|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## debug\_print\_rewritten

For each query run, prints the query rewriter output. *client\_min\_messages* or *log\_min\_messages* must be DEBUG1 or lower.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## debug\_print\_slice\_table

For each query run, prints the Greenplum query slice plan. `client_min_messages` or `log_min_messages` must be `DEBUG1` or lower.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## default\_statistics\_target

Sets the default statistics sampling target (the number of values that are stored in the list of common values) for table columns that have not had a column-specific target set via `ALTER TABLE SET STATISTICS`. Larger values may improve the quality of the Postgres Planner estimates.

| Value Range         | Default | Set Classifications     |
|---------------------|---------|-------------------------|
| 0 > Integer > 10000 | 100     | master, session, reload |

## default\_tablespace

The default tablespace in which to create objects (tables and indexes) when a `CREATE` command does not explicitly specify a tablespace.

| Value Range          | Default | Set Classifications     |
|----------------------|---------|-------------------------|
| name of a tablespace | unset   | master, session, reload |

## default\_text\_search\_config

Selects the text search configuration that is used by those variants of the text search functions that do not have an explicit argument specifying the configuration. See [Using Full Text Search](#) for further information. The built-in default is `pg_catalog.simple`, but `initdb` will initialize the configuration file with a setting that corresponds to the chosen `lc_ctype` locale, if a configuration matching that locale can be identified.

| Value Range                              | Default                        | Set Classifications     |
|--|--------------------------------|-------------------------|
| The name of a text search configuration. | <code>pg_catalog.simple</code> | master, session, reload |

## default\_transaction\_deferrable

When running at the `SERIALIZABLE` isolation level, a deferrable read-only SQL transaction may be delayed before it is allowed to proceed. However, once it begins running it does not incur any of the overhead required to ensure serializability; so serialization code will have no reason to force it to abort because of concurrent updates, making this option suitable for long-running read-only transactions.

This parameter controls the default deferrable status of each new transaction. It currently has no effect on read-write transactions or those operating at isolation levels lower than `SERIALIZABLE`. The default is `off`.

**Note:** Setting `default_transaction_deferrable` to `on` has no effect in Greenplum Database. Only read-only, `SERIALIZABLE` transactions can be deferred. However, Greenplum Database does not support the `SERIALIZABLE` transaction isolation level. See [SET TRANSACTION](#).

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## default\_transaction\_isolation

Controls the default isolation level of each new transaction. Greenplum Database treats `read uncommitted` the same as `read committed`, and treats `serializable` the same as `repeatable read`.

| Value Range      | Default        | Set Classifications     |
|------------------|----------------|-------------------------|
| read committed   | read committed | master, session, reload |
| read uncommitted |                |                         |
| repeatable read  |                |                         |
| serializable     |                |                         |

## default\_transaction\_read\_only

Controls the default read-only status of each new transaction. A read-only SQL transaction cannot alter non-temporary tables.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## dtx\_phase2\_retry\_count

The maximum number of retries attempted by Greenplum Database during the second phase of a two phase commit. When one or more segments cannot successfully complete the commit phase, the master retries the commit a maximum of `dtx_phase2_retry_count` times. If the commit continues to fail on the last retry attempt, the master generates a PANIC.

When the network is unstable, the master may be unable to connect to one or more segments; increasing the number of two phase commit retries may improve high availability of Greenplum when the master encounters transient network issues.

| Value Range              | Default | Set Classifications     |
|--------------------------|---------|-------------------------|
| 0 - <code>INT_MAX</code> | 10      | master, system, restart |

## dynamic\_library\_path

If a dynamically loadable module needs to be opened and the file name specified in the `CREATE FUNCTION` or `LOAD` command does not have a directory component (i.e. the name does not contain a slash), the system will search this path for the required file. The compiled-in PostgreSQL package

library directory is substituted for `$libdir`. This is where the modules provided by the standard PostgreSQL distribution are installed.

| Value Range  | Default               | Set Classifications   |
|--|-----------------------|-----------------------|
| a list of absolute directory paths separated by colons | <code>\$libdir</code> | local, system, reload |

## effective\_cache\_size

Sets the assumption about the effective size of the disk cache that is available to a single query for the Postgres Planner. This is factored into estimates of the cost of using an index; a higher value makes it more likely index scans will be used, a lower value makes it more likely sequential scans will be used. When setting this parameter, you should consider both Greenplum Database's shared buffers and the portion of the kernel's disk cache that will be used for data files (though some data might exist in both places). Take also into account the expected number of concurrent queries on different tables, since they will have to share the available space. This parameter has no effect on the size of shared memory allocated by a Greenplum server instance, nor does it reserve kernel disk cache; it is used only for estimation purposes.

