

Greenplum Database allows `INSERT`, `UPDATE`, and `DELETE` to be used as `WITH` queries. This is not found in the SQL standard.

### Nonstandard Clauses

The clause `DISTINCT ON` is not defined in the SQL standard.

### Limited Use of STABLE and VOLATILE Functions

To prevent data from becoming out-of-sync across the segments in Greenplum Database, any function classified as `STABLE` or `VOLATILE` cannot be run at the segment database level if it contains SQL or modifies the database in any way. See [CREATE FUNCTION](#) for more information.

## SELECT INTO

Defines a new table from the results of a query.

## Synopsis

```
[ WITH [ RECURSIVE ] <with_query> [, ...] ]
SELECT [ALL | DISTINCT [ON ( <expression> [, ...] )]]
    * | <expression> [AS <output_name>] [, ...]
INTO [TEMPORARY | TEMP | UNLOGGED ] [TABLE] <new_table>
[FROM <from_item> [, ...]]
[WHERE <condition>]
[GROUP BY <expression> [, ...]]
[HAVING <condition> [, ...]]
[UNION | INTERSECT | EXCEPT] [ALL | DISTINCT ] <select>]
[ORDER BY <expression> [ASC | DESC | USING <operator>] [NULLS {FIRST | LAST}] [,
...]]
[LIMIT {<count> | ALL}]
[OFFSET <start> [ ROW | ROWS ] ]
[FETCH { FIRST | NEXT } [ <count> ] { ROW | ROWS } ONLY ]
[FOR {UPDATE | SHARE} [OF <table_name> [, ...]] [NOWAIT]
[...]]
```

## Description

`SELECT INTO` creates a new table and fills it with data computed by a query. The data is not returned to the client, as it is with a normal `SELECT`. The new table's columns have the names and data types associated with the output columns of the `SELECT`.

## Parameters

The majority of parameters for `SELECT INTO` are the same as `SELECT`.

TEMPORARY

TEMP

If specified, the table is created as a temporary table.

UNLOGGED

If specified, the table is created as an unlogged table. Data written to unlogged tables is not written to the write-ahead (WAL) log, which makes them considerably faster than ordinary tables. However, the contents of an unlogged table are not replicated to mirror segment instances. Also an unlogged table is not crash-safe. After a segment instance crash or unclean shutdown, the data for the unlogged table on that segment is truncated. Any indexes created on an unlogged table are automatically unlogged as well.

new\_table

The name (optionally schema-qualified) of the table to be created.

## Examples

Create a new table `films_recent` consisting of only recent entries from the table `films`:

```
SELECT * INTO films_recent FROM films WHERE date_prod >=
'2016-01-01';
```

## Compatibility

The SQL standard uses `SELECT INTO` to represent selecting values into scalar variables of a host program, rather than creating a new table. The Greenplum Database usage of `SELECT INTO` to represent table creation is historical. It is best to use `CREATE TABLE AS` for this purpose in new applications.

## SET

Changes the value of a Greenplum Database configuration parameter.

## Synopsis

```
SET [SESSION | LOCAL] <configuration_parameter> {TO | =} <value> |
    '<value>' | DEFAULT}

SET [SESSION | LOCAL] TIME ZONE {<timezone> | LOCAL | DEFAULT}
```

## Description

The `SET` command changes server configuration parameters. Any configuration parameter classified as a session parameter can be changed on-the-fly with `SET`. `SET` affects only the value used by the current session.

If `SET` or `SET SESSION` is issued within a transaction that is later cancelled, the effects of the `SET` command disappear when the transaction is rolled back. Once the surrounding transaction is committed, the effects will persist until the end of the session, unless overridden by another `SET`.

The effects of `SET LOCAL` last only till the end of the current transaction, whether committed or not. A special case is `SET` followed by `SET LOCAL` within a single transaction: the `SET LOCAL` value will be seen until the end of the transaction, but afterwards (if the transaction is committed) the `SET` value will take effect.

If `SET LOCAL` is used within a function that includes a `SET` option for the same configuration parameter (see [CREATE FUNCTION](#)), the effects of the `SET LOCAL` command disappear at function exit; the value in effect when the function was called is restored anyway. This allows `SET LOCAL` to be used for dynamic or repeated changes of a parameter within a function, while retaining the convenience of using the `SET` option to save and restore the caller's value. Note that a regular `SET` command overrides any surrounding function's `SET` option; its effects persist unless rolled back.

If you create a cursor with the `DECLARE` command in a transaction, you cannot use the `SET` command in the transaction until you close the cursor with the `CLOSE` command.

See [Server Configuration Parameters](#) for information about server parameters.

## Parameters

**SESSION**

Specifies that the command takes effect for the current session. This is the default.

**LOCAL**

Specifies that the command takes effect for only the current transaction. After `COMMIT` or `ROLLBACK`, the session-level setting takes effect again. Note that `SET LOCAL` will appear to have no effect if it is run outside of a transaction.

**configuration\_parameter**

The name of a Greenplum Database configuration parameter. Only parameters classified as *session* can be changed with `SET`. See [Server Configuration Parameters](#) for details.

**value**

New value of parameter. Values can be specified as string constants, identifiers, numbers, or comma-separated lists of these. `DEFAULT` can be used to specify resetting the parameter to its default value. If specifying memory sizing or time units, enclose the value in single quotes.

**TIME ZONE**

`SET TIME ZONE value` is an alias for `SET timezone TO value`. The syntax `SET TIME ZONE` allows special syntax for the time zone specification. Here are examples of valid values:

```
'PST8PDT'
```

```
'Europe/Rome'
```

```
-7 (time zone 7 hours west from UTC)
```

```
INTERVAL '-08:00' HOUR TO MINUTE (time zone 8 hours west from UTC).
```

**LOCAL****DEFAULT**

Set the time zone to your local time zone (that is, server's default value of `timezone`). See the [Time zone section of the PostgreSQL documentation](#) for more information about time zones in Greenplum Database.

## Examples

Set the schema search path:

```
SET search_path TO my_schema, public;
```

Increase the segment host memory per query to 200 MB:

```
SET statement_mem TO '200MB';
```

Set the style of date to traditional POSTGRES with "day before month" input convention:

```
SET datestyle TO postgres, dmy;
```

Set the time zone for San Mateo, California (Pacific Time):

```
SET TIME ZONE 'PST8PDT';
```

Set the time zone for Italy:

```
SET TIME ZONE 'Europe/Rome';
```

## Compatibility

`SET TIME ZONE` extends syntax defined in the SQL standard. The standard allows only numeric time zone offsets while Greenplum Database allows more flexible time-zone specifications. All other `SET` features are Greenplum Database extensions.

## SET CONSTRAINTS

Sets constraint check timing for the current transaction.

**Note:** Referential integrity syntax (foreign key constraints) is accepted but not enforced.

## Synopsis

```
SET CONSTRAINTS { ALL | <name> [, ...] } { DEFERRED | IMMEDIATE }
```

## Description

`SET CONSTRAINTS` sets the behavior of constraint checking within the current transaction. `IMMEDIATE` constraints are checked at the end of each statement. `DEFERRED` constraints are not checked until transaction commit. Each constraint has its own `IMMEDIATE` or `DEFERRED` mode.

Upon creation, a constraint is given one of three characteristics: `DEFERRABLE INITIALLY DEFERRED`, `DEFERRABLE INITIALLY IMMEDIATE`, or `NOT DEFERRABLE`. The third class is always `IMMEDIATE` and is not affected by the `SET CONSTRAINTS` command. The first two classes start every transaction in the indicated mode, but their behavior can be changed within a transaction by `SET CONSTRAINTS`.

`SET CONSTRAINTS` with a list of constraint names changes the mode of just those constraints (which must all be deferrable). Each constraint name can be schema-qualified. The current schema search path is used to find the first matching name if no schema name is specified. `SET CONSTRAINTS ALL` changes the mode of all deferrable constraints.

When `SET CONSTRAINTS` changes the mode of a constraint from `DEFERRED` to `IMMEDIATE`, the new mode takes effect retroactively: any outstanding data modifications that would have been checked at the end of the transaction are instead checked during the execution of the `SET CONSTRAINTS` command. If any such constraint is violated, the `SET CONSTRAINTS` fails (and does not change the constraint mode). Thus, `SET CONSTRAINTS` can be used to force checking of constraints to occur at a specific point in a transaction.

Currently, only `UNIQUE`, `PRIMARY KEY`, `REFERENCES` (foreign key), and `EXCLUDE` constraints are affected by this setting. `NOT NULL` and `CHECK` constraints are always checked immediately when a row is

inserted or modified (*not* at the end of the statement). Uniqueness and exclusion constraints that have not been declared `DEFERRABLE` are also checked immediately.

The firing of triggers that are declared as "constraint triggers" is also controlled by this setting — they fire at the same time that the associated constraint should be checked.

## Notes

Because Greenplum Database does not require constraint names to be unique within a schema (but only per-table), it is possible that there is more than one match for a specified constraint name. In this case `SET CONSTRAINTS` will act on all matches. For a non-schema-qualified name, once a match or matches have been found in some schema in the search path, schemas appearing later in the path are not searched.

This command only alters the behavior of constraints within the current transaction. Issuing this outside of a transaction block emits a warning and otherwise has no effect.

## Compatibility

This command complies with the behavior defined in the SQL standard, except for the limitation that, in Greenplum Database, it does not apply to `NOT NULL` and `CHECK` constraints. Also, Greenplum Database checks non-deferrable uniqueness constraints immediately, not at end of statement as the standard would suggest.

**Parent topic:** [SQL Commands](#)

## SET ROLE

Sets the current role identifier of the current session.

## Synopsis

```
SET [SESSION | LOCAL] ROLE <rolename>

SET [SESSION | LOCAL] ROLE NONE

RESET ROLE
```

## Description

This command sets the current role identifier of the current SQL-session context to be `rolename`. The role name may be written as either an identifier or a string literal. After `SET ROLE`, permissions checking for SQL commands is carried out as though the named role were the one that had logged in originally.

The specified `rolename` must be a role that the current session user is a member of. If the session user is a superuser, any role can be selected.

The `NONE` and `RESET` forms reset the current role identifier to be the current session role identifier. These forms may be run by any user.

## Parameters

### SESSION

Specifies that the command takes effect for the current session. This is the default.

### LOCAL

Specifies that the command takes effect for only the current transaction. After `COMMIT` or `ROLLBACK`, the session-level setting takes effect again. Note that `SET LOCAL` will appear to have no effect if it is run outside of a transaction.

### rolename

The name of a role to use for permissions checking in this session.

### NONE

### RESET

Reset the current role identifier to be the current session role identifier (that of the role used to log in).

## Notes

Using this command, it is possible to either add privileges or restrict privileges. If the session user role has the `INHERITS` attribute, then it automatically has all the privileges of every role that it could `SET ROLE` to; in this case `SET ROLE` effectively drops all the privileges assigned directly to the session user and to the other roles it is a member of, leaving only the privileges available to the named role. On the other hand, if the session user role has the `NOINHERITS` attribute, `SET ROLE` drops the privileges assigned directly to the session user and instead acquires the privileges available to the named role.

In particular, when a superuser chooses to `SET ROLE` to a non-superuser role, they lose their superuser privileges.

`SET ROLE` has effects comparable to `SET SESSION AUTHORIZATION`, but the privilege checks involved are quite different. Also, `SET SESSION AUTHORIZATION` determines which roles are allowable for later `SET ROLE` commands, whereas changing roles with `SET ROLE` does not change the set of roles allowed to a later `SET ROLE`.

`SET ROLE` does not process session variables specified by the role's `ALTER ROLE` settings; the session variables are only processed during login.

## Examples

```
SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
-----+-----
 peter          | peter

SET ROLE 'paul';

SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
-----+-----
 peter          | paul
```

## Compatibility

Greenplum Database allows identifier syntax (rolename), while the SQL standard requires the role name to be written as a string literal. SQL does not allow this command during a transaction; Greenplum Database does not make this restriction. The `SESSION` and `LOCAL` modifiers are a Greenplum Database extension, as is the `RESET` syntax.

## See Also

[SET SESSION AUTHORIZATION](#)

Parent topic: [SQL Commands](#)

## SET SESSION AUTHORIZATION

Sets the session role identifier and the current role identifier of the current session.

## Synopsis

```
SET [SESSION | LOCAL] SESSION AUTHORIZATION <rolename>

SET [SESSION | LOCAL] SESSION AUTHORIZATION DEFAULT

RESET SESSION AUTHORIZATION
```

## Description

This command sets the session role identifier and the current role identifier of the current SQL-session context to be rolename. The role name may be written as either an identifier or a string literal. Using this command, it is possible, for example, to temporarily become an unprivileged user and later switch back to being a superuser.

The session role identifier is initially set to be the (possibly authenticated) role name provided by the client. The current role identifier is normally equal to the session user identifier, but may change temporarily in the context of `setuid` functions and similar mechanisms; it can also be changed by [SET ROLE](#). The current user identifier is relevant for permission checking.

The session user identifier may be changed only if the initial session user (the authenticated user) had the superuser privilege. Otherwise, the command is accepted only if it specifies the authenticated user name.

The `DEFAULT` and `RESET` forms reset the session and current user identifiers to be the originally authenticated user name. These forms may be run by any user.

## Parameters

`SESSION`

Specifies that the command takes effect for the current session. This is the default.

`LOCAL`

Specifies that the command takes effect for only the current transaction. After `COMMIT` or `ROLLBACK`, the session-level setting takes effect again. Note that `SET LOCAL` will appear to have no effect if it is run outside of a transaction.

rolename

The name of the role to assume.

NONE

RESET

Reset the session and current role identifiers to be that of the role used to log in.

## Examples

```
SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
-----+-----
 peter          | peter

SET SESSION AUTHORIZATION 'paul';

SELECT SESSION_USER, CURRENT_USER;
 session_user | current_user
-----+-----
 paul          | paul
```

## Compatibility

The SQL standard allows some other expressions to appear in place of the literal rolename, but these options are not important in practice. Greenplum Database allows identifier syntax (rolename), which SQL does not. SQL does not allow this command during a transaction; Greenplum Database does not make this restriction. The `SESSION` and `LOCAL` modifiers are a Greenplum Database extension, as is the `RESET` syntax.

## SET TRANSACTION

Sets the characteristics of the current transaction.

## Synopsis

```
SET TRANSACTION [<transaction_mode>] [READ ONLY | READ WRITE]

SET TRANSACTION SNAPSHOT <snapshot_id>

SET SESSION CHARACTERISTICS AS TRANSACTION <transaction_mode>
 [READ ONLY | READ WRITE]
 [NOT] DEFERRABLE
```

where `transaction_mode` is one of:

```
ISOLATION LEVEL {SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ UNCOMMITTED}
```

and `snapshot_id` is the id of the existing transaction whose snapshot you want this transaction to run with.

## Description

The `SET TRANSACTION` command sets the characteristics of the current transaction. It has no effect on any subsequent transactions.

The available transaction characteristics are the transaction isolation level, the transaction access mode (read/write or read-only), and the deferrable mode.

**Note:** Deferrable transactions require the transaction to be serializable. Greenplum Database does not support serializable transactions, so including the `DEFERRABLE` clause has no effect.

The isolation level of a transaction determines what data the transaction can see when other transactions are running concurrently.

- **READ COMMITTED** — A statement can only see rows committed before it began. This is the default.
- **REPEATABLE READ** — All statements in the current transaction can only see rows committed before the first query or data-modification statement run in the transaction.

The SQL standard defines two additional levels, `READ UNCOMMITTED` and `SERIALIZABLE`. In Greenplum Database `READ UNCOMMITTED` is treated as `READ COMMITTED`. If you specify `SERIALIZABLE`, Greenplum Database falls back to `REPEATABLE READ`.

The transaction isolation level cannot be changed after the first query or data-modification statement (`SELECT`, `INSERT`, `DELETE`, `UPDATE`, `FETCH`, or `COPY`) of a transaction has been run.

The transaction access mode determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: `INSERT`, `UPDATE`, `DELETE`, and `COPY FROM` if the table they would write to is not a temporary table; all `CREATE`, `ALTER`, and `DROP` commands; `GRANT`, `REVOKE`, `TRUNCATE`; and `EXPLAIN ANALYZE` and `EXECUTE` if the command they would run is among those listed. This is a high-level notion of read-only that does not prevent all writes to disk.

The `DEFERRABLE` transaction property has no effect unless the transaction is also `SERIALIZABLE` and `READ ONLY`. When all of these properties are set on a transaction, the transaction may block when first acquiring its snapshot, after which it is able to run without the normal overhead of a `SERIALIZABLE` transaction and without any risk of contributing to or being cancelled by a serialization failure. Because Greenplum Database does not support serializable transactions, the `DEFERRABLE` transaction property has no effect in Greenplum Database.

## Parameters

SNAPSHOT

Allows a new transaction to run with the same snapshot as an existing transaction. You pass the id of the existing transaction to the `SET TRANSACTION SNAPSHOT` command. You must first call the `pg_export_snapshot` function to obtain the existing transaction's id.

#### SESSION CHARACTERISTICS

Sets the default transaction characteristics for subsequent transactions of a session.

READ UNCOMMITTED

READ COMMITTED

REPEATABLE READ

SERIALIZABLE

The SQL standard defines four transaction isolation levels: `READ UNCOMMITTED`, `READ COMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.

`READ UNCOMMITTED` allows transactions to see changes made by uncommitted concurrent transactions. This is not possible in Greenplum Database, so `READ UNCOMMITTED` is treated the same as `READ COMMITTED`.

`READ COMMITTED`, the default isolation level in Greenplum Database, guarantees that a statement can only see rows committed before it began. The same statement run twice in a transaction can produce different results if another concurrent transaction commits after the statement is run the first time.

The `REPEATABLE READ` isolation level guarantees that a transaction can only see rows committed before it began. `REPEATABLE READ` is the strictest transaction isolation level Greenplum Database supports. Applications that use the `REPEATABLE READ` isolation level must be prepared to retry transactions due to serialization failures.

The `SERIALIZABLE` transaction isolation level guarantees that all statements of the current transaction can only see rows committed before the first query or data-modification statement was run in this transaction. If a pattern of reads and writes among concurrent serializable transactions would create a situation which could not have occurred for any serial (one-at-a-time) execution of those transactions, one of the transactions will be rolled back with a `serialization_failure` error. Greenplum Database does not fully support `SERIALIZABLE` as defined by the standard, so if you specify `SERIALIZABLE`, Greenplum Database falls back to `REPEATABLE READ`. See [Compatibility](#) for more information about transaction serializability in Greenplum Database.

READ WRITE

READ ONLY

Determines whether the transaction is read/write or read-only. Read/write is the default. When a transaction is read-only, the following SQL commands are disallowed: `INSERT`, `UPDATE`, `DELETE`, and `COPY FROM` if the table they would write to is not a temporary table; all `CREATE`, `ALTER`, and `DROP` commands; `GRANT`, `REVOKE`, `TRUNCATE`; and `EXPLAIN ANALYZE` and `EXECUTE` if the command they would run is among those listed.

[NOT] DEFERRABLE

The `DEFERRABLE` transaction property has no effect in Greenplum Database because `SERIALIZABLE` transactions are not supported. If `DEFERRABLE` is specified and the transaction is also `SERIALIZABLE` and `READ ONLY`, the transaction may block when first acquiring its snapshot, after which it is able to run without the normal overhead of a `SERIALIZABLE` transaction and without any risk of contributing to or being cancelled by a serialization failure. This mode is well suited for long-running reports or backups.

## Notes

If `SET TRANSACTION` is run without a prior `START TRANSACTION` or `BEGIN`, a warning is issued and the command has no effect.

It is possible to dispense with `SET TRANSACTION` by instead specifying the desired transaction modes in `BEGIN` or `START TRANSACTION`.

The session default transaction modes can also be set by setting the configuration parameters `default_transaction_isolation`, `default_transaction_read_only`, and `default_transaction_deferrable`.

## Examples

Set the transaction isolation level for the current transaction:

```
BEGIN;
SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;
```

## Compatibility

Both commands are defined in the SQL standard. `SERIALIZABLE` is the default transaction isolation level in the standard. In Greenplum Database the default is `READ COMMITTED`. Due to lack of predicate locking, Greenplum Database does not fully support the `SERIALIZABLE` level, so it falls back to the `REPEATABLE READ` level when `SERIAL` is specified. Essentially, a predicate-locking system prevents phantom reads by restricting what is written, whereas a multi-version concurrency control model (MVCC) as used in Greenplum Database prevents them by restricting what is read.

PostgreSQL provides a true serializable isolation level, called serializable snapshot isolation (SSI), which monitors concurrent transactions and rolls back transactions that could introduce serialization anomalies. Greenplum Database does not implement this isolation mode.

In the SQL standard, there is one other transaction characteristic that can be set with these commands: the size of the diagnostics area. This concept is specific to embedded SQL, and therefore is not implemented in the Greenplum Database server.

The `DEFERRABLE` transaction mode is a Greenplum Database language extension.

The SQL standard requires commas between successive `transaction_modes`, but for historical reasons Greenplum Database allows the commas to be omitted.

## SHOW

Shows the value of a system configuration parameter.

## Synopsis

```
SHOW <configuration_parameter>

SHOW ALL
```

## Description

`SHOW` displays the current settings of Greenplum Database system configuration parameters. You can set these parameters with the `SET` statement, or by editing the `postgresql.conf` configuration file of the Greenplum Database master. Note that some parameters viewable by `SHOW` are read-only — their values can be viewed but not set. See the Greenplum Database Reference Guide for details.

## Parameters

`configuration_parameter`

The name of a system configuration parameter.

`ALL`

Shows the current value of all configuration parameters.

## Examples

Show the current setting of the parameter `DateStyle`:

```
SHOW DateStyle;
 DateStyle
-----
 ISO, MDY
(1 row)
```

Show the current setting of the parameter `geqo`:

```
SHOW geqo;
 geqo
-----
 off
(1 row)
```

Show the current setting of all parameters:

```
SHOW ALL;
   name          | setting | description
-----+-----+-----
 application_name | psql    | Sets the application name to be reported in sta...
 .
 .
 .
 xmlbinary       | base64  | Sets how binary values are to be encoded in XML.
 xmloption       | content | Sets whether XML data in implicit parsing and s...
(331 rows)
```

# Compatibility

`SHOW` is a Greenplum Database extension.

## See Also

[SET](#), [RESET](#)

Parent topic: [SQL Commands](#)

## START TRANSACTION

Starts a transaction block.

## Synopsis

```
START TRANSACTION [<transaction_mode>] [READ WRITE | READ ONLY]
```

where `transaction_mode` is:

```
ISOLATION LEVEL {SERIALIZABLE | READ COMMITTED | READ UNCOMMITTED}
```

## Description

`START TRANSACTION` begins a new transaction block. If the isolation level or read/write mode is specified, the new transaction has those characteristics, as if `SET TRANSACTION` was run. This is the same as the `BEGIN` command.

## Parameters

READ UNCOMMITTED

READ COMMITTED

REPEATABLE READ

SERIALIZABLE

The SQL standard defines four transaction isolation levels: `READ UNCOMMITTED`, `READ COMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`.

`READ UNCOMMITTED` allows transactions to see changes made by uncommitted concurrent transactions. This is not possible in Greenplum Database, so `READ UNCOMMITTED` is treated the same as `READ COMMITTED`.

`READ COMMITTED`, the default isolation level in Greenplum Database, guarantees that a statement can only see rows committed before it began. The same statement run twice in a transaction can produce different results if another concurrent transaction commits after the statement is run the first time.

The `REPEATABLE READ` isolation level guarantees that a transaction can only see rows committed before it began. `REPEATABLE READ` is the strictest transaction isolation level

Greenplum Database supports. Applications that use the `REPEATABLE READ` isolation level must be prepared to retry transactions due to serialization failures.

The `SERIALIZABLE` transaction isolation level guarantees that running multiple concurrent transactions produces the same effects as running the same transactions one at a time. If you specify `SERIALIZABLE`, Greenplum Database falls back to `REPEATABLE READ`.

`READ WRITE`

`READ ONLY`

Determines whether the transaction is read/write or read-only. Read/write is the default.

When a transaction is read-only, the following SQL commands are disallowed: `INSERT`, `UPDATE`, `DELETE`, and `COPY FROM` if the table they would write to is not a temporary table; all `CREATE`, `ALTER`, and `DROP` commands; `GRANT`, `REVOKE`, `TRUNCATE`; and `EXPLAIN ANALYZE` and `EXECUTE` if the command they would run is among those listed.

## Examples

To begin a transaction block:

```
START TRANSACTION;
```

## Compatibility

In the standard, it is not necessary to issue `START TRANSACTION` to start a transaction block: any SQL command implicitly begins a block. Greenplum Database behavior can be seen as implicitly issuing a `COMMIT` after each command that does not follow `START TRANSACTION` (or `BEGIN`), and it is therefore often called 'autocommit'. Other relational database systems may offer an autocommit feature as a convenience.

The SQL standard requires commas between successive `transaction_modes`, but for historical reasons Greenplum Database allows the commas to be omitted.

See also the compatibility section of [SET TRANSACTION](#).

## See Also

[BEGIN](#), [SET TRANSACTION](#)

Parent topic: [SQL Commands](#)

## TRUNCATE

Empties a table of all rows.

**Note:** Greenplum Database does not enforce referential integrity syntax (foreign key constraints). As of version 6.12 `TRUNCATE` truncates a table that is referenced in a foreign key constraint even if the `CASCADE` option is omitted.

## Synopsis

```
TRUNCATE [TABLE] [ONLY] <name> [ * ] [, ...]
      [ RESTART IDENTITY | CONTINUE IDENTITY ] [CASCADE | RESTRICT]
```

## Description

**TRUNCATE** quickly removes all rows from a table or set of tables. It has the same effect as an unqualified **DELETE** on each table, but since it does not actually scan the tables it is faster. This is most useful on large tables.

You must have the **TRUNCATE** privilege on the table to truncate table rows.

**TRUNCATE** acquires an access exclusive lock on the tables it operates on, which blocks all other concurrent operations on the table. When **RESTART IDENTITY** is specified, any sequences that are to be restarted are likewise locked exclusively. If concurrent access to a table is required, then the **DELETE** command should be used instead.

## Parameters

name

The name (optionally schema-qualified) of a table to truncate. If **ONLY** is specified before the table name, only that table is truncated. If **ONLY** is not specified, the table and all its descendant tables (if any) are truncated. Optionally, **\*** can be specified after the table name to explicitly indicate that descendant tables are included.

CASCADE

Because this key word applies to foreign key references (which are not supported in Greenplum Database) it has no effect.

RESTART IDENTITY

Automatically restart sequences owned by columns of the truncated table(s).

CONTINUE IDENTITY

Do not change the values of sequences. This is the default.

RESTRICT

Because this key word applies to foreign key references (which are not supported in Greenplum Database) it has no effect.

## Notes

**TRUNCATE** will not run any user-defined **ON DELETE** triggers that might exist for the tables.

**TRUNCATE** will not truncate any tables that inherit from the named table. Only the named table is truncated, not its child tables.

**TRUNCATE** will not truncate any sub-tables of a partitioned table. If you specify a sub-table of a partitioned table, **TRUNCATE** will not remove rows from the sub-table and its child tables.

**TRUNCATE** is not MVCC-safe. After truncation, the table will appear empty to concurrent transactions, if they are using a snapshot taken before the truncation occurred.

**TRUNCATE** is transaction-safe with respect to the data in the tables: the truncation will be safely rolled back if the surrounding transaction does not commit.

`TRUNCATE` acquires an `ACCESS EXCLUSIVE` lock on each table it operates on, which blocks all other concurrent operations on the table. If concurrent access to a table is required, then the `DELETE` command should be used instead.

When `RESTART IDENTITY` is specified, the implied `ALTER SEQUENCE RESTART` operations are also done transactionally; that is, they will be rolled back if the surrounding transaction does not commit. This is unlike the normal behavior of `ALTER SEQUENCE RESTART`. Be aware that if any additional sequence operations are done on the restarted sequences before the transaction rolls back, the effects of these operations on the sequences will be rolled back, but not their effects on `currval()`; that is, after the transaction `currval()` will continue to reflect the last sequence value obtained inside the failed transaction, even though the sequence itself may no longer be consistent with that. This is similar to the usual behavior of `currval()` after a failed transaction.

## Examples

Empty the tables `films` and `distributors`:

```
TRUNCATE films, distributors;
```

The same, and also reset any associated sequence generators:

```
TRUNCATE films, distributors RESTART IDENTITY;
```

## Compatibility

The SQL:2008 standard includes a `TRUNCATE` command with the syntax `TRUNCATE TABLE tablename`. The clauses `CONTINUE IDENTITY/RESTART IDENTITY` also appear in that standard, but have slightly different though related meanings. Some of the concurrency behavior of this command is left implementation-defined by the standard, so the above notes should be considered and compared with other implementations if necessary.

## See Also

[DELETE, DROP TABLE](#)

Parent topic: [SQL Commands](#)

## UNLISTEN

Stops listening for a notification.

## Synopsis

```
UNLISTEN { <channel> | * }
```

## Description

`UNLISTEN` is used to remove an existing registration for `NOTIFY` events. `UNLISTEN` cancels any existing registration of the current Greenplum Database session as a listener on the notification channel named `channel`. The special wildcard `*` cancels all listener registrations for the current session.

`NOTIFY` contains a more extensive discussion of the use of `LISTEN` and `NOTIFY`.

## Parameters

`channel`

The name of a notification channel (any identifier).

`*`

All current listen registrations for this session are cleared.

## Notes

You can unlisten something you were not listening for; no warning or error will appear.

At the end of each session, `UNLISTEN *` is automatically executed.

A transaction that has executed `UNLISTEN` cannot be prepared for two-phase commit.

## Examples

To make a registration:

```
LISTEN virtual;
NOTIFY virtual;
Asynchronous notification "virtual" received from server process with PID 8448.
```

Once `UNLISTEN` has been executed, further `NOTIFY` messages will be ignored:

```
UNLISTEN virtual;
NOTIFY virtual;
-- no NOTIFY event is received
```

## Compatibility

There is no `UNLISTEN` statement in the SQL standard.

## See Also

[LISTEN, NOTIFY](#)

Parent topic: [SQL Commands](#)

## UPDATE

Updates rows of a table.

## Synopsis

```
[ WITH [ RECURSIVE ] <with_query> [, ...] ]
UPDATE [ONLY] <table> [[AS] <alias>]
  SET {<column> = {<expression> | DEFAULT} |
      (<column> [, ...]) = ({<expression> | DEFAULT} [, ...])} [, ...]
  [FROM <fromlist>]
  [WHERE <condition >| WHERE CURRENT OF <cursor_name> ]
```

## Description

**UPDATE** changes the values of the specified columns in all rows that satisfy the condition. Only the columns to be modified need be mentioned in the **SET** clause; columns not explicitly modified retain their previous values.

By default, **UPDATE** will update rows in the specified table and all its subtables. If you wish to only update the specific table mentioned, you must use the **ONLY** clause.

There are two ways to modify a table using information contained in other tables in the database: using sub-selects, or specifying additional tables in the **FROM** clause. Which technique is more appropriate depends on the specific circumstances.

If the **WHERE CURRENT OF** clause is specified, the row that is updated is the one most recently fetched from the specified cursor.

The **WHERE CURRENT OF** clause is not supported with replicated tables.

You must have the **UPDATE** privilege on the table, or at least on the column(s) that are listed to be updated. You must also have the **SELECT** privilege on any column whose values are read in the expressions or condition.

**Note:** As the default, Greenplum Database acquires an **EXCLUSIVE** lock on tables for **UPDATE** operations on heap tables. When the Global Deadlock Detector is enabled, the lock mode for **UPDATE** operations on heap tables is **ROW EXCLUSIVE**. See [Global Deadlock Detector](#).

### Outputs

On successful completion, an **UPDATE** command returns a command tag of the form:

```
UPDATE <count>
```

where count is the number of rows updated. If count is 0, no rows matched the condition (this is not considered an error).

## Parameters

### with\_query

The **WITH** clause allows you to specify one or more subqueries that can be referenced by name in the **UPDATE** query.

For an **UPDATE** command that includes a **WITH** clause, the clause can only contain **SELECT** commands, the **WITH** clause cannot contain a data-modifying command (**INSERT**, **UPDATE**, or **DELETE**).

It is possible for the query (**SELECT** statement) to also contain a **WITH** clause. In such a case both sets of **with\_query** can be referenced within the **UPDATE** query, but the second one

takes precedence since it is more closely nested.

See [WITH Queries \(Common Table Expressions\)](#) and [SELECT](#) for details.

#### ONLY

If specified, update rows from the named table only. When not specified, any tables inheriting from the named table are also processed.

#### table

The name (optionally schema-qualified) of an existing table.

#### alias

A substitute name for the target table. When an alias is provided, it completely hides the actual name of the table. For example, given `UPDATE foo AS f`, the remainder of the `UPDATE` statement must refer to this table as `f` not `foo`.

#### column

The name of a column in table. The column name can be qualified with a subfield name or array subscript, if needed. Do not include the table's name in the specification of a target column.

#### expression

An expression to assign to the column. The expression may use the old values of this and other columns in the table.

#### DEFAULT

Set the column to its default value (which will be NULL if no specific default expression has been assigned to it).

#### fromlist

A list of table expressions, allowing columns from other tables to appear in the `WHERE` condition and the update expressions. This is similar to the list of tables that can be specified in the `FROM` clause of a `SELECT` statement. Note that the target table must not appear in the fromlist, unless you intend a self-join (in which case it must appear with an alias in the fromlist).

#### condition

An expression that returns a value of type boolean. Only rows for which this expression returns true will be updated.

#### cursor\_name

The name of the cursor to use in a `WHERE CURRENT OF` condition. The row to be updated is the one most recently fetched from the cursor. The cursor must be a non-grouping query on the `UPDATE` command target table. See [DECLARE](#) for more information about creating cursors.

`WHERE CURRENT OF` cannot be specified together with a Boolean condition.

Note that `WHERE CURRENT OF` cannot be specified together with a Boolean condition. The `UPDATE...WHERE CURRENT OF` statement can only be run on the server, for example in an interactive psql session or a script. Language extensions such as PL/pgSQL do not have support for updatable cursors.

See [DECLARE](#) for more information about creating cursors.

#### output\_expression

An expression to be computed and returned by the `UPDATE` command after each row is updated. The expression may use any column names of the table or table(s) listed in `FROM`. Write `*` to return all columns.

#### output\_name

A name to use for a returned column.

## Notes

`SET` is not allowed on the Greenplum distribution key columns of a table.

When a `FROM` clause is present, what essentially happens is that the target table is joined to the tables mentioned in the from list, and each output row of the join represents an update operation for the target table. When using `FROM` you should ensure that the join produces at most one output row for each row to be modified. In other words, a target row should not join to more than one row from the other table(s). If it does, then only one of the join rows will be used to update the target row, but which one will be used is not readily predictable.