Set this parameter to a number of `block_size` blocks (default 32K) with no units; for example, `262144` for 8GB. You can also directly specify the size of the effective cache; for example, `'1GB'` specifies a size of 32768 blocks. The `gpconfig` utility and `SHOW` command display the effective cache size value in units such as 'GB', 'MB', or 'kB'.

| Value Range                    | Default       | Set Classifications     |
|--------------------------------|---------------|-------------------------|
| 1 - INT_MAX or number and unit | 524288 (16GB) | master, session, reload |

## enable\_bitmapscan

Activates or deactivates the use of bitmap-scan plan types by the Postgres Planner. Note that this is different than a Bitmap Index Scan. A Bitmap Scan means that indexes will be dynamically converted to bitmaps in memory when appropriate, giving faster index performance on complex queries against very large tables. It is used when there are multiple predicates on different indexed columns. Each bitmap per column can be compared to create a final list of selected tuples.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## enable\_groupagg

Activates or deactivates the use of group aggregation plan types by the Postgres Planner.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## enable\_hashagg

Activates or deactivates the use of hash aggregation plan types by the Postgres Planner.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## enable\_hashjoin

Activates or deactivates the use of hash-join plan types by the Postgres Planner.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## enable\_implicit\_timeformat\_YYYYMMDDHH24MISS

Activates or deactivates the deprecated implicit conversion of a string with the `YYYYMMDDHH24MISS` timestamp format to a valid date/time type.

The default value is `off`. When this parameter is set to `on`, Greenplum Database converts a string with the timestamp format `YYYYMMDDHH24MISS` into a valid date/time type. You may require this conversion when loading data from Greenplum Database 5.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## enable\_indexscan

Activates or deactivates the use of index-scan plan types by the Postgres Planner.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## enable\_mergejoin

Activates or deactivates the use of merge-join plan types by the Postgres Planner. Merge join is based on the idea of sorting the left- and right-hand tables into order and then scanning them in parallel. So, both data types must be capable of being fully ordered, and the join operator must be one that can only succeed for pairs of values that fall at the 'same place' in the sort order. In practice this means that the join operator must behave like equality.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## enable\_nestloop

Activates or deactivates the use of nested-loop join plans by the Postgres Planner. It's not possible to suppress nested-loop joins entirely, but turning this variable off discourages the Postgres Planner

from using one if there are other methods available.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## enable\_seqscan

Activates or deactivates the use of sequential scan plan types by the Postgres Planner. It's not possible to suppress sequential scans entirely, but turning this variable off discourages the Postgres Planner from using one if there are other methods available.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## enable\_sort

Activates or deactivates the use of explicit sort steps by the Postgres Planner. It's not possible to suppress explicit sorts entirely, but turning this variable off discourages the Postgres Planner from using one if there are other methods available.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## enable\_tidscan

Activates or deactivates the use of tuple identifier (TID) scan plan types by the Postgres Planner.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## escape\_string\_warning

When on, a warning is issued if a backslash (\) appears in an ordinary string literal ('...' syntax). Escape string syntax (E'...') should be used for escapes, because in future versions, ordinary strings will have the SQL standard-conforming behavior of treating backslashes literally.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## explain\_pretty\_print

Determines whether EXPLAIN VERBOSE uses the indented or non-indented format for displaying detailed query-tree dumps.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## extra\_float\_digits

Adjusts the number of digits displayed for floating-point values, including float4, float8, and geometric data types. The parameter value is added to the standard number of digits. The value can be set as high as 3, to include partially-significant digits; this is especially useful for dumping float data that needs to be restored exactly. Or it can be set negative to suppress unwanted digits.

| Value Range        | Default | Set Classifications     |
|--------------------|---------|-------------------------|
| integer (-15 to 3) | 0       | master, session, reload |

## from\_collapse\_limit

The Postgres Planner will merge sub-queries into upper queries if the resulting FROM list would have no more than this many items. Smaller values reduce planning time but may yield inferior query plans.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| 1- <i>n</i> | 20      | master, session, reload |

## gp\_add\_column\_inherits\_table\_setting

When adding a column to an append-optimized, column-oriented table with the [ALTER TABLE](#) command, this parameter controls whether the table's data compression parameters for a column ([compressstype](#), [compresslevel](#), and [blocksize](#)) can be inherited from the table values. The default is `off`, the table's data compression settings are not considered when adding a column to the table. If the value is `on`, the table's settings are considered.

When you create an append-optimized column-oriented table, you can set the table's data compression parameters [compressstype](#), [compresslevel](#), and [blocksize](#) for the table in the [WITH](#) clause. When you add a column, Greenplum Database sets each data compression parameter based on one of the following settings, in order of preference.

1. The data compression setting specified in the [ALTER TABLE](#) command [ENCODING](#) clause.
2. If this server configuration parameter is set to `on`, the table's data compression setting specified in the [WITH](#) clause when the table was created. Otherwise, the table's data compression setting is ignored.
3. The data compression setting specified in the server configuration parameter [gp\\_default\\_storage\\_options](#).
4. The default data compression setting.

You must specify `--skipvalidation` when modifying this parameter as it is a restricted configuration parameter. Use extreme caution when setting configuration parameters with this option. For example:

```
gpconfig --skipvalidation -c gp_add_column_inherits_table_setting -v on
```

For information about the data storage compression parameters, see [CREATE TABLE](#).

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## gp\_adjust\_selectivity\_for\_outerjoins

Enables the selectivity of NULL tests over outer joins.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_appendonly\_compaction

Enables compacting segment files during `VACUUM` commands. When deactivated, `VACUUM` only truncates the segment files to the EOF value, as is the current behavior. The administrator may want to deactivate compaction in high I/O load situations or low space situations.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_appendonly\_compaction\_threshold

Specifies the threshold ratio (as a percentage) of hidden rows to total rows that triggers compaction of the segment file when `VACUUM` is run without the `FULL` option (a lazy vacuum). If the ratio of hidden rows in a segment file on a segment is less than this threshold, the segment file is not compacted, and a log message is issued.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| integer (%) | 10      | master, session, reload |

## gp\_autostats\_allow\_nonowner

The `gp_autostats_allow_nonowner` server configuration parameter determines whether or not to allow Greenplum Database to trigger automatic statistics collection when a table is modified by a non-owner.

The default value is `false`; Greenplum Database does not trigger automatic statistics collection on a table that is updated by a non-owner.

When set to `true`, Greenplum Database will also trigger automatic statistics collection on a table when:

- `gp_autostats_mode=on_change` and the table is modified by a non-owner.

- `gp_autostats_mode=on_no_stats` and the first user to `INSERT` or `COPY` into the table is a non-owner.

The `gp_autostats_allow_nonowner` configuration parameter can be changed only by a superuser.

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| Boolean     | false   | master, session, reload, superuser |

## gp\_autostats\_mode

Specifies the mode for triggering automatic statistics collection with `ANALYZE`. The `on_no_stats` option triggers statistics collection for `CREATE TABLE AS SELECT`, `INSERT`, or `COPY` operations on any table that has no existing statistics.

The `on_change` option triggers statistics collection only when the number of rows affected exceeds the threshold defined by `gp_autostats_on_change_threshold`. Operations that can trigger automatic statistics collection with `on_change` are:

```
CREATE TABLE AS SELECT
```

```
UPDATE
```

```
DELETE
```

```
INSERT
```

```
COPY
```

Default is `on_no_stats`.

**Note:** For partitioned tables, automatic statistics collection is not triggered if data is inserted from the top-level parent table of a partitioned table.

Automatic statistics collection is triggered if data is inserted directly in a leaf table (where the data is stored) of the partitioned table. Statistics are collected only on the leaf table.

| Value Range              | Default                  | Set Classifications     |
|--------------------------|--------------------------|-------------------------|
| none                     | <code>on_no_stats</code> | master, session, reload |
| <code>on_change</code>   |                          |                         |
| <code>on_no_stats</code> |                          |                         |

## gp\_autostats\_mode\_in\_functions

Specifies the mode for triggering automatic statistics collection with `ANALYZE` for statements in procedural language functions. The `none` option deactivates statistics collection. The `on_no_stats` option triggers statistics collection for `CREATE TABLE AS SELECT`, `INSERT`, or `COPY` operations that are run in functions on any table that has no existing statistics.

The `on_change` option triggers statistics collection only when the number of rows affected exceeds the threshold defined by `gp_autostats_on_change_threshold`. Operations in functions that can trigger automatic statistics collection with `on_change` are:

```
CREATE TABLE AS SELECT
```

UPDATE

DELETE

INSERT

COPY

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| none        | none    | master, session, reload |
| on_change   |         |                         |
| on_no_stats |         |                         |

## gp\_autostats\_on\_change\_threshold

Specifies the threshold for automatic statistics collection when `gp_autostats_mode` is set to `on_change`. When a triggering table operation affects a number of rows exceeding this threshold, `ANALYZE` is added and statistics are collected for the table.

| Value Range | Default    | Set Classifications     |
|-------------|------------|-------------------------|
| integer     | 2147483647 | master, session, reload |

## gp\_cached\_segworkers\_threshold

When a user starts a session with Greenplum Database and issues a query, the system creates groups or 'gangs' of worker processes on each segment to do the work. After the work is done, the segment worker processes are destroyed except for a cached number which is set by this parameter. A lower setting conserves system resources on the segment hosts, but a higher setting may improve performance for power-users that want to issue many complex queries in a row.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| integer > 0 | 5       | master, session, reload |

## gp\_command\_count

Shows how many commands the master has received from the client. Note that a single SQLcommand might actually involve more than one command internally, so the counter may increment by more than one for a single query. This counter also is shared by all of the segment processes working on the command.

| Value Range | Default | Set Classifications |
|-------------|---------|---------------------|
| integer > 0 | 1       | read only           |