Because of this indeterminacy, referencing other tables only within sub-selects is safer, though often harder to read and slower than using a join.

Running `UPDATE` and `DELETE` commands directly on a specific partition (child table) of a partitioned table is not supported. Instead, run these commands on the root partitioned table, the table created with the `CREATE TABLE` command.

For a partitioned table, all the child tables are locked during the `UPDATE` operation when the Global Deadlock Detector is not enabled (the default). Only some of the leaf child tables are locked when the Global Deadlock Detector is enabled. For information about the Global Deadlock Detector, see [Global Deadlock Detector](#).

## Examples

Change the word `Drama` to `Dramatic` in the column `kind` of the table `films`:

```
UPDATE films SET kind = 'Dramatic' WHERE kind = 'Drama';
```

Adjust temperature entries and reset precipitation to its default value in one row of the table `weather`:

```
UPDATE weather SET temp_lo = temp_lo+1, temp_hi =
temp_lo+15, prcp = DEFAULT
WHERE city = 'San Francisco' AND date = '2016-07-03';
```

Use the alternative column-list syntax to do the same update:

```
UPDATE weather SET (temp_lo, temp_hi, prcp) = (temp_lo+1,
temp_lo+15, DEFAULT)
WHERE city = 'San Francisco' AND date = '2016-07-03';
```

Increment the sales count of the salesperson who manages the account for Acme Corporation, using the `FROM` clause syntax (assuming both tables being joined are distributed in Greenplum Database on the `id` column):

```
UPDATE employees SET sales_count = sales_count + 1 FROM
accounts
WHERE accounts.name = 'Acme Corporation'
AND employees.id = accounts.id;
```

Perform the same operation, using a sub-select in the `WHERE` clause:

```
UPDATE employees SET sales_count = sales_count + 1 WHERE id =
(SELECT id FROM accounts WHERE name = 'Acme Corporation');
```

Attempt to insert a new stock item along with the quantity of stock. If the item already exists, instead update the stock count of the existing item. To do this without failing the entire transaction, use savepoints.

```
BEGIN;
-- other operations
SAVEPOINT sp1;
INSERT INTO wines VALUES('Chateau Lafite 2003', '24');
-- Assume the above fails because of a unique key violation,
-- so now we issue these commands:
ROLLBACK TO sp1;
UPDATE wines SET stock = stock + 24 WHERE winename = 'Chateau
Lafite 2003';
-- continue with other operations, and eventually
COMMIT;
```

## Compatibility

This command conforms to the SQL standard, except that the `FROM` clause is a Greenplum Database extension.

According to the standard, the column-list syntax should allow a list of columns to be assigned from a single row-valued expression, such as a sub-select:

```
UPDATE accounts SET (contact_last_name, contact_first_name) =
(SELECT last_name, first_name FROM salesmen
WHERE salesmen.id = accounts.sales_id);
```

This is not currently implemented — the source must be a list of independent expressions.

Some other database systems offer a `FROM` option in which the target table is supposed to be listed again within `FROM`. That is not how Greenplum Database interprets `FROM`. Be careful when porting applications that use this extension.

## VACUUM

Garbage-collects and optionally analyzes a database.

## Synopsis

```
VACUUM [( { FULL | FREEZE | VERBOSE | ANALYZE } [, ...] )] [<table> [( <column> [, ...] )]]
```

```
VACUUM [FULL] [FREEZE] [VERBOSE] [<table>]

VACUUM [FULL] [FREEZE] [VERBOSE] ANALYZE
      [<table> [(<column> [, ...] )]]
```

## Description

`VACUUM` reclaims storage occupied by deleted tuples. In normal Greenplum Database operation, tuples that are deleted or obsoleted by an update are not physically removed from their table; they remain present on disk until a `VACUUM` is done. Therefore it is necessary to do `VACUUM` periodically, especially on frequently-updated tables.

With no parameter, `VACUUM` processes every table in the current database. With a parameter, `VACUUM` processes only that table.

`VACUUM ANALYZE` performs a `VACUUM` and then an `ANALYZE` for each selected table. This is a handy combination form for routine maintenance scripts. See [ANALYZE](#) for more details about its processing.

`VACUUM` (without `FULL`) marks deleted and obsoleted data in tables and indexes for future reuse and reclaims space for re-use only if the space is at the end of the table and an exclusive table lock can be easily obtained. Unused space at the start or middle of a table remains as is. With heap tables, this form of the command can operate in parallel with normal reading and writing of the table, as an exclusive lock is not obtained. However, extra space is not returned to the operating system (in most cases); it's just kept available for re-use within the same table. `VACUUM FULL` rewrites the entire contents of the table into a new disk file with no extra space, allowing unused space to be returned to the operating system. This form is much slower and requires an exclusive lock on each table while it is being processed.

With append-optimized tables, `VACUUM` compacts a table by first vacuuming the indexes, then compacting each segment file in turn, and finally vacuuming auxiliary relations and updating statistics. On each segment, visible rows are copied from the current segment file to a new segment file, and then the current segment file is scheduled to be dropped and the new segment file is made available. Plain `VACUUM` of an append-optimized table allows scans, inserts, deletes, and updates of the table while a segment file is compacted. However, an Access Exclusive lock is taken briefly to drop the current segment file and activate the new segment file.

`VACUUM FULL` does more extensive processing, including moving of tuples across blocks to try to compact the table to the minimum number of disk blocks. This form is much slower and requires an Access Exclusive lock on each table while it is being processed. The Access Exclusive lock guarantees that the holder is the only transaction accessing the table in any way.

When the option list is surrounded by parentheses, the options can be written in any order. Without parentheses, options must be specified in exactly the order shown above. The parenthesized syntax was added in Greenplum Database 6.0; the unparenthesized syntax is deprecated.

**Important:** For information on the use of `VACUUM`, `VACUUM FULL`, and `VACUUM ANALYZE`, see [Notes](#).

### Outputs

When `VERBOSE` is specified, `VACUUM` emits progress messages to indicate which table is currently being processed. Various statistics about the tables are printed as well.

## Parameters

### FULL

Selects a full vacuum, which may reclaim more space, but takes much longer and exclusively locks the table. This method also requires extra disk space, since it writes a new copy of the table and doesn't release the old copy until the operation is complete. Usually this should only be used when a significant amount of space needs to be reclaimed from within the table.

### FREEZE

Specifying `FREEZE` is equivalent to performing `VACUUM` with the `vacuum_freeze_min_age` server configuration parameter set to zero. See [Server Configuration Parameters](#) for information about `vacuum_freeze_min_age`.

### VERBOSE

Prints a detailed vacuum activity report for each table.

### ANALYZE

Updates statistics used by the planner to determine the most efficient way to run a query.

### table

The name (optionally schema-qualified) of a specific table to vacuum. Defaults to all tables in the current database.

### column

The name of a specific column to analyze. Defaults to all columns. If a column list is specified, `ANALYZE` is implied.

## Notes

`VACUUM` cannot be run inside a transaction block.

Vacuum active databases frequently (at least nightly), in order to remove expired rows. After adding or deleting a large number of rows, running the `VACUUM ANALYZE` command for the affected table might be useful. This updates the system catalogs with the results of all recent changes, and allows the Greenplum Database query optimizer to make better choices in planning queries.

**Important:** PostgreSQL has a separate optional server process called the *autovacuum daemon*, whose purpose is to automate the execution of `VACUUM` and `ANALYZE` commands. Greenplum Database enables the autovacuum daemon to perform `VACUUM` operations only on the Greenplum Database template database `template0`. Autovacuum is enabled for `template0` because connections are not allowed to `template0`. The autovacuum daemon performs `VACUUM` operations on `template0` to manage transaction IDs (XIDs) and help avoid transaction ID wraparound issues in `template0`.

Manual `VACUUM` operations must be performed in user-defined databases to manage transaction IDs (XIDs) in those databases.

`VACUUM` causes a substantial increase in I/O traffic, which can cause poor performance for other active sessions. Therefore, it is advisable to vacuum the database at low usage times.

`VACUUM` commands skip external and foreign tables.

`VACUUM FULL` reclaims all expired row space, however it requires an exclusive lock on each table being processed, is a very expensive operation, and might take a long time to complete on large, distributed Greenplum Database tables. Perform `VACUUM FULL` operations during database maintenance periods.

The `FULL` option is not recommended for routine use, but might be useful in special cases. An example is when you have deleted or updated most of the rows in a table and would like the table to physically shrink to occupy less disk space and allow faster table scans. `VACUUM FULL` will usually shrink the table more than a plain `VACUUM` would.

As an alternative to `VACUUM FULL`, you can re-create the table with a `CREATE TABLE AS` statement and drop the old table.

For append-optimized tables, `VACUUM` requires enough available disk space to accommodate the new segment file during the `VACUUM` process. If the ratio of hidden rows to total rows in a segment file is less than a threshold value (10, by default), the segment file is not compacted. The threshold value can be configured with the `gp_appendonly_compaction_threshold` server configuration parameter. `VACUUM FULL` ignores the threshold and rewrites the segment file regardless of the ratio. `VACUUM` can be deactivated for append-optimized tables using the `gp_appendonly_compaction` server configuration parameter. See [Server Configuration Parameters](#) for information about the server configuration parameters.

If a concurrent serializable transaction is detected when an append-optimized table is being vacuumed, the current and subsequent segment files are not compacted. If a segment file has been compacted but a concurrent serializable transaction is detected in the transaction that drops the original segment file, the drop is skipped. This could leave one or two segment files in an "awaiting drop" state after the vacuum has completed.

For more information about concurrency control in Greenplum Database, see "Routine System Maintenance Tasks" in *Greenplum Database Administrator Guide*.

## Examples

To clean a single table `onek`, analyze it for the optimizer and print a detailed vacuum activity report:

```
VACUUM (VERBOSE, ANALYZE) onek;
```

Vacuum all tables in the current database:

```
VACUUM;
```

Vacuum a specific table only:

```
VACUUM (VERBOSE, ANALYZE) mytable;
```

Vacuum all tables in the current database and collect statistics for the query optimizer:

```
VACUUM ANALYZE;
```

## Compatibility

There is no `VACUUM` statement in the SQL standard.

## VALUES

Computes a set of rows.

### Synopsis

```
VALUES ( <expression> [, ...] ) [, ...]
  [ORDER BY <sort_expression> [ ASC | DESC | USING <operator> ] [, ...] ]
  [LIMIT { <count> | ALL } ]
  [OFFSET <start> [ ROW | ROWS ] ]
  [FETCH { FIRST | NEXT } [<count> ] { ROW | ROWS } ONLY ]
```

### Description

**VALUES** computes a row value or set of row values specified by value expressions. It is most commonly used to generate a "constant table" within a larger command, but it can be used on its own.

When more than one row is specified, all the rows must have the same number of elements. The data types of the resulting table's columns are determined by combining the explicit or inferred types of the expressions appearing in that column, using the same rules as for **UNION**.

Within larger commands, **VALUES** is syntactically allowed anywhere that **SELECT** is. Because it is treated like a **SELECT** by the grammar, it is possible to use the **ORDER BY**, **LIMIT** (or equivalent **FETCH FIRST**), and **OFFSET** clauses with a **VALUES** command.

### Parameters

expression

A constant or expression to compute and insert at the indicated place in the resulting table (set of rows). In a **VALUES** list appearing at the top level of an **INSERT**, an expression can be replaced by **DEFAULT** to indicate that the destination column's default value should be inserted. **DEFAULT** cannot be used when **VALUES** appears in other contexts.

sort\_expression

An expression or integer constant indicating how to sort the result rows. This expression may refer to the columns of the **VALUES** result as **column1**, **column2**, etc. For more details, see "The ORDER BY Clause" in the parameters for **SELECT**.

operator

A sorting operator. For more details, see "The ORDER BY Clause" in the parameters for **SELECT**.

LIMIT count

OFFSET start

The maximum number of rows to return. For more details, see "The LIMIT Clause" in the parameters for **SELECT**.

### Notes

`VALUES` lists with very large numbers of rows should be avoided, as you may encounter out-of-memory failures or poor performance. `VALUES` appearing within `INSERT` is a special case (because the desired column types are known from the `INSERT`'s target table, and need not be inferred by scanning the `VALUES` list), so it can handle larger lists than are practical in other contexts.

## Examples

A bare `VALUES` command:

```
VALUES (1, 'one'), (2, 'two'), (3, 'three');
```

This will return a table of two columns and three rows. It is effectively equivalent to:

```
SELECT 1 AS column1, 'one' AS column2
UNION ALL
SELECT 2, 'two'
UNION ALL
SELECT 3, 'three';
```

More usually, `VALUES` is used within a larger SQL command. The most common use is in `INSERT`:

```
INSERT INTO films (code, title, did, date_prod, kind)
VALUES ('T_601', 'Yojimbo', 106, '1961-06-16', 'Drama');
```

In the context of `INSERT`, entries of a `VALUES` list can be `DEFAULT` to indicate that the column default should be used here instead of specifying a value:

```
INSERT INTO films VALUES
('UA502', 'Bananas', 105, DEFAULT, 'Comedy', '82
minutes'),
('T_601', 'Yojimbo', 106, DEFAULT, 'Drama', DEFAULT);
```

`VALUES` can also be used where a sub-`SELECT` might be written, for example in a `FROM` clause:

```
SELECT f.* FROM films f, (VALUES('MGM', 'Horror'), ('UA',
'Sci-Fi')) AS t (studio, kind) WHERE f.studio = t.studio AND
f.kind = t.kind;
UPDATE employees SET salary = salary * v.increase FROM
(VALUES(1, 200000, 1.2), (2, 400000, 1.4)) AS v (depno,
target, increase) WHERE employees.depno = v.depno AND
employees.sales >= v.target;
```

Note that an `AS` clause is required when `VALUES` is used in a `FROM` clause, just as is true for `SELECT`. It is not required that the `AS` clause specify names for all the columns, but it is good practice to do so. The default column names for `VALUES` are `column1`, `column2`, etc. in Greenplum Database, but these names might be different in other database systems.

When `VALUES` is used in `INSERT`, the values are all automatically coerced to the data type of the corresponding destination column. When it is used in other contexts, it may be necessary to specify the correct data type. If the entries are all quoted literal constants, coercing the first is sufficient to determine the assumed type for all:

```
SELECT * FROM machines WHERE ip_address IN
(VALUE ('192.168.0.1'::inet), ('192.168.0.10'),
('192.0.2.43'));
```

**Note:** For simple `IN` tests, it is better to rely on the list-of-scalars form of `IN` than to write a `VALUES` query as shown above. The list of scalars method requires less writing and is often more efficient.

## Compatibility

`VALUES` conforms to the SQL standard. `LIMIT` and `OFFSET` are Greenplum Database extensions; see also under `SELECT`.

## Data Types

Greenplum Database has a rich set of native data types available to users. Users may also define new data types using the `CREATE TYPE` command. This reference shows all of the built-in data types. In addition to the types listed here, there are also some internally used data types, such as `oid` (object identifier), but those are not documented in this guide.

Additional modules that you register may also install new data types. The `hstore` module, for example, introduces a new data type and associated functions for working with key-value pairs. See [hstore](#). The `citext` module adds a case-insensitive text data type. See [citext](#).

The following data types are specified by SQL: *bit*, *bit varying*, *boolean*, *character varying*, *varchar*, *character*, *char*, *date*, *double precision*, *integer*, *interval*, *numeric*, *decimal*, *real*, *smallint*, *time* (with or without time zone), and *timestamp* (with or without time zone).

Each data type has an external representation determined by its input and output functions. Many of the built-in types have obvious external formats. However, several types are either unique to PostgreSQL (and Greenplum Database), such as geometric paths, or have several possibilities for formats, such as the date and time types. Some of the input and output functions are not invertible. That is, the result of an output function may lose accuracy when compared to the original input.

<sup>1</sup> For variable length data types, if the data is greater than or equal to 127 bytes, the storage overhead is 4 bytes instead of 1.

## Date/Time Types

Greenplum supports the full set of SQL date and time types, shown in [Table 1](#). The operations available on these data types are described in [Date/Time Functions and Operators](#) in the PostgreSQL documentation. Dates are counted according to the Gregorian calendar, even in years before that calendar was introduced (see [History of Units](#) in the PostgreSQL documentation for more information).

| Name                                    | Storage Size | Description                        | Low Value        | High Value      | Resolution                |
|---|--------------|------------------------------------|------------------|-----------------|---------------------------|
| timestamp [ (p) ] [ without time zone ] | 8 bytes      | both date and time (no time zone)  | 4713 BC          | 294276 AD       | 1 microsecond / 14 digits |
| timestamp [ (p) ] with time zone        | 8 bytes      | both date and time, with time zone | 4713 BC          | 294276 AD       | 1 microsecond / 14 digits |
| date                                    | 4 bytes      | date (no time of day)              | 4713 BC          | 5874897 AD      | 1 day                     |
| time [ (p) ] [ without time zone ]      | 8 bytes      | time of day (no date)              | 00:00:00         | 24:00:00        | 1 microsecond / 14 digits |
| time [ (p) ] with time zone             | 12 bytes     | times of day only, with time zone  | 00:00:00+1459    | 24:00:00-1459   | 1 microsecond / 14 digits |
| interval [ fields ] [ (p) ]             | 16 bytes     | time interval                      | -178000000 years | 178000000 years | 1 microsecond / 14 digits |

**Note:** The SQL standard requires that writing just `timestamp` be equivalent to `timestamp without time zone`, and Greenplum honors that behavior. `timestamptz` is accepted as an abbreviation for `timestamp with time zone`; this is a PostgreSQL extension.

`time`, `timestamp`, and `interval` accept an optional precision value `p` which specifies the number of fractional digits retained in the seconds field. By default, there is no explicit bound on precision. The allowed range of `p` is from 0 to 6 for the `timestamp` and `interval` types.

**Note:** When `timestamp` values are stored as eight-byte integers (currently the default), microsecond precision is available over the full range of values. When `timestamp` values are stored as double precision floating-point numbers instead (a deprecated compile-time option), the effective limit of precision might be less than 6. `timestamp` values are stored as seconds before or after midnight 2000-01-01. When `timestamp` values are implemented using floating-point numbers, microsecond precision is achieved for dates within a few years of 2000-01-01, but the precision degrades for dates further away. Note that using floating-point datetimes allows a larger range of `timestamp` values to be represented than shown above: from 4713 BC up to 5874897 AD.

The same compile-time option also determines whether `time` and `interval` values are stored as floating-point numbers or eight-byte integers. In the floating-point case, large `interval` values degrade in precision as the size of the interval increases.

For the `time` types, the allowed range of `p` is from 0 to 6 when eight-byte integer storage is used, or from 0 to 10 when floating-point storage is used.

The `interval` type has an additional option, which is to restrict the set of stored fields by writing one of these phrases:

```
YEAR
MONTH
DAY
HOUR
MINUTE
SECOND
YEAR TO MONTH
DAY TO HOUR
DAY TO MINUTE
```

```
DAY TO SECOND
HOUR TO MINUTE
HOUR TO SECOND
MINUTE TO SECOND
```

Note that if both fields and `p` are specified, the fields must include `SECOND`, since the precision applies only to the seconds.

The type `time with time zone` is defined by the SQL standard, but the definition exhibits properties which lead to questionable usefulness. In most cases, a combination of `date`, `time`, `timestamp without time zone`, and `timestamp with time zone` should provide a complete range of date/time functionality required by any application.

The types `abstime` and `reltime` are lower precision types which are used internally. You are discouraged from using these types in applications; these internal types might disappear in a future release.

Greenplum Database 6 and later releases do not automatically cast text from the deprecated timestamp format `YYYYMMDDHH24MISS`. The format could not be parsed unambiguously in previous Greenplum Database releases.

For example, this command returns an error in Greenplum Database 6. In previous releases, a timestamp is returned.

```
# select to_timestamp('20190905140000');
```

In Greenplum Database 6, this command returns a timestamp.

```
# select to_timestamp('20190905140000','YYYYMMDDHH24MISS');
```

## Date/Time Input

Date and time input is accepted in almost any reasonable format, including ISO 8601, SQL-compatible, traditional POSTGRES, and others. For some formats, ordering of day, month, and year in date input is ambiguous and there is support for specifying the expected ordering of these fields. Set the `DateStyle` parameter to `MDY` to select month-day-year interpretation, `DMY` to select day-month-year interpretation, or `YMD` to select year-month-day interpretation.

Greenplum is more flexible in handling date/time input than the SQL standard requires. See [Appendix B. Date/Time Support](#) in the PostgreSQL documentation for the exact parsing rules of date/time input and for the recognized text fields including months, days of the week, and time zones.

Remember that any date or time literal input needs to be enclosed in single quotes, like text strings. SQL requires the following syntax

```
<type> [ (<p>) ] '<value>'
```

where `p` is an optional precision specification giving the number of fractional digits in the seconds field. Precision can be specified for `time`, `timestamp`, and `interval` types. The allowed values are

mentioned above. If no precision is specified in a constant specification, it defaults to the precision of the literal value.

## Dates

Table 2 shows some possible inputs for the `date` type.

| Example          | Description  |
|------------------|--|
| 1999-01-08       | ISO 8601; January 8 in any mode (recommended format)   |
| January 8, 1999  | unambiguous in any datestyle input mode  |
| 1/8/1999         | January 8 in <code>MDY</code> mode; August 1 in <code>DMY</code> mode  |
| 1/18/1999        | January 18 in <code>MDY</code> mode; rejected in other modes   |
| 01/02/03         | January 2, 2003 in <code>MDY</code> mode; February 1, 2003 in <code>DMY</code> mode; February 3, 2001 in <code>YMD</code> mode |
| 1999-Jan-08      | January 8 in any mode  |
| Jan-08-1999      | January 8 in any mode  |
| 08-Jan-1999      | January 8 in any mode  |
| 99-Jan-08        | January 8 in <code>YMD</code> mode, else error   |
| 08-Jan-99        | January 8, except error in <code>YMD</code> mode   |
| Jan-08-99        | January 8, except error in <code>YMD</code> mode   |
| 19990108         | ISO 8601; January 8, 1999 in any mode  |
| 990108           | ISO 8601; January 8, 1999 in any mode  |
| 1999.008         | year and day of year   |
| J2451187         | Julian date  |
| January 8, 99 BC | year 99 BC   |

## Times

The time-of-day types are `time [ (p) ] without time zone` and `time [ (p) ] with time zone`. `time` alone is equivalent to `time without time zone`.

Valid input for these types consists of a time of day followed by an optional time zone. (See Table 3 and Table 4.) If a time zone is specified in the input for `time without time zone`, it is silently ignored. You can also specify a date but it will be ignored, except when you use a time zone name that involves a daylight-savings rule, such as `America/New_York`. In this case specifying the date is required in order to determine whether standard or daylight-savings time applies. The appropriate time zone offset is recorded in the `time with time zone` value.

| Example      | Description |
|--------------|-------------|
| 04:05:06.789 | ISO 8601    |
| 04:05:06     | ISO 8601    |

| Example   | Description                             |
|---|---|
| <code>04:05</code>                                | ISO 8601                                |
| <code>040506</code>                               | ISO 8601                                |
| <code>04:05 AM</code>                             | same as 04:05; AM does not affect value |
| <code>04:05 PM</code>                             | same as 16:05; input hour must be ≤ 12  |
| <code>04:05:06.789-8</code>                       | ISO 8601                                |
| <code>04:05:06-08:00</code>                       | ISO 8601                                |
| <code>04:05-08:00</code>                          | ISO 8601                                |
| <code>040506-08</code>                            | ISO 8601                                |
| <code>04:05:06 PST</code>                         | time zone specified by abbreviation     |
| <code>2003-04-12 04:05:06 America/New_York</code> | time zone specified by full name        |

| Example                       | Description                              |
|-------------------------------|--|
| <code>PST</code>              | Abbreviation (for Pacific Standard Time) |
| <code>America/New_York</code> | Full time zone name                      |
| <code>PST8PDT</code>          | POSIX-style time zone specification      |
| <code>-8:00</code>            | ISO-8601 offset for PST                  |
| <code>-800</code>             | ISO-8601 offset for PST                  |
| <code>-8</code>               | ISO-8601 offset for PST                  |
| <code>zulu</code>             | Military abbreviation for UTC            |
| <code>z</code>                | Short form of <code>zulu</code>          |

Refer to [Time Zones](#) for more information on how to specify time zones.

## Time Stamps

Valid input for the time stamp types consists of the concatenation of a date and a time, followed by an optional time zone, followed by an optional `AD` or `BC`. (Alternatively, `AD/BC` can appear before the time zone, but this is not the preferred ordering.) Thus: `1999-01-08 04:05:06` and: `1999-01-08 04:05:06 -8:00` are valid values, which follow the ISO 8601 standard. In addition, the common format: `January 8 04:05:06 1999 PST` is supported.

The SQL standard differentiates `timestamp without time zone` and `timestamp with time zone` literals by the presence of a `+` or `-` symbol and time zone offset after the time. Hence, according to the standard, `TIMESTAMP '2004-10-19 10:23:54'` is a `timestamp without time zone`, while `TIMESTAMP '2004-10-19 10:23:54+02'` is a `timestamp with time zone`. Greenplum never examines the content of a literal string before determining its type, and therefore will treat both of the above as `timestamp without time zone`. To ensure that a literal is treated as `timestamp with time zone`, give it the correct explicit type: `TIMESTAMP WITH TIME ZONE '2004-10-19 10:23:54+02'` In a literal that has been determined to be `timestamp without time zone`, Greenplum will silently ignore any

time zone indication. That is, the resulting value is derived from the date/time fields in the input value, and is not adjusted for time zone.

For `timestamp with time zone`, the internally stored value is always in UTC (Universal Coordinated Time, traditionally known as Greenwich Mean Time, GMT). An input value that has an explicit time zone specified is converted to UTC using the appropriate offset for that time zone. If no time zone is stated in the input string, then it is assumed to be in the time zone indicated by the system's `TimeZone` parameter, and is converted to UTC using the offset for the timezone zone.

When a `timestamp with time zone` value is output, it is always converted from UTC to the current timezone zone, and displayed as local time in that zone. To see the time in another time zone, either change timezone or use the `AT TIME ZONE` construct (see `AT TIME ZONE` in the PostgreSQL documentation).

Conversions between `timestamp without time zone` and `timestamp with time zone` normally assume that the `timestamp without time zone` value should be taken or given as timezone local time. A different time zone can be specified for the conversion using `AT TIME ZONE`.

## Special Values

Greenplum supports several special date/time input values for convenience, as shown in [Table 5](#). The values `infinity` and `-infinity` are specially represented inside the system and will be displayed unchanged; but the others are simply notational shorthands that will be converted to ordinary date/time values when read. (In particular, `now` and related strings are converted to a specific time value as soon as they are read.) All of these values need to be enclosed in single quotes when used as constants in SQL commands.

| Input String           | Valid Types                        | Description                                    |
|------------------------|------------------------------------|--|
| <code>epoch</code>     | <code>date, timestamp</code>       | 1970-01-01 00:00:00+00 (Unix system time zero) |
| <code>infinity</code>  | <code>date, timestamp</code>       | later than all other time stamps               |
| <code>-infinity</code> | <code>date, timestamp</code>       | earlier than all other time stamps             |
| <code>now</code>       | <code>date, time, timestamp</code> | current transaction's start time               |
| <code>today</code>     | <code>date, timestamp</code>       | midnight today                                 |
| <code>tomorrow</code>  | <code>date, timestamp</code>       | midnight tomorrow                              |
| <code>yesterday</code> | <code>date, timestamp</code>       | midnight yesterday                             |
| <code>allballs</code>  | <code>time</code>                  | 00:00:00.00 UTC                                |

The following SQL-compatible functions can also be used to obtain the current time value for the corresponding data type: `CURRENT_DATE`, `CURRENT_TIME`, `CURRENT_TIMESTAMP`, `LOCALTIME`, `LOCALTIMESTAMP`. The latter four accept an optional subsecond precision specification. (See [Current Date/Time](#) in the PostgreSQL documentation.) Note that these are SQL functions and are *not* recognized in data input strings.

## Date/Time Output

The output format of the date/time types can be set to one of the four styles ISO 8601, SQL (Ingres), traditional POSTGRES (Unix `date` format), or German. The default is the ISO format. (The SQL standard requires the use of the ISO 8601 format. The name of the SQL output format is a historical accident.) Table 6 shows examples of each output style. The output of the `date` and `time` types is generally only the date or time part in accordance with the given examples. However, the POSTGRES style outputs date-only values in ISO format.

| Style Specification | Description            | Example                      |
|---------------------|------------------------|------------------------------|
| ISO                 | ISO 8601, SQL standard | 1997-12-17 07:37:16-08       |
| SQL                 | traditional style      | 12/17/1997 07:37:16.00 PST   |
| Postgres            | original style         | Wed Dec 17 07:37:16 1997 PST |
| German              | regional style         | 17.12.1997 07:37:16.00 PST   |

**Note:** ISO 8601 specifies the use of uppercase letter `T` to separate the date and time. Greenplum accepts that format on input, but on output it uses a space rather than `T`, as shown above. This is for readability and for consistency with RFC 3339 as well as some other database systems.

In the SQL and POSTGRES styles, day appears before month if DMY field ordering has been specified, otherwise month appears before day. (See Table 2 for how this setting also affects interpretation of input values.) Table 7 shows examples.

| datestyle Setting | Input Ordering | Example Output               |
|-------------------|----------------|------------------------------|
| SQL, DMY          | day/month/year | 17/12/1997 15:37:16.00 CET   |
| SQL, MDY          | month/day/year | 12/17/1997 07:37:16.00 PST   |
| Postgres, DMY     | day/month/year | Wed 17 Dec 07:37:16 1997 PST |

The date/time style can be selected by the user using the `SET datestyle` command, the `DateStyle` parameter in the `postgresql.conf` configuration file, or the `PGDATESTYLE` environment variable on the server or client.

The formatting function `to_char` (see [Data Type Formatting Functions](#)) is also available as a more flexible way to format date/time output.

## Time Zones

Time zones, and time-zone conventions, are influenced by political decisions, not just earth geometry. Time zones around the world became somewhat standardized during the 1900s, but continue to be prone to arbitrary changes, particularly with respect to daylight-savings rules. Greenplum uses the widely-used IANA (Olson) time zone database for information about historical time zone rules. For times in the future, the assumption is that the latest known rules for a given time zone will continue to be observed indefinitely far into the future.

Greenplum endeavors to be compatible with the SQL standard definitions for typical usage. However, the SQL standard has an odd mix of date and time types and capabilities. Two obvious problems are:

1. Although the `date` type cannot have an associated time zone, the `time` type can. Time zones in the real world have little meaning unless associated with a date as well as a time,

since the offset can vary through the year with daylight-saving time boundaries.

2. The default time zone is specified as a constant numeric offset from UTC. It is therefore impossible to adapt to daylight-saving time when doing date/time arithmetic across DST boundaries.

To address these difficulties, we recommend using date/time types that contain both date and time when using time zones. We do *not* recommend using the type `time with time zone` (though it is supported by Greenplum for legacy applications and for compliance with the SQL standard). Greenplum assumes your local time zone for any type containing only date or time.

All timezone-aware dates and times are stored internally in UTC. They are converted to local time in the zone specified by the `TimeZone` configuration parameter before being displayed to the client.

Greenplum allows you to specify time zones in three different forms:

1. A full time zone name, for example `America/New_York`. The recognized time zone names are listed in the `pg_timezone_names` view. Greenplum uses the widely-used IANA time zone data for this purpose, so the same time zone names are also recognized by other software.
2. A time zone abbreviation, for example `PST`. Such a specification merely defines a particular offset from UTC, in contrast to full time zone names which can imply a set of daylight savings transition-date rules as well. The recognized abbreviations are listed in the `pg_timezone_abbrevs` view. You cannot set the configuration parameters `TimeZone` or `log_timezone` to a time zone abbreviation, but you can use abbreviations in date/time input values and with the `AT TIME ZONE` operator.
3. In addition to the timezone names and abbreviations, Greenplum will accept POSIX-style time zone specifications of the form `STDoffset` or `STDoffsetDST`, where `STD` is a zone abbreviation, `offset` is a numeric offset in hours west from UTC, and `DST` is an optional daylight-savings zone abbreviation, assumed to stand for one hour ahead of the given offset. For example, if `EST5EDT` were not already a recognized zone name, it would be accepted and would be functionally equivalent to United States East Coast time. In this syntax, a zone abbreviation can be a string of letters, or an arbitrary string surrounded by angle brackets (`<>`). When a daylight-savings zone abbreviation is present, it is assumed to be used according to the same daylight-savings transition rules used in the IANA time zone database's entry. In a standard Greenplum installation, is the same as `US/Eastern`, so that POSIX-style time zone specifications follow USA daylight-savings rules. If needed, you can adjust this behavior by replacing the file.

In short, this is the difference between abbreviations and full names: abbreviations represent a specific offset from UTC, whereas many of the full names imply a local daylight-savings time rule, and so have two possible UTC offsets. As an example, `2014-06-04 12:00 America/New_York` represents noon local time in New York, which for this particular date was Eastern Daylight Time (UTC-4). So `2014-06-04 12:00 EDT` specifies that same time instant. But `2014-06-04 12:00 EST` specifies noon Eastern Standard Time (UTC-5), regardless of whether daylight savings was nominally in effect on that date.

To complicate matters, some jurisdictions have used the same timezone abbreviation to mean different UTC offsets at different times; for example, in Moscow `MSK` has meant UTC+3 in some years and UTC+4 in others. Greenplum interprets such abbreviations according to whatever they meant (or had most recently meant) on the specified date; but, as with the `EST` example above, this is not necessarily the same as local civil time on that date.

One should be wary that the POSIX-style time zone feature can lead to silently accepting bogus input, since there is no check on the reasonableness of the zone abbreviations. For example, `SET TIMEZONE TO FOOBAR0` will work, leaving the system effectively using a rather peculiar abbreviation for UTC. Another issue to keep in mind is that in POSIX time zone names, positive offsets are used for locations of Greenwich. Everywhere else, Greenplum follows the ISO-8601 convention that positive timezone offsets are of Greenwich.

In all cases, timezone names and abbreviations are recognized case-insensitively.

Neither timezone names nor abbreviations are hard-wired into the server; they are obtained from configuration files (see [Configuring Localization Settings](#)).

The `TimeZone` configuration parameter can be set in the file `postgresql.conf`, or in any of the other standard ways for setting configuration parameters. There are also some special ways to set it:

1. The SQL command `SET TIME ZONE` sets the time zone for the session. This is an alternative spelling of `SET TIMEZONE TO` with a more SQL-spec-compatible syntax.
2. The `PGTZ` environment variable is used by `libpq` clients to send a `SET TIME ZONE` command to the server upon connection.

## Interval Input

`interval` values can be written using the following verbose syntax:

```
<@> <quantity> <unit> <quantity> <unit>... <direction>
```

where quantity is a number (possibly signed); unit is `microsecond`, `millisecond`, `second`, `minute`, `hour`, `day`, `week`, `month`, `year`, `decade`, `century`, `millennium`, or abbreviations or plurals of these units; direction can be `ago` or empty. The at sign (`@`) is optional noise. The amounts of the different units are implicitly added with appropriate sign accounting. `ago` negates all the fields. This syntax is also used for interval output, if `IntervalStyle` is set to `postgres_verbose`.