## gp\_connection\_send\_timeout

Timeout for sending data to unresponsive Greenplum Database user clients during query processing. A value of 0 deactivates the timeout, Greenplum Database waits indefinitely for a client. When the timeout is reached, the query is cancelled with this message:

```
Could not send data to client: Connection timed out.
```

| Value Range       | Default       | Set Classifications    |
|-------------------|---------------|------------------------|
| number of seconds | 3600 (1 hour) | master, system, reload |

## gp\_content

The local content id if a segment.

| Value Range | Default | Set Classifications |
|-------------|---------|---------------------|
| integer     |         | read only           |

## gp\_create\_table\_random\_default\_distribution

Controls table creation when a Greenplum Database table is created with a CREATE TABLE or CREATE TABLE AS command that does not contain a DISTRIBUTED BY clause.

For CREATE TABLE, if the value of the parameter is `off` (the default), and the table creation command does not contain a DISTRIBUTED BY clause, Greenplum Database chooses the table distribution key based on the command:

- If a `LIKE` or `INHERITS` clause is specified, then Greenplum copies the distribution key from the source or parent table.
- If a `PRIMARY KEY` or `UNIQUE` constraints are specified, then Greenplum chooses the largest subset of all the key columns as the distribution key.
- If neither constraints nor a `LIKE` or `INHERITS` clause is specified, then Greenplum chooses the first suitable column as the distribution key. (Columns with geometric or user-defined data types are not eligible as Greenplum distribution key columns.)

If the value of the parameter is set to `on`, Greenplum Database follows these rules to create a table when the DISTRIBUTED BY clause is not specified:

- If PRIMARY KEY or UNIQUE columns are not specified, the distribution of the table is random (DISTRIBUTED RANDOMLY). Table distribution is random even if the table creation command contains the LIKE or INHERITS clause.
- If PRIMARY KEY or UNIQUE columns are specified, a DISTRIBUTED BY clause must also be specified. If a DISTRIBUTED BY clause is not specified as part of the table creation command, the command fails.

For a CREATE TABLE AS command that does not contain a distribution clause:

- If the Postgres Planner creates the table, and the value of the parameter is `off`, the table distribution policy is determined based on the command.

- If the Postgres Planner creates the table, and the value of the parameter is `on`, the table distribution policy is random.
- If GPORCA creates the table, the table distribution policy is random. The parameter value has no affect.

For information about the Postgres Planner and GPORCA, see "Querying Data" in the *Greenplum Database Administrator Guide*.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| boolean     | off     | master, session, reload |

## gp\_dbid

The local content dbid of a segment.

| Value Range | Default | Set Classifications |
|-------------|---------|---------------------|
| integer     |         | read only           |

## gp\_debug\_linger

Number of seconds for a Greenplum process to linger after a fatal internal error.

| Value Range                                 | Default | Set Classifications     |
|---|---------|-------------------------|
| Any valid time expression (number and unit) | 0       | master, session, reload |

## gp\_default\_storage\_options

Set the default values for the following table storage options when a table is created with the `CREATE TABLE` command.

- `appendoptimized`

**Note:** You use the `appendoptimized=value` syntax to specify the append-optimized table storage type. `appendoptimized` is a thin alias for the `appendonly` legacy storage option. Greenplum Database stores `appendonly` in the catalog, and displays the same when listing the storage options for append-optimized tables.
- `blocksize`
- `checksum`
- `compressstype`
- `compresslevel`
- `orientation`

Specify multiple storage option values as a comma separated list.

You can set the storage options with this parameter instead of specifying the table storage options in the `WITH` of the `CREATE TABLE` command. The table storage options that are specified with the `CREATE TABLE` command override the values specified by this parameter.

Not all combinations of storage option values are valid. If the specified storage options are not valid, an error is returned. See the `CREATE TABLE` command for information about table storage options.

The defaults can be set for a database and user. If the server configuration parameter is set at different levels, this the order of precedence, from highest to lowest, of the table storage values when a user logs into a database and creates a table:

1. The values specified in a `CREATE TABLE` command with the `WITH` clause or `ENCODING` clause
2. The value of `gp_default_storage_options` that set for the user with the `ALTER ROLE...SET` command
3. The value of `gp_default_storage_options` that is set for the database with the `ALTER DATABASE...SET` command
4. The value of `gp_default_storage_options` that is set for the Greenplum Database system with the `gpconfig` utility

The parameter value is not cumulative. For example, if the parameter specifies the `appendoptimized` and `compresstype` options for a database and a user logs in and sets the parameter to specify the value for the `orientation` option, the `appendoptimized`, and `compresstype` values set at the database level are ignored.

This example `ALTER DATABASE` command sets the default `orientation` and `compresstype` table storage options for the database `mytest`.

```
ALTER DATABASE mytest SET gp_default_storage_options = 'orientation=column, compresstype=rle_type'
```

To create an append-optimized table in the `mytest` database with column-oriented table and RLE compression. The user needs to specify only `appendoptimized=TRUE` in the `WITH` clause.