Quantities of days, hours, minutes, and seconds can be specified without explicit unit markings. For example, `'1 12:59:10'` is read the same as `'1 day 12 hours 59 min 10 sec'`. Also, a combination of years and months can be specified with a dash; for example `'200-10'` is read the same as `'200 years 10 months'`. (These shorter forms are in fact the only ones allowed by the SQL standard, and are used for output when `IntervalStyle` is set to `sql_standard`.)

Interval values can also be written as ISO 8601 time intervals, using either the `format with designators` of the standard's section 4.4.3.2 or the `alternative format` of section 4.4.3.3. The format with designators looks like this:

```
P <quantity> <unit> <quantity> <unit> ... T <quantity> <unit> ...
```

The string must start with a `P`, and may include a `T` that introduces the time-of-day units. The available unit abbreviations are given in [Table 8](#). Units may be omitted, and may be specified in any order, but units smaller than a day must appear after `T`. In particular, the meaning of `M` depends on whether it is before or after `T`.

| Abbreviation | Meaning                    |
|--------------|----------------------------|
| Y            | Years                      |
| M            | Months (in the date part)  |
| W            | Weeks                      |
| D            | Days                       |
| H            | Hours                      |
| M            | Minutes (in the time part) |
| S            | Seconds                    |

In the alternative format:

```
P <years>-<months>-<days> T <hours>:<minutes>:<seconds>
```

the string must begin with **P**, and a **T** separates the date and time parts of the interval. The values are given as numbers similar to ISO 8601 dates.

When writing an interval constant with a fields specification, or when assigning a string to an interval column that was defined with a fields specification, the interpretation of unmarked quantities depends on the fields. For example `INTERVAL '1' YEAR` is read as 1 year, whereas `INTERVAL '1'` means 1 second. Also, field values to the right of the least significant field allowed by the fields specification are silently discarded. For example, writing `INTERVAL '1 day 2:03:04' HOUR TO MINUTE` results in dropping the seconds field, but not the day field.

According to the SQL standard all fields of an interval value must have the same sign, so a leading negative sign applies to all fields; for example the negative sign in the interval literal `'-1 2:03:04'` applies to both the days and hour/minute/second parts. Greenplum allows the fields to have different signs, and traditionally treats each field in the textual representation as independently signed, so that the hour/minute/second part is considered positive in this example. If `IntervalStyle` is set to `sql_standard` then a leading sign is considered to apply to all fields (but only if no additional signs appear). Otherwise the traditional Greenplum interpretation is used. To avoid ambiguity, it's recommended to attach an explicit sign to each field if any field is negative.

In the verbose input format, and in some fields of the more compact input formats, field values can have fractional parts; for example `'1.5 week'` or `'01:02:03.45'`. Such input is converted to the appropriate number of months, days, and seconds for storage. When this would result in a fractional number of months or days, the fraction is added to the lower-order fields using the conversion factors 1 month = 30 days and 1 day = 24 hours. For example, `'1.5 month'` becomes 1 month and 15 days. Only seconds will ever be shown as fractional on output.

Table 9 shows some examples of valid `interval` input.

| Example   | Description   |
|-----------|---|
| 1-2       | SQL standard format: 1 year 2 months                    |
| 3 4:05:06 | SQL standard format: 3 days 4 hours 5 minutes 6 seconds |

| Example  | Description   |
|--|---|
| 1 year 2 months 3 days 4 hours 5 minutes 6 seconds | Traditional Postgres format: 1 year 2 months 3 days 4 hours 5 minutes 6 seconds |
| P1Y2M3DT4H5M6S                                     | ISO 8601 <i>format with designators</i> : same meaning as above                 |
| P0001-02-03T04:05:06                               | ISO 8601 <i>alternative format</i> : same meaning as above                      |

Internally `interval` values are stored as months, days, and seconds. This is done because the number of days in a month varies, and a day can have 23 or 25 hours if a daylight savings time adjustment is involved. The months and days fields are integers while the seconds field can store fractions. Because intervals are usually created from constant strings or `timestamp` subtraction, this storage method works well in most cases, but can cause unexpected results: `SELECT EXTRACT(hours from '80 minutes'::interval); date_part ----- 1` `SELECT EXTRACT(days from '80 hours'::interval); date_part ----- 0` Functions `justify_days` and `justify_hours` are available for adjusting days and hours that overflow their normal ranges.

## Interval Output

The output format of the interval type can be set to one of the four styles `sql_standard`, `postgres`, `postgres_verbose`, or `iso_8601`, using the command `SET intervalstyle`. The default is the `postgres` format. [Table 10](#) shows examples of each output style.

The `sql_standard` style produces output that conforms to the SQL standard's specification for interval literal strings, if the interval value meets the standard's restrictions (either year-month only or day-time only, with no mixing of positive and negative components). Otherwise the output looks like a standard year-month literal string followed by a day-time literal string, with explicit signs added to disambiguate mixed-sign intervals.

The output of the `postgres` style matches the output of PostgreSQL releases prior to 8.4 when the `DateStyle` parameter was set to `ISO`.

The output of the `postgres_verbose` style matches the output of PostgreSQL releases prior to 8.4 when the `DateStyle` parameter was set to non-`ISO` output.

The output of the `iso_8601` style matches the *format with designators* described in section 4.4.3.2 of the ISO 8601 standard.

| Style Specification           | Year-Month Interval | Day-Time Interval              | Mixed Interval                                    |
|-------------------------------|---------------------|--------------------------------|---|
| <code>sql_standard</code>     | 1-2                 | 3 4:05:06                      | -1-2 +3 -4:05:06                                  |
| <code>postgres</code>         | 1 year 2 mons       | 3 days 04:05:06                | -1 year -2 mons +3 days -04:05:06                 |
| <code>postgres_verbose</code> | @ 1 year 2 mons     | @ 3 days 4 hours 5 mins 6 secs | @ 1 year 2 mons -3 days 4 hours 5 mins 6 secs ago |
| <code>iso_8601</code>         | P1Y2M               | P3DT4H5M6S                     | P-1Y-2M3DT-4H-5M-6S                               |

Parent topic: [Data Types](#)

## Pseudo-Types

Greenplum Database supports special-purpose data type entries that are collectively called *pseudo-types*. A pseudo-type cannot be used as a column data type, but it can be used to declare a function's argument or result type. Each of the available pseudo-types is useful in situations where a function's behavior does not correspond to simply taking or returning a value of a specific SQL data type.

Functions coded in procedural languages can use pseudo-types only as allowed by their implementation languages. The procedural languages all forbid use of a pseudo-type as an argument type, and allow only *void* and *record* as a result type.

A function with the pseudo-type *record* as a return data type returns an unspecified row type. The *record* represents an array of possibly-anonymous composite types. Since composite datums carry their own type identification, no extra knowledge is needed at the array level.

The pseudo-type *void* indicates that a function returns no value.

**Note:** Greenplum Database does not support triggers and the pseudo-type *trigger*.

The types *anyelement*, *anyarray*, *anynonarray*, and *anyenum* are pseudo-types called polymorphic types. Some procedural languages also support polymorphic functions using the types *anyarray*, *anyelement*, *anyenum*, and *anynonarray*.

The pseudo-type *anytable* is a Greenplum Database type that specifies a table expression—an expression that computes a table. Greenplum Database allows this type only as an argument to a user-defined function. See [Table Value Expressions](#) for more about the *anytable* pseudo-type.

For more information about pseudo-types, see the PostgreSQL documentation about [Pseudo-Types](#).

**Parent topic:** [Data Types](#)

## Polymorphic Types

Four pseudo-types of special interest are *anyelement*, *anyarray*, *anynonarray*, and *anyenum*, which are collectively called *polymorphic* types. Any function declared using these types is said to be a polymorphic function. A polymorphic function can operate on many different data types, with the specific data types being determined by the data types actually passed to it at runtime.

Polymorphic arguments and results are tied to each other and are resolved to a specific data type when a query calling a polymorphic function is parsed. Each position (either argument or return value) declared as *anyelement* is allowed to have any specific actual data type, but in any given call they must all be the same actual type. Each position declared as *anyarray* can have any array data type, but similarly they must all be the same type. If there are positions declared *anyarray* and others declared *anyelement*, the actual array type in the *anyarray* positions must be an array whose elements are the same type appearing in the *anyelement* positions. *anynonarray* is treated exactly the same as *anyelement*, but adds the additional constraint that the actual type must not be an array type. *anyenum* is treated exactly the same as *anyelement*, but adds the additional constraint that the actual type must be an `enum` type.

When more than one argument position is declared with a polymorphic type, the net effect is that only certain combinations of actual argument types are allowed. For example, a function declared as `equal(*anyelement*, *anyelement*)` takes any two input values, so long as they are of the same data type.

When the return value of a function is declared as a polymorphic type, there must be at least one argument position that is also polymorphic, and the actual data type supplied as the argument determines the actual result type for that call. For example, if there were not already an array subscripting mechanism, one could define a function that implements subscripting as `subscript(*anyarray*, integer) returns *anyelement*`. This declaration constrains the actual first argument to be an array type, and allows the parser to infer the correct result type from the actual first argument's type. Another example is that a function declared as `myfunc(*anyarray*) returns *anyenum*` will only accept arrays of `enum` types.

Note that `anynonarray` and `anyenum` do not represent separate type variables; they are the same type as `anyelement`, just with an additional constraint. For example, declaring a function as `myfunc(*anyelement*, *anyenum*)` is equivalent to declaring it as `myfunc(*anyenum*, *anyenum*)`: both actual arguments must be the same `enum` type.

A variadic function (one taking a variable number of arguments) is polymorphic when its last parameter is declared as `VARIADIC *anyarray*`. For purposes of argument matching and determining the actual result type, such a function behaves the same as if you had declared the appropriate number of `anynonarray` parameters.

For more information about polymorphic types, see the PostgreSQL documentation about [Polymorphic Arguments and Return Types](#).

## Table Value Expressions

The `anytable` pseudo-type declares a function argument that is a table value expression. The notation for a table value expression is a `SELECT` statement enclosed in a `TABLE()` function. You can specify a distribution policy for the table by adding `SCATTER RANDOMLY`, or a `SCATTER BY` clause with a column list to specify the distribution key.

The `SELECT` statement is run when the function is called and the result rows are distributed to segments so that each segment runs the function with a subset of the result table.

For example, this table expression selects three columns from a table named `customer` and sets the distribution key to the first column:

```
TABLE(SELECT cust_key, name, address FROM customer SCATTER BY 1)
```

The `SELECT` statement may include joins on multiple base tables, `WHERE` clauses, aggregates, and any other valid query syntax.

The `anytable` type is only permitted in functions implemented in the C or C++ languages. The body of the function can access the table using the Greenplum Database Server Programming Interface (SPI) or the Greenplum Partner Connector (GPPC) API.

The `anytable` type is used in some user-defined functions in the Tanzu Greenplum Text API. The following GPText example uses the `TABLE` function with the `SCATTER BY` clause in the GPText function `gptext.index()` to populate the index `mydb.mytest.articles` with data from the messages table:

```
SELECT * FROM gptext.index(TABLE(SELECT * FROM mytest.messages
    SCATTER BY distrib_id), 'mydb.mytest.messages');
```

For information about the function `gptext.index()`, see the Tanzu Greenplum Text documentation.

## Text Search Data Types

Greenplum Database provides two data types that are designed to support full text search, which is the activity of searching through a collection of natural-language *documents* to locate those that best match a *query*. The `tsvector` type represents a document in a form optimized for text search; the `tsquery` type similarly represents a text query. [Using Full Text Search](#) provides a detailed explanation of this facility, and [Text Search Functions and Operators](#) summarizes the related functions and operators.

The `tsvector` and `tsquery` types cannot be part of the distribution key of a Greenplum Database table.

Parent topic: [Data Types](#)

### tsvector

A `tsvector` value is a sorted list of distinct *lexemes*, which are words that have been *normalized* to merge different variants of the same word (see [Using Full Text Search](#) for details). Sorting and duplicate-elimination are done automatically during input, as shown in this example:

```
SELECT 'a fat cat sat on a mat and ate a fat rat'::tsvector;
           tsvector
-----
'a' 'and' 'ate' 'cat' 'fat' 'mat' 'on' 'rat' 'sat'
```

To represent lexemes containing whitespace or punctuation, surround them with quotes:

```
SELECT $$the lexeme ' ' contains spaces$$::tsvector;
           tsvector
-----
' ' 'contains' 'lexeme' 'spaces' 'the'
```

(We use dollar-quoted string literals in this example and the next one to avoid the confusion of having to double quote marks within the literals.) Embedded quotes and backslashes must be doubled:

```
SELECT $$the lexeme 'Joe''s' contains a quote$$::tsvector;
           tsvector
-----
'Joe''s' 'a' 'contains' 'lexeme' 'quote' 'the'
```

Optionally, integer *positions* can be attached to lexemes:

```
SELECT 'a:1 fat:2 cat:3 sat:4 on:5 a:6 mat:7 and:8 ate:9 a:10 fat:11 rat:12'::tsvector;
           tsvector
-----
'a':1,6,10 'and':8 'ate':9 'cat':3 'fat':2,11 'mat':7 'on':5 'rat':12 'sat':4
```

A position normally indicates the source word's location in the document. Positional information can be used for *proximity ranking*. Position values can range from 1 to 16383; larger numbers are

silently set to 16383. Duplicate positions for the same lexeme are discarded.

Lexemes that have positions can further be labeled with a *weight*, which can be **A**, **B**, **C**, or **D**. **D** is the default and hence is not shown on output:

```
SELECT 'a:1A fat:2B,4C cat:5D'::tsvector;
      tsvector
-----
'a':1A 'cat':5 'fat':2B,4C
```

Weights are typically used to reflect document structure, for example by marking title words differently from body words. Text search ranking functions can assign different priorities to the different weight markers.

It is important to understand that the `tsvector` type itself does not perform any normalization; it assumes the words it is given are normalized appropriately for the application. For example,

```
select 'The Fat Rats'::tsvector;
      tsvector
-----
'Fat' 'Rats' 'The'
```

For most English-text-searching applications the above words would be considered non-normalized, but `tsvector` doesn't care. Raw document text should usually be passed through `to_tsvector` to normalize the words appropriately for searching:

```
SELECT to_tsvector('english', 'The Fat Rats');
      to_tsvector
-----
'fat':2 'rat':3
```

## tsquery

A `tsquery` value stores lexemes that are to be searched for, and combines them honoring the Boolean operators `&` (AND), `|` (OR), and `!` (NOT). Parentheses can be used to enforce grouping of the operators:

```
SELECT 'fat & rat'::tsquery;
      tsquery
-----
'fat' & 'rat'

SELECT 'fat & (rat | cat)'::tsquery;
      tsquery
-----
'fat' & ( 'rat' | 'cat' )

SELECT 'fat & rat & ! cat'::tsquery;
      tsquery
-----
'fat' & 'rat' & !'cat'
```

In the absence of parentheses, `!` (NOT) binds most tightly, and `&` (AND) binds more tightly than `|` (OR).

Optionally, lexemes in a `tsquery` can be labeled with one or more weight letters, which restricts them to match only `tsvector` lexemes with matching weights:

```
SELECT 'fat:ab & cat'::tsquery;
      tsquery
-----
'fat':AB & 'cat'
```

Also, lexemes in a `tsquery` can be labeled with `*` to specify prefix matching:

```
SELECT 'super:*'::tsquery;
      tsquery
-----
'super':*
```

This query will match any word in a `tsvector` that begins with "super". Note that prefixes are first processed by text search configurations, which means this comparison returns true:

```
SELECT to_tsvector( 'postgraduate' ) @@ to_tsquery( 'postgres:*' );
?column?
-----
t
(1 row)
```

because `postgres` gets stemmed to `postgr`:

```
SELECT to_tsquery('postgres:*');
      to_tsquery
-----
'postgr':*
(1 row)
```

which then matches `postgraduate`.

Quoting rules for lexemes are the same as described previously for lexemes in `tsvector`; and, as with `tsvector`, any required normalization of words must be done before converting to the `tsquery` type. The `to_tsquery` function is convenient for performing such normalization:

```
SELECT to_tsquery('Fat:ab & Cats');
      to_tsquery
-----
'fat':AB & 'cat'
```

## Range Types

Range types are data types representing a range of values of some element type (called the range's subtype). For instance, ranges of `timestamp` might be used to represent the ranges of time that a meeting room is reserved. In this case the data type is `tsrange` (short for "timestamp range"), and `timestamp` is the subtype. The subtype must have a total order so that it is well-defined whether element values are within, before, or after a range of values.

Range types are useful because they represent many element values in a single range value, and because concepts such as overlapping ranges can be expressed clearly. The use of time and date

ranges for scheduling purposes is the clearest example; but price ranges, measurement ranges from an instrument, and so forth can also be useful.

Parent topic: [Data Types](#)

## Built-in Range Types

Greenplum Database comes with the following built-in range types:

- `int4range` -- Range of `integer`
- `int8range` -- Range of `bigint`
- `numrange` -- Range of `numeric`
- `tsrange` -- Range of `timestamp without time zone`
- `tstzrange` -- Range of `timestamp with time zone`
- `daterange` -- Range of `date`

In addition, you can define your own range types; see [CREATE TYPE](#) for more information.

## Examples

```
CREATE TABLE reservation (room int, during tsrange);
INSERT INTO reservation VALUES
    (1108, '[2010-01-01 14:30, 2010-01-01 15:30)');

-- Containment
SELECT int4range(10, 20) @> 3;

-- Overlaps
SELECT numrange(11.1, 22.2) && numrange(20.0, 30.0);

-- Extract the upper bound
SELECT upper(int8range(15, 25));

-- Compute the intersection
SELECT int4range(10, 20) * int4range(15, 25);

-- Is the range empty?
SELECT isempty(numrange(1, 5));
```

See [Range Functions and Operators](#) for complete lists of operators and functions on range types.

## Inclusive and Exclusive Bounds

Every non-empty range has two bounds, the lower bound and the upper bound. All points between these values are included in the range. An inclusive bound means that the boundary point itself is included in the range as well, while an exclusive bound means that the boundary point is not included in the range.

In the text form of a range, an inclusive lower bound is represented by `[` while an exclusive lower bound is represented by `(`. Likewise, an inclusive upper bound is represented by `]`, while an exclusive upper bound is represented by `)`. (See [Range Functions and Operators](#) for more details.)

The functions `lower_inc` and `upper_inc` test the inclusivity of the lower and upper bounds of a range value, respectively.

## Infinite (Unbounded) Ranges

The lower bound of a range can be omitted, meaning that all points less than the upper bound are included in the range. Likewise, if the upper bound of the range is omitted, then all points greater than the lower bound are included in the range. If both lower and upper bounds are omitted, all values of the element type are considered to be in the range.

This is equivalent to considering that the lower bound is “minus infinity”, or the upper bound is “plus infinity”, respectively. But note that these infinite values are never values of the range's element type, and can never be part of the range. (So there is no such thing as an inclusive infinite bound -- if you try to write one, it will automatically be converted to an exclusive bound.)

Also, some element types have a notion of “infinity”, but that is just another value so far as the range type mechanisms are concerned. For example, in timestamp ranges, `[today,]` means the same thing as `[today,)`. But `[today,infinity]` means something different from `[today,infinity)` -- the latter excludes the special timestamp value `infinity`.

The functions `lower_inf` and `upper_inf` test for infinite lower and upper bounds of a range, respectively.

## Range Input/Output

The input for a range value must follow one of the following patterns:

```
(<lower-bound>,<upper-bound>)
(<lower-bound>,<upper-bound>]
[<lower-bound>,<upper-bound>)
[<lower-bound>,<upper-bound>]
empty
```

The parentheses or brackets indicate whether the lower and upper bounds are exclusive or inclusive, as described previously. Notice that the final pattern is `empty`, which represents an empty range (a range that contains no points).

The lower-bound may be either a string that is valid input for the subtype, or empty to indicate no lower bound. Likewise, upper-bound may be either a string that is valid input for the subtype, or empty to indicate no upper bound.

Each bound value can be quoted using `"` (double quote) characters. This is necessary if the bound value contains parentheses, brackets, commas, double quotes, or backslashes, since these characters would otherwise be taken as part of the range syntax. To put a double quote or backslash in a quoted bound value, precede it with a backslash. (Also, a pair of double quotes within a double-quoted bound value is taken to represent a double quote character, analogously to the

rules for single quotes in SQL literal strings.) Alternatively, you can avoid quoting and use backslash-escaping to protect all data characters that would otherwise be taken as range syntax. Also, to write a bound value that is an empty string, write "", since writing nothing means an infinite bound.

Whitespace is allowed before and after the range value, but any whitespace between the parentheses or brackets is taken as part of the lower or upper bound value. (Depending on the element type, it might or might not be significant.)

Examples:

```
-- includes 3, does not include 7, and does include all points in between
SELECT '[3,7)>:::int4range;

-- does not include either 3 or 7, but includes all points in between
SELECT '(3,7)>:::int4range;

-- includes only the single point 4
SELECT '[4,4]>:::int4range;

-- includes no points (and will be normalized to 'empty')
SELECT '[4,4)>:::int4range;
```

## Constructing Ranges

Each range type has a constructor function with the same name as the range type. Using the constructor function is frequently more convenient than writing a range literal constant, since it avoids the need for extra quoting of the bound values. The constructor function accepts two or three arguments. The two-argument form constructs a range in standard form (lower bound inclusive, upper bound exclusive), while the three-argument form constructs a range with bounds of the form specified by the third argument. The third argument must be one of the strings (), [], (), or []. For example:

```
-- The full form is: lower bound, upper bound, and text argument indicating
-- inclusivity/exclusivity of bounds.
SELECT numrange(1.0, 14.0, '()');

-- If the third argument is omitted, '()' is assumed.
SELECT numrange(1.0, 14.0);

-- Although '()' is specified here, on display the value will be converted to
-- canonical form, since int8range is a discrete range type (see below).
SELECT int8range(1, 14, '()');

-- Using NULL for either bound causes the range to be unbounded on that side.
SELECT numrange(NULL, 2.2);
```

## Discrete Range Types

A discrete range is one whose element type has a well-defined “step”, such as `integer` or `date`. In these types two elements can be said to be adjacent, when there are no valid values between them. This contrasts with continuous ranges, where it's always (or almost always) possible to identify other element values between two given values. For example, a range over the `numeric` type is continuous, as is a range over `timestamp`. (Even though `timestamp` has limited precision, and so could theoretically be treated as discrete, it's better to consider it continuous since the step size is normally not of interest.)

Another way to think about a discrete range type is that there is a clear idea of a “next” or “previous” value for each element value. Knowing that, it is possible to convert between inclusive and exclusive representations of a range's bounds, by choosing the next or previous element value instead of the one originally given. For example, in an integer range type `[4,8]` and `(3,9)` denote the same set of values; but this would not be so for a range over `numeric`.

A discrete range type should have a *canonicalization* function that is aware of the desired step size for the element type. The canonicalization function is charged with converting equivalent values of the range type to have identical representations, in particular consistently inclusive or exclusive bounds. If a canonicalization function is not specified, then ranges with different formatting will always be treated as unequal, even though they might represent the same set of values in reality.

The built-in range types `int4range`, `int8range`, and `daterange` all use a canonical form that includes the lower bound and excludes the upper bound; that is, `[ )`. User-defined range types can use other conventions, however.

## Defining New Range Types

Users can define their own range types. The most common reason to do this is to use ranges over subtypes not provided among the built-in range types. For example, to define a new range type of subtype `float8`:

```
CREATE TYPE floatrange AS RANGE (
    subtype = float8,
    subtype_diff = float8mi
);

SELECT '[1.234, 5.678]':floatrange;
```

Because `float8` has no meaningful “step”, we do not define a canonicalization function in this example.

Defining your own range type also allows you to specify a different subtype B-tree operator class or collation to use, so as to change the sort ordering that determines which values fall into a given range.

If the subtype is considered to have discrete rather than continuous values, the `CREATE TYPE` command should specify a `canonical` function. The canonicalization function takes an input range value, and must return an equivalent range value that may have different bounds and formatting. The canonical output for two ranges that represent the same set of values, for example the integer ranges `[1, 7]` and `[1, 8)`, must be identical. It doesn't matter which representation you choose to be the canonical one, so long as two equivalent values with different formattings are always

mapped to the same value with the same formatting. In addition to adjusting the inclusive/exclusive bounds format, a canonicalization function might round off boundary values, in case the desired step size is larger than what the subtype is capable of storing. For instance, a range type over `timestamp` could be defined to have a step size of an hour, in which case the canonicalization function would need to round off bounds that weren't a multiple of an hour, or perhaps throw an error instead.

In addition, any range type that is meant to be used with GiST or SP-GiST indexes should define a subtype difference, or `subtype_diff`, function. (The index will still work without `subtype_diff`, but it is likely to be considerably less efficient than if a difference function is provided.) The subtype difference function takes two input values of the subtype, and returns their difference (i.e., X minus Y) represented as a `float8` value. In our example above, the function `float8mi` that underlies the regular `float8` minus operator can be used; but for any other subtype, some type conversion would be necessary. Some creative thought about how to represent differences as numbers might be needed, too. To the greatest extent possible, the `subtype_diff` function should agree with the sort ordering implied by the selected operator class and collation; that is, its result should be positive whenever its first argument is greater than its second according to the sort ordering.

A less-oversimplified example of a `subtype_diff` function is:

```
CREATE FUNCTION time_subtype_diff(x time, y time) RETURNS float8 AS
'SELECT EXTRACT(EPOCH FROM (x - y))' LANGUAGE sql STRICT IMMUTABLE;

CREATE TYPE timerange AS RANGE (
    subtype = time,
    subtype_diff = time_subtype_diff
);

SELECT '[11:10, 23:00]':timerange;
```

See [CREATE TYPE](#) for more information about creating range types.

## Indexing

GiST and SP-GiST indexes can be created for table columns of range types. For instance, to create a GiST index:

```
CREATE INDEX reservation_idx ON reservation USING GIST (during);
```

A GiST or SP-GiST index can accelerate queries involving these range operators: `=`, `&&`, `<@`, `@>`, `<<`, `>>`, `-|-`, `&<`, and `&>` (see [Range Functions and Operators](#) for more information).

In addition, B-tree and hash indexes can be created for table columns of range types. For these index types, basically the only useful range operation is equality. There is a B-tree sort ordering defined for range values, with corresponding `<` and `>` operators, but the ordering is rather arbitrary and not usually useful in the real world. Range types' B-tree and hash support is primarily meant to allow sorting and hashing internally in queries, rather than creation of actual indexes.

## Summary of Built-in Functions

Greenplum Database supports built-in functions and operators including analytic functions and window functions that can be used in window expressions. For information about using built-in Greenplum Database functions see, "Using Functions and Operators" in the *Greenplum Database Administrator Guide*.

- [Greenplum Database Function Types](#)
- [Built-in Functions and Operators](#)

- [Range Functions and Operators](#)

**Parent topic:** [Greenplum Database Reference Guide](#)

## Greenplum Database Function Types

Greenplum Database evaluates functions and operators used in SQL expressions. Some functions and operators are only allowed to run on the master since they could lead to inconsistencies in Greenplum Database segment instances. This table describes the Greenplum Database Function Types.

| Function Type | Greenplum Support  | Description   | Comments  |
|---------------|--------------------|---|---|
| IMMUTABLE     | Yes                | Relies only on information directly in its argument list. Given the same argument values, always returns the same result. |   |
| STABLE        | Yes, in most cases | Within a single table scan, returns the same result for same argument values, but results change across SQL statements.   | Results depend on database lookups or parameter values. <code>current_timestamp</code> family of functions is <code>STABLE</code> ; values do not change within an execution. |
| VOLATILE      | Restricted         | Function values can change within a single table scan. For example: <code>random()</code> , <code>timeofday()</code> .    | Any function with side effects is volatile, even if its result is predictable. For example: <code>setval()</code> .   |

In Greenplum Database, data is divided up across segments — each segment is a distinct PostgreSQL database. To prevent inconsistent or unexpected results, do not run functions classified as `VOLATILE` at the segment level if they contain SQL commands or modify the database in any way. For example, functions such as `setval()` are not allowed to run on distributed data in Greenplum Database because they can cause inconsistent data between segment instances.

To ensure data consistency, you can safely use `VOLATILE` and `STABLE` functions in statements that are evaluated on and run from the master. For example, the following statements run on the master (statements without a `FROM` clause):

```
SELECT setval('myseq', 201);
SELECT foo();
```

If a statement has a **FROM** clause containing a distributed table *and* the function in the **FROM** clause returns a set of rows, the statement can run on the segments:

```
SELECT * from foo();
```

Greenplum Database does not support functions that return a table reference (**rangeFuncs**) or functions that use the **refCursor** datatype.

## Built-in Functions and Operators

The following table lists the categories of built-in functions and operators supported by PostgreSQL. All functions and operators are supported in Greenplum Database as in PostgreSQL with the exception of **STABLE** and **VOLATILE** functions, which are subject to the restrictions noted in [Greenplum Database Function Types](#). See the [Functions and Operators](#) section of the PostgreSQL documentation for more information about these built-in functions and operators.

| Operator/Function Category            | VOLATILE Functions                       | STABLE Functions              | Restrictions |
|---------------------------------------|--|-------------------------------|--------------|
| Logical Operators                     |  |                               |              |
| Comparison Operators                  |  |                               |              |
| Mathematical Functions and Operators  | random<br>setseed                        |                               |              |

# JSON Functions and Operators

Greenplum Database includes built-in functions and operators that create and manipulate JSON data.

- [JSON Operators](#)
- [JSON Creation Functions](#)
- [JSON Aggregate Functions](#)
- [JSON Processing Functions](#)

**Note:** For `json` data type values, all key/value pairs are kept even if a JSON object contains duplicate keys. For duplicate keys, JSON processing functions consider the last value as the operative one. For the `jsonb` data type, duplicate object keys are not kept. If the input includes duplicate keys, only the last value is kept. See [About JSON Data](#) in the *Greenplum Database Administrator Guide*.

## JSON Operators

This table describes the operators that are available for use with the `json` and `jsonb` data types.

| Operator               | Right Operand Type  | Description  | Example   | Example Result            |
|------------------------|---------------------|--|---|---------------------------|
| <code>-&gt;</code>     | <code>int</code>    | Get the JSON array element (indexed from zero).              | <code>'[{"a": "foo"}, {"b": "bar"}, {"c": "baz"}]'::json-&gt;2</code> | <code>{"c": "baz"}</code> |
| <code>-&gt;</code>     | <code>text</code>   | Get the JSON object field by key.                            | <code>'{"a": {"b": "foo"}}'::json-&gt;'a'</code>                      | <code>{"b": "foo"}</code> |
| <code>-&gt;&gt;</code> | <code>int</code>    | Get the JSON array element as <code>text</code> .            | <code>'[1,2,3]'::json-&gt;&gt;2</code>                                | <code>3</code>            |
| <code>-&gt;&gt;</code> | <code>text</code>   | Get the JSON object field as <code>text</code> .             | <code>'{"a":1,"b":2}'::json-&gt;&gt;'b'</code>                        | <code>2</code>            |
| <code>#&gt;</code>     | <code>text[]</code> | Get the JSON object at specified path.                       | <code>'{"a": {"b": {"c": "foo"}}}'::json#&gt;'a,b'</code>             | <code>{"c": "foo"}</code> |
| <code>#&gt;&gt;</code> | <code>text[]</code> | Get the JSON object at specified path as <code>text</code> . | <code>'{"a": [1,2,3], "b": [4,5,6]}'::json#&gt;&gt;'a,2'</code>       | <code>3</code>            |

**Note:** There are parallel variants of these operators for both the `json` and `jsonb` data types. The field, element, and path extraction operators return the same data type as their left-hand input (either `json` or `jsonb`), except for those specified as returning `text`, which coerce the value to `text`. The field, element, and path extraction operators return `NULL`, rather than failing, if the JSON input does not have the right structure to match the request; for example if no such element exists.

Operators that require the `jsonb` data type as the left operand are described in the following table. Many of these operators can be indexed by `jsonb` operator classes. For a full description of `jsonb` containment and existence semantics, see [jsonb Containment and Existence](#) in the *Greenplum Database Administrator Guide*. For information about how these operators can be used to effectively index `jsonb` data, see [jsonb Indexing](#) in the *Greenplum Database Administrator Guide*.

| Operator | Right Operand Type | Description   | Example  |
|----------|--------------------|---|--|
| @>       | jsonb              | Does the left JSON value contain within it the right value? | <code>'{"a":1, "b":2}'::jsonb @&gt; '{"b":2}'::jsonb</code>    |
| <@       | jsonb              | Is the left JSON value contained within the right value?    | <code>'{"b":2}'::jsonb &lt;@ '{"a":1, "b":2}'::jsonb</code>    |
| ?        | text               | Does the key/element string exist within the JSON value?    | <code>'{"a":1, "b":2}'::jsonb ? 'b'</code>                     |
| ?        | text[]             | Do any of these key/element strings exist?                  | <code>'{"a":1, "b":2, "c":3}'::jsonb ?  array['b', 'c']</code> |
| ?&       | text[]             | Do all of these key/element strings exist?                  | <code>'["a", "b"]'::jsonb ?&amp; array['a', 'b']</code>        |

The standard comparison operators in the following table are available only for the `jsonb` data type, not for the `json` data type. They follow the ordering rules for B-tree operations described in [jsonb Indexing](#) in the *Greenplum Database Administrator Guide*.

| Operator | Description              |
|----------|--------------------------|
| <        | less than                |
| >        | greater than             |
| <=       | less than or equal to    |
| >=       | greater than or equal to |
| =        | equal                    |
| <> or != | not equal                |

**Note:** The `!=` operator is converted to `<>` in the parser stage. It is not possible to implement `!=` and `<>` operators that do different things.

## JSON Creation Functions

This table describes the functions that create `json` data type values. (Currently, there are no equivalent functions for `jsonb`, but you can cast the result of one of these functions to `jsonb`.)

| Function                      | Description   | Example   | Example Result                       |
|-------------------------------|---|---|--------------------------------------|
| <code>to_json(element)</code> | Returns the value as a JSON object. Arrays and composites are processed recursively and are converted to arrays and objects. If the input contains a cast from the type to <code>json</code> , the cast function is used to perform the conversion; otherwise, a JSON scalar value is produced. For any scalar type other than a number, a Boolean, or a null value, the text representation will be used, properly quoted and escaped so that it is a valid JSON string. | <code>to_json('Fred said<br/>Hi.'::text)</code> | <code>"Fred said<br/>\\Hi.\\"</code> |

| Function   | Description  | Example  | Example Result                                  |
|--|--|--|---|
| <code>array_to_json(anyarray [, pretty_bool])</code> | Returns the array as a JSON array. A multidimensional array becomes a JSON array of arrays. Line feeds will be added between dimension-1 elements if <code>pretty_bool</code> is true.   | <code>array_to_json('{{{1,5}, {99,100}}}'::int[])</code>   | <code>[[1,5], [99,100]]</code>                  |
| <code>row_to_json(record [, pretty_bool])</code>     | Returns the row as a JSON object. Line feeds will be added between level-1 elements if <code>pretty_bool</code> is true.   | <code>row_to_json(row(1,'foo'))</code>   | <code>{"f1":1,"f2":"foo"}</code>                |
| <code>json_build_array(VARIADIC "any")</code>        | Builds a possibly-heterogeneously-typed JSON array out of a VARIADIC argument list.  | <code>json_build_array(1,2,'3',4,5)</code>   | <code>[1, 2, "3", 4, 5]</code>                  |
| <code>json_build_object(VARIADIC "any")</code>       | Builds a JSON object out of a VARIADIC argument list. The argument list is taken in order and converted to a set of key/value pairs.   | <code>json_build_object('foo',1,'bar',2)</code>  | <code>{"foo": 1, "bar": 2}</code>               |
| <code>json_object(text[])</code>                     | Builds a JSON object out of a text array. The array must be either a one or a two dimensional array.<br><br>The one dimensional array must have an even number of elements. The elements are taken as key/value pairs.<br><br>For a two dimensional array, each inner array must have exactly two elements, which are taken as a key/value pair. | <code>json_object('{a, 1, b, "def", c, 3.5}')</code><br><br><code>json_object('{{a, 1},{b, "def"}',{c, 3.5}')</code> | <code>{"a": "1", "b": "def", "c": "3.5"}</code> |
| <code>json_object(keys text[], values text[])</code> | Builds a JSON object out of a text array. This form of <code>json_object</code> takes keys and values pairwise from two separate arrays. In all other respects it is identical to the one-argument form.   | <code>json_object('{a, b}','{1,2}')</code>   | <code>{"a": "1", "b": "2"}</code>               |

**Note:** `array_to_json` and `row_to_json` have the same behavior as `to_json` except for offering a pretty-printing option. The behavior described for `to_json` likewise applies to each individual value converted by the other JSON creation functions.

**Note:** The `hstore` extension has a cast from `hstore` to `json`, so that `hstore` values converted via the JSON creation functions will be represented as JSON objects, not as primitive string values.

## JSON Aggregate Functions

This table shows the functions aggregate records to an array of JSON objects and pairs of values to a JSON object

| Function                                  | Argument Types              | Return Type       | Description                                    |
|---|-----------------------------|-------------------|--|
| <code>json_agg(record)</code>             | <code>record</code>         | <code>json</code> | Aggregates records as a JSON array of objects. |
| <code>json_object_agg(name, value)</code> | <code>("any", "any")</code> | <code>json</code> | Aggregates name/value pairs as a JSON object.  |

## JSON Processing Functions

This table shows the functions that are available for processing `json` and `jsonb` values.

Many of these processing functions and operators convert Unicode escapes in JSON strings to the appropriate single character. This is a not an issue if the input data type is `jsonb`, because the conversion was already done. However, for `json` data type input, this might result in an error being thrown. See [About JSON Data](#).

Table 8. JSON Processing Functions

| Function   | Return Type   | Description  | Example   | Example Result   |
|--|---|--|---|--|
| <pre>json_array_length(json) jsonb_array_length(jsonb)</pre>   | int   | Returns the number of elements in the outermost JSON array.  | <pre>json_array_length('[1,2,3,{"f1":1,"f2":[5,6]},4]')</pre>                                       | 5  |
| <pre>json_each(json) jsonb_each(jsonb)</pre>   | <pre>setof key text, value json setof key text, value jsonb</pre> | Expands the outermost JSON object into a set of key/value pairs.   | <pre>select * from json_each('{ "a": "foo", "b": "bar" }')</pre>                                    | <pre>key   value -----+----- - a     "foo" b     "bar"</pre> |
| <pre>json_each_text(json) jsonb_each_text(jsonb)</pre>   | <pre>setof key text, value text</pre>                             | Expands the outermost JSON object into a set of key/value pairs. The returned values will be of type <code>text</code> .           | <pre>select * from json_each_text('{ "a": "foo", "b": "bar" }')</pre>                               | <pre>key   value -----+----- - a     foo b     bar</pre>     |
| <pre>json_extract_path(from_json json, VARIADIC path_elems text[]) jsonb_extract_path(from_json jsonb, VARIADIC path_elems text[])</pre>           | <pre>json jsonb</pre>   | Returns the JSON value pointed to by <code>path_elems</code> (equivalent to <code>#&gt;</code> operator).                          | <pre>json_extract_path('{ "f2": {"f3": 1}, "f4": {"f5": 99, "f6": "foo"} }', 'f4')</pre>            | { "f5": 99, "f6": "foo" }                                    |
| <pre>json_extract_path_text(from_json json, VARIADIC path_elems text[]) jsonb_extract_path_text(from_json jsonb, VARIADIC path_elems text[])</pre> | text  | Returns the JSON value pointed to by <code>path_elems</code> as <code>text</code> . Equivalent to <code>#&gt;&gt;</code> operator. | <pre>json_extract_path_text('{ "f2": {"f3": 1}, "f4": {"f5": 99, "f6": "foo"} }', 'f4', 'f6')</pre> | foo  |
| <pre>json_object_keys(json) jsonb_object_keys(jsonb)</pre>   | setof text  | Returns set of keys in the outermost JSON object.  | <pre>json_object_keys('{ "f1": "abc", "f2": {"f3": "a", "f4": "b"} }')</pre>                        | <pre>json_object_keys ----- ----- f1 f2</pre>                |

| Function  | Return Type               | Description  | Example   | Example Result  |
|---|---------------------------|--|---|---|
| <pre>json_populate_record(base anyelement, from_json json)  jsonb_populate_record(base anyelement, from_json jsonb)</pre>       | anyelement                | Expands the object in <code>from_json</code> to a row whose columns match the record type defined by base. See <a href="#">Note 1</a> .  | <pre>select * from json_populate_record( null::myrowtype,  '{"a":1,"b":2}')</pre>                       | <pre>a   b ---+--- 1   2</pre>                          |
| <pre>json_populate_recordset(base anyelement, from_json json)  jsonb_populate_recordset(base anyelement, from_json jsonb)</pre> | setof anyelement          | Expands the outermost array of objects in <code>from_json</code> to a set of rows whose columns match the record type defined by base. See <a href="#">Note 1</a> .  | <pre>select * from json_populate_recordset( null::myrowtype,  ' [{"a":1,"b":2},  {"a":3,"b":4}]')</pre> | <pre>a   b ---+--- 1   2 3   4</pre>                    |
| <pre>json_array_elements(json)  jsonb_array_elements(jsonb)</pre>   | setof json<br>setof jsonb | Expands a JSON array to a set of JSON values.  | <pre>select * from json_array_elements(' [1,true, [2,false]]')</pre>                                    | <pre>value ----- 1 true [2,false]</pre>                 |
| <pre>json_array_elements_text(json)  jsonb_array_elements_text(jsonb)</pre>   | setof text                | Expands a JSON array to a set of text values.  | <pre>select * from json_array_elements_text('["foo", "bar"]')</pre>                                     | <pre>value ----- foo bar</pre>                          |
| <pre>json_typeof(json)  jsonb_typeof(jsonb)</pre>   | text                      | Returns the type of the outermost JSON value as a text string. Possible types are <code>object</code> , <code>array</code> , <code>string</code> , <code>number</code> , <code>boolean</code> , and <code>null</code> . See <a href="#">Note 2</a> | <pre>json_typeof('-123.4')</pre>  | number  |
| <pre>json_to_record(json)  jsonb_to_record(jsonb)</pre>   | record                    | Builds an arbitrary record from a JSON object. See <a href="#">Note 1</a> .<br><br>As with all functions returning record, the caller must explicitly define the structure of the record with an <code>AS</code> clause.                           | <pre>select * from json_to_record('{"a": 1,"b": [1,2,3],"c":"bar"}') as x(a int, b text, d text)</pre>  | <pre>a        b   d ---+----- -+--- 1   [1,2,3]  </pre> |

| Function   | Return Type  | Description   | Example  | Example Result                         |
|--|--------------|---|--|--|
| <pre>json_to_recordset( json) jsonb_to_recordset (jsonb)</pre> | setof record | <p>Builds an arbitrary set of records from a JSON array of objects See <a href="#">Note 1</a>.</p> <p>As with all functions returning record, the caller must explicitly define the structure of the record with an <code>AS</code> clause.</p> | <pre>select * from json_to_recordset('[{ "a":1,"b":"foo"}, {"a":"2","c":"bar"}]') ) as x(a int, b text);</pre> | <pre>a   b ---+----- 1   foo 2  </pre> |

**Note:**

1. The examples for the functions `json_populate_record()`, `json_populate_recordset()`, `json_to_record()` and `json_to_recordset()` use constants. However, the typical use would be to reference a table in the `FROM` clause and use one of its `json` or `jsonb` columns as an argument to the function. The extracted key values can then be referenced in other parts of the query. For example the value can be referenced in `WHERE` clauses and target lists. Extracting multiple values in this way can improve performance over extracting them separately with per-key operators.

JSON keys are matched to identical column names in the target row type. JSON type coercion for these functions might not result in desired values for some types. JSON fields that do not appear in the target row type will be omitted from the output, and target columns that do not match any JSON field will be `NULL`.

2. The `json_typeof` function null return value of `null` should not be confused with a SQL `NULL`. While calling `json_typeof('null'::json)` will return `null`, calling `json_typeof(NULL::json)` will return a SQL `NULL`.

## Window Functions

The following are Greenplum Database built-in window functions. All window functions are *immutable*. For more information about window functions, see "Window Expressions" in the *Greenplum Database Administrator Guide*.

| Function                  | Return Type      | Full Syntax  | Description   |
|---------------------------|------------------|--|---|
| <code>cume_dist()</code>  | double precision | <code>CUME_DIST() OVER ( [PARTITION BY expr ] ORDER BY expr )</code>   | Calculates the cumulative distribution of a value in a group of values. Rows with equal values always evaluate to the same cumulative distribution value. |
| <code>dense_rank()</code> | bigint           | <code>DENSE_RANK () OVER ( [PARTITION BY expr ] ORDER BY expr )</code> | Computes the rank of a row in an ordered group of rows without skipping rank values. Rows with equal values are given the same rank value.                |

| Function  | Return Type             | Full Syntax  | Description  |
|---|-------------------------|--|--|
| <code>first_value(*expr*)</code>                      | same as input expr type | <code>FIRST_VALUE ( expr ) OVER ( [PARTITION BY expr ] ORDER BY expr [ROWS RANGE frame_expr ] )</code>       | Returns the first value in an ordered set of values.   |
| <code>lag(*expr* [, *offset*] [, *default*] )</code>  | same as input expr type | <code>LAG ( expr [, offset ] [, default ] ) OVER ( [PARTITION BY expr ] ORDER BY expr )</code>               | Provides access to more than one row of the same table without doing a self join. Given a series of rows returned from a query and a position of the cursor, <code>LAG</code> provides access to a row at a given physical offset prior to that position. The default <code>offset</code> is 1. <code>default</code> sets the value that is returned if the offset goes beyond the scope of the window. If <code>default</code> is not specified, the default value is null.                           |
| <code>last_value(*expr*)</code>                       | same as input expr type | <code>LAST_VALUE(*expr*) OVER ( [PARTITION BY *expr*] ORDER BY *expr* [ROWS RANGE *frame\_expr* ] )</code>   | Returns the last value in an ordered set of values.  |
| <code>lead(*expr* [, *offset*] [, *default*] )</code> | same as input expr type | <code>LEAD(*expr* [, *offset*] [, *expr* *default* ] ) OVER ( [PARTITION BY *expr*] ORDER BY *expr* )</code> | Provides access to more than one row of the same table without doing a self join. Given a series of rows returned from a query and a position of the cursor, <code>lead</code> provides access to a row at a given physical offset after that position. If <code>offset</code> is not specified, the default offset is 1. <code>default</code> sets the value that is returned if the offset goes beyond the scope of the window. If <code>default</code> is not specified, the default value is null. |
| <code>ntile(*expr*)</code>                            | bigint                  | <code>NTILE(*expr*) OVER ( [PARTITION BY *expr*] ORDER BY *expr* )</code>                                    | Divides an ordered data set into a number of buckets (as defined by <code>expr</code> ) and assigns a bucket number to each row.   |
| <code>percent_rank()</code>                           | double precision        | <code>PERCENT_RANK () OVER ( [PARTITION BY *expr*] ORDER BY *expr* )</code>                                  | Calculates the rank of a hypothetical row <code>R</code> minus 1, divided by 1 less than the number of rows being evaluated (within a window partition).   |
| <code>rank()</code>                                   | bigint                  | <code>RANK () OVER ( [PARTITION BY *expr*] ORDER BY *expr* )</code>  | Calculates the rank of a row in an ordered group of values. Rows with equal values for the ranking criteria receive the same rank. The number of tied rows are added to the rank number to calculate the next rank value. Ranks may not be consecutive numbers in this case.   |
| <code>row_number()</code>                             | bigint                  | <code>ROW_NUMBER () OVER ( [PARTITION BY *expr*] ORDER BY *expr* )</code>                                    | Assigns a unique number to each row to which it is applied (either each row in a window partition or each row of the query).   |

## Advanced Aggregate Functions

The following built-in advanced analytic functions are Greenplum extensions of the PostgreSQL database. Analytic functions are *immutable*.

**Note:** The Greenplum MADlib Extension for Analytics provides additional advanced functions to perform statistical analysis and machine learning with Greenplum Database data. See [MADlib Extension for Analytics](#).

Table 10. Advanced Aggregate Functions

| Function  | Return Type                                     | Full Syntax   | Description   |
|---|---|---|---|
| <code>MEDIAN (expr)</code>  | timestamp,<br>timestampz,<br>interval,<br>float | <code>MEDIAN (expression)</code><br><br><i>Example:</i><br><br><pre>SELECT department_id, MEDIAN(salary) FROM employees GROUP BY department_id;</pre>   | Can take a two-dimensional array as input. Treats such arrays as matrices.  |
| <code>PERCENTILE_CONT (expr) WITHIN GROUP (ORDER BY expr [DESC/ASC])</code> | timestamp,<br>timestampz,<br>interval,<br>float | <code>PERCENTILE_CONT (percentage) WITHIN GROUP (ORDER BY expression)</code><br><br><i>Example:</i><br><br><pre>SELECT department_id, PERCENTILE_CONT (0.5) WITHIN GROUP (ORDER BY salary DESC) "Median_cont"; FROM employees GROUP BY department_id;</pre> | Performs an inverse distribution function that assumes a continuous distribution model. It takes a percentile value and a sort specification and returns the same datatype as the numeric datatype of the argument. This returned value is a computed result after performing linear interpolation. Null are ignored in this calculation. |
| <code>PERCENTILE_DISC (expr) WITHIN GROUP (ORDER BY expr [DESC/ASC])</code> | timestamp,<br>timestampz,<br>interval,<br>float | <code>PERCENTILE_DISC (percentage) WITHIN GROUP (ORDER BY expression)</code><br><br><i>Example:</i><br><br><pre>SELECT department_id, PERCENTILE_DISC (0.5) WITHIN GROUP (ORDER BY salary DESC) "Median_desc"; FROM employees GROUP BY department_id;</pre> | Performs an inverse distribution function that assumes a discrete distribution model. It takes a percentile value and a sort specification. This returned value is an element from the set. Null are ignored in this calculation.   |

| Function                                      | Return Type  | Full Syntax   | Description   |
|---|--|---|---|
| <code>sum(array[])</code>                     | <code>smallint[]</code><br><code>int[]</code> ,<br><code>bigint[]</code> ,<br><code>float[]</code> | <code>sum(array[[1,2],[3,4]])</code><br><i>Example:</i><br><pre>CREATE TABLE mymatrix (myvalue int[]); INSERT INTO mymatrix VALUES (array[[1,2],[3,4]]); INSERT INTO mymatrix VALUES (array[[0,1],[1,0]]); SELECT sum(myvalue) FROM mymatrix; sum ----- {{1,3},{4,4}}</pre> | Performs matrix summation. Can take as input a two-dimensional array that is treated as a matrix.   |
| <code>pivot_sum (label[], label, expr)</code> | <code>int[]</code> ,<br><code>bigint[]</code> ,<br><code>float[]</code>                            | <code>pivot_sum( array['A1','A2'], attr, value)</code>  | A pivot aggregation using sum to resolve duplicate entries.   |
| <code>unnest (array[])</code>                 | set of<br>anyelement   | <code>unnest( array['one', 'row', 'per', 'item'])</code>  | Transforms a one dimensional array into rows. Returns a set of <code>anyelement</code> , a polymorphic <code>pseudotype</code> in PostgreSQL. |

## Text Search Functions and Operators

The following tables summarize the functions and operators that are provided for full text searching. See [Using Full Text Search](#) for a detailed explanation of Greenplum Database's text search facility.

| Operator                | Description  | Example   | Result                    |
|-------------------------|--|---|---------------------------|
| <code>@@</code>         | <code>tsvector</code> matches <code>tsquery</code> ? | <code>to_tsvector('fat cats ate rats') @@ to_tsquery('cat &amp; rat')</code>  | t                         |
| <code>@@@</code>        | deprecated synonym for <code>@@</code>               | <code>to_tsvector('fat cats ate rats') @@@ to_tsquery('cat &amp; rat')</code> | t                         |
| <code>  </code>         | concatenate <code>tsvectors</code>                   | <code>'a:1 b:2'::tsvector    'c:1 d:2 b:3'::tsvector</code>                   | 'a':1 'b':2,5 'c':3 'd':4 |
| <code>&amp;&amp;</code> | AND <code>tsquery</code> s together                  | <code>'fat   rat'::tsquery &amp;&amp; 'cat'::tsquery</code>                   | ( 'fat'   'rat' ) & 'cat' |
| <code>  </code>         | OR <code>tsquery</code> s together                   | <code>'fat   rat'::tsquery    'cat'::tsquery</code>                           | ( 'fat'   'rat' )   'cat' |
| <code>!!</code>         | negate <code>atsquery</code>                         | <code>!! 'cat'::tsquery</code>  | !'cat'                    |
| <code>@&gt;</code>      | <code>tsquery</code> contains another?               | <code>'cat'::tsquery @&gt; 'cat &amp; rat'::tsquery</code>                    | f                         |
| <code>&lt;@</code>      | <code>tsquery</code> is contained in?                | <code>'cat'::tsquery &lt;@ 'cat &amp; rat'::tsquery</code>                    | t                         |

**Note:** The `tsquery` containment operators consider only the lexemes listed in the two queries, ignoring the combining operators.

In addition to the operators shown in the table, the ordinary B-tree comparison operators (`=`, `<`, etc) are defined for types `tsvector` and `tsquery`. These are not very useful for text searching but allow, for example, unique indexes to be built on columns of these types.

| Function   | Return Type | Description  | Example  | Result                              |
|--|-------------|--|--|-------------------------------------|
| <code>get_current_ts_config()</code>   | regconfig   | get default text search configuration                      | <code>get_current_ts_config()</code>   | english                             |
| <code>length(tsvector)</code>  | integer     | number of lexemes in tsvector                              | <code>length('fat:2,4 cat:3 rat:5A':tsvector)</code>                           | 3                                   |
| <code>numnode(tsquery)</code>  | integer     | number of lexemes plus operators in tsquery                | <code>numnode('(fat &amp; rat)   cat':tsquery)</code>                          | 5                                   |
| <code>plainto_tsquery([ config regconfig , ] querytext)</code>   | tsquery     | produce tsquery ignoring punctuation                       | <code>plainto_tsquery('english', 'The Fat Rats')</code>                        | 'fat' & 'rat'                       |
| <code>querytree(query tsquery)</code>  | text        | get indexable part of a tsquery                            | <code>querytree('foo &amp; ! bar':tsquery)</code>                              | 'foo'                               |
| <code>setweight(tsvector, "char")</code>   | tsvector    | assign weight to each element of tsvector                  | <code>setweight('fat:2,4 cat:3 rat:5B':tsvector, 'A')</code>                   | 'cat':3A<br>'fat':2A,4A<br>'rat':5A |
| <code>strip(tsvector)</code>   | tsvector    | remove positions and weights from tsvector                 | <code>strip('fat:2,4 cat:3 rat:5A':tsvector)</code>                            | 'cat' 'fat'<br>'rat'                |
| <code>to_tsquery([ config regconfig , ] query text)</code>   | tsquery     | normalize words and convert to tsquery                     | <code>to_tsquery('english', 'The &amp; Fat &amp; Rats')</code>                 | 'fat' & 'rat'                       |
| <code>to_tsvector([ config regconfig , ] documenttext)</code>  | tsvector    | reduce document text to tsvector                           | <code>to_tsvector('english', 'The Fat Rats')</code>                            | 'fat':2<br>'rat':3                  |
| <code>ts_headline([ config regconfig, ] documenttext, query tsquery [, options text ])</code>          | text        | display a query match                                      | <code>ts_headline('x y z', 'z':tsquery)</code>                                 | xy<br><b>z</b>                      |
| <code>ts_rank([ weights float4[], ] vector tsvector, query tsquery [, normalization integer ])</code>  | float4      | rank document for query                                    | <code>ts_rank(textsearch, query)</code>  | 0.818                               |
| <code>ts_rank_cd([ weights float4[], ] vectortsvector, query tsquery [, normalizationinteger ])</code> | float4      | rank document for query using cover density                | <code>ts_rank_cd('{0.1, 0.2, 0.4, 1.0}', textsearch, query)</code>             | 2.01317                             |
| <code>ts_rewrite(query tsquery, target tsquery, substitute tsquery)</code>                             | tsquery     | replace target with substitute within query                | <code>ts_rewrite('a &amp; b':tsquery, 'a':tsquery, 'foolbar':tsquery)</code>   | 'b' & ( 'foo'   'bar' )             |
| <code>ts_rewrite(query tsquery, select text)</code>  | tsquery     | replace using targets and substitutes from a SELECTcommand | <code>SELECT ts_rewrite('a &amp; b':tsquery, 'SELECT t,s FROM aliases')</code> | 'b' & ( 'foo'   'bar' )             |

| Function                                      | Return Type | Description   | Example  | Result |
|---|-------------|---|--|--------|
| <code>tsvector_update_trigger()</code>        | trigger     | trigger function for automatic tsvector column update | CREATE TRIGGER ...<br>tsvector_update_trigger(tsvcol, 'pg_catalog.swedish', title, body) |        |
| <code>tsvector_update_trigger_column()</code> | trigger     | trigger function for automatic tsvector column update | CREATE TRIGGER ...<br>tsvector_update_trigger_column(tsvcol, configcol, title, body)     |        |

**Note:** All the text search functions that accept an optional `regconfig` argument will use the configuration specified by `default_text_search_config` when that argument is omitted.

The functions in the following table are listed separately because they are not usually used in everyday text searching operations. They are helpful for development and debugging of new text search configurations.

| Function   | Return Type  | Description                        | Example  | Result   |
|--|--------------|------------------------------------|--|--|
| <code>ts_debug([ *config* regconfig, ] *document* text, OUT *alias* text, OUT *description* text, OUT *token* text, OUT *dictionaries* regdictionary[], OUT *dictionary* regdictionary, OUT *lexemes* text[])</code> | setof record | test a configuration               | <code>ts_debug('english', 'The Brightest supernovae')</code> | <code>(asciword, "Word", all ASCII, The, {english_stem}, english_stem, {})</code><br>... |
| <code>ts_lexize(*dict* regdictionary, *token* text)</code>   | text[]       | test a dictionary                  | <code>ts_lexize('english_stem', 'stars')</code>              | <code>{star}</code>  |
| <code>ts_parse(*parser_name* text, *document* text, OUT *tokid* integer, OUT *token* text)</code>  | setof record | test a parser                      | <code>ts_parse('default', 'foo - bar')</code>                | <code>(1,foo) ...</code>   |
| <code>ts_parse(*parser_oid* oid, *document* text, OUT *tokid* integer, OUT *token* text)</code>  | setof record | test a parser                      | <code>ts_parse(3722, 'foo - bar')</code>                     | <code>(1,foo) ...</code>   |
| <code>ts_token_type(*parser_name* text, OUT *tokid* integer, OUT *alias* text, OUT *description* text)</code>  | setof record | get token types defined by parser  | <code>ts_token_type('default')</code>                        | <code>(1,asciword, "Word", all ASCII)</code><br>...                                      |
| <code>ts_token_type(*parser_oid* oid, OUT *tokid* integer, OUT *alias* text, OUT *description* text)</code>  | setof record | get token types defined by parser  | <code>ts_token_type(3722)</code>                             | <code>(1,asciword, "Word", all ASCII)</code><br>...                                      |
| <code>ts_stat(*sqlquery* text, [ *weights* text, ] OUT *word* text, OUT *ndocinteger*, OUT *nentry* integer)</code>  | setof record | get statistics of a tsvectorcolumn | <code>ts_stat('SELECT vector from apod')</code>              | <code>(foo,10,15) ...</code>   |

## Range Functions and Operators

See [Range Types](#) for an overview of range types.

The following table shows the operators available for range types.

| Operator | Description                     | Example   | Result  |
|----------|---------------------------------|---|---------|
| =        | equal                           | <code>int4range(1,5) = '[1,4]':int4range</code>                             | t       |
| <>       | not equal                       | <code>numrange(1.1,2.2) &lt;&gt; numrange(1.1,2.3)</code>                   | t       |
| <        | less than                       | <code>int4range(1,10) &lt; int4range(2,3)</code>                            | t       |
| >        | greater than                    | <code>int4range(1,10) &gt; int4range(1,5)</code>                            | t       |
| <=       | less than or equal              | <code>numrange(1.1,2.2) &lt;= numrange(1.1,2.2)</code>                      | t       |
| >=       | greater than or equal           | <code>numrange(1.1,2.2) &gt;= numrange(1.1,2.0)</code>                      | t       |
| @>       | contains range                  | <code>int4range(2,4) @&gt; int4range(2,3)</code>                            | t       |
| @>       | contains element                | <code>'[2011-01-01,2011-03-01]':tsrange @&gt; '2011-01-10':timestamp</code> | t       |
| <@       | range is contained by           | <code>int4range(2,4) &lt;@ int4range(1,7)</code>                            | t       |
| <@       | element is contained by         | <code>42 &lt;@ int4range(1,7)</code>  | f       |
| &&       | overlap (have points in common) | <code>int8range(3,7) &amp;&amp; int8range(4,12)</code>                      | t       |
| <<       | strictly left of                | <code>int8range(1,10) &lt;&lt; int8range(100,110)</code>                    | t       |
| >>       | strictly right of               | <code>int8range(50,60) &gt;&gt; int8range(20,30)</code>                     | t       |
| &<       | does not extend to the right of | <code>int8range(1,20) &amp;&lt; int8range(18,20)</code>                     | t       |
| &>       | does not extend to the left of  | <code>int8range(7,20) &amp;&gt; int8range(5,10)</code>                      | t       |
| - -      | is adjacent to                  | <code>numrange(1.1,2.2) - - numrange(2.2,3.3)</code>                        | t       |
| +        | union                           | <code>numrange(5,15) + numrange(10,20)</code>                               | [5,20)  |
| *        | intersection                    | <code>int8range(5,15) * int8range(10,20)</code>                             | [10,15) |
| -        | difference                      | <code>int8range(5,15) - int8range(10,20)</code>                             | [5,10)  |

The simple comparison operators `<`, `>`, `<=`, and `>=` compare the lower bounds first, and only if those are equal, compare the upper bounds. These comparisons are not usually very useful for ranges, but are provided to allow B-tree indexes to be constructed on ranges.

The left-of/right-of/adjacent operators always return false when an empty range is involved; that is, an empty range is not considered to be either before or after any other range.

The union and difference operators will fail if the resulting range would need to contain two disjoint sub-ranges, as such a range cannot be represented.

The following table shows the functions available for use with range types.

| Function                     | Return Type          | Description          | Example                               | Result |
|------------------------------|----------------------|----------------------|---------------------------------------|--------|
| <code>lower(anyrange)</code> | range's element type | lower bound of range | <code>lower(numrange(1.1,2.2))</code> | 1.1    |

| Function                                     | Return Type          | Description  | Example  | Result |
|--|----------------------|--|--|--------|
| <code>upper(anyrange)</code>                 | range's element type | upper bound of range                                       | <code>upper(numrange(1.1,2.2))</code>                            | 2.2    |
| <code>isempty(anyrange)</code>               | boolean              | is the range empty?  | <code>isempty(numrange(1.1,2.2))</code>                          | false  |
| <code>lower_inc(anyrange)</code>             | boolean              | is the lower bound inclusive?                              | <code>lower_inc(numrange(1.1,2.2))</code>                        | true   |
| <code>upper_inc(anyrange)</code>             | boolean              | is the upper bound inclusive?                              | <code>upper_inc(numrange(1.1,2.2))</code>                        | false  |
| <code>lower_inf(anyrange)</code>             | boolean              | is the lower bound infinite?                               | <code>lower_inf('(',')'::daterange)</code>                       | true   |
| <code>upper_inf(anyrange)</code>             | boolean              | is the upper bound infinite?                               | <code>upper_inf('(',')'::daterange)</code>                       | true   |
| <code>range_merge(anyrange, anyrange)</code> | anyrange             | the smallest range which includes both of the given ranges | <code>range_merge('[1,2]'::int4range, '[3,4]'::int4range)</code> | [1,4)  |

The `lower` and `upper` functions return null if the range is empty or the requested bound is infinite. The `lower_inc`, `upper_inc`, `lower_inf`, and `upper_inf` functions all return false for an empty range.

## Additional Supplied Modules

This section describes additional modules available in the Greenplum Database installation. These modules may be PostgreSQL- or Greenplum-sourced.

`contrib` modules are typically packaged as extensions. You register a module in a database using the `CREATE EXTENSION` command. You remove a module from a database with `DROP EXTENSION`.

The following Greenplum Database and PostgreSQL `contrib` modules are installed; refer to the linked module documentation for usage instructions.

- `advanced_password_check` Provides password quality checking and policy definition for Greenplum Database.
- `auto_explain` Provides a means for logging execution plans of slow statements automatically.
- `btree_gin` - Provides sample generalized inverted index (GIN) operator classes that implement B-tree equivalent behavior for certain data types.
- `citext` - Provides a case-insensitive, multibyte-aware text data type.
- `dblink` - Provides connections to other Greenplum databases.
- `diskquota` - Allows administrators to set disk usage quotas for Greenplum Database roles and schemas.
- `fuzzystrmatch` - Determines similarities and differences between strings.
- `gp_array_agg` - Implements a parallel `array_agg()` aggregate function for Greenplum Database.
- `gp_legacy_string_agg` - Implements a legacy, single-argument `string_agg()` aggregate function that was present in Greenplum Database 5.
- `gp_parallel_retrieve_cursor` - Provides extended cursor functionality to retrieve data, in parallel, directly from Greenplum Database segments.

- [gp\\_percentile\\_agg](#) - Improves GPORCA performance for ordered-set aggregate functions.
- [gp\\_pitr](#) - Supports implementing Point-in-Time Recovery for Greenplum Database 6.
- [gp\\_sparse\\_vector](#) - Implements a Greenplum Database data type that uses compressed storage of zeros to make vector computations on floating point numbers faster.
- [greenplum\\_fdw](#) - Provides a foreign data wrapper (FDW) for accessing data stored in one or more external Greenplum Database clusters.
- [gp\\_subtransaction\\_overflow](#) - Provides a view and user-defined function for querying for suboverflowed backends.
- [hstore](#) - Provides a data type for storing sets of key/value pairs within a single PostgreSQL value.
- [ip4r](#) - Provides data types for operations on IPv4 and IPv6 IP addresses.
- [orafce](#) - Provides Greenplum Database-specific Oracle SQL compatibility functions.
- [pageinspect](#) - Provides functions for low level inspection of the contents of database pages; available to superusers only.
- [pg\\_trgm](#) - Provides functions and operators for determining the similarity of alphanumeric text based on trigram matching. The module also provides index operator classes that support fast searching for similar strings.
- [pgcrypto](#) - Provides cryptographic functions for Greenplum Database.
- [postgres\\_fdw](#) - Provides a foreign data wrapper (FDW) for accessing data stored in an external PostgreSQL or Greenplum database.
- [postgresql-hll](#) - Provides HyperLogLog data types for PostgreSQL and Greenplum Database.
- [sslinfo](#) - Provides information about the SSL certificate that the current client provided when connecting to Greenplum.

## advanced\_password\_check

The [advanced\\_password\\_check](#) module provides password quality checking for Greenplum Database.

The Greenplum Database [advanced\\_password\\_check](#) module is based on the [passwordcheck\\_extra](#) module, which enhances the PostgreSQL [passwordcheck](#) module to support user-defined policies to strengthen [passwordcheck](#)'s minimum password requirements.

## Loading the Module

The [advanced\\_password\\_check](#) module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session by entering this command as a superuser:

```
# LOAD 'advanced_password_check';
```

More typical usage is to preload it into all sessions by including `advanced_password_check` in `shared_preload_libraries` in `postgresql.conf`:

```
shared_preload_libraries = '<other_libraries>,advanced_password_check'
```

and then restarting the Greenplum Database server.

## Using the `advanced_password_check` Module

`advanced_password_check` is a Greenplum Database module that you can enable and configure to check password strings against one or more user-defined policies. You can configure policies that:

- Set a minimum password string length.
- Set a maximum password string length.
- Define a custom list of special characters.
- Define rules for special character, upper/lower case character, and number inclusion in the password string.

The `advanced_password_check` module defines server configuration parameters that you set to configure password setting policies. These parameters include:

| Parameter Name                | Type   | Default Value                              | Description   |
|-------------------------------|--------|--|---|
| <code>minimum_length</code>   | int    | 8  | The minimum allowable length of a Greenplum Database password.                                  |
| <code>maximum_length</code>   | int    | 15   | The maximum allowable length of Greenplum Database password.                                    |
| <code>special_chars</code>    | string | <code>!@#\$%^&amp;*()_+{ &lt;&gt;?=</code> | The set of characters that Greenplum Database considers to be special characters in a password. |
| <code>restrict_upper</code>   | bool   | true                                       | Specifies whether or not the password string must contain at least one upper case character.    |
| <code>restrict_lower</code>   | bool   | true                                       | Specifies whether or not the password string must contain at least one lower case character.    |
| <code>restrict_numbers</code> | bool   | true                                       | Specifies whether or not the password string must contain at least one number.                  |
| <code>restrict_special</code> | bool   | true                                       | Specifies whether or not the password string must contain at least one special character.       |

After you define your password policies, you run the `gpconfig` command for each configuration parameter that you must set. When you run the command, you must qualify the parameter with the module name. For example, to configure Greenplum Database to remove any requirements for a lower case letter in the password string, you run the following command:

```
gpadmin@gpmaster$ gpconfig -c advanced_password_check.restrict_lower -v false
```

After you set or change module configuration in this manner, you must reload the Greenplum Database configuration:

```
gpadmin@gpmaster$ gpstop -u
```

## Example

Suppose that you have defined the following password policies:

- The password must contain a minimum of 10 characters and a maximum of 18.
- The password must contain a mixture of upper case and lower case characters.
- The password must contain at least one of the default special characters.
- There are no requirements that the password contain a number.