This example `gpconfig` utility command sets the default storage option for a Greenplum Database system. If you set the defaults for multiple table storage options, the value must be enclosed in single quotes.

```
gpconfig -c 'gp_default_storage_options' -v 'appendoptimized=true, orientation=column'
```

This example `gpconfig` utility command shows the value of the parameter. The parameter value must be consistent across the Greenplum Database master and all segments.

```
gpconfig -s 'gp_default_storage_options'
```

| Value Range   | Default                            | Set Classifications <sup>1</sup> |
|---|------------------------------------|----------------------------------|
| <code>appendoptimized= TRUE OR FALSE</code>   | <code>appendoptimized=FALSE</code> | master, session, reload          |
| <code>blocksize= integer between 8192 and 2097152</code>                            | <code>blocksize=32768</code>       |                                  |
| <code>checksum= TRUE OR FALSE</code>  | <code>checksum=TRUE</code>         |                                  |
| <code>compressstype= ZLIB OR ZSTD OR QUICKLZ<sup>2</sup> OR RLE_TYPE OR NONE</code> | <code>compressstype=none</code>    |                                  |
| <code>compresslevel= integer between 0 and 19</code>                                | <code>compresslevel=0</code>       |                                  |
| <code>orientation= ROW   COLUMN</code>  | <code>orientation=ROW</code>       |                                  |

**Note:** <sup>1</sup>The set classification when the parameter is set at the system level with the `gpconfig` utility.

**Note:** <sup>2</sup>QuickLZ compression is available only in the commercial release of Tanzu Greenplum.

## gp\_dispatch\_keepalives\_count

Maximum number of TCP keepalive retransmits from a Greenplum Query Dispatcher to its Query Executors. It controls the number of consecutive keepalive retransmits that can be lost before a connection between a Query Dispatcher and a Query Executor is considered dead.

| Value Range | Default                        | Set Classifications     |
|-------------|--------------------------------|-------------------------|
| 0 to 127    | 0 (it uses the system default) | master, system, restart |

## gp\_dispatch\_keepalives\_idle

Time in seconds between issuing TCP keepalives from a Greenplum Query Dispatcher to its Query Executors.

| Value Range | Default                        | Set Classifications     |
|-------------|--------------------------------|-------------------------|
| 0 to 32767  | 0 (it uses the system default) | master, system, restart |

## gp\_dispatch\_keepalives\_interval

Time in seconds between TCP keepalive retransmits from a Greenplum Query Dispatcher to its Query Executors.

| Value Range | Default                        | Set Classifications     |
|-------------|--------------------------------|-------------------------|
| 0 to 32767  | 0 (it uses the system default) | master, system, restart |

## gp\_dynamic\_partition\_pruning

Enables plans that can dynamically eliminate the scanning of partitions.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_eager\_two\_phase\_agg

Activates or deactivates two-phase aggregation for the Postgres Planner.

The default value is `off`; the Planner chooses the best aggregate path for a query based on the cost. When set to `on`, the Planner adds a deactivation cost to each of the first stage aggregate paths, which in turn forces the Planner to generate and choose a multi-stage aggregate path.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## gp\_enable\_agg\_distinct

Activates or deactivates two-phase aggregation to compute a single distinct-qualified aggregate. This applies only to subqueries that include a single distinct-qualified aggregate function.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_enable\_agg\_distinct\_pruning

Activates or deactivates three-phase aggregation and join to compute distinct-qualified aggregates. This applies only to subqueries that include one or more distinct-qualified aggregate functions.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_enable\_direct\_dispatch

Activates or deactivates the dispatching of targeted query plans for queries that access data on a single segment. When on, queries that target rows on a single segment will only have their query plan dispatched to that segment (rather than to all segments). This significantly reduces the response time of qualifying queries as there is no interconnect setup involved. Direct dispatch does require more CPU utilization on the master.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_enable\_exchange\_default\_partition

Controls availability of the `EXCHANGE DEFAULT PARTITION` clause for `ALTER TABLE`. The default value for the parameter is `off`. The clause is not available and Greenplum Database returns an error if the clause is specified in an `ALTER TABLE` command.

If the value is `on`, Greenplum Database returns a warning stating that exchanging the default partition might result in incorrect results due to invalid data in the default partition.

**Warning:** Before you exchange the default partition, you must ensure the data in the table to be exchanged, the new default partition, is valid for the default partition. For example, the data in the new default partition must not contain data that would be valid in other leaf child partitions of the partitioned table. Otherwise, queries against the partitioned table with the exchanged default partition that are run by GPORCA might return incorrect results.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## gp\_enable\_fast\_sri

When set to `on`, the Postgres Planner plans single row inserts so that they are sent directly to the correct segment instance (no motion operation required). This significantly improves performance of single-row-insert statements.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_enable\_global\_deadlock\_detector

Controls whether the Greenplum Database Global Deadlock Detector is enabled to manage concurrent `UPDATE` and `DELETE` operations on heap tables to improve performance. See [Inserting, Updating, and Deleting Data](#) in the *Greenplum Database Administrator Guide*. The default is `off`, the Global Deadlock Detector is deactivated.