You would run the following commands to configure Greenplum Database to enforce these policies:

```
gpadmin@gpmaster$ gpconfig -c advanced_password_check.minimum_length -v 10
gpadmin@gpmaster$ gpconfig -c advanced_password_check.maximum_length -v 18
gpadmin@gpmaster$ gpconfig -c advanced_password_check.restrict_number -v false
gpadmin@gpmaster$ gpstop -u
```

After loading the new configuration, passwords that the Greenplum superuser sets must now follow the policies, and Greenplum returns an error for every policy that is not met. Note that Greenplum checks the password string against all of the policies, and concatenates together the messages for any errors that it encounters. For example (line breaks added for better viewability):

```
# testdb=# CREATE role r1 PASSWORD '12345678901112';
ERROR:  Incorrect password format: lower-case character missing, upper-case character
missing, special character missing (needs to be one listed in "<list-of-special-chars
>")
```

## Additional Module Documentation

Refer to the [passwordcheck](#) PostgreSQL documentation for more information about this module.

### auto\_explain

The `auto_explain` module provides a means for logging execution plans of slow statements automatically, without having to run `EXPLAIN` by hand.

The Greenplum Database `auto_explain` module runs only on the Greenplum Database master segment host. It is otherwise equivalent in functionality to the PostgreSQL `auto_explain` module.

### Loading the Module

The `auto_explain` module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session by entering this command as a superuser:

```
LOAD 'auto_explain';
```

More typical usage is to preload it into some or all sessions by including `auto_explain` in `session_preload_libraries` or `shared_preload_libraries` in `postgresql.conf`. Then you can track unexpectedly slow queries no matter when they happen. However, this does introduce overhead for all queries.

## Module Documentation

See [auto\\_explain](#) in the PostgreSQL documentation for detailed information about the configuration parameters that control this module's behavior.

## btree\_gin

The `btree_gin` module provides sample generalized inverted index (GIN) operator classes that implement B-tree equivalent behavior for certain data types.

The Greenplum Database `btree_gin` module is equivalent to the PostgreSQL `btree_gin` module. There are no Greenplum Database or MPP-specific considerations for the module.

## Installing and Registering the Module

The `btree_gin` module is installed when you install Greenplum Database. Before you can use any of the functions defined in the module, you must register the `btree_gin` extension in each database in which you want to use the functions:

```
CREATE EXTENSION btree_gin;
```

Refer to [Installing Additional Supplied Modules](#) for more information.

## Greenplum Database Limitations

The Tanzu Greenplum Query Optimizer (GPORCA) does not support queries that access an index with `op_class`, such queries will fall back to the Postgres Planner

## Module Documentation

See [btree\\_gin](#) in the PostgreSQL documentation for detailed information about the individual functions in this module.

## citext

The `citext` module provides a case-insensitive character string data type, `citext`. Essentially, it internally calls the `lower()` function when comparing values. Otherwise, it behaves almost exactly like the `text` data type.

The Greenplum Database `citext` module is equivalent to the PostgreSQL `citext` module. There are no Greenplum Database or MPP-specific considerations for the module.

## Installing and Registering the Module

The `citext` module is installed when you install Greenplum Database. Before you can use any of the data types, operators, or functions defined in the module, you must register the `citext` extension in each database in which you want to use the objects. Refer to [Installing Additional Supplied Modules](#) for more information.

## Module Documentation

See `citext` in the PostgreSQL documentation for detailed information about the data types, operators, and functions defined in this module.

## dblink

The `dblink` module supports connections to other Greenplum Database databases from within a database session. These databases can reside in the same Greenplum Database system, or in a remote system.

Greenplum Database supports `dblink` connections between databases in Greenplum Database installations with the same major version number. You can also use `dblink` to connect to other Greenplum Database installations that use compatible `libpq` libraries.

**Note:** `dblink` is intended for database users to perform short ad hoc queries in other databases. `dblink` is not intended for use as a replacement for external tables or for administrative tools such as `gpcopy`.

The Greenplum Database `dblink` module is a modified version of the PostgreSQL `dblink` module. There are some restrictions and limitations when you use the module in Greenplum Database.

## Installing and Registering the Module

The `dblink` module is installed when you install Greenplum Database. Before you can use any of the functions defined in the module, you must register the `dblink` extension in each database in which you want to use the functions. Refer to [Installing Additional Supplied Modules](#) for more information.

## Greenplum Database Considerations

In this release of Greenplum Database, statements that modify table data cannot use named or implicit `dblink` connections. Instead, you must provide the connection string directly in the `dblink()` function. For example:

```
gpadmin=# CREATE TABLE testdbllocal (a int, b text) DISTRIBUTED BY (a);
CREATE TABLE
gpadmin=# INSERT INTO testdbllocal select * FROM dblink('dbname=postgres', 'SELECT * FROM testdblink') AS dbltab(id int, product text);
INSERT 0 2
```

The Greenplum Database version of `dblink` deactivates the following asynchronous functions:

- `dblink_send_query()`

- `dblink_is_busy()`
- `dblink_get_result()`

## Using dblink

The following procedure identifies the basic steps for configuring and using `dblink` in Greenplum Database. The examples use `dblink_connect()` to create a connection to a database and `dblink()` to run an SQL query.

1. Begin by creating a sample table to query using the `dblink` functions. These commands create a small table in the `postgres` database, which you will later query from the `testdb` database using `dblink`:

```
$ psql -d postgres
psql (9.4.20)
Type "help" for help.

postgres=# CREATE TABLE testdblink (a int, b text) DISTRIBUTED BY (a);
CREATE TABLE
postgres=# INSERT INTO testdblink VALUES (1, 'Cheese'), (2, 'Fish');
INSERT 0 2
postgres=# \q
$
```

2. Log into a different database as a superuser. In this example, the superuser `gpadmin` logs into the database `testdb`. If the `dblink` functions are not already available, register the `dblink` extension in the database:

```
$ psql -d testdb
psql (9.4beta1)
Type "help" for help.

testdb=# CREATE EXTENSION dblink;
CREATE EXTENSION
```

3. Use the `dblink_connect()` function to create either an implicit or a named connection to another database. The connection string that you provide should be a `libpq`-style keyword/value string. This example creates a connection named `mylocalconn` to the `postgres` database on the local Greenplum Database system:

```
testdb=# SELECT dblink_connect('mylocalconn', 'dbname=postgres user=gpadmin');
 dblink_connect
-----
OK
(1 row)
```

**Note:** If a `user` is not specified, `dblink_connect()` uses the value of the `PGUSER` environment variable when Greenplum Database was started. If `PGUSER` is not set, the default is the system user that started Greenplum Database.

4. Use the `dblink()` function to query a database using a configured connection. Keep in mind that this function returns a record type, so you must assign the columns returned in the

`dblink()` query. For example, the following command uses the named connection to query the table you created earlier:

```
testdb=# SELECT * FROM dblink('mylocalconn', 'SELECT * FROM testdblink') AS dblink
tab(id int, product text);
 id | product
----+-----
  1 | Cheese
  2 | Fish
(2 rows)
```

To connect to the local database as another user, specify the `user` in the connection string. This example connects to the database as the user `test_user`. Using `dblink_connect()`, a superuser can create a connection to another local database without specifying a password.

```
testdb=# SELECT dblink_connect('localconn2', 'dbname=postgres user=test_user');
```

To make a connection to a remote database system, include host and password information in the connection string. For example, to create an implicit `dblink` connection to a remote system:

```
testdb=# SELECT dblink_connect('host=remotehost port=5432 dbname=postgres user=gpadmin
password=secret');
```

## Using dblink as a Non-Superuser

To make a connection to a database with `dblink_connect()`, non-superusers must include host, user, and password information in the connection string. The host, user, and password information must be included even when connecting to a local database. You must also include an entry in `pg_hba.conf` for this non-superuser and the target database. For example, the user `test_user` can create a `dblink` connection to the local system `mdw` with this command:

```
testdb=> SELECT dblink_connect('host=mdw port=5432 dbname=postgres user=test_user password=secret');
```

If non-superusers need to create `dblink` connections that do not require a password, they can use the `dblink_connect_u()` function. The `dblink_connect_u()` function is identical to `dblink_connect()`, except that it allows non-superusers to create connections that do not require a password.

`dblink_connect_u()` is initially installed with all privileges revoked from `PUBLIC`, making it un-callable except by superusers. In some situations, it may be appropriate to grant `EXECUTE` permission on `dblink_connect_u()` to specific users who are considered trustworthy, but this should be done with care.

**Warning:** If a Greenplum Database system has configured users with an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur when a non-superuser runs `dblink_connect_u()`. The `dblink` connection will appear to have originated from the user specified by the function. For example, a non-superuser can run `dblink_connect_u()` and specify a user that is configured with `trust` authentication.

Also, even if the `dblink` connection requires a password, it is possible for the password to be supplied from the server environment, such as a `~/.pgpass` file belonging to the server's user. It is

recommended that any `~/.pgpass` file belonging to the server's user not contain any records specifying a wildcard host name.

1. As a superuser, grant the `EXECUTE` privilege on the `dblink_connect_u()` functions in the user database. This example grants the privilege to the non-superuser `test_user` on the functions with the signatures for creating an implicit or a named `dblink` connection. The server and database will be identified through a standard `libpq` connection string and optionally, a name can be assigned to the connection.

```
testdb=# GRANT EXECUTE ON FUNCTION dblink_connect_u(text) TO test_user;
testdb=# GRANT EXECUTE ON FUNCTION dblink_connect_u(text, text) TO test_user;
```

2. Now `test_user` can create a connection to another local database without a password. For example, `test_user` can log into the `testdb` database and run this command to create a connection named `testconn` to the local `postgres` database.

```
testdb=> SELECT dblink_connect_u('testconn', 'dbname=postgres user=test_user');
```

**Note:** If a `user` is not specified, `dblink_connect_u()` uses the value of the `PGUSER` environment variable when Greenplum Database was started. If `PGUSER` is not set, the default is the system user that started Greenplum Database.

3. `test_user` can use the `dblink()` function to run a query using a `dblink` connection. For example, this command uses the `dblink` connection named `testconn` created in the previous step. `test_user` must have appropriate access to the table.

```
testdb=> SELECT * FROM dblink('testconn', 'SELECT * FROM testdblink') AS dbltab
(id int, product text);
```

## Using dblink as a Non-Superuser without Authentication Checks

In rare cases you may need to allow non-superusers to access to `dblink` without making any authentication checks. The function `dblink_connect_no_auth()` provides this functionality as it bypasses the `pg_hba.conf` file.

**Warning:** Using this function introduces a security risk; ensure that you grant unauthorized access only to trusted user accounts. Also note that `dblink_connect_no_auth()` functions limit connections to the local cluster, and do not permit connections to a remote database.

These functions are not available by default; the `gpadmin` superuser must grant permission to the non-superuser beforehand:

1. As a superuser, grant the `EXECUTE` privilege on the `dblink_connect_no_auth()` functions in the user database. This example grants the privilege to the non-superuser `test_user` on the functions with the signatures for creating an implicit or a named `dblink` connection.

```
testdb=# GRANT EXECUTE ON FUNCTION dblink_connect_no_auth(text) TO test_user;
testdb=# GRANT EXECUTE ON FUNCTION dblink_connect_no_auth(text, text) TO test_u
ser;
```

2. Now `test_user` can create a connection to another local database without providing a password, regardless of what is specified in `pg_hba.conf`. For example, `test_user` can log

into the `testdb` database and execute this command to create a connection named `testconn` to the local `postgres` database.

```
testdb=> SELECT dblink_connect_no_auth('testconn', 'dbname=postgres user=test_u
ser');
```

3. `test_user` can use the `dblink()` function to execute a query using a `dblink` connection. For example, this command uses the `dblink` connection named `testconn` created in the previous step. `test_user` must have appropriate access to the table.

```
testdb=> SELECT * FROM dblink('testconn', 'SELECT * FROM testdblink') AS dbltab
(id int, product text);
```

## Using dblink with SSL-Encrypted Connections to Greenplum

When you use `dblink` to connect to Greenplum Database over an encrypted connection, you must specify the `sslmode` property in the connection string. Set `sslmode` to at least `require` to disallow unencrypted transfers. For example:

```
testdb=# SELECT dblink_connect('greenplum_con_sales', 'dbname=sales host=gpmaster user
=gpadmin sslmode=require');
```

Refer to [SSL Client Authentication](#) for information about configuring Greenplum Database to use SSL.

## Additional Module Documentation

Refer to the [dblink PostgreSQL](#) documentation for detailed information about the individual functions in this module.

## diskquota

The `diskquota` module allows Greenplum Database administrators to limit the amount of disk space used by schemas, roles, or tablespaces in a database.

This topic includes the following sections:

- [Installing and Registering the Module \(First Use\)](#)
- [About the diskquota Module](#)
- [Understanding How diskquota Monitors Disk Usage](#)
- [About the diskquota Functions and Views](#)
- [Configuring the diskquota Module](#)
- [Using the diskquota Module](#)
- [Known Issues and Limitations](#)
- [Notes](#)
- [Upgrading the Module to Version 2.0](#)

- [Examples](#)

## Installing and Registering the Module (First Use)

The `diskquota` module is installed when you install Greenplum Database.

Before you can use the module, you must perform these steps:

1. Create the `diskquota` database. The `diskquota` module uses this database to store the list of databases where the module is enabled.

```
$ createdb diskquota;
```

2. Add the `diskquota` shared library to the Greenplum Database `shared_preload_libraries` server configuration parameter and restart Greenplum Database. Be sure to retain the previous setting of the configuration parameter. For example:

```
$ gpconfig -s shared_preload_libraries
Values on all segments are consistent
GUC           : shared_preload_libraries
Master       value: auto_explain
Segment      value: auto_explain
$ gpconfig -c shared_preload_libraries -v 'auto_explain,diskquota-2.0'
$ gpstop -ar
```

3. Register the `diskquota` extension in each database in which you want to enforce disk usage quotas. You can register `diskquota` in up to ten databases.

```
$ psql -d testdb -c "CREATE EXTENSION diskquota"
```

4. If you register the `diskquota` extension in a database that already contains data, you must initialize the `diskquota` table size data by running the `diskquota.init_table_size_table()` UDF in the database. In a database with many files, this can take some time. The `diskquota` module cannot be used until the initialization is complete.

```
=# SELECT diskquota.init_table_size_table();
```

**Note:** You must run the `diskquota.init_table_size_table()` UDF for `diskquota` to work.

## About the `diskquota` Module

The disk usage for a table includes the table data, indexes, toast tables, and free space map. For append-optimized tables, the calculation includes the visibility map and index, and the block directory table.

The `diskquota` module allows a Greenplum Database administrator to limit the amount of disk space used by tables in schemas or owned by roles in up to 10 databases. The administrator can also use the module to limit the amount of disk space used by schemas and roles on a per-tablespace basis, as well as to limit the disk space used per Greenplum Database segment for a tablespace.

**Note:** A role-based disk quota cannot be set for the Greenplum Database system owner (the user that creates the Greenplum cluster).

You can set the following quotas with the `diskquota` module:

- A *schema disk quota* sets a limit on the disk space that can be used by all tables in a database that reside in a specific schema. The disk usage of a schema is defined as the total of disk usage on all segments for all tables in the schema.
- A *role disk quota* sets a limit on the disk space that can be used by all tables in a database that are owned by a specific role. The disk usage for a role is defined as the total of disk usage on all segments for all tables the role owns. Although a role is a cluster-level database object, the disk usage for roles is calculated separately for each database.
- A *schema tablespace disk quota* sets a limit on the disk space that can be used by all tables in a database that reside in a specific schema and tablespace.
- A *role tablespace disk quota* sets a limit on the disk space that can be used by all tables in a database that are owned by a specific role and reside in a specific tablespace.
- A *per-segment tablespace disk quota* sets a limit on the disk space that can be used by a Greenplum Database segment when a tablespace quota is set for a schema or role.

## Understanding How `diskquota` Monitors Disk Usage

A single `diskquota` launcher process runs on the active Greenplum Database master node. The `diskquota` launcher process creates and launches a `diskquota` worker process on the master for each `diskquota`-enabled database. A worker process is responsible for monitoring the disk usage of tablespaces, schemas, and roles in the target database, and communicates with the Greenplum segments to obtain the sizes of active tables. The worker process also performs quota enforcement, placing tablespaces, schemas, or roles on a denylist when they reach their quota.

When a query plan for a data-adding query is generated, and the tablespace, schema, or role into which data would be loaded is on the denylist, `diskquota` cancels the query before it starts executing, and reports an error message that the quota has been exceeded.

A query that does not add data, such as a simple `SELECT` query, is always allowed to run, even when the tablespace, role, or schema is on the denylist.

Diskquota can enforce both *soft limits* and *hard limits* for disk usage:

- By default, `diskquota` always enforces soft limits. `diskquota` checks quotas before a query runs. If quotas are not exceeded when a query is initiated, `diskquota` allows the query to run, even if it were to eventually cause a quota to be exceeded.
- When hard limit enforcement of disk usage is enabled, `diskquota` also monitors disk usage during query execution. If a query exceeds a disk quota during execution, `diskquota` terminates the query.

Administrators can enable enforcement of a disk usage hard limit by setting the `diskquota.hard_limit` server configuration parameter as described in [Activating/Deactivating Hard Limit Disk Usage Enforcement](#).

There is some delay after a quota has been reached before the schema or role is added to the denylist. Other queries could add more data during the delay. The delay occurs because `diskquota` processes that calculate the disk space used by each table run periodically with a pause between executions (two seconds by default). The delay also occurs when disk usage falls beneath a quota,

due to operations such as `DROP`, `TRUNCATE`, or `VACUUM FULL` that remove data. Administrators can change the amount of time between disk space checks by setting the `diskquota.naptime` server configuration parameter as described in [Setting the Delay Between Disk Usage Updates](#).

If a query is unable to run because the tablespace, schema, or role has been denylisted, an administrator can increase the exceeded quota to allow the query to run. The module provides views that you can use to find the tablespaces, schemas, or roles that have exceeded their limits.

## About the diskquota Functions and Views

The `diskquota` module provides user-defined functions (UDFs) and views that you can use to manage and monitor disk space usage in your Greenplum Database deployment.

The functions and views provided by the `diskquota` module are available in the Greenplum Database schema named `diskquota`.

**Note:** You may be required to prepend the schema name (`diskquota.`) to any UDF or view that you access.

User-defined functions provided by the module include:

| Function Signature  | Description  |
|---|--|
| <code>void init_table_size_table()</code>   | Sizes the existing tables in the current database.   |
| <code>void set_role_quota( role_name text, quota text )</code>                                      | Sets a disk quota for a specific role in the current database.<br><br><b>Note:</b> A role-based disk quota cannot be set for the Greenplum Database system owner.                            |
| <code>void set_role_tablespace_quota( role_name text, tablespace_name text, quota text )</code>     | Sets a disk quota for a specific role and tablespace combination in the current database.<br><br><b>Note:</b> A role-based disk quota cannot be set for the Greenplum Database system owner. |
| <code>void set_schema_quota( schema_name text, quota text )</code>                                  | Sets a disk quota for a specific schema in the current database.   |
| <code>void set_schema_tablespace_quota( schema_name text, tablespace_name text, quota text )</code> | Sets a disk quota for a specific schema and tablespace combination in the current database.  |
| <code>void set_per_segment_quota( tablespace_name text, ratio float4 )</code>                       | Sets a per-segment disk quota for a tablespace in the current database.  |
| <code>void pause()</code>   | Instructs the module to continue to count disk usage for the current database, but pause and cease emitting an error when the limit is exceeded.   |
| <code>void resume()</code>  | Instructs the module to resume emitting an error when the disk usage limit is exceeded in the current database.  |
| <code>status()</code> RETURNS table   | Displays the <code>diskquota</code> binary and schema versions and the status of soft and hard limit disk usage enforcement in the current database.   |

Views available in the `diskquota` module include:

| View Name                              | Description  |
|--|--|
| show_fast_database_size_view           | Displays the disk space usage in the current database.   |
| show_fast_role_quota_view              | Lists active quotas for roles in the current database.   |
| show_fast_role_tablespace_quota_view   | List active quotas for roles per tablespace in the current database.   |
| show_fast_schema_quota_view            | Lists active quotas for schemas in the current database.   |
| show_fast_schema_tablespace_quota_view | Lists active quotas for schemas per tablespace in the current database.                                      |
| show_segment_ratio_quota_view          | Displays the per-segment disk quota ratio for any per-segment tablespace quotas set in the current database. |

## Configuring the diskquota Module

`diskquota` exposes server configuration parameters that allow you to control certain module functionality:

- `diskquota.naptime` - Controls how frequently (in seconds) that `diskquota` recalculates the table sizes.
- `diskquota.max_active_tables` - Identifies the maximum number of relations (including tables, indexes, etc.) that the `diskquota` module can monitor at the same time.
- `diskquota.hard_limit` - Activates or deactivates the hard limit enforcement of disk usage.

You use the `gpconfig` command to set these parameters in the same way that you would set any Greenplum Database server configuration parameter.

## Setting the Delay Between Disk Usage Updates

The `diskquota.naptime` server configuration parameter specifies how frequently (in seconds) `diskquota` recalculates the table sizes. The smaller the `naptime` value, the less delay in detecting changes in disk usage. This example sets the `naptime` to ten seconds and restarts Greenplum Database:

```
$ gpconfig -c diskquota.naptime -v 10
$ gpstop -ar
```

## About Shared Memory and the Maximum Number of Relations

The `diskquota` module uses shared memory to save the denylist and to save the active table list.

The denylist shared memory can hold up to one million database objects that exceed the quota limit. If the denylist shared memory fills, data may be loaded into some schemas or roles after they have reached their quota limit.

Active table shared memory holds up to one million of active tables by default. Active tables are tables that may have changed sizes since `diskquota` last recalculated the table sizes. `diskquota` hook functions are called when the storage manager on each Greenplum Database segment

creates, extends, or truncates a table file. The hook functions store the identity of the file in shared memory so that its file size can be recalculated the next time the table size data is refreshed.

The `diskquota.max_active_tables` server configuration parameter identifies the maximum number of relations (including tables, indexes, etc.) that the `diskquota` module can monitor at the same time. The default value is `1 * 1024 * 1024`. This value should be sufficient for most Greenplum Database installations. Should you change the value of this configuration parameter, you must restart the Greenplum Database server.

## Activating/Deactivating Hard Limit Disk Usage Enforcement

When you enable enforcement of a hard limit of disk usage, `diskquota` checks the quota during query execution. If at any point a currently running query exceeds a quota limit, `diskquota` terminates the query.

By default, hard limit disk usage enforcement is deactivated for all databases. To activate hard limit enforcement for all databases, set the `diskquota.hard_limit` server configuration parameter to `'on'`, and then reload the Greenplum Database configuration:

```
$ gpconfig -c diskquota.hard_limit -v 'on'
$ gpstop -u
```

Run the following query to view the hard limit enforcement setting:

```
SELECT * from diskquota.status();
```

## Using the diskquota Module

You can perform the following tasks with the `diskquota` module:

- [View the diskquota Status](#)
- [Pause and Resume Disk Quota Exceeded Notifications](#)
- [Set a Schema or Role Disk Quota](#)
- [Set a Tablespace Disk Quota for a Schema or Role](#)
- [Set a Per-Segment Tablespace Disk Quota](#)
- [Display Disk Quotas and Disk Usage](#)
- [Temporarily Deactivate Disk Quota Monitoring](#)

## Viewing the diskquota Status

To view the `diskquota` module and schema version numbers, and the state of soft and hard limit enforcement in the current database, invoke the `status()` command:

```
SELECT diskquota.status();
      name          | status
-----+-----
soft limits        | on
hard limits         | on
```

```
current binary version | 2.0.1
current schema version | 2.0
```

## Pausing and Resuming Disk Quota Exceeded Notifications

If you do not care to be notified of disk quota exceeded events for a period of time, you can pause and resume error notification in the current database as shown below:

```
SELECT diskquota.pause();
-- perform table operations where you do not care to be notified
-- when a disk quota exceeded
SELECT diskquota.resume();
```

## Setting a Schema or Role Disk Quota

Use the `diskquota.set_schema_quota()` and `diskquota.set_role_quota()` user-defined functions in a database to set, update, or delete disk quota limits for schemas and roles in the database. The functions take two arguments: the schema or role name, and the quota to set. You can specify the quota in units of MB, GB, TB, or PB; for example, `'2TB'`.

The following example sets a 250GB quota for the `acct` schema:

```
SELECT diskquota.set_schema_quota('acct', '250GB');
```

This example sets a 500MB disk quota for the `nickd` role:

```
SELECT diskquota.set_role_quota('nickd', '500MB');
```

To change a quota, invoke the `diskquota.set_schema_quota()` or `diskquota.set_role_quota()` function again with the new quota value.

To remove a schema or role quota, set the quota value to `'-1'` and invoke the function.

## Setting a Tablespace Disk Quota

Use the `diskquota.set_schema_tablespace_quota()` and `diskquota.set_role_tablespace_quota()` user-defined functions in a database to set, update, or delete per-tablespace disk quota limits for schemas and roles in the current database. The functions take three arguments: the schema or role name, the tablespace name, and the quota to set. You can specify the quota in units of MB, GB, TB, or PB; for example, `'2TB'`.

The following example sets a 50GB disk quota for the tablespace named `tspaced1` and the `acct` schema:

```
SELECT diskquota.set_schema_tablespace_quota('acct', 'tspaced1', '250GB');
```

This example sets a 500MB disk quota for the `tspaced2` tablespace and the `nickd` role:

```
SELECT diskquota.set_role_tablespace_quota('nickd', 'tspaced2', '500MB');
```

To change a quota, invoke the `diskquota.set_schema_tablespace_quota()` or `diskquota.set_role_tablespace_quota()` function again with the new quota value.

To remove a schema or role tablespace quota, set the quota value to `'-1'` and invoke the function.

## Setting a Per-Segment Tablespace Disk Quota

When an administrator sets a tablespace quota for a schema or a role, they may also choose to define a per-segment disk quota for the tablespace. Setting a per-segment quota limits the amount of disk space on a single Greenplum Database segment that a single tablespace may consume, and may help prevent a segment's disk from filling due to data skew.

You can use the `diskquota.set_per_segment_quota()` function to set, update, or delete a per-segment tablespace disk quota limit. The function takes two arguments: the tablespace name and a ratio. The ratio identifies how much more of the disk quota a single segment can use than the average segment quota. A ratio that you specify must be greater than zero.

You can calculate the average segment quota as follows:

```
avg_seg_quota = tablespace_quota / number_of_segments
```

For example, if your Greenplum Database cluster has 8 segments and you set the following schema tablespace quota:

```
SELECT diskquota.set_schema_tablespace_quota( 'accts', 'tspaced1', '800GB' );
```

The average segment quota for the `tspaced1` tablespace is  $800\text{GB} / 8 = 100\text{GB}$ .

If you set the following per-segment tablespace quota:

```
SELECT diskquota.set_per_segment_quota( 'tspaced1', '2.0' );
```

You can calculate the the maximum allowed disk usage per segment allowed as follows:

```
max_disk_usage_per_seg = average_segment_quota * ratio
```

In this example, the maximum disk usage allowed per segment is  $100\text{GB} * 2.0 = 200\text{GB}$ .

`diskquota` will allow a query to run if the disk usage on all segments for all tables that are in tablespace `tblspc1` and that are goverend by a role or schema quota does not exceed  $200\text{GB}$ .

You can change the per-segment tablespace quota by invoking the `diskquota.set_per_segment_quota()` function again with the new quota value.

To remove a per-segment tablespace quota, set the quota value to `'-1'` and invoke the function.

To view the per-segment quota ratio set for a tablespace, display the `show_segment_ratio_quota_view` view. For example:

```
SELECT tablespace_name, per_seg_quota_ratio
FROM diskquota.show_segment_ratio_quota_view WHERE tablespace_name in ('tspaced1');
 tablespace_name | per_seg_quota_ratio
-----+-----
tspaced1        |                    2
(1 rows)
```

## Displaying Disk Quotas and Disk Usage

The `diskquota` module provides four views to display active quotas and the current computed disk space used.

The `diskquota.show_fast_schema_quota_view` view lists active quotas for schemas in the current database. The `nspsize_in_bytes` column contains the calculated size for all tables that belong to the schema.

```
SELECT * FROM diskquota.show_fast_schema_quota_view;
 schema_name | schema_oid | quota_in_mb | nspsize_in_bytes
-----+-----+-----+-----
 acct        |      16561 |      256000 |          131072
 analytics   |      16519 | 1073741824 |         144670720
 eng         |      16560 |      5242880 |         117833728
 public      |       2200 |          250 |          3014656
(4 rows)
```

The `diskquota.show_fast_role_quota_view` view lists the active quotas for roles in the current database. The `rolsize_in_bytes` column contains the calculated size for all tables that are owned by the role.

```
SELECT * FROM diskquota.show_fast_role_quota_view;
 role_name | role_oid | quota_in_mb | rolsize_in_bytes
-----+-----+-----+-----
 mdach     |      16558 |          500 |          131072
 adam      |      16557 |          300 |         117833728
 nickd     |      16577 |          500 |         144670720
(3 rows)
```

You can view the per-tablespace disk quotas for schemas and roles with the `diskquota.show_fast_schema_tablespace_quota_view` and `diskquota.show_fast_role_tablespace_quota_view` views. For example:

```
SELECT schema_name, tablespace_name, quota_in_mb, nspsize_tablespace_in_bytes
FROM diskquota.show_fast_schema_tablespace_quota_view
WHERE schema_name = 'acct' and tablespace_name = 'tblspc1';
 schema_name | tablespace_name | quota_in_mb | nspsize_tablespace_in_bytes
-----+-----+-----+-----
 acct        | tspaced1        |      250000 |          131072
(1 row)
```

## About Temporarily Deactivating diskquota

You can temporarily deactivate the `diskquota` module by removing the shared library from `shared_preload_libraries`. For example::

```
$ gpconfig -s shared_preload_libraries
Values on all segments are consistent
GUC                : shared_preload_libraries
Master              value: auto_explain,diskquota-2.0
Segment             value: auto_explain,diskquota-2.0
```

```
$ gpconfig -c shared_preload_libraries -v 'auto_explain'
$ gpstop -ar
```

**Note:** When you deactivate the `diskquota` module in this manner, disk quota monitoring ceases. To re-initiate disk quota monitoring in this scenario, you must:

1. Re-add the library to `shared_preload_libraries`.
2. Restart Greenplum Database.
3. Re-size the existing tables in the database by running: `SELECT diskquota.init_table_size_table();`
4. Restart Greenplum Database again.

## Known Issues and Limitations

The `diskquota` module has the following limitations and known issues:

- `diskquota` does not automatically work on a segment when the segment is replaced by a mirror. You must manually restart Greenplum Database in this circumstance.
- `diskquota` cannot enforce a hard limit on `ALTER TABLE ADD COLUMN DEFAULT` operations.
- If Greenplum Database restarts due to a crash, you must run `SELECT diskquota.init_table_size_table();` to ensure that the disk usage statistics are accurate.
- To avoid the chance of deadlock, you must first pause the `diskquota` extension before you drop the extension in any database:

```
SELECT diskquota.pause();
DROP EXTENSION diskquota;
```

- `diskquota` may record an incorrect table size after `ALTER TABLESPACE`, `TRUNCATE`, or other operations that modify the `relfilenode` of the table.

Cause: `diskquota` does not acquire any locks on a relation when computing the table size. If another session is updating the table's tablespace while `diskquota` is calculating the table size, an error can occur.

In most cases, you can ignore the difference; `diskquota` will update the size when new data is next ingested. To immediately ensure that the disk usage statistics are accurate, invoke:

```
SELECT diskquota.init_table_size_table();
```

And then restart Greenplum Database.

- In rare cases, a `VACUUM FULL` operation may exceed a quota limit. To remedy the situation, pause `diskquota` before the operation and then resume `diskquota` after:

```
SELECT diskquota.pause();
-- perform the VACUUM FULL
SELECT diskquota.resume();
```

If you do not want to pause/resume `diskquota`, you may choose to temporarily set a higher quota for the operation and then set it back when the `VACUUM FULL` completes. Consider the

following:

- If you `VACUUM FULL` only a single table, set the quota to be no smaller than the size of that table.
- If you `VACUUM FULL` all tables, set the quota to be no smaller than the size of the largest table in the database.
- The size of uncommitted tables are not counted in quota views. Even though the `diskquota.show_fast_role_quota_view` view may display a smaller used quota than the quota limit, a new query may trigger a quota exceeded condition in the following circumstance:
  - Hard limit enforcement of disk usage is deactivated.
  - A long-running query in a session has consumed the full disk quota. `diskquota` does update the denylist in this scenario, but the `diskquota.show_fast_role_quota_view` may not represent the actual used quota because the long-running query is not yet committed. If you execute a new query while the original is still running, the new query will trigger a quota exceeded error.

## Notes

The `diskquota` module can detect a newly created table inside of an uncommitted transaction. The size of the new table is included in the disk usage calculated for the corresponding schema or role. Hard limit enforcement of disk usage must be enabled for a quota-exceeding operation to trigger a `quota exceeded` error in this scenario.

Deleting rows or running `VACUUM` on a table does not release disk space, so these operations cannot alone remove a schema or role from the `diskquota` denylist. The disk space used by a table can be reduced by running `VACUUM FULL` or `TRUNCATE TABLE`.

The `diskquota` module supports high availability features provided by the background worker framework. The `diskquota` launcher process only runs on the active master node. The postmaster on the standby master does not start the `diskquota` launcher process when it is in standby mode. When the master is down and the administrator runs the `gpactivatestandby` command, the standby master changes its role to master and the `diskquota` launcher process is forked automatically. Using the `diskquota`-enabled database list in the `diskquota` database, the `diskquota` launcher creates the `diskquota` worker processes that manage disk quotas for each database.

## Upgrading the Module to Version 2.0

The `diskquota` 2.0 module is installed when you install or upgrade Greenplum Database. Version 1.x of the module will continue to work after you upgrade Greenplum.

If you are using version 1.x of the module and you want to upgrade to `diskquota` version 2.0, you must perform the following procedure:

**Note:** `diskquota` will be paused during the upgrade procedure and will be automatically resumed when the upgrade completes.