If the Global Deadlock Detector is deactivated (the default), Greenplum Database runs concurrent update and delete operations on a heap table serially.

If the Global Deadlock Detector is enabled, concurrent updates are permitted and the Global Deadlock Detector determines when a deadlock exists, and breaks the deadlock by cancelling one or more backend processes associated with the youngest transaction(s) involved.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, system, restart |

## gp\_enable\_gpperfmon

Activates or deactivates the data collection agents that populate the `gpperfmon` database.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| Boolean     | off     | local, system, restart |

## gp\_enable\_grouptext\_distinct\_gather

Activates or deactivates gathering data to a single node to compute distinct-qualified aggregates on grouping extension queries. When this parameter and `gp_enable_groupest_distinct_pruning` are both enabled, the Postgres Planner uses the cheaper plan.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_enable\_groupest\_distinct\_pruning

Activates or deactivates three-phase aggregation and join to compute distinct-qualified aggregates on grouping extension queries. Usually, enabling this parameter generates a cheaper query plan that the Postgres Planner will use in preference to existing plan.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_enable\_multiphase\_agg

Activates or deactivates the use of two or three-stage parallel aggregation plans Postgres Planner. This approach applies to any subquery with aggregation. If `gp_enable_multiphase_agg` is off, then `gp_enable_agg_distinct` and `gp_enable_agg_distinct_pruning` are deactivated.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_enable\_predicate\_propagation

When enabled, the Postgres Planner applies query predicates to both table expressions in cases where the tables are joined on their distribution key column(s). Filtering both tables prior to doing the join (when possible) is more efficient.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_enable\_preunique

Enables two-phase duplicate removal for `SELECT DISTINCT` queries (not `SELECT COUNT(DISTINCT)`). When enabled, it adds an extra `SORT DISTINCT` set of plan nodes before motioning. In cases where the distinct operation greatly reduces the number of rows, this extra `SORT DISTINCT` is much cheaper than the cost of sending the rows across the Interconnect.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_enable\_query\_metrics

Enables collection of query metrics. When query metrics collection is enabled, Greenplum Database collects metrics during query execution. The default is off.

After changing this configuration parameter, Greenplum Database must be restarted for the change to take effect.

The Greenplum Database metrics collection extension, when enabled, sends the collected metrics over UDP to a Tanzu Greenplum Command Center agent<sup>1</sup>.

**Note:** <sup>1</sup>The metrics collection extension is included in VMware's commercial version of Greenplum Database. Tanzu Greenplum Command Center is supported only with Tanzu Greenplum.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, system, restart |

## gp\_enable\_resize\_collection

Enables GPORCA and the Postgres Planner to use the estimated size of a table (`pg_relation_size` function) if there are no statistics for the table. By default, GPORCA and the planner use a default value to estimate the number of rows if statistics are not available. The default behavior improves query optimization time and reduces resource queue usage in heavy workloads, but can lead to suboptimal plans.

This parameter is ignored for a root partition of a partitioned table. When GPORCA is enabled and the root partition does not have statistics, GPORCA always uses the default value. You can use `ANALYZE ROOTPARTITION` to collect statistics on the root partition. See [ANALYZE](#).

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## gp\_enable\_segment\_copy\_checking

Controls whether the distribution policy for a table (from the table `DISTRIBUTED` clause) is checked when data is copied into the table with the `COPY FROM...ON SEGMENT` command. If true, an error is returned if a row of data violates the distribution policy for a segment instance. The default is `true`.

If the value is `false`, the distribution policy is not checked. The data added to the table might violate the table distribution policy for the segment instance. Manual redistribution of table data might be required. See the `ALTER TABLE` clause `WITH REORGANIZE`.

The parameter can be set for a database system or a session. The parameter cannot be set for a specific database.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | true    | master, session, reload |

## gp\_enable\_sort\_distinct

Enable duplicates to be removed while sorting.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_enable\_sort\_limit

Enable `LIMIT` operation to be performed while sorting. Sorts more efficiently when the plan requires the first `limit_number` of rows at most.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_external\_enable\_exec

Activates or deactivates the use of external tables that run OS commands or scripts on the segment hosts (`CREATE EXTERNAL TABLE EXECUTE` syntax). Must be enabled if using the Command Center or MapReduce features.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, system, restart |

## gp\_external\_max\_segs

Sets the number of segments that will scan external table data during an external table operation, the purpose being not to overload the system with scanning data and take away resources from other concurrent operations. This only applies to external tables that use the `gpfdist://` protocol to access external table data.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| integer     | 64      | master, session, reload |