1. Replace the `diskquota` shared library in the Greenplum Database `shared_preload_libraries` server configuration parameter setting and restart Greenplum

Database. Be sure to retain the other libraries. For example:

```
$ gpconfig -s shared_preload_libraries
Values on all segments are consistent
GUC           : shared_preload_libraries
Master       value: auto_explain,diskquota
Segment      value: auto_explain,diskquota
$ gpconfig -c shared_preload_libraries -v 'auto_explain,diskquota-2.0'
$ gpstop -ar
```

2. Update the `diskquota` extension in every database in which you registered the module:

```
$ psql -d testdb -c "ALTER EXTENSION diskquota UPDATE TO '2.0';"
```

3. Re-initialize `diskquota` table size data:

```
=# SELECT diskquota.init_table_size_table();
```

4. Restart Greenplum Database:

```
$ gpstop -ar
```

After upgrade, your existing disk quota rules continue to be enforced, and you can define new tablespace or per-segment rules. You can also utilize the new pause/resume disk quota enforcement functions.

## Examples

### Setting a Schema Quota

This example demonstrates how to configure a schema quota and then observe `diskquota` soft limit behavior as data is added to the schema. The example assumes that the `diskquota` processes are configured and running.

1. Create a database named `testdb` and connect to it.

```
$ createdb testdb
$ psql -d testdb
```

2. Create the `diskquota` extension in the database.

```
CREATE EXTENSION diskquota;
```

3. Create a schema named `s1`:

```
CREATE SCHEMA s1;
```

4. Set a 1MB disk quota for the `s1` schema.

```
SELECT diskquota.set_schema_quota('s1', '1MB');
```

5. Run the following commands to create a table in the `s1` schema and insert a small amount of data into it. The schema has no data yet, so it is not on the denylist.

```
SET search_path TO s1;
CREATE TABLE a(i int);
INSERT INTO a SELECT generate_series(1,100);
```

6. Insert a large amount of data, enough to exceed the 1MB quota that was set for the schema. Before the `INSERT` command, the `s1` schema is still not on the denylist, so this command should be allowed to run with only soft limit disk usage enforcement in effect, even though the operation will exceed the limit set for the schema.

```
INSERT INTO a SELECT generate_series(1,10000000);
```

7. Attempt to insert a small amount of data. Because the previous command exceeded the schema's disk quota soft limit, the schema should be denylisted and any data loading command should be cancelled.

```
INSERT INTO a SELECT generate_series(1,100);
ERROR: schema's disk space quota exceeded with name: s1
```

8. Remove the quota from the `s1` schema by setting it to `-1` and again inserts a small amount of data. A 5-second sleep before the `INSERT` command ensures that the `diskquota` table size data is updated before the command is run.

```
SELECT diskquota.set_schema_quota('s1', '-1');
-- Wait for 5 seconds to ensure that the denylist is updated
SELECT pg_sleep(5);
INSERT INTO a SELECT generate_series(1,100);
```

## Enabling Hard Limit Disk Usage Enforcement and Exceeding Quota

In this example, we enable hard limit enforcement of disk usage, and re-run commands from the previous example.

1. Enable hard limit disk usage enforcement:

```
$ gpconfig -c diskquota.hard_limit -v 'on'
$ gpstop -u
```

2. Run the following query to view the hard limit enforcement setting:

```
SELECT * from diskquota.status();
```

3. Re-set a 1MB disk quota for the `s1` schema.

```
SELECT diskquota.set_schema_quota('s1', '1MB');
```

4. Insert a large amount of data, enough to exceed the 1MB quota that was set for the schema. Before the `INSERT` command, the `s1` schema is still not on the denylist, so this command should be allowed to start. When the operation exceeds the schema quota, `diskquota` will terminate the query.

```
INSERT INTO a SELECT generate_series(1,10000000);
[hardlimit] schema's disk space quota exceeded
```

- Remove the quota from the `s1` schema:

```
SELECT diskquota.set_schema_quota('s1', '-1');
```

## Setting a Per-Segment Tablespace Quota

This example demonstrates how to configure tablespace and per-segment tablespace quotas. In addition to using the `testdb` database and the `s1` schema that you created in the previous example, this example assumes the following:

- Hard limit enforcement of disk usage is enabled (as in the previous example).
- The Greenplum Database cluster has 8 primary segments.
- A tablespace named `tbsp1` has been created in the cluster.

Procedure:

- Set a disk quota of 1 MB for the tablespace named `tbsp1` and the schema named `s1`:

```
SELECT diskquota.set_schema_tablespace_quota('s1', 'tbsp1', '1MB');
```

- Set a per-segment ratio of 2 for the `tbsp1` tablespace:

```
SELECT diskquota.set_per_segment_quota('tbsp1', 2);
```

With this ratio setting, the average segment quota is  $1\text{MB} / 8 = 125\text{KB}$ , and the max per-segment disk usage for the tablespace is  $125\text{KB} * 2 = 250\text{KB}$ .

- Create a new table named `b` and insert some data:

```
CREATE TABLE b(i int);
INSERT INTO b SELECT generate_series(1,100);
```

- Insert a large amount of data into the table, enough to exceed the 250KB per-segment quota that was set for the tablespace. When the operation exceeds the per-segment tablespace quota, `diskquota` will terminate the query.

```
INSERT INTO b SELECT generate_series(1,10000000);
ERROR: tablespace: tbsp1, schema: s1 diskquota exceeded per segment quota
```

## fuzzystrmatch

The `fuzzystrmatch` module provides functions to determine similarities and distance between strings based on various algorithms.

The Greenplum Database `fuzzystrmatch` module is equivalent to the PostgreSQL `fuzzystrmatch` module. There are no Greenplum Database or MPP-specific considerations for the module.

## Installing and Registering the Module

The `fuzzystmatch` module is installed when you install Greenplum Database. Before you can use any of the functions defined in the module, you must register the `fuzzystmatch` extension in each database in which you want to use the functions. Refer to [Installing Additional Supplied Modules](#) for more information.

## Module Documentation

See `fuzzystmatch` in the PostgreSQL documentation for detailed information about the individual functions in this module.

### gp\_array\_agg

The `gp_array_agg` module introduces a parallel `array_agg()` aggregate function that you can use in Greenplum Database.

The `gp_array_agg` module is a Greenplum Database extension.

## Installing and Registering the Module

The `gp_array_agg` module is installed when you install Greenplum Database. Before you can use the aggregate function defined in the module, you must register the `gp_array_agg` extension in each database where you want to use the function:

```
CREATE EXTENSION gp_array_agg;
```

Refer to [Installing Additional Supplied Modules](#) for more information.

## Using the Module

The `gp_array_agg()` function has the following signature:

```
gp_array_agg( anyelement )
```

You can use the function to create an array from input values, including nulls. For example:

```
SELECT gp_array_agg(a) FROM t1;
 gp_array_agg
-----
 {2,1,3,NULL,1,2}
(1 row)
```

`gp_array_agg()` assigns each input value to an array element, and then returns the array. The function returns null rather than an empty array when there are no input rows.

`gp_array_agg()` produces results that depend on the ordering of the input rows. The ordering is unspecified by default; you can control the ordering by specifying an `ORDER BY` clause within the aggregate. For example:

```
CREATE TABLE table1(a int4, b int4);
INSERT INTO table1 VALUES (4,5), (2,1), (1,3), (3,null), (3,7);
SELECT gp_array_agg(a ORDER BY b NULLS FIRST) FROM table1;
```

```
gp_array_agg
-----
{3,2,1,4,7}
(1 row)
```

## Additional Module Documentation

Refer to [Aggregate Functions](#) in the PostgreSQL documentation for more information about aggregates.

### gp\_legacy\_string\_agg

The `gp_legacy_string_agg` module re-introduces the single-argument `string_agg()` function that was present in Greenplum Database 5.

The `gp_legacy_string_agg` module is a Greenplum Database extension.

**Note:** Use this module to aid migration from Greenplum Database 5 to the native, two-argument `string_agg()` function included in Greenplum 6.

## Installing and Registering the Module

The `gp_legacy_string_agg` module is installed when you install Greenplum Database. Before you can use the function defined in the module, you must register the `gp_legacy_string_agg` extension in each database where you want to use the function. Refer to [Installing Additional Supplied Modules](#) for more information about registering the module.

## Using the Module

The single-argument `string_agg()` function has the following signature:

```
string_agg( text )
```

You can use the function to concatenate non-null input values into a string. For example:

```
SELECT string_agg(a) FROM (VALUES('aaaa'),('bbbb'),('cccc'),(NULL)) g(a);
WARNING:  Deprecated call to string_agg(text), use string_agg(text, text) instead
 string_agg
-----
aaaabbbbcccc
(1 row)
```

The function concatenates each string value until it encounters a null value, and then returns the string. The function returns a null value when no rows are selected in the query.

`string_agg()` produces results that depend on the ordering of the input rows. The ordering is unspecified by default; you can control the ordering by specifying an `ORDER BY` clause within the aggregate. For example:

```
CREATE TABLE table1(a int, b text);
INSERT INTO table1 VALUES(4, 'aaaa'),(2, 'bbbb'),(1, 'cccc'), (3, NULL);
SELECT string_agg(b ORDER BY a) FROM table1;
```

```
WARNING:  Deprecated call to string_agg(text), use string_agg(text, text) instead
 string_agg
-----
 ccccbbbb
(1 row)
```

## Migrating to the Two-Argument string\_agg() Function

Greenplum Database 6 includes a native, two-argument, text input `string_agg()` function:

```
string_agg( text, text )
```

The following function invocation is equivalent to the single-argument `string_agg()` function that is provided in this module:

```
string_agg( text, '' )
```

You can use this conversion when you are ready to migrate from this contrib module.

## gp\_parallel\_retrieve\_cursor

The `gp_parallel_retrieve_cursor` module is an enhanced cursor implementation that you can use to create a special kind of cursor on the Greenplum Database master node, and retrieve query results, on demand and in parallel, directly from the Greenplum segments. Greenplum refers to such a cursor as a *parallel retrieve cursor*.

The `gp_parallel_retrieve_cursor` module is a Greenplum Database-specific cursor implementation loosely based on the PostgreSQL cursor.

This topic includes the following sections:

- [Installing and Registering the Module](#)
- [About the gp\\_parallel\\_retrieve\\_cursor Module](#)
- [Using the gp\\_parallel\\_retrieve\\_cursor Module](#)
- [Known Issues and Limitations](#)
- [Additional Module Documentation](#)
- [Example](#)

## Installing and Registering the Module

The `gp_parallel_retrieve_cursor` module is installed when you install Greenplum Database. Before you can use any of the functions or views defined in the module, you must register the `gp_parallel_retrieve_cursor` extension in each database where you want to use the functionality:

```
CREATE EXTENSION gp_parallel_retrieve_cursor;
```

Refer to [Installing Additional Supplied Modules](#) for more information.

## About the `gp_parallel_retrieve_cursor` Module

You use a cursor to retrieve a smaller number of rows at a time from a larger query. When you declare a parallel retrieve cursor, the Greenplum Database Query Dispatcher (QD) dispatches the query plan to each Query Executor (QE), and creates an *endpoint* on each QE before it executes the query. An endpoint is a query result source for a parallel retrieve cursor on a specific QE. Instead of returning the query result to the QD, an endpoint retains the query result for retrieval via a different process: a direct connection to the endpoint. You open a special retrieve mode connection, called a *retrieve session*, and use the new `RETRIEVE` SQL command to retrieve query results from each parallel retrieve cursor endpoint. You can retrieve from parallel retrieve cursor endpoints on demand and in parallel.

The `gp_parallel_retrieve_cursor` module provides the following functions and views that you can use to examine and manage parallel retrieve cursors and endpoints:

| Function, View Name   | Description  |
|---|--|
| <code>gp_get_endpoints()</code><br><br><a href="#">gp_endpoints</a>                 | List the endpoints associated with all active parallel retrieve cursors declared by the current session user in the current database. When the Greenplum Database superuser invokes this function, it returns a list of all endpoints for all parallel retrieve cursors declared by all users in the current database. |
| <code>gp_get_session_endpoints()</code><br><br><a href="#">gp_session_endpoints</a> | List the endpoints associated with all parallel retrieve cursors declared in the current session for the current session user.   |
| <code>gp_get_segment_endpoints()</code><br><br><a href="#">gp_segment_endpoints</a> | List the endpoints created in the QE for all active parallel retrieve cursors declared by the current session user. When the Greenplum Database superuser accesses this view, it returns a list of all endpoints on the QE created for all parallel retrieve cursors declared by all users.                            |
| <code>gp_wait_parallel_retrieve_cursor(cursorname text, timeout_sec int4)</code>    | Return cursor status or block and wait for results to be retrieved from all endpoints associated with the specified parallel retrieve cursor.  |

**Note:** Each of these functions and views is located in the `pg_catalog` schema, and each `RETURNS TABLE`.

## Using the `gp_parallel_retrieve_cursor` Module

You will perform the following tasks when you use a Greenplum Database parallel retrieve cursor to read query results in parallel from Greenplum segments:

1. [Declare the parallel retrieve cursor.](#)
2. [List the endpoints of the parallel retrieve cursor.](#)
3. [Open a retrieve connection to each endpoint.](#)
4. [Retrieve data from each endpoint.](#)
5. [Wait for data retrieval to complete.](#)
6. [Handle data retrieval errors.](#)
7. [Close the parallel retrieve cursor.](#)

In addition to the above, you may optionally choose to open a utility-mode connection to an endpoint to [List segment-specific retrieve session information](#).

## Declaring a Parallel Retrieve Cursor

You **DECLARE** a cursor to retrieve a smaller number of rows at a time from a larger query. When you declare a parallel retrieve cursor, you can retrieve the query results directly from the Greenplum Database segments.

The syntax for declaring a parallel retrieve cursor is similar to that of declaring a regular cursor; you must additionally include the **PARALLEL RETRIEVE** keywords in the command. You can declare a parallel retrieve cursor only within a transaction, and the cursor name that you specify when you declare the cursor must be unique within the transaction.

For example, the following commands begin a transaction and declare a parallel retrieve cursor named `prc1` to retrieve the results from a specific query:

```
BEGIN;
DECLARE prc1 PARALLEL RETRIEVE CURSOR FOR <query>;
```

Greenplum Database creates the endpoint(s) on the QD or QEs, depending on the *query* parameters:

- Greenplum Database creates an endpoint on the QD when the query results must be gathered by the master. For example, this **DECLARE** statement requires that the master gather the query results:

```
DECLARE c1 PARALLEL RETRIEVE CURSOR FOR SELECT * FROM t1 ORDER BY a;
```

**Note:** You may choose to run the **EXPLAIN** command on the parallel retrieve cursor query to identify when motion is involved. Consider using a regular cursor for such queries.

- When the query involves direct dispatch to a segment (the query is filtered on the distribution key), Greenplum Database creates the endpoint(s) on specific segment host(s). For example, this **DECLARE** statement may result in the creation of single endpoint:

```
DECLARE c2 PARALLEL RETRIEVE CURSOR FOR SELECT * FROM t1 WHERE a=1;
```

- Greenplum Database creates the endpoints on all segment hosts when all hosts contribute to the query results. This example **DECLARE** statement results in all segments contributing query results:

```
DECLARE c3 PARALLEL RETRIEVE CURSOR FOR SELECT * FROM t1;
```

The **DECLARE** command returns when the endpoints are ready and query execution has begun.

## Listing a Parallel Retrieve Cursor's Endpoints

You can obtain the information that you need to initiate a retrieve connection to an endpoint by invoking the `gp_get_endpoints()` function or examining the `gp_endpoints` view in a session on the Greenplum Database master host:

```
SELECT * FROM gp_get_endpoints();
SELECT * FROM gp_endpoints;
```

These commands return the list of endpoints in a table with the following columns:

| Column Name   | Description  |
|---------------|--|
| gp_segment_id | The QE's endpoint <code>gp_segment_id</code> .   |
| auth_token    | The authentication token for a retrieve session.   |
| cursorname    | The name of the parallel retrieve cursor.  |
| sessionid     | The identifier of the session in which the parallel retrieve cursor was created.   |
| hostname      | The name of the host from which to retrieve the data for the endpoint.   |
| port          | The port number from which to retrieve the data for the endpoint.  |
| username      | The name of the session user (not the current user); <i>you must initiate the retrieve session as this user</i> .  |
| state         | The state of the endpoint; the valid states are:<br><br>READY: The endpoint is ready to be retrieved.<br><br>ATTACHED: The endpoint is attached to a retrieve connection.<br><br>RETRIEVING: A retrieve session is retrieving data from the endpoint at this moment.<br><br>FINISHED: The endpoint has been fully retrieved.<br><br>RELEASED: Due to an error, the endpoint has been released and the connection closed. |
| endpointname  | The endpoint identifier; you provide this identifier to the <code>RETRIEVE</code> command.   |

Refer to the [gp\\_endpoints](#) view reference page for more information about the endpoint attributes returned by these commands.

You can similarly invoke the `gp_get_session_endpoints()` function or examine the `gp_session_endpoints` view to list the endpoints created for the parallel retrieve cursors declared in the current session and by the current user.

## Opening a Retrieve Session

After you declare a parallel retrieve cursor, you can open a retrieve session to each endpoint. Only a single retrieve session may be open to an endpoint at any given time.

**Note:** A retrieve session is independent of the parallel retrieve cursor itself and the endpoints.

Retrieve session authentication does not depend on the `pg_hba.conf` file, but rather on an authentication token (`auth_token`) generated by Greenplum Database.

**Note:** Because Greenplum Database skips `pg_hba.conf`-controlled authentication for a retrieve session, for security purposes you may invoke only the `RETRIEVE` command in the session.

When you initiate a retrieve session to an endpoint:

- The user that you specify for the retrieve session must be the session user that declared the parallel retrieve cursor (the `username` returned by `gp_endpoints`). This user must have

Greenplum Database login privileges.

- You specify the `hostname` and `port` returned by `gp_endpoints` for the endpoint.
- You authenticate the retrieve session by specifying the `auth_token` returned for the endpoint via the `PGPASSWORD` environment variable, or when prompted for the retrieve session `Password`.
- You must specify the `gp_retrieve_conn` server configuration parameter on the connection request, and set the value to `true`.

For example, if you are initiating a retrieve session via `psql`:

```
PGOPTIONS='-c gp_retrieve_conn=true' psql -h <hostname> -p <port> -U <username> -d <db name>
```

To distinguish a retrieve session from other sessions running on a segment host, Greenplum Database includes the `[retrieve]` tag on the `ps` command output display for the process.

## Retrieving Data From the Endpoint

Once you establish a retrieve session, you retrieve the tuples associated with a query result on that endpoint using the `RETRIEVE` command.

You can specify a (positive) number of rows to retrieve, or `ALL` rows:

```
RETRIEVE 7 FROM ENDPOINT prc10000003300000003;
RETRIEVE ALL FROM ENDPOINT prc10000003300000003;
```

Greenplum Database returns an empty set if there are no more rows to retrieve from the endpoint.

**Note:** You can retrieve from multiple parallel retrieve cursors from the same retrieve session only when their `auth_tokens` match.

## Waiting for Data Retrieval to Complete

Use the `gp_wait_parallel_retrieve_cursor()` function to display the the status of data retrieval from a parallel retrieve cursor, or to wait for all endpoints to finishing retrieving the data. You invoke this function in the transaction block in which you declared the parallel retrieve cursor.

`gp_wait_parallel_retrieve_cursor()` returns `true` only when all tuples are fully retrieved from all endpoints. In all other cases, the function returns `false` and may additionally throw an error.

The function signatures of `gp_wait_parallel_retrieve_cursor()` follow:

```
gp_wait_parallel_retrieve_cursor( cursorname text )
gp_wait_parallel_retrieve_cursor( cursorname text, timeout_sec int4 )
```

You must identify the name of the cursor when you invoke this function. The timeout argument is optional:

- The default timeout is 0 seconds: Greenplum Database checks the retrieval status of all endpoints and returns the result immediately.
- A timeout value of -1 seconds instructs Greenplum to block until all data from all endpoints has been retrieved, or block until an error occurs.

- The function reports the retrieval status after a timeout occurs for any other positive timeout value that you specify.

`gp_wait_parallel_retrieve_cursor()` returns when it encounters one of the following conditions:

- All data has been retrieved from all endpoints.
- A timeout has occurred.
- An error has occurred.

## Handling Data Retrieval Errors

An error can occur in a retrieve session when:

- You cancel or interrupt the retrieve operation.
- The endpoint is only partially retrieved when the retrieve session quits.

When an error occurs in a specific retrieve session, Greenplum Database removes the endpoint from the QE. Other retrieve sessions continue to function as normal.

If you close the transaction before fully retrieving from all endpoints, or if `gp_wait_parallel_retrieve_cursor()` returns an error, Greenplum Database terminates all remaining open retrieve sessions.

## Closing the Cursor

When you have completed retrieving data from the parallel retrieve cursor, close the cursor and end the transaction:

```
CLOSE prcl;
END;
```

**Note:** When you close a parallel retrieve cursor, Greenplum Database terminates any open retrieve sessions associated with the cursor.

On closing, Greenplum Database frees all resources associated with the parallel retrieve cursor and its endpoints.

## Listing Segment-Specific Retrieve Session Information

You can obtain information about all retrieve sessions to a specific QE endpoint by invoking the `gp_get_segment_endpoints()` function or examining the `gp_segment_endpoints` view:

```
SELECT * FROM gp_get_segment_endpoints();
SELECT * FROM gp_segment_endpoints;
```

These commands provide information about the retrieve sessions associated with a QE endpoint for all active parallel retrieve cursors declared by the current session user. When the Greenplum Database superuser invokes the command, it returns the retrieve session information for all endpoints on the QE created for all parallel retrieve cursors declared by all users.

You can obtain segment-specific retrieve session information in two ways: from the QD, or via a utility-mode connection to the endpoint:

- QD example:

```
SELECT * from gp_dist_random('gp_segment_endpoints');
```

Display the information filtered to a specific segment:

```
SELECT * from gp_dist_random('gp_segment_endpoints') WHERE gp_segment_id = 0;
```

- Example utilizing a utility-mode connection to the endpoint:

```
$ PGOPTIONS='-c gp_session_role=utility' psql -h sdw3 -U localuser -p 6001 -d t
estdb

testdb=> SELECT * from gp_segment_endpoints;
```

The commands return endpoint and retrieve session information in a table with the following columns:

| Column Name   | Description  |
|---------------|--|
| auth_token    | The authentication token for a the retrieve session.   |
| databaseid    | The identifier of the database in which the parallel retrieve cursor was created.  |
| senderpid     | The identifier of the process sending the query results.   |
| receiverpid   | The process identifier of the retrieve session that is receiving the query results.  |
| state         | The state of the endpoint; the valid states are:<br><br>READY: The endpoint is ready to be retrieved.<br><br>ATTACHED: The endpoint is attached to a retrieve connection.<br><br>RETRIEVING: A retrieve session is retrieving data from the endpoint at this moment.<br><br>FINISHED: The endpoint has been fully retrieved.<br><br>RELEASED: Due to an error, the endpoint has been released and the connection closed. |
| gp_segment_id | The QE's endpoint <code>gp_segment_id</code> .   |
| sessionid     | The identifier of the session in which the parallel retrieve cursor was created.   |
| username      | The name of the session user that initiated the retrieve session.  |
| endpointname  | The endpoint identifier.   |
| cursorname    | The name of the parallel retrieve cursor.  |

Refer to the [gp\\_segment\\_endpoints](#) view reference page for more information about the endpoint attributes returned by these commands.

## Known Issues and Limitations

The `gp_parallel_retrieve_cursor` module has the following limitations:

- The Tanzu Greenplum Query Optimizer (GPORCA) does not support queries on a parallel retrieve cursor.
- Greenplum Database ignores the `BINARY` clause when you declare a parallel retrieve cursor.
- Parallel retrieve cursors cannot be declared `WITH HOLD`.
- Parallel retrieve cursors do not support the `FETCH` and `MOVE` cursor operations.
- Parallel retrieve cursors are not supported in SPI; you cannot declare a parallel retrieve cursor in a PL/pgSQL function.

## Additional Module Documentation

Refer to the [gp\\_parallel\\_retrieve\\_cursor README](#) in the Greenplum Database [github](#) repository for additional information about this module. You can also find parallel retrieve cursor [programming examples](#) in the repository.

## Example

Create a parallel retrieve cursor and use it to pull query results from a Greenplum Database cluster:

1. Open a `psql` session to the Greenplum Database master host:

```
psql -d testdb
```

2. Register the `gp_parallel_retrieve_cursor` extension if it does not already exist:

```
CREATE EXTENSION IF NOT EXISTS gp_parallel_retrieve_cursor;
```

3. Start the transaction:

```
BEGIN;
```

4. Declare a parallel retrieve cursor named `prc1` for a `SELECT *` query on a table:

```
DECLARE prc1 PARALLEL RETRIEVE CURSOR FOR SELECT * FROM t1;
```

5. Obtain the endpoints for this parallel retrieve cursor:

```
SELECT * FROM gp_endpoints WHERE cursorname='prc1';
 gp_segment_id |          auth_token          | cursorname | sessionid | ho
stname | port | username | state | endpointname
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
w1      | 6000 | bill      | READY | prc10000003300000003 | prc1 | 51 | sd
        |      |          |      |          |      |   |   |
w1      | 6001 | bill      | READY | prc10000003300000003 | prc1 | 51 | sd
        |      |          |      |          |      |   |   |
w2      | 6000 | bill      | READY | prc10000003300000003 | prc1 | 51 | sd
        |      |          |      |          |      |   |   |
w2      | 6001 | bill      | READY | prc10000003300000003 | prc1 | 51 | sd
        |      |          |      |          |      |   |   |
w3      | 6000 | bill      | READY | prc10000003300000003 | prc1 | 51 | sd
```

```

          7 | 037f8c747a5dc1b75fb10524b676b9e8 | prc1          |          51 | sd
w3      | 6001 | bill          | READY | prc10000003300000003
          8 | c43ac67030dbc819da9d2fd8b576410c | prc1          |          51 | sd
w4      | 6000 | bill          | READY | prc10000003300000003
          9 | e514ee276f6b2863142aa2652cbccd85 | prc1          |          51 | sd
w4      | 6001 | bill          | READY | prc10000003300000003
(8 rows)

```

- Wait until all endpoints are fully retrieved:

```
SELECT gp_wait_parallel_retrieve_cursor( 'prc1', -1 );
```

- For each endpoint:

- Open a retrieve session. For example, to open a retrieve session to the segment instance running on `sdw3`, port number `6001`, run the following command in a *different terminal window*; when prompted for the password, provide the `auth_token` identified in row 7 of the `gp_endpoints` output:

```
$ PGOPTIONS='-c gp_retrieve_conn=true' psql -h sdw3 -U localuser -p 6001
-d testdb
Password:
```

- Retrieve data from the endpoint:

```
-- Retrieve 7 rows of data from this session
RETRIEVE 7 FROM ENDPOINT prc10000003300000003
-- Retrieve the remaining rows of data from this session
RETRIEVE ALL FROM ENDPOINT prc10000003300000003
```

- Exit the retrieve session.

```
\q
```

- In the original `psql` session (the session in which you declared the parallel retrieve cursor), verify that the `gp_wait_parallel_retrieve_cursor()` function returned `t`. Then close the cursor and complete the transaction:

```
CLOSE prc1;
END;
```

## gp\_percentile\_agg

The `gp_percentile_agg` module introduces improved Tanzu Greenplum Query Optimizer (GPORCA) performance for ordered-set aggregate functions including `percentile_cont()`, `percentile_disc()`, and `median()`. These improvements particularly benefit MADlib, which internally invokes these functions.

GPORCA generates a more performant query plan when:

- The sort expression does not include any computed columns.
- The `<fraction>` provided to the function is a `const` and not an `ARRAY`.

- The query does not contain a `GROUP BY` clause.

The `gp_percentile_agg` module is a Greenplum Database extension.

## Installing and Registering the Module

The `gp_percentile_agg` module is installed when you install Greenplum Database. You must register the `gp_percentile_agg` extension in each database where you want to use the module:

```
CREATE EXTENSION gp_percentile_agg;
```

Refer to [Installing Additional Supplied Modules](#) for more information.

## Upgrading the Module

If you upgraded from and used the `gp_percentile_agg` module in Greenplum Database version 6.21.x, you must upgrade the module to obtain the bug fix and improvements introduced in Greenplum Database version 6.22.0.

To upgrade, drop and recreate the `gp_percentile_agg` extension in each database in which you are using the module:

```
DROP EXTENSION gp_percentile_agg;
CREATE EXTENSION gp_percentile_agg;
```

## About Using the Module

To realize the GPORCA performance benefits when using ordered-set aggregate functions, in addition to registering the extension you must also enable the `optimizer_enable_orderedagg` server configuration parameter before you run the query. For example, to enable this parameter in a `psql` session:

```
SET optimizer_enable_orderedagg = on;
```

When the extension is registered, `optimizer_enable_orderedagg` is enabled, and you invoke the `percentile_cont()`, `percentile_disc()`, or `median()` functions, GPORCA generates the more performant query plan.

## Additional Module Documentation

Refer to [Ordered-Set Aggregate Functions](#) in the PostgreSQL documentation for more information about using ordered-set aggregates.

### `gp_sparse_vector`

The `gp_sparse_vector` module implements a Greenplum Database data type and associated functions that use compressed storage of zeros to make vector computations on floating point numbers faster.

The `gp_sparse_vector` module is a Greenplum Database extension.

## Installing and Registering the Module

The `gp_sparse_vector` module is installed when you install Greenplum Database. Before you can use any of the functions defined in the module, you must register the `gp_sparse_vector` extension in each database where you want to use the functions. Refer to [Installing Additional Supplied Modules](#) for more information.

## Upgrading the Module

You must upgrade the `gp_sparse_vector` module to obtain bug fixes.

**Note:** Starting in Greenplum Database 6.16, `gp_sparse_vector` functions and objects are installed in the schema named `sparse_vector`. Upgrading the module requires that you update any scripts that reference the module's objects. You must also adjust how you reference these objects in a client session. **If you have not done this already, you will need to** either add the `sparse_vector` schema to a `search_path`, or alternatively you can choose to prepend `sparse_vector.` to all non-CAST `gp_sparse_vector` function or object name references.

Update the `gp_sparse_vector` module in each database in which you are using the module:

```
DROP EXTENSION gp_sparse_vector;
CREATE EXTENSION gp_sparse_vector;
```

## About the `gp_sparse_vector` Module

`gp_sparse_vector` functions and objects are installed in the schema named `sparse_vector` starting in Greenplum Database version 6.16. In earlier versions of Greenplum Database, the `gp_sparse_vector` objects are installed in the `public` schema.

To access `gp_sparse_vector` objects, you must add `sparse_vector` to a `search_path`, or alternative you can prepend `sparse_vector.` to the function or object name. For example:

```
SELECT sparse_vector.array_agg( coll ) FROM table1;
```

CASTs that are created by the `gp_sparse_vector` module remain in the `public` schema.

## Using the `gp_sparse_vector` Module

When you use arrays of floating point numbers for various calculations, you will often have long runs of zeros. This is common in scientific, retail optimization, and text processing applications. Each floating point number takes 8 bytes of storage in memory and/or disk. Saving those zeros is often impractical. There are also many computations that benefit from skipping over the zeros.

For example, suppose the following array of `doubles` is stored as a `float8[]` in Greenplum Database:

```
'{0, 33, <40,000 zeros>, 12, 22 }'::float8[]
```

This type of array arises often in text processing, where a dictionary may have 40-100K terms and the number of words in a particular document is stored in a vector. This array would occupy slightly

more than 320KB of memory/disk, most of it zeros. Any operation that you perform on this data works on 40,001 fields that are not important.

The Greenplum Database built-in `array` datatype utilizes a bitmap for null values, but it is a poor choice for this use case because it is not optimized for `float8[]` or for long runs of zeros instead of nulls, and the bitmap is not run-length-encoding- (RLE) compressed. Even if each zero were stored as a `NULL` in the array, the bitmap for nulls would use 5KB to mark the nulls, which is not nearly as efficient as it could be.

The Greenplum Database `gp_sparse_vector` module defines a data type and a simple RLE-based scheme that is biased toward being efficient for zero value bitmaps. This scheme uses only 6 bytes for bitmap storage.

**Note:** The sparse vector data type defined by the `gp_sparse_vector` module is named `svec`. `svec` supports only `float8` vector values.

You can construct an `svec` directly from a float array as follows:

```
SELECT ('{0, 13, 37, 53, 0, 71 }'::float8[])::svec;
```

The `gp_sparse_vector` module supports the vector operators `<`, `>`, `*`, `**`, `/`, `=`, `+`, `sum()`, `vec_count_nonzero()`, and so on. These operators take advantage of the efficient sparse storage format, making computations on `svecs` faster.

The plus (+) operator adds each of the terms of two vectors of the same dimension together. For example, if vector `a = {0,1,5}` and vector `b = {4,3,2}`, you would compute the vector addition as follows:

```
SELECT ('{0,1,5}'::float8[])::svec + '{4,3,2}'::float8[])::svec)::float8[];
 float8
-----
 {4,4,7}
```

A vector dot product (`***`) between vectors `a` and `b` returns a scalar result of type `float8`. Compute the dot product  $((0*4+1*3+5*2)=13)$  as follows:

```
SELECT '{0,1,5}'::float8[])::svec *** '{4,3,2}'::float8[])::svec;
 ?column?
-----
      13
```

Special vector aggregate functions are also useful. `sum()` is self explanatory. `vec_count_nonzero()` evaluates the count of non-zero terms found in a set of `svec` and returns an `svec` with the counts. For instance, for the set of vectors `{0,1,5}`, `{10,0,3}`, `{0,0,3}`, `{0,1,0}`, the count of non-zero terms would be `{1,2,3}`. Use `vec_count_nonzero()` to compute the count of these vectors:

```
CREATE TABLE listvecs( a svec );

INSERT INTO listvecs VALUES ('{0,1,5}'::float8[]),
 ('{10,0,3}'::float8[]),
 ('{0,0,3}'::float8[]),
 ('{0,1,0}'::float8[]);

SELECT vec_count_nonzero( a )::float8[] FROM listvecs;
```

```
count_vec
-----
{1,2,3}
(1 row)
```

## Additional Module Documentation

Refer to the [gp\\_sparse\\_vector](#) READMEs in the [Greenplum Database github repository](#) for additional information about this module.

Apache MADlib includes an extended implementation of sparse vectors. See the [MADlib Documentation](#) for a description of this MADlib module.

## Example

A text classification example that describes a dictionary and some documents follows. You will create Greenplum Database tables representing a dictionary and some documents. You then perform document classification using vector arithmetic on word counts and proportions of dictionary words in each document.