## gp\_external\_enable\_filter\_pushdown

Enable filter pushdown when reading data from external tables. If pushdown fails, a query is run without pushing filters to the external data source (instead, Greenplum Database applies the same constraints to the result). See [Defining External Tables](#) for more information.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_fts\_probe\_interval

Specifies the polling interval for the fault detection process (`ftsprobe`). The `ftsprobe` process will take approximately this amount of time to detect a segment failure.

| Value Range       | Default | Set Classifications    |
|-------------------|---------|------------------------|
| 10 - 3600 seconds | 1min    | master, system, reload |

## gp\_fts\_probe\_retries

Specifies the number of times the fault detection process (`ftsprobe`) attempts to connect to a segment before reporting segment failure.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| integer     | 5       | master, system, reload |

## gp\_fts\_probe\_timeout

Specifies the allowed timeout for the fault detection process (`ftsprobe`) to establish a connection to a segment before declaring it down.

| Value Range       | Default | Set Classifications    |
|-------------------|---------|------------------------|
| 10 - 3600 seconds | 20 secs | master, system, reload |

## gp\_fts\_replication\_attempt\_count

Specifies the maximum number of times that Greenplum Database attempts to establish a primary-mirror replication connection. When this count is exceeded, the fault detection process (`ftsprobe`) stops retrying and marks the mirror down.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| 0 - 100     | 10      | master, system, reload |

## gp\_global\_deadlock\_detector\_period

Specifies the executing interval (in seconds) of the global deadlock detector background worker process.

| Value Range                   | Default  | Set Classifications    |
|-------------------------------|----------|------------------------|
| 5 - <code>INT_MAX</code> secs | 120 secs | master, system, reload |

## gp\_log\_endpoints

Controls the amount of parallel retrieve cursor endpoint detail that Greenplum Database writes to the server log file.

The default value is `false`, Greenplum Database does not log endpoint details to the log file. When set to `true`, Greenplum writes endpoint detail information to the log file.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | false   | master, session, reload |

## gp\_log\_fts

Controls the amount of detail the fault detection process (`ftsprobe`) writes to the log file.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| OFF         | TERSE   | master, system, restart |
| TERSE       |         |                         |
| VERBOSE     |         |                         |
| DEBUG       |         |                         |

## gp\_log\_interconnect

Controls the amount of information that is written to the log file about communication between Greenplum Database segment instance worker processes. The default value is `terse`. The log information is written to both the master and segment instance logs.

Increasing the amount of logging could affect performance and increase disk space usage.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| off         | terse   | master, session, reload |
| terse       |         |                         |
| verbose     |         |                         |
| debug       |         |                         |

## gp\_log\_gang

Controls the amount of information that is written to the log file about query worker process creation and query management. The default value is `OFF`, do not log information.

| Value Range | Default | Set Classifications      |
|-------------|---------|--------------------------|
| OFF         | OFF     | master, session, restart |
| TERSE       |         |                          |
| VERBOSE     |         |                          |
| DEBUG       |         |                          |

## gp\_log\_resqueue\_priority\_sleep\_time

Controls the logging of per-statement sleep time when resource queue-based resource management is active. You can use this information for analysis of sleep time for queries.

The default value is `false`, do not log the statement sleep time. When set to `true`, Greenplum Database:

- Logs the current amount of sleep time for a running query every two minutes.
- Logs the total of sleep time duration for a query at the end of a query.

The information is written to the server log.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | false   | master, session, reload |

## gp\_log\_suboverflowed\_statements

Controls whether Greenplum logs statements that cause subtransaction overflow. See [Checking for and Terminating Overflowed Backends](#).

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| Boolean     | off     | master, session, reload, superuser |

## gp\_gpperfmon\_send\_interval

Sets the frequency that the Greenplum Database server processes send query execution updates to the data collection agent processes used to populate the `gpperfmon` database. Query operations executed during this interval are sent through UDP to the segment monitor agents. If you find that an excessive number of UDP packets are dropped during long-running, complex queries, you may consider increasing this value.

| Value Range                                 | Default | Set Classifications                |
|---|---------|------------------------------------|
| Any valid time expression (number and unit) | 1sec    | master, session, reload, superuser |

## gpfdist\_retry\_timeout

Controls the time (in seconds) that Greenplum Database waits before returning an error when Greenplum Database is attempting to connect or write to a `gpfdist` server and `gpfdist` does not respond. The default value is 300 (5 minutes). A value of 0 deactivates the timeout.

| Value Range                           | Default | Set Classifications    |
|---------------------------------------|---------|------------------------|
| 0 - <code>INT_MAX</code> (2147483647) | 300     | local, session, reload |

## gpperfmon\_log\_alert\_level

Controls which message levels are written to the `gpperfmon` log. Each level includes all the levels that follow it. The later the level, the fewer messages are sent to the log.