Suppose that you have a dictionary composed of words in a text array. Create a table to store the dictionary data and insert some data (words) into the table. For example:

```
CREATE TABLE features (dictionary text[[]]) DISTRIBUTED RANDOMLY;
INSERT INTO features
VALUES ('{am,before,being,bothered,corpus,document,i,in,is,me,never,now,
      'one,really,second,the,third,this,until}');
```

You have a set of documents, also defined as an array of words. Create a table to represent the documents and insert some data into the table:

```
CREATE TABLE documents(docnum int, document text[]) DISTRIBUTED RANDOMLY;
INSERT INTO documents VALUES
(1, '{this,is,one,document,in,the,corpus}'),
(2, '{i,am,the,second,document,in,the,corpus}'),
(3, '{being,third,never,really,bothered,me,until,now}'),
(4, '{the,document,before,me,is,the,third,document}');
```

Using the dictionary and document tables, find the dictionary words that are present in each document. To do this, you first prepare a *Sparse Feature Vector*, or SFV, for each document. An SFV is a vector of dimension  $N$ , where  $N$  is the number of dictionary words, and each SFV contains a count of each dictionary word in the document.

You can use the `gp_extract_feature_histogram()` function to create an SFV from a document. `gp_extract_feature_histogram()` outputs an `svec` for each document that contains the count of each of the dictionary words in the ordinal positions of the dictionary.

```
SELECT gp_extract_feature_histogram(
      (SELECT dictionary FROM features LIMIT 1), document)::float8[], document
FROM documents ORDER BY docnum;

gp_extract_feature_histogram | document
-----+-----
```

```

-----
{0,0,0,0,1,1,0,1,1,0,0,0,1,0,0,1,0,1,0} | {this,is,one,document,in,the,corpus}
{1,0,0,0,1,1,1,1,0,0,0,0,0,0,1,2,0,0,0} | {i,am,the,second,document,in,the,corpus}
{0,0,1,1,0,0,0,0,0,1,1,1,0,1,0,0,1,0,1} | {being,third,never,really,bothered,me,until,now}
{0,1,0,0,0,2,0,0,1,1,0,0,0,0,0,2,1,0,0} | {the,document,before,me,is,the,third,document}

SELECT * FROM features;
                                dictionary
-----
-----
{am,before,being,bothered,corpus,document,i,in,is,me,never,now,one,really,second,the,third,this,until}

```

The SFV of the second document, "i am the second document in the corpus", is  $\{1,3*0,1,1,1,1,6*0,1,2\}$ . The word "am" is the first ordinate in the dictionary, and there is 1 instance of it in the SFV. The word "before" has no instances in the document, so its value is 0; and so on.

`gp_extract_feature_histogram()` is very speed optimized - it is a single routine version of a hash join that processes large numbers of documents into their SFVs in parallel at the highest possible speeds.

For the next part of the processing, generate a sparse vector of the dictionary dimension (19). The vectors that you generate for each document are referred to as the *corpus*.

```

CREATE table corpus (docnum int, feature_vector svec) DISTRIBUTED RANDOMLY;

INSERT INTO corpus
  (SELECT docnum,
    gp_extract_feature_histogram(
      (select dictionary FROM features LIMIT 1), document) from documents);

```

Count the number of times each feature occurs at least once in all documents:

```

SELECT (vec_count_nonzero(feature_vector))::float8[] AS count_in_document FROM corpus;

count_in_document
-----
{1,1,1,1,2,3,1,2,2,2,1,1,1,1,1,3,2,1,1}

```

Count all occurrences of each term in all documents:

```

SELECT (sum(feature_vector))::float8[] AS sum_in_document FROM corpus;

sum_in_document
-----
{1,1,1,1,2,4,1,2,2,2,1,1,1,1,1,5,2,1,1}

```

The remainder of the classification process is vector math. The count is turned into a weight that reflects *Term Frequency / Inverse Document Frequency* (tf/idf). The calculation for a given term in a given document is:

```

#_times_term_appears_in_this_doc * log( #_docs / #_docs_the_term_appears_in )

```

`#_docs` is the total number of documents (4 in this case). Note that there is one divisor for each dictionary word and its value is the number of times that word appears in the document.

For example, the term "document" in document 1 would have a weight of  $1 * \log(4/3)$ . In document 4, the term would have a weight of  $2 * \log(4/3)$ . Terms that appear in every document would have weight 0.

This single vector for the whole corpus is then scalar product multiplied by each document SFV to produce the tf/idf.

Calculate the tf/idf:

```
SELECT docnum, (feature_vector*logidf)::float8[] AS tf_idf
  FROM (SELECT log(count(feature_vector)/vec_count_nonzero(feature_vector)) AS logidf
  FROM corpus)
  AS foo, corpus ORDER BY docnum;
```

| docnum | tf_idf  |
|--------|---|
| 1      | {0,0,0,0,0.693147180559945,0.287682072451781,0,0.693147180559945,0.693147180559945,0,0,0,1.38629436111989,0,0,0.287682072451781,0,1.38629436111989,0}           |
| 2      | {1.38629436111989,0,0,0,0.693147180559945,0.287682072451781,1.38629436111989,0.693147180559945,0,0,0,0,0,1.38629436111989,0.575364144903562,0,0,0}              |
| 3      | {0,0,1.38629436111989,1.38629436111989,0,0,0,0,0.693147180559945,1.38629436111989,1.38629436111989,0,1.38629436111989,0,0,0.693147180559945,0,1.38629436111989} |
| 4      | {0,1.38629436111989,0,0,0,0.575364144903562,0,0,0.693147180559945,0.693147180559945,0,0,0,0,0.575364144903562,0.693147180559945,0,0}                            |

You can determine the *angular distance* between one document and the rest of the documents using the ACOS of the dot product of the document vectors:

```
CREATE TABLE weights AS
  (SELECT docnum, (feature_vector*logidf) tf_idf
  FROM (SELECT log(count(feature_vector)/vec_count_nonzero(feature_vector))
  AS logidf FROM corpus) foo, corpus ORDER BY docnum)
  DISTRIBUTED RANDOMLY;
```

Calculate the angular distance between the first document and every other document:

```
SELECT docnum, trunc((180.*(ACOS(dmin(1.,(tf_idf%*%testdoc)/(l2norm(tf_idf)*l2norm(testdoc)))/(4.*ATAN(1.))))):numeric,2)
  AS angular_distance FROM weights,
  (SELECT tf_idf testdoc FROM weights WHERE docnum = 1 LIMIT 1) foo
ORDER BY 1;
```

| docnum | angular_distance |
|--------|------------------|
| 1      | 0.00             |
| 2      | 78.82            |
| 3      | 90.00            |
| 4      | 80.02            |

You can see that the angular distance between document 1 and itself is 0 degrees, and between document 1 and 3 is 90 degrees because they share no features at all.

# greenplum\_fdw

The `greenplum_fdw` module is a foreign-data wrapper (FDW) that you can use to run queries across one or more Greenplum Database version 6.20+ clusters.

The Greenplum Database `greenplum_fdw` module is an MPP extension of the PostgreSQL `postgres_fdw` module.

This topic includes the following sections:

- [Installing and Registering the Module](#)
- [About Module Dependencies](#)
- [About the greenplum\\_fdw Module](#)
- [Using the greenplum\\_fdw Module](#)
- [Additional Information](#)
- [Known Issues and Limitations](#)
- [Compatibility](#)
- [Example](#)

## Installing and Registering the Module

The `greenplum_fdw` module is installed when you install Greenplum Database. Before you can use this FDW, you must register the `greenplum_fdw` extension in each database in the source Greenplum Database cluster in which you plan to use it:

```
CREATE EXTENSION greenplum_fdw;
```

Refer to [Installing Additional Supplied Modules](#) for more information about installing and registering modules in Greenplum Database.

## About Module Dependencies

`greenplum_fdw` depends on the `gp_parallel_retrieve_cursor` module.

**Note:** You must register the `gp_parallel_retrieve_cursor` module in **each remote Greenplum database** with tables that you plan to access using the `greenplum_fdw` foreign-data wrapper.

## About the greenplum\_fdw Module

`greenplum_fdw` is an MPP version of the `postgres_fdw` foreign-data wrapper. While it behaves similarly to `postgres_fdw` in many respects, `greenplum_fdw` uses a Greenplum Database parallel retrieve cursor to pull data directly from the segments of a remote Greenplum cluster to the segments in the source Greenplum cluster, in parallel.

By supporting predicate pushdown, `greenplum_fdw` minimizes the amount of data transferred between the Greenplum clusters by sending a query filter condition to the remote Greenplum server where it is applied there.

## Using the `greenplum_fdw` Module

You will perform the following tasks when you use `greenplum_fdw` to access data that resides in a remote Greenplum Database cluster(s):

1. [Create a server](#) to represent each remote Greenplum database to which you want to connect.
2. [Create a user mapping](#) for each (source) Greenplum Database user that you want to allow to access each server.
3. [Create a foreign table](#) for each remote Greenplum table that you want to access.
4. [Construct and run queries](#).

### Creating a Server

To access a remote Greenplum Database cluster, you must first create a foreign server object which specifies the host, port, and database connection details. You provide these connection parameters in the `OPTIONS` clause of the `CREATE SERVER` command.

A foreign server using the `greenplum_fdw` foreign-data wrapper accepts and disallows the same options as that of a foreign server using the `postgres_fdw` FDW; refer to the [Connection Options](#) topic in the PostgreSQL `postgres_fdw` documentation for more information about these options.

To obtain the full benefits of the parallel transfer feature provided by `greenplum_fdw`, you must also specify:

```
mpp_execute 'all segments'
```

and

```
num_segments '<num>'
```

in the `OPTIONS` clause when you create the server. Set `num` to the number of segments in the the remote Greenplum Database cluster. If you do not provide the

```
num_segments
```

option, the default value is the number of segments on the local/source Greenplum Database cluster.

The following example command creates a server named `gpcl_testdb` that will be used to access tables residing in the database named `testdb` on the remote 8-segment Greenplum Database cluster whose master is running on the host `gpcl_master`, port `5432`:

```
CREATE SERVER gpcl_testdb FOREIGN DATA WRAPPER greenplum_fdw
  OPTIONS (host 'gpcl_master', port '5432', dbname 'testdb', mpp_execute 'all segmen
ts', num_segments '8');
```

### Creating a User Mapping

After you identify which users you will allow to access the remote Greenplum Database cluster, you must create one or more mappings between a source Greenplum user and a user on the remote

Greenplum cluster. You create these mappings with the `CREATE USER MAPPING` command.

User mappings that you create may include the following `OPTIONS`:

| Option Name | Description  | Default Value                                    |
|-------------|--|--|
| user        | The name of the remote Greenplum Database user to connect as.  | The name of the current Greenplum Database user. |
| password    | The password for user on the remote Greenplum Database system. | No default value.                                |

Only a Greenplum Database superuser may connect to a Greenplum foreign server without password authentication. Always specify the `password` option for user mappings that you create for non-superusers.

The following command creates a default user mapping on the source Greenplum cluster to the user named `bill` on the remote Greenplum cluster that allows access to the database identified by the `gpcl_testdb` server. Specifying the `PUBLIC` source user name creates a mapping for all current and future users when no user-specific mapping is applicable.

```
CREATE USER MAPPING FOR PUBLIC SERVER gpcl_testdb
  OPTIONS (user 'bill', password 'changeme');
```

The remote user must have the appropriate privileges to access any table(s) of interest in the database identified by the specified `SERVER`.

If the mapping is used to access a foreign-data wrapper across multiple Greenplum clusters, then the remote user also requires `SELECT` access to the `pg_catalog.gp_endpoints` view. For example:

```
GRANT SELECT ON TABLE pg_catalog.gp_endpoints TO bill;
```

## Creating a Foreign Table

You invoke the `CREATE FOREIGN TABLE` command to create a foreign table. The column data types that you specify when you create the foreign table should exactly match those in the referenced remote table. It is also recommended that the columns be declared with exactly the same collations, if applicable, as the referenced columns of the remote table.

Because `greenplum_fdw` matches foreign table columns to the remote table by name, not position, you can create a foreign table with fewer columns, or with a different column order, than the underlying remote table.

Foreign tables that you create may include the following `OPTIONS`:

| Option Name | Description  | Default Value  |
|-------------|--|--|
| schema_name | The name of the schema in which the remote Greenplum Database table resides. | The name of the schema in which the foreign table resides. |
| table_name  | The name of the remote Greenplum Database table.                             | The name of the foreign table.                             |

The following command creates a foreign table named `f_gpcl_orders` that references a table named `orders` located in the `public` schema of the database identified by the `gpcl_testdb` server

(`testdb`):

```
CREATE FOREIGN TABLE f_gpcl_orders ( id int, qty int, item text )
  SERVER gpcl_testdb OPTIONS (schema_name 'public', table_name 'orders');
```

You can additionally specify column name mappings via `OPTIONS` that you provide in the column declaration of the foreign table. The `column_name` option identifies the name of the associated column in the remote Greenplum Database table, and defaults to the foreign table column name when not specified.

## Constructing and Running Queries

You `SELECT` from a foreign table to access the data stored in the underlying remote Greenplum Database table. By default, you can also modify the remote table using the `INSERT` command, provided that the remote user specified the user mapping has the privileges to perform these operations. (Refer to [About the Updatability Option](#) for information about changing the updatability of foreign tables.)

`greenplum_fdw` attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is achieved by sending query `WHERE` clauses to the remote Greenplum Database server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, `greenplum_fdw` does not send `WHERE` clauses to the remote server unless they use only built-in data types, operators, and functions. Operators and functions in the clauses must be `IMMUTABLE` as well.

You can run the `EXPLAIN VERBOSE` command to examine the query that is actually sent to the remote Greenplum Database server for execution.

## Additional Information

For more information about `greenplum_fdw` updatability and cost estimation options, connection management, and transaction management, refer to the individual topics below.

### About the Updatability Option

By default, all foreign tables created with `greenplum_fdw` are assumed to be updatable. You can override this for a foreign server or a foreign table using the following option:

`updatable`

Controls whether `greenplum_fdw` allows foreign tables to be modified using the `INSERT` command. The default is true.

Setting this option at the foreign table-level overrides a foreign server-level option setting.

### About the Cost Estimation Options

`greenplum_fdw` supports the same cost estimation options as described in the [Cost Estimation Options](#) topic in the PostgreSQL `postgres_fdw` documentation.

### About Connection Management

`greenplum_fdw` establishes a connection to a foreign server during the first query on any foreign table associated with the server. `greenplum_fdw` retains and reuses this connection for subsequent queries submitted in the same session. However, if multiple user identities (user mappings) are used to access the foreign server, `greenplum_fdw` establishes a connection for each user mapping.

## About Transaction Management

`greenplum_fdw` manages transactions as described in the [Transaction Management](#) topic in the PostgreSQL `postgres_fdw` documentation.

## Known Issues and Limitations

The `greenplum_fdw` module has the following known issues and limitations:

- The Tanzu Greenplum Query Optimizer (GPORCA) does not support queries on foreign tables that you create with the `greenplum_fdw` foreign-data wrapper.
- `greenplum_fdw` does not support `UPDATE` and `DELETE` operations on foreign tables.

## Compatibility

You can use `greenplum_fdw` to access other remote Greenplum Database clusters running version 6.20+.

## Example

In this example, you query data residing in a database named `rdb` on the remote 16-segment Greenplum Database cluster whose master is running on host `gpc2_master`, port `5432`:

1. Open a `psql` session to the master host of the remote Greenplum Database cluster:

```
psql -h gpc2_master -d rdb
```

2. Register the `gp_parallel_retrieve_cursor` extension in the database if it does not already exist:

```
CREATE EXTENSION IF NOT EXISTS gp_parallel_retrieve_cursor;
```

3. Exit the session.
4. Initiate a `psql` session to the database named `testdb` on the source (local in this case) Greenplum Database master host:

```
$ psql -d testdb
```

5. Register the `greenplum_fdw` extension in the database if it does not already exist:

```
CREATE EXTENSION IF NOT EXISTS greenplum_fdw;
```

6. Create a server to access the remote Greenplum Database cluster:

```
CREATE SERVER gpc2_rdb FOREIGN DATA WRAPPER greenplum_fdw
  OPTIONS (host 'gpc2_master', port '5432', dbname 'rdb', mpp_execute 'all segments', num_segments '16');
```

7. Create a user mapping for a user named `jane` on the local Greenplum Database cluster and the user named `john` on the remote Greenplum cluster and database represented by the server named `gpc2_rdb`:

```
CREATE USER MAPPING FOR jane SERVER gpc2_rdb OPTIONS (user 'john', password 'changeme');
```

8. Create a foreign table named `f_gpc2_emea` to reference the table named `emea` that resides in the `public` schema of the database identified by the `gpc2_rdb` server (`rdb`):

```
CREATE FOREIGN TABLE f_gpc2_emea( bu text, income int )
  SERVER gpc2_rdb OPTIONS (schema_name 'public', table_name 'emea');
```

9. Query the foreign table:

```
SELECT * FROM f_gpc2_emea;
```

10. Join the results of a foreign table query with a local table named `amer` that has similarly-named columns:

```
SELECT amer.bu, amer.income as amer_in, f_gpc2_emea.income as emea_in
  FROM amer, f_gpc2_emea
 WHERE amer.bu = f_gpc2_emea.bu;
```

## hstore

The `hstore` module implements a data type for storing sets of (key,value) pairs within a single Greenplum Database data field. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data.

The Greenplum Database `hstore` module is equivalent to the PostgreSQL `hstore` module. There are no Greenplum Database or MPP-specific considerations for the module.

## Installing and Registering the Module

The `hstore` module is installed when you install Greenplum Database. Before you can use any of the data types or functions defined in the module, you must register the `hstore` extension in each database in which you want to use the objects. Refer to [Installing Additional Supplied Modules](#) for more information.

## Module Documentation

See [hstore](#) in the PostgreSQL documentation for detailed information about the data types and functions defined in this module.

## ip4r

The `ip4r` module provides IPv4 and IPv6 data types, IPv4 and IPv6 range index data types, and related functions and operators.

The Greenplum Database `ip4r` module is equivalent to version 2.4.1 of the `ip4r` module used with PostgreSQL. There are no Greenplum Database or MPP-specific considerations for the module.

## Installing and Registering the Module

The `ip4r` module is installed when you install Greenplum Database. Before you can use any of the data types defined in the module, you must register the `ip4r` extension in each database in which you want to use the types:

```
CREATE EXTENSION ip4r;
```

Refer to [Installing Additional Supplied Modules](#) for more information.

## Module Documentation

Refer to the [ip4r github documentation](#) for detailed information about using the module.

## orafce

The `orafce` module provides Oracle Compatibility SQL functions in Greenplum Database. These functions target PostgreSQL but can also be used in Greenplum.

The Greenplum Database `orafce` module is a modified version of the [open source Orafce PostgreSQL module extension](#). The modified `orafce` source files for Greenplum Database can be found in the `gpcontrib/orafce` directory in the [Greenplum Database open source project](#). The source reflects the Orafce 3.6.1 release and additional commits to [3af70a28f6](#).

There are some restrictions and limitations when you use the module in Greenplum Database.

## Installing and Registering the Module

**Note:** Always use the Oracle Compatibility Functions module included with your Greenplum Database version. Before upgrading to a new Greenplum Database version, uninstall the compatibility functions from each of your databases, and then, when the upgrade is complete, reinstall the compatibility functions from the new Greenplum Database release. See the Greenplum Database release notes for upgrade prerequisites and procedures.

The `orafce` module is installed when you install Greenplum Database. Before you can use any of the functions defined in the module, you must register the `orafce` extension in each database in which you want to use the functions. Refer to [Installing Additional Supplied Modules](#) for more information.

## Greenplum Database Considerations

The following functions are available by default in Greenplum Database and do not require installing the Oracle Compatibility Functions:

- `sinh()`
- `tanh()`
- `cosh()`
- `decode()` (See [Greenplum Implementation Differences](#) for more information.)

## Greenplum Implementation Differences

There are differences in the implementation of the compatibility functions in Greenplum Database from the original PostgreSQL `orafce` module extension implementation. Some of the differences are as follows:

- The original `orafce` module implementation performs a decimal round off, the Greenplum Database implementation does not:
  - 2.00 becomes 2 in the original module implementation
  - 2.00 remains 2.00 in the Greenplum Database implementation
- The provided Oracle compatibility functions handle implicit type conversions differently. For example, using the `decode` function:

```
decode(<expression>, <value>, <return> [,<value>, <return>]...
      [, default])
```

The original `orafce` module implementation automatically converts expression and each value to the data type of the first value before comparing. It automatically converts return to the same data type as the first result.

The Greenplum Database implementation restricts return and `default` to be of the same data type. The expression and value can be different types if the data type of value can be converted into the data type of the expression. This is done implicitly. Otherwise, `decode` fails with an `invalid input syntax` error. For example:

```
SELECT decode('a', 'M', true, false);
CASE
-----
 f
(1 row)
SELECT decode(1, 'M', true, false);
ERROR: Invalid input syntax for integer:*"M"
*LINE 1: SELECT decode(1, 'M', true, false);
```

- Numbers in `bigint` format are displayed in scientific notation in the original `orafce` module implementation but not in the Greenplum Database implementation:
  - 9223372036854775 displays as 9.2234E+15 in the original implementation
  - 9223372036854775 remains 9223372036854775 in the Greenplum Database implementation

- The default date and timestamp format in the original `orafce` module implementation is different than the default format in the Greenplum Database implementation. If the following code is run:

```
CREATE TABLE TEST(date1 date, time1 timestamp, time2
                  timestamp with time zone);
INSERT INTO TEST VALUES ('2001-11-11','2001-12-13
                          01:51:15','2001-12-13 01:51:15 -08:00');
SELECT DECODE(date1, '2001-11-11', '2001-01-01') FROM TEST;
```

The Greenplum Database implementation returns the row, but the original implementation returns no rows.

**Note:** The correct syntax when using the original `orafce` implementation to return the row is:

```
SELECT DECODE(to_char(date1, 'YYYY-MM-DD'), '2001-11-11',
              '2001-01-01') FROM TEST
```

- The functions in the Oracle Compatibility Functions `dbms_alert` package are not implemented for Greenplum Database.
- The `decode()` function is removed from the Greenplum Database Oracle Compatibility Functions. The Greenplum Database parser internally converts a `decode()` function call to a `CASE` statement.

## Using orafce

Some Oracle Compatibility Functions reside in the `oracle` schema. To access them, set the search path for the database to include the `oracle` schema name. For example, this command sets the default search path for a database to include the `oracle` schema:

```
ALTER DATABASE <db_name> SET <search_path> = "$user", public, oracle;
```

Note the following differences when using the Oracle Compatibility Functions with PostgreSQL vs. using them with Greenplum Database:

- If you use validation scripts, the output may not be exactly the same as with the original `orafce` module implementation.
- The functions in the Oracle Compatibility Functions `dbms_pipe` package run only on the Greenplum Database master host.
- The upgrade scripts in the `Orafce` project do not work with Greenplum Database.

## Additional Module Documentation

Refer to the [README](#) and [Greenplum Database orafce documentation](#) in the Greenplum Database github repository for detailed information about the individual functions and supporting objects provided in this module.

## pageinspect

The `pageinspect` module provides functions for low level inspection of the contents of database pages. `pageinspect` is available only to Greenplum Database superusers.

The Greenplum Database `pageinspect` module is based on the PostgreSQL `pageinspect` module. The Greenplum version of the module differs as described in the [Greenplum Database Considerations](#) topic.

## Installing and Registering the Module

The `pageinspect` module is installed when you install Greenplum Database. Before you can use any of the functions defined in the module, you must register the `pageinspect` extension in each database in which you want to use the functions:

```
CREATE EXTENSION pageinspect;
```

Refer to [Installing Additional Supplied Modules](#) for more information.

## Upgrading the Module

If you are currently using `pageinspect` in your Greenplum installation and you want to access newly-released module functionality, you must update the `pageinspect` extension in every database in which it is currently registered:

```
ALTER EXTENSION pageinspect UPDATE;
```

## Module Documentation

See [pageinspect](#) in the PostgreSQL documentation for detailed information about the majority of functions in this module.

The next topic includes documentation for Greenplum-added `pageinspect` functions.

## Greenplum Database Considerations

When using this module with Greenplum Database, consider the following:

- The Greenplum Database version of the `pageinspect` does not allow inspection of pages belonging to append-optimized or external relations.
- For `pageinspect` functions that read data from a database, the function reads data only from the segment instance where the function is run. For example, the `get_raw_page()` function returns a `block number out of range` error when you try to read data from a user-defined table on the Greenplum Database master because there is no data in the table on the master segment. The function will read data from a system catalog table on the master segment.

## Greenplum-Added Functions

In addition to the functions specified in the PostgreSQL documentation, Greenplum Database provides these additional `pageinspect` functions for inspecting bitmap index pages:

| Function Name  | Description   |
|--|---|
| bm_metap(relname text) returns record                              | Returns information about a bitmap index's meta page.   |
| bm_bitmap_page_header(relname text, blkno int) returns record      | Returns the header information for a bitmap page; this corresponds to the opaque section from the page header.      |
| bm_lov_page_items(relname text, blkno int) returns setof record    | Returns the list of value (LOV) items present in a bitmap LOV page.   |
| bm_bitmap_page_items(relname text, blkno int) returns setof record | Returns the content words and their compression statuses for a bitmap page.   |
| bm_bitmap_page_items(page bytea) returns setof record              | Returns the content words and their compression statuses for a page image obtained by <code>get_raw_page()</code> . |

## Examples

Greenplum-added `pageinspect` function usage examples follow.

Obtain information about the meta page of the bitmap index named `i1`:

```
testdb=# SELECT * FROM bm_metap('i1');
 magic      | version | auxrelid | auxindexrelid | lovlastblknum
-----+-----+-----+-----+-----
 1112101965 |      2 |   169980 |           169982 |           1
(1 row)
```

Display the header information for the second block of the bitmap index named `i1`:

```
testdb=# SELECT * FROM bm_bitmap_page_header('i1', 2);
 num_words | next_blkno | last_tid
-----+-----+-----
      3    | 4294967295 | 65536
(1 row)
```

Display the LOV items located in the first block of the bitmap index named `i1`:

```
testdb=# SELECT * FROM bm_lov_page_items('i1', 1) ORDER BY itemoffset;
 itemoffset | lov_head_blkno | lov_tail_blkno | last_complete_word | last_word
-----+-----+-----+-----+-----
      1    | 4294967295    | 4294967295    | ff ff ff ff ff ff ff ff | 00 00 00 00
00 00 00 00 | 0            | 0            | f                        | f
      2    | 2            | 2            | 80 00 00 00 00 00 00 01 | 00 00 00 00
07 ff ff ff | 65600       | 65627       | t                        | f
      3    | 3            | 3            | 80 00 00 00 00 00 00 02 | 00 3f ff ff
ff ff ff ff | 131200      | 131254      | t                        | f
(3 rows)
```

Return the content words located in the second block of the bitmap index named `i1`:

```
testdb=# SELECT * FROM bm_bitmap_page_items('i1', 2) ORDER BY word_num;
 word_num | compressed | content_word
-----+-----+-----
```

```

0          | t          | 80 00 00 00 00 00 00 0e
1          | f          | 00 00 00 00 00 00 1f ff
2          | t          | 00 00 00 00 00 00 03 f1
(3 rows)

```

Alternatively, return the content words located in the heap page image of the same bitmap index and block:

```

testdb=# SELECT * FROM bm_bitmap_page_items(get_raw_page('i1', 2)) ORDER BY word_num;
 word_num | compressed | content_word
-----+-----+-----
0          | t          | 80 00 00 00 00 00 00 0e
1          | f          | 00 00 00 00 00 00 1f ff
2          | t          | 00 00 00 00 00 00 03 f1
(3 rows)

```

## pg\_trgm

The `pg_trgm` module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching. The module also provides index operator classes that support fast searching for similar strings.

The Greenplum Database `pg_trgm` module is equivalent to the PostgreSQL `pg_trgm` module. There are no Greenplum Database or MPP-specific considerations for the module.

## Installing and Registering the Module

The `pg_trgm` module is installed when you install Greenplum Database. Before you can use any of the functions defined in the module, you must register the `pg_trgm` extension in each database in which you want to use the functions:

```
CREATE EXTENSION pg_trgm;
```

Refer to [Installing Additional Supplied Modules](#) for more information.

## Module Documentation

See [pg\\_trgm](#) in the PostgreSQL documentation for detailed information about the individual functions in this module.

## pgcrypto

Greenplum Database is installed with an optional module of encryption/decryption functions called `pgcrypto`. The `pgcrypto` functions allow database administrators to store certain columns of data in encrypted form. This adds an extra layer of protection for sensitive data, as data stored in Greenplum Database in encrypted form cannot be read by anyone who does not have the encryption key, nor can it be read directly from the disks.

**Note:** The `pgcrypto` functions run inside the database server, which means that all the data and passwords move between `pgcrypto` and the client application in clear-text. For optimal security, consider also using SSL connections between the client and the Greenplum master server.

## Installing and Registering the Module

The `pgcrypto` module is installed when you install Greenplum Database. Before you can use any of the functions defined in the module, you must register the `pgcrypto` extension in each database in which you want to use the functions. Refer to [Installing Additional Supplied Modules](#) for more information.

## Configuring FIPS Encryption

Starting with Greenplum 6.22, the `pgcrypto` extension provides a module-specific configuration parameter, `pgcrypto.fips`. This parameter configures Greenplum Database support for a limited set of FIPS encryption functionality (*Federal Information Processing Standard* (FIPS) 140-2). For information about FIPS, see <https://www.nist.gov/itl/popular-links/federal-information-processing-standards-fips>. The default setting is `off`, FIPS encryption is not enabled.

Before enabling this parameter, ensure that FIPS is enabled on all Greenplum Database system hosts.

When this parameter is enabled, these changes occur:

- FIPS mode is initialized in the OpenSSL library
- The functions `digest()` and `hmac()` allow only the SHA encryption algorithm (MD5 is not allowed)
- The functions for the `crypt` and `gen_salt` algorithms are deactivated
- PGP encryption and decryption functions support only AES and 3DES encryption algorithms (other algorithms such as blowfish are not allowed)
- RAW encryption and decryption functions support only AES and 3DES (other algorithms such as blowfish are not allowed)

**To enable `pgcrypto.fips`**

1. Enable the `pgcrypto` functions as an extension if it is not enabled. See [Installing Additional Supplied Modules](#). This example `psql` command creates the `pgcrypto` extension in the database `testdb`.

```
psql -d testdb -c 'CREATE EXTENSION pgcrypto'
```

2. Configure the Greenplum Database server configuration parameter `shared_preload_libraries` to load the `pgcrypto` library. This example uses the `gpconfig` utility to update the parameter in the Greenplum Database `postgresql.conf` files.

```
gpconfig -c shared_preload_libraries -v '\$libdir/pgcrypto'
```

This command displays the value of `shared_preload_libraries`.

```
gpconfig -s shared_preload_libraries
```

3. Restart the Greenplum Database system.

```
gpstop -ra
```

4. Set the `pgcrypto.fips` server configuration parameter to `on` for each database that uses FIPS encryption. For example, these commands set the parameter to `on` for the database `testdb`.

```
psql -d postgres
```

```
ALTER DATABASE testdb SET pgcrypto.fips TO on;
```

**Important:** You must use the `ALTER DATABASE` command to set the parameter. You cannot use the `SET` command that updates the parameter for a session, or use the `gpconfig` utility that updates `postgresql.conf` files.

5. After setting the parameter, reconnect to the database to enable encryption support for a session. This example uses the `psql` meta command `\c` to connect to the `testdb` database.

```
\c testdb
```

### To deactivate `pgcrypto.fips`

1. If the database does not use `pgcrypto` functions, deactivate the `pgcrypto` extension. This example `psql` command drops the `pgcrypto` extension in the database `testdb`.

```
psql -d testdb -c 'DROP EXTENSION pgcrypto'
```

2. Remove `\$libdir/pgcrypto` from the `shared_preload_libraries` parameter, and restart Greenplum Database. This `gpconfig` command displays the value of the parameter from the Greenplum Database `postgresql.conf` files.

```
gpconfig -s shared_preload_libraries
```

Use the `gpconfig` utility with the `-c` and `-v` options to change the value of the parameter. Use the `-r` option to remove the parameter.

3. Restart the Greenplum Database system.

```
gpstop -ra
```

## Additional Module Documentation

Refer to [pgcrypto](#) in the PostgreSQL documentation for more information about the individual functions in this module.

### postgres\_fdw

The `postgres_fdw` module is a foreign data wrapper (FDW) that you can use to access data stored in a remote PostgreSQL or Greenplum database.

The Greenplum Database `postgres_fdw` module is a modified version of the PostgreSQL `postgres_fdw` module. The module behaves as described in the PostgreSQL [postgres\\_fdw](#) documentation when you use it to access a remote PostgreSQL database.

**Note:** There are some restrictions and limitations when you use this foreign data wrapper module to access Greenplum Database, described below.

## Installing and Registering the Module

The `postgres_fdw` module is installed when you install Greenplum Database. Before you can use the foreign data wrapper, you must register the `postgres_fdw` extension in each database in which you want to use the foreign data wrapper. Refer to [Installing Additional Supplied Modules](#) for more information.

## Greenplum Database Limitations

When you use the foreign data wrapper to access Greenplum Database, `postgres_fdw` has the following limitations:

- The `ctid` is not guaranteed to uniquely identify the physical location of a row within its table. For example, the following statements may return incorrect results when the foreign table references a Greenplum Database table:

```
INSERT INTO rem1(f2) VALUES ('test') RETURNING ctid;
SELECT * FROM ft1, t1 WHERE t1.ctid = '(0,2)';
```

- `postgres_fdw` does not support local or remote triggers when you use it to access a foreign table that references a Greenplum Database table.
- `UPDATE` or `DELETE` operations on a foreign table that references a Greenplum table are not guaranteed to work correctly.

## Additional Module Documentation

Refer to the [postgres\\_fdw](#) PostgreSQL documentation for detailed information about this module.

### postgresql-hll

The `postgresql-hll` module provides native HyperLogLog data types and relation functions, operators, and aggregates.

The Greenplum Database `postgresql-hll` module is equivalent to version 2.16 of the `postgresql-hll` used with PostgreSQL. There are no Greenplum Database or MPP-specific considerations for the module.

## Installing and Registering the Module

The `postgresql-hll` module is installed when you install Greenplum Database. Before you can use the data types defined in the module, you must register the `hll` extension in each database in which you want to use the types:

```
CREATE EXTENSION hll;
```

Refer to [Installing Additional Supplied Modules](#) for more information.

## Module Documentation

Refer to the [postgresql-hll github documentation](#) for detailed information about using the module.

### sslinfo

The `sslinfo` module provides information about the SSL certificate that the current client provided when connecting to Greenplum. Most functions in this module return NULL if the current connection does not use SSL.

The Greenplum Database `sslinfo` module is equivalent to the PostgreSQL `sslinfo` module. There are no Greenplum Database or MPP-specific considerations for the module.

## Installing and Registering the Module

The `sslinfo` module is installed when you install Greenplum Database. Before you can use any of the functions defined in the module, you must register the `sslinfo` extension in each database in which you want to use the functions. Refer to [Installing Additional Supplied Modules](#) for more information.

## Module Documentation

See `sslinfo` in the PostgreSQL documentation for detailed information about the individual functions in this module.

## Character Set Support

The character set support in Greenplum Database allows you to store text in a variety of character sets, including single-byte character sets such as the ISO 8859 series and multiple-byte character sets such as EUC (Extended Unix Code), UTF-8, and Mule internal code. All supported character sets can be used transparently by clients, but a few are not supported for use within the server (that is, as a server-side encoding)<sup>1</sup>. The default character set is selected while initializing your Greenplum Database array using `gpinitssystem`. It can be overridden when you create a database, so you can have multiple databases each with a different character set.

| Name    | Description           | Language                       | Server? | Bytes/Char | Aliases            |
|---------|-----------------------|--------------------------------|---------|------------|--------------------|
| BIG5    | Big Five              | Traditional Chinese            | No      | 1-2        | WIN950, Windows950 |
| EUC_CN  | Extended UNIX Code-CN | Simplified Chinese             | Yes     | 1-3        |                    |
| EUC_JP  | Extended UNIX Code-JP | Japanese                       | Yes     | 1-3        |                    |

## Setting the Character Set

`gpinitssystem` defines the default character set for a Greenplum Database system by reading the setting of the `ENCODING` parameter in the `gp_init_config` file at initialization time. The default character set is `UNICODE` or `UTF8`.

You can create a database with a different character set besides what is used as the system-wide default. For example:

```
=> CREATE DATABASE korean WITH ENCODING 'EUC_KR';
```

**Important:** Although you can specify any encoding you want for a database, it is unwise to choose an encoding that is not what is expected by the locale you have selected. The `LC_COLLATE` and `LC_CTYPE` settings imply a particular encoding, and locale-dependent operations (such as sorting) are likely to misinterpret data that is in an incompatible encoding.

Since these locale settings are frozen by `gpinitssystem`, the apparent flexibility to use different encodings in different databases is more theoretical than real.

One way to use multiple encodings safely is to set the locale to `C` or `POSIX` during initialization time, thus deactivating any real locale awareness.

## Character Set Conversion Between Server and Client

Greenplum Database supports automatic character set conversion between server and client for certain character set combinations. The conversion information is stored in the master `pg_conversion` system catalog table. Greenplum Database comes with some predefined conversions or you can create a new conversion using the SQL command `CREATE CONVERSION`.

| Server Character Set | Available Client Character Sets    |
|----------------------|------------------------------------|
| BIG5                 | not supported as a server encoding |
| EUC_CN               | EUC_CN, MULE_INTERNAL, UTF8        |
| EUC_JP               | EUC_JP, MULE_INTERNAL, SJIS, UTF8  |

| Server Character Set | Available Client Character Sets   |
|----------------------|---|
| EUC_KR               | EUC_KR, MULE_INTERNAL, UTF8   |
| EUC_TW               | EUC_TW, BIG5, MULE_INTERNAL, UTF8   |
| GB18030              | not supported as a server encoding  |

| WIN874               | WIN874, UTF8  |
| WIN1250              | WIN1250, LATIN2, MULE_INTERNAL, UTF8  |
| WIN1251              | WIN1251, ISO_8859_5, KOI8, MULE_INTERNAL, UTF8, WIN866  |

| Server Character Set | Available Client Character Sets |
|----------------------|---------------------------------|
| WIN1252              | WIN1252, UTF8                   |
| WIN1253              | WIN1253, UTF8                   |
| WIN1254              | WIN1254, UTF8                   |
| WIN1255              | WIN1255, UTF8                   |
| WIN1256              | WIN1256, UTF8                   |
| WIN1257              | WIN1257, UTF8                   |
| WIN1258              | WIN1258, UTF8                   |

To enable automatic character set conversion, you have to tell Greenplum Database the character set (encoding) you would like to use in the client. There are several ways to accomplish this:

- Using the `\encoding` command in `psql`, which allows you to change client encoding on the fly.
- Using `SET client_encoding TO`.

To set the client encoding, use the following SQL command:

```
=> SET CLIENT_ENCODING TO '<value>';
```

To query the current client encoding:

```
=> SHOW client_encoding;
```

To return to the default encoding:

```
=> RESET client_encoding;
```

- Using the `PGCLIENTENCODING` environment variable. When `PGCLIENTENCODING` is defined in the client's environment, that client encoding is automatically selected when a connection to the server is made. (This can subsequently be overridden using any of the other methods mentioned above.)
- Setting the configuration parameter `client_encoding`. If `client_encoding` is set in the master `postgresql.conf` file, that client encoding is automatically selected when a connection to Greenplum Database is made. (This can subsequently be overridden using any of the other methods mentioned above.)

If the conversion of a particular character is not possible (suppose you chose `EUC_JP` for the server and `LATIN1` for the client, then some Japanese characters do not have a representation in `LATIN1`) then an error is reported.

If the client character set is defined as `SQL_ASCII`, encoding conversion is deactivated, regardless of the server's character set. The use of `SQL_ASCII` is unwise unless you are working with all-ASCII data. `SQL_ASCII` is not supported as a server encoding.

<sup>1</sup>Not all APIs support all the listed character sets. For example, the JDBC driver does not support MULE\_INTERNAL, LATIN6, LATIN8, and LATIN10.

<sup>2</sup>The SQL\_ASCII setting behaves considerably differently from the other settings. Byte values 0-127 are interpreted according to the ASCII standard, while byte values 128-255 are taken as uninterpreted characters. If you are working with any non-ASCII data, it is unwise to use the SQL\_ASCII setting as a client encoding. SQL\_ASCII is not supported as a server encoding.

## Server Configuration Parameters

There are many Greenplum server configuration parameters that affect the behavior of the Greenplum Database system. Many of these configuration parameters have the same names, settings, and behaviors as in a regular PostgreSQL database system.

- [Parameter Types and Values](#) describes the parameter data types and values.
- [Setting Parameters](#) describes limitations on who can change them and where or when they can be set.
- [Parameter Categories](#) organizes parameters by functionality.
- [Configuration Parameters](#) lists the parameter descriptions in alphabetic order.

## Parameter Types and Values

All parameter names are case-insensitive. Every parameter takes a value of one of the following types: `Boolean`, `integer`, `floating point`, `enum`, or `string`.

Boolean values may be specified as `ON`, `OFF`, `TRUE`, `FALSE`, `YES`, `NO`, `1`, `0` (all case-insensitive).

Enum-type parameters are specified in the same manner as string parameters, but are restricted to a limited set of values. Enum parameter values are case-insensitive.

Some settings specify a memory size or time value. Each of these has an implicit unit, which is either kilobytes, blocks (typically eight kilobytes), milliseconds, seconds, or minutes. Valid memory size units are `kB` (kilobytes), `MB` (megabytes), and `GB` (gigabytes). Valid time units are `ms` (milliseconds), `s` (seconds), `min` (minutes), `h` (hours), and `d` (days). Note that the multiplier for memory units is 1024, not 1000. A valid time expression contains a number and a unit. When specifying a memory or time unit using the `SET` command, enclose the value in quotes. For example:

```
SET statement_mem TO '200MB';
```

**Note:** There is no space between the value and the unit names.

## Setting Parameters

Many of the configuration parameters have limitations on who can change them and where or when they can be set. For example, to change certain parameters, you must be a Greenplum Database superuser. Other parameters require a restart of the system for the changes to take effect. A parameter that is classified as *session* can be set at the system level (in the `postgresql.conf` file), at the database-level (using `ALTER DATABASE`), at the role-level (using `ALTER`

ROLE), at the database- and role-level (`ALTER ROLE...IN DATABASE...SET`, or at the session-level (using `SET`). System parameters can only be set in the `postgresql.conf` file.

In Greenplum Database, the master and each segment instance has its own `postgresql.conf` file (located in their respective data directories). Some parameters are considered *local* parameters, meaning that each segment instance looks to its own `postgresql.conf` file to get the value of that parameter. You must set local parameters on every instance in the system (master and segments). Others parameters are considered *master* parameters. Master parameters need only be set at the master instance.

This table describes the values in the Settable Classifications column of the table in the description of a server configuration parameter.

| Set Classification | Description   |
|--------------------|---|
| master or local    | <p>A <i>master</i> parameter only needs to be set in the <code>postgresql.conf</code> file of the Greenplum master instance. The value for this parameter is then either passed to (or ignored by) the segments at run time.</p> <p>A <i>local</i> parameter must be set in the <code>postgresql.conf</code> file of the master AND each segment instance. Each segment instance looks to its own configuration to get the value for the parameter. Local parameters always requires a system restart for changes to take effect.</p>   |
| session or system  | <p><i>Session</i> parameters can be changed on the fly within a database session, and can have a hierarchy of settings: at the system level (<code>postgresql.conf</code>), at the database level (<code>ALTER DATABASE...SET</code>), at the role level (<code>ALTER ROLE...SET</code>), at the database and role level (<code>ALTER ROLE...IN DATABASE...SET</code>), or at the session level (<code>SET</code>). If the parameter is set at multiple levels, then the most granular setting takes precedence (for example, session overrides database and role, database and role overrides role, role overrides database, and database overrides system).</p> <p>A <i>system</i> parameter can only be changed via the <code>postgresql.conf</code>file(s).</p> |
| restart or reload  | <p>When changing parameter values in the <code>postgresql.conf</code> file(s), some require a <i>restart</i> of Greenplum Database for the change to take effect. Other parameter values can be refreshed by just reloading the server configuration file (using <code>gpstop -u</code>), and do not require stopping the system.</p>   |
| superuser          | <p>These session parameters can only be set by a database superuser. Regular database users cannot set this parameter.</p>  |
| read only          | <p>These parameters are not settable by database users or superusers. The current value of the parameter can be shown but not altered.</p>  |

## Parameter Categories

Configuration parameters affect categories of server behaviors, such as resource consumption, query tuning, and authentication. The following topics describe Greenplum configuration parameter categories.

- [Connection and Authentication Parameters](#)
- [System Resource Consumption Parameters](#)
- [GPORCA Parameters](#)
- [Query Tuning Parameters](#)
- [Error Reporting and Logging Parameters](#)

- [System Monitoring Parameters](#)
- [Runtime Statistics Collection Parameters](#)
- [Automatic Statistics Collection Parameters](#)
- [Client Connection Default Parameters](#)
- [Lock Management Parameters](#)
- [Resource Management Parameters \(Resource Queues\)](#)
- [Resource Management Parameters \(Resource Groups\)](#)
- [External Table Parameters](#)
- [Database Table Parameters](#)
- [Past Version Compatibility Parameters](#)
- [Greenplum Database Array Configuration Parameters](#)
- [Greenplum Mirroring Parameters for Master and Segments](#)
- [Greenplum PL/Java Parameters](#)

## Connection and Authentication Parameters

These parameters control how clients connect and authenticate to Greenplum Database.

### Connection Parameters

- [client\\_connection\\_check\\_interval](#)
- [gp\\_connection\\_send\\_timeout](#)
- [gp\\_dispatch\\_keepalives\\_count](#)
- [gp\\_dispatch\\_keepalives\\_idle](#)
- [gp\\_dispatch\\_keepalives\\_interval](#)
- [gp\\_vmem\\_idle\\_resource\\_timeout](#)
- [listen\\_addresses](#)
- [max\\_connections](#)
- [max\\_prepared\\_transactions](#)

- [tcp\\_keepalives\\_count](#)
- [tcp\\_keepalives\\_idle](#)
- [tcp\\_keepalives\\_interval](#)
- [unix\\_socket\\_directories](#)
- [unix\\_socket\\_group](#)
- [unix\\_socket\\_permissions](#)

## Security and Authentication Parameters

- [authentication\\_timeout](#)
- [db\\_user\\_namespace](#)
- [krb\\_caseins\\_users](#)
- [krb\\_server\\_keyfile](#)
- [password\\_encryption](#)
- [password\\_hash\\_algorithm](#)
- [ssl](#)
- [ssl\\_ciphers](#)

## System Resource Consumption Parameters

These parameters set the limits for system resources consumed by Greenplum Database.

### Memory Consumption Parameters

These parameters control system memory usage.

- [gp\\_vmem\\_idle\\_resource\\_timeout](#)
- [gp\\_resource\\_group\\_memory\\_limit](#) (resource group-based resource management)
- [gp\\_vmem\\_protect\\_limit](#) (resource queue-based resource management)
- [gp\\_vmem\\_protect\\_segworker\\_cache\\_limit](#)
- [gp\\_workfile\\_limit\\_files\\_per\\_query](#)
- [gp\\_workfile\\_limit\\_per\\_query](#)
- [gp\\_workfile\\_limit\\_per\\_segment](#)
- [maintenance\\_work\\_mem](#)
- [max\\_stack\\_depth](#)
- [shared\\_buffers](#)
- [temp\\_buffers](#)

### OS Resource Parameters

- [max\\_files\\_per\\_process](#)
- [shared\\_preload\\_libraries](#)

### Cost-Based Vacuum Delay Parameters

**Warning:** Do not use cost-based vacuum delay because it runs asynchronously among the segment instances. The vacuum cost limit and delay is invoked at the segment level without taking into account the state of the entire Greenplum Database array

You can configure the execution cost of `VACUUM` and `ANALYZE` commands to reduce the I/O impact on concurrent database activity. When the accumulated cost of I/O operations reaches the limit, the process performing the operation sleeps for a while, Then resets the counter and continues execution

- `vacuum_cost_delay`
- `vacuum_cost_limit`
- `vacuum_cost_page_dirty`
- `vacuum_cost_page_hit`
- `vacuum_cost_page_miss`

## Transaction ID Management Parameters

- `xid_stop_limit`
- `xid_warn_limit`

## GPORCA Parameters

These parameters control the usage of GPORCA by Greenplum Database. For information about GPORCA, see [About GPORCA](#) in the *Greenplum Database Administrator Guide*.

- `gp_enable_resize_collection`
- `optimizer`
- `optimizer_analyze_root_partition`
- `optimizer_array_expansion_threshold`
- `optimizer_control`
- `optimizer_cost_model`
- `optimizer_cte_inlining_bound`
- `optimizer_dpe_stats`
- `optimizer_enable_associativity`
- `optimizer_enable_dml`
- `optimizer_enable_indexonlyscan`
- `optimizer_enable_master_only_queries`
- `optimizer_enable_multiple_distinct_aggs`
- `optimizer_enable_orderedagg`
- `optimizer_enable_replicated_table`
- `optimizer_force_agg_skew_avoidance`
- `optimizer_force_comprehensive_join_implementation`
- `optimizer_force_multistage_agg`
- `optimizer_force_three_stage_scalar_dqa`

- `optimizer_join_arity_for_associativity_commutativity`
- `optimizer_join_order`
- `optimizer_join_order_threshold`
- `optimizer_mdcache_size`
- `optimizer_metadata_caching`
- `optimizer_parallel_union`
- `optimizer_penalize_skew`
- `optimizer_print_missing_stats`
- `optimizer_print_optimization_stats`
- `optimizer_sort_factor`
- `optimizer_use_gpdb_allocators`
- `optimizer_xform_bind_threshold`

## Query Tuning Parameters

These parameters control aspects of SQL query processing such as query operators and operator settings and statistics sampling.

## Postgres Planner Control Parameters

The following parameters control the types of plan operations the Postgres Planner can use. Enable or deactivate plan operations to force the Postgres Planner to choose a different plan. This is useful for testing and comparing query performance using different plan types.

- `enable_bitmapscan`
- `enable_groupagg`
- `enable_hashagg`
- `enable_hashjoin`
- `enable_indexscan`
- `enable_mergejoin`
- `enable_nestloop`
- `enable_seqscan`
- `enable_sort`
- `enable_tidscan`
- `gp_eager_two_phase_agg`
- `gp_enable_agg_distinct`
- `gp_enable_agg_distinct_pruning`
- `gp_enable_direct_dispatch`

- `gp_enable_fast_sri`
- `gp_enable_groupext_distinct_gather`
- `gp_enable_groupext_distinct_pruning`
- `gp_enable_multiphase_agg`
- `gp_enable_predicate_propagation`
- `gp_enable_preunique`
- `gp_enable_resize_collection`
- `gp_enable_sort_distinct`
- `gp_enable_sort_limit`

## Postgres Planner Costing Parameters

**Warning:** Do not adjust these query costing parameters. They are tuned to reflect Greenplum Database hardware configurations and typical workloads. All of these parameters are related. Changing one without changing the others can have adverse effects on performance.

- `cpu_index_tuple_cost`
- `cpu_operator_cost`
- `cpu_tuple_cost`
- `cursor_tuple_fraction`
- `effective_cache_size`
- `gp_motion_cost_per_row`
- `gp_segments_for_planner`
- `random_page_cost`
- `seq_page_cost`

## Database Statistics Sampling Parameters

These parameters adjust the amount of data sampled by an `ANALYZE` operation. Adjusting these parameters affects statistics collection system-wide. You can configure statistics collection on particular tables and columns by using the `ALTER TABLE SET STATISTICS` clause.

- `default_statistics_target`

## Sort Operator Configuration Parameters

- `gp_enable_sort_distinct`
- `gp_enable_sort_limit`

## Aggregate Operator Configuration Parameters

- `gp_enable_agg_distinct`
- `gp_enable_agg_distinct_pruning`

- `gp_enable_multiphase_agg`
- `gp_enable_preunique`
- `gp_enable_groupext_distinct_gather`
- `gp_enable_groupext_distinct_pruning`
- `gp_workfile_compression`

## Join Operator Configuration Parameters

- `join_collapse_limit`
- `gp_adjust_selectivity_for_outerjoins`
- `gp_hashjoin_tuples_per_bucket`
- `gp_statistics_use_fkeys`
- `gp_workfile_compression`

## Other Postgres Planner Configuration Parameters

- `from_collapse_limit`
- `gp_enable_predicate_propagation`
- `gp_max_plan_size`
- `gp_statistics_pullup_from_child_partition`

## Query Plan Execution

Control the query plan execution.

- `gp_max_slices`
- `plan_cache_mode`

## Error Reporting and Logging Parameters

These configuration parameters control Greenplum Database logging.

### Log Rotation

- `log_rotation_age`
- `log_rotation_size`
- `log_truncate_on_rotation`

### When to Log

- `client_min_messages`
- `gp_interconnect_debug_retry_interval`
- `log_error_verbosity`

- `log_file_mode`
- `log_min_duration_statement`
- `log_min_error_statement`
- `log_min_messages`
- `optimizer_minidump`

## What to Log

- `debug_pretty_print`
- `debug_print_parse`
- `debug_print_plan`
- `debug_print_prelim_plan`
- `debug_print_rewritten`
- `debug_print_slice_table`
- `gp_log_format`
- `gp_log_interconnect`
- `gp_log_resqueue_priority_sleep_time`
- `log_autostats`
- `log_connections`
- `log_disconnections`
- `log_dispatch_stats`
- `log_duration`
- `log_executor_stats`
- `log_hostname`
- `gp_log_endpoints`
- `gp_log_interconnect`
- `log_parser_stats`
- `log_planner_stats`
- `log_statement`
- `log_statement_stats`
- `log_timezone`
- `gp_debug_linger`
- `gp_reraise_signal`

## System Monitoring Parameters

These configuration parameters control Greenplum Database data collection and notifications related to database monitoring.

## Greenplum Performance Database

The following parameters configure the data collection agents that populate the `gpperfmon` database.

- `gp_enable_gpperfmon`
- `gp_gpperfmon_send_interval`
- `gpperfmon_log_alert_level`
- `gpperfmon_port`

## Query Metrics Collection Parameters

These parameters enable and configure query metrics collection. When enabled, Greenplum Database saves metrics to shared memory during query execution. These metrics are used by Tanzu Greenplum Command Center, which is included with VMware's commercial version of Greenplum Database.

- `gp_enable_query_metrics`
- `gp_instrument_shmem_size`

## Runtime Statistics Collection Parameters

These parameters control the server statistics collection feature. When statistics collection is enabled, you can access the statistics data using the `pg_stat` family of system catalog views.

- `stats_queue_level`
- `track_activities`
- `track_counts`
- `update_process_title`

## Automatic Statistics Collection Parameters

When automatic statistics collection is enabled, you can run `ANALYZE` automatically in the same transaction as an `INSERT`, `UPDATE`, `DELETE`, `COPY` or `CREATE TABLE...AS SELECT` statement when a certain threshold of rows is affected (`on_change`), or when a newly generated table has no statistics (`on_no_stats`). To enable this feature, set the following server configuration parameters in your Greenplum Database master `postgresql.conf` file and restart Greenplum Database:

- `gp_autostats_allow_nonowner`
- `gp_autostats_mode`
- `gp_autostats_mode_in_functions`
- `gp_autostats_on_change_threshold`
- `log_autostats`

**Warning:** Depending on the specific nature of your database operations, automatic statistics collection can have a negative performance impact. Carefully evaluate whether the default setting of `on_no_stats` is appropriate for your system.

## Client Connection Default Parameters

These configuration parameters set defaults that are used for client connections.

### Statement Behavior Parameters

- `check_function_bodies`
- `default_tablespace`
- `default_transaction_deferrable`
- `default_transaction_isolation`
- `default_transaction_read_only`
- `search_path`
- `statement_timeout`
- `temp_tablespaces`
- `vacuum_freeze_min_age`

### Locale and Formatting Parameters

- `client_encoding`
- `DateStyle`
- `extra_float_digits`
- `IntervalStyle`
- `lc_collate`
- `lc_ctype`
- `lc_messages`
- `lc_monetary`
- `lc_numeric`
- `lc_time`
- `TimeZone`

### Other Client Default Parameters

- `dynamic_library_path`
- `explain_pretty_print`
- `local_preload_libraries`

## Lock Management Parameters

These configuration parameters set limits for locks and deadlocks.

- `deadlock_timeout`
- `[gp_enable_global_deadlock_detector](guc-list.html#gp_enable_global_deadlock_detector)`
- `gp_global_deadlock_detector_period`
- `lock_timeout`
- `max_locks_per_transaction`

## Resource Management Parameters (Resource Queues)

The following configuration parameters configure the Greenplum Database resource management feature (resource queues), query prioritization, memory utilization and concurrency control.

- `gp_log_resqueue_priority_sleep_time`
- `gp_resqueue_memory_policy`
- `gp_resqueue_priority`
- `gp_resqueue_priority_cpuscores_per_segment`
- `gp_resqueue_priority_sweeper_interval`
- `gp_vmem_idle_resource_timeout`
- `gp_vmem_protect_limit`
- `gp_vmem_protect_segworker_cache_limit`
- `max_resource_queues`
- `max_resource_portals_per_transaction`
- `max_statement_mem`
- `resource_cleanup_gangs_on_wait`
- `resource_select_only`
- `runaway_detector_activation_percent`
- `statement_mem`
- `stats_queue_level`
- `vmem_process_interrupt`

## Resource Management Parameters (Resource Groups)

The following parameters configure the Greenplum Database resource group workload management feature.

- `gp_resgroup_memory_policy`
- `gp_resource_group_bypass`

- `gp_resource_group_cpu_ceiling_enforcement`
- `gp_resource_group_cpu_limit`
- `gp_resource_group_enable_recalculate_query_mem`
- `gp_resource_group_memory_limit`
- `gp_resource_group_queuing_timeout`
- `gp_resource_manager`
- `gp_vmem_idle_resource_timeout`
- `gp_vmem_protect_segworker_cache_limit`
- `max_statement_mem`
- `memory_spill_ratio`
- `runaway_detector_activation_percent`
- `statement_mem`
- `vmem_process_interrupt`

## External Table Parameters

The following parameters configure the external tables feature of Greenplum Database.

- `gp_external_enable_exec`
- `gp_external_enable_filter_pushdown`
- `gp_external_max_segs`
- `gp_initial_bad_row_limit`
- `gp_reject_percent_threshold`
- `gpfdist_retry_timeout`
- `readable_external_table_timeout`
- `writable_external_table_bufsize`
- `verify_gpfdists_cert`

## Database Table Parameters

The following parameter configures default option settings for Greenplum Database tables.

- `gp_create_table_random_default_distribution`
- `gp_default_storage_options`
- `gp_enable_exchange_default_partition`
- `gp_enable_segment_copy_checking`
- `gp_use_legacy_hashops`

## Append-Optimized Table Parameters

The following parameters configure the append-optimized tables feature of Greenplum Database.

- [max\\_appendonly\\_tables](#)
- [gp\\_add\\_column\\_inherits\\_table\\_setting](#) [[gp\\_appendonly\\_compaction](#)]([guc-list.html#gp\\_add\\_column\\_inherits\\_table\\_setting](#))([guc-list.html](#)) [[gp\\_appendonly\\_compaction](#)]
- [gp\\_appendonly\\_compaction\\_threshold](#)
- [validate\\_previous\\_free\\_tid](#)

## Past Version Compatibility Parameters

The following parameters provide compatibility with older PostgreSQL and Greenplum Database versions. You do not need to change these parameters in Greenplum Database.

### PostgreSQL

- [array\\_nulls](#)
- [backslash\\_quote](#)
- [escape\\_string\\_warning](#)
- [quote\\_all\\_identifiers](#)
- [regex\\_flavor](#)
- [standard\\_conforming\\_strings](#)
- [transform\\_null\\_equals](#)

### Greenplum Database

- [enable\\_implicit\\_timeformat\\_YYYYMMDDHH24MISS](#)
- [gp\\_ignore\\_error\\_table](#)

## Greenplum Database Array Configuration Parameters

The parameters in this topic control the configuration of the Greenplum Database array and its components: segments, master, distributed transaction manager, master mirror, and interconnect.

### Interconnect Configuration Parameters

- [gp\\_interconnect\\_address\\_type](#)
- [gp\\_interconnect\\_fc\\_method](#)
- [gp\\_interconnect\\_proxy\\_addresses](#)
- [gp\\_interconnect\\_queue\\_depth](#)
- [gp\\_interconnect\\_setup\\_timeout](#)
- [gp\\_interconnect\\_snd\\_queue\\_depth](#)
- [gp\\_interconnect\\_transmit\\_timeout](#)

- `gp_interconnect_type`
- `gp_max_packet_size`

**Note:** Greenplum Database supports only the UDPIFC (default) and TCP interconnect types.

## Dispatch Configuration Parameters

- `gp_cached_segworkers_threshold`
- `gp_enable_direct_dispatch`
- `gp_segment_connect_timeout`
- `gp_set_proc_affinity`

## Fault Operation Parameters

- `gp_set_read_only`
- `gp_fts_probe_interval`
- `gp_fts_probe_retries`
- `gp_fts_probe_timeout`
- `gp_fts_replication_attempt_count`
- `gp_log_fts`

## Distributed Transaction Management Parameters

- `gp_max_local_distributed_cache`
- `dtx_phase2_retry_count`

## Read-Only Parameters

- `gp_command_count`
- `gp_content`
- `gp_dbid`
- `gp_retrieve_conn`
- `gp_role`
- `gp_session_id`
- `gp_server_version`
- `gp_server_version_num`

## Greenplum Mirroring Parameters for Master and Segments

These parameters control the configuration of the replication between Greenplum Database primary master and standby master.

- `max_slot_wal_keep_size`

- [repl\\_catchup\\_within\\_range](#)
- [replication\\_timeout](#)
- [wait\\_for\\_replication\\_threshold](#)
- [wal\\_keep\\_segments](#)
- [wal\\_receiver\\_status\\_interval](#)

## Greenplum PL/Java Parameters

The parameters in this topic control the configuration of the Greenplum Database PL/Java language.

- [pljava\\_classpath](#)
- [pljava\\_classpath\\_insecure](#)
- [pljava\\_statement\\_cache\\_size](#)
- [pljava\\_release\\_lingering\\_savepoints](#)
- [pljava\\_vmoptions](#)

## XML Data Parameters

The parameters in this topic control the configuration of the Greenplum Database XML data type.

- [xmlbinary](#)
- [xmloption](#)

## Configuration Parameters

Descriptions of the Greenplum Database server configuration parameters listed alphabetically.

### application\_name

Sets the application name for a client session. For example, if connecting via [psql](#), this will be set to [psql](#). Setting an application name allows it to be reported in log messages and statistics views.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| string      |         | master, session, reload |

### array\_nulls

This controls whether the array input parser recognizes unquoted NULL as specifying a null array element. By default, this is on, allowing array values containing null values to be entered. Greenplum Database versions before 3.0 did not support null values in arrays, and therefore would treat NULL as specifying a normal array element with the string value 'NULL'.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## authentication\_timeout

Maximum time to complete client authentication. This prevents hung clients from occupying a connection indefinitely.

| Value Range                                 | Default | Set Classifications    |
|---|---------|------------------------|
| Any valid time expression (number and unit) | 1min    | local, system, restart |

## backslash\_quote

This controls whether a quote mark can be represented by `\'` in a string literal. The preferred, SQL-standard way to represent a quote mark is by doubling it (`'`) but PostgreSQL has historically also accepted `\'`. However, use of `\'` creates security risks because in some client character set encodings, there are multibyte characters in which the last byte is numerically equivalent to ASCII `\`.

| Value Range  | Default       | Set Classifications     |
|--|---------------|-------------------------|
| on (allow <code>\'</code> always)  | safe_encoding | master, session, reload |
| off (reject always)  |               |                         |
| safe_encoding (allow only if client encoding does not allow ASCII <code>\</code> within a multibyte character) |               |                         |

## block\_size

Reports the size of a disk block.

| Value Range     | Default | Set Classifications |
|-----------------|---------|---------------------|
| number of bytes | 32768   | read only           |

## bonjour\_name

Specifies the Bonjour broadcast name. By default, the computer name is used, specified as an empty string. This option is ignored if the server was not compiled with Bonjour support.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| string      | unset   | master, system, restart |

## check\_function\_bodies

When set to off, deactivates validation of the function body string during `CREATE FUNCTION`. Deactivating validation is occasionally useful to avoid problems such as forward references when

restoring function definitions from a dump.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## client\_connection\_check\_interval

Sets the time interval between optional checks that the client is still connected, while running queries. 0 deactivates connection checks.

| Value Range            | Default | Set Classifications     |
|------------------------|---------|-------------------------|
| number of milliseconds | 0       | master, session, reload |

## client\_encoding

Sets the client-side encoding (character set). The default is to use the same as the database encoding. See [Supported Character Sets](#) in the PostgreSQL documentation.

| Value Range   | Default | Set Classifications     |
|---------------|---------|-------------------------|
| character set | UTF8    | master, session, reload |

## client\_min\_messages

Controls which message levels are sent to the client. Each level includes all the levels that follow it. The later the level, the fewer messages are sent.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| DEBUG5      | NOTICE  | master, session, reload |
| DEBUG4      |         |                         |
| DEBUG3      |         |                         |
| DEBUG2      |         |                         |
| DEBUG1      |         |                         |
| LOG         |         |                         |
| NOTICE      |         |                         |
| WARNING     |         |                         |
| ERROR       |         |                         |
| FATAL       |         |                         |
| PANIC       |         |                         |

**INFO** level messages are always sent to the client.

## cpu\_index\_tuple\_cost

For the Postgres Planner, sets the estimate of the cost of processing each index row during an index scan. This is measured as a fraction of the cost of a sequential page fetch.

| Value Range    | Default | Set Classifications     |
|----------------|---------|-------------------------|
| floating point | 0.005   | master, session, reload |

## cpu\_operator\_cost

For the Postgres Planner, sets the estimate of the cost of processing each operator in a WHERE clause. This is measured as a fraction of the cost of a sequential page fetch.

| Value Range    | Default | Set Classifications     |
|----------------|---------|-------------------------|
| floating point | 0.0025  | master, session, reload |

## cpu\_tuple\_cost

For the Postgres Planner, Sets the estimate of the cost of processing each row during a query. This is measured as a fraction of the cost of a sequential page fetch.

| Value Range    | Default | Set Classifications     |
|----------------|---------|-------------------------|
| floating point | 0.01    | master, session, reload |

## cursor\_tuple\_fraction

Tells the Postgres Planner how many rows are expected to be fetched in a cursor query, thereby allowing the Postgres Planner to use this information to optimize the query plan. The default of 1 means all rows will be fetched.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| integer     | 1       | master, session, reload |

## data\_checksums

Reports whether checksums are enabled for heap data storage in the database system. Checksums for heap data are enabled or deactivated when the database system is initialized and cannot be changed.

Heap data pages store heap tables, catalog tables, indexes, and database metadata. Append-optimized storage has built-in checksum support that is unrelated to this parameter.

Greenplum Database uses checksums to prevent loading data corrupted in the file system into memory managed by database processes. When heap data checksums are enabled, Greenplum Database computes and stores checksums on heap data pages when they are written to disk. When a page is retrieved from disk, the checksum is verified. If the verification fails, an error is generated and the page is not permitted to load into managed memory.

If the `ignore_checksum_failure` configuration parameter has been set to on, a failed checksum verification generates a warning, but the page is allowed to be loaded into managed memory. If the page is then updated, it is flushed to disk and replicated to the mirror. This can cause data corruption to propagate to the mirror and prevent a complete recovery. Because of the potential for data loss, the `ignore_checksum_failure` parameter should only be enabled when needed to recover data. See [ignore\\_checksum\\_failure](#) for more information.

| Value Range | Default | Set Classifications |
|-------------|---------|---------------------|
| Boolean     | on      | read only           |

## DateStyle

Sets the display format for date and time values, as well as the rules for interpreting ambiguous date input values. This variable contains two independent components: the output format specification and the input/output specification for year/month/day ordering.

| Value Range            | Default  | Set Classifications     |
|------------------------|----------|-------------------------|
| <format>, <date style> | ISO, MDY | master, session, reload |

where:

<format> is ISO, Postgres, SQL, or German

<date style> is DMY, MDY, or YMD

## db\_user\_namespace

This enables per-database user names. If on, you should create users as `username@dbname`. To create ordinary global users, simply append @ when specifying the user name in the client.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| Boolean     | off     | local, system, restart |

## deadlock\_timeout

The time to wait on a lock before checking to see if there is a deadlock condition. On a heavily loaded server you might want to raise this value. Ideally the setting should exceed your typical transaction time, so as to improve the odds that a lock will be released before the waiter decides to check for deadlock.

| Value Range                                 | Default | Set Classifications    |
|---|---------|------------------------|
| Any valid time expression (number and unit) | 1s      | local, system, restart |

## debug\_assertions

Turns on various assertion checks.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| Boolean     | off     | local, system, restart |

## debug\_pretty\_print

Indents debug output to produce a more readable but much longer output format. *client\_min\_messages* or *log\_min\_messages* must be DEBUG1 or lower.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## debug\_print\_parse

For each query run, prints the resulting parse tree. *client\_min\_messages* or *log\_min\_messages* must be DEBUG1 or lower.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## debug\_print\_plan

For each query run, prints the Greenplum parallel query execution plan. *client\_min\_messages* or *log\_min\_messages* must be DEBUG1 or lower.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## debug\_print\_prelim\_plan

For each query run, prints the preliminary query plan. *client\_min\_messages* or *log\_min\_messages* must be DEBUG1 or lower.

| Value Range | Default | Set Classifications     |