**Note:** If the `gpperfmon` database is installed and is monitoring the database, the default value is warning.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| none        | none    | local, session, reload |
| warning     |         |                        |
| error       |         |                        |
| fatal       |         |                        |
| panic       |         |                        |

## gp\_hashjoin\_tuples\_per\_bucket

Sets the target density of the hash table used by HashJoin operations. A smaller value will tend to produce larger hash tables, which can increase join performance.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| integer     | 5       | master, session, reload |

## gp\_ignore\_error\_table

Controls Greenplum Database behavior when the deprecated `INTO ERROR TABLE` clause is specified in a `CREATE EXTERNAL TABLE` or `COPY` command.

**Note:** The `INTO ERROR TABLE` clause was deprecated and removed in Greenplum Database 5. In Greenplum Database 7, this parameter will be removed as well, causing all `INTO ERROR TABLE` invocations to yield a syntax error.

The default value is `false`, Greenplum Database returns an error if the `INTO ERROR TABLE` clause is specified in a command.

If the value is `true`, Greenplum Database ignores the clause, issues a warning, and runs the command without the `INTO ERROR TABLE` clause. In Greenplum Database 5.x and later, you access the error log information with built-in SQL functions. See the `CREATE EXTERNAL TABLE` or `COPY` command.

You can set this value to `true` to avoid the Greenplum Database error when you run applications that run `CREATE EXTERNAL TABLE` or `COPY` commands that include the Greenplum Database 4.3.x `INTO ERROR TABLE` clause.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | false   | master, session, reload |

## gp\_initial\_bad\_row\_limit

For the parameter value  $n$ , Greenplum Database stops processing input rows when you import data with the `COPY` command or from an external table if the first  $n$  rows processed contain formatting

errors. If a valid row is processed within the first  $n$  rows, Greenplum Database continues processing input rows.

Setting the value to 0 deactivates this limit.

The `SEGMENT REJECT LIMIT` clause can also be specified for the `COPY` command or the external table definition to limit the number of rejected rows.

`INT_MAX` is the largest value that can be stored as an integer on your system.

| Value Range                      | Default | Set Classifications     |
|----------------------------------|---------|-------------------------|
| integer 0 - <code>INT_MAX</code> | 1000    | master, session, reload |

## gp\_instrument\_shmem\_size

The amount of shared memory, in kilobytes, allocated for query metrics. The default is 5120 and the maximum is 131072. At startup, if `gp_enable_query_metrics` is set to on, Greenplum Database allocates space in shared memory to save query metrics. This memory is organized as a header and a list of slots. The number of slots needed depends on the number of concurrent queries and the number of execution plan nodes per query. The default value, 5120, is based on a Greenplum Database system that runs a maximum of about 250 concurrent queries with 120 nodes per query. If the `gp_enable_query_metrics` configuration parameter is off, or if the slots are exhausted, the metrics are maintained in local memory instead of in shared memory.

| Value Range        | Default | Set Classifications     |
|--------------------|---------|-------------------------|
| integer 0 - 131072 | 5120    | master, system, restart |

## gp\_interconnect\_address\_type

Specifies the type of address binding strategy Greenplum Database uses for communication between segment host sockets. There are two types: `unicast` and `wildcard`. The default is `wildcard`.

- When this parameter is set to `unicast`, Greenplum Database uses the `gp_segment_configuration.address` field to perform address binding. This reduces port usage on segment hosts and prevents interconnect traffic from being routed through unintended (and possibly slower) network interfaces.
- When this parameter is set to `wildcard`, Greenplum Database uses a wildcard address for binding, enabling the use of any network interface compliant with routing rules.

**NOTE:** In some cases, inter-segment communication using the unicast strategy may not be possible. One example is if the source segment's address field and the destination segment's address field are on different subnets and/or existing routing rules do not allow for such communication. In these cases, you must configure this parameter to use a wildcard address for address binding.

| Value Range      | Default  | Set Classifications   |
|------------------|----------|-----------------------|
| wildcard,unicast | wildcard | local, system, reload |

## gp\_interconnect\_debug\_retry\_interval

Specifies the interval, in seconds, to log Greenplum Database interconnect debugging messages when the server configuration parameter `gp_log_interconnect` is set to `DEBUG`. The default is 10 seconds.

The log messages contain information about the interconnect communication between Greenplum Database segment instance worker processes. The information can be helpful when debugging network issues between segment instances.

| Value Range         | Default | Set Classifications     |
|---------------------|---------|-------------------------|
| 1 =< Integer < 4096 | 10      | master, session, reload |

## gp\_interconnect\_fc\_method

Specifies the flow control method used for the default Greenplum Database UDPIFC interconnect.

For capacity based flow control, senders do not send packets when receivers do not have the capacity.

Loss based flow control is based on capacity based flow control, and also tunes the sending speed according to packet losses.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| CAPACITY    | LOSS    | master, session, reload |
| LOSS        |         |                         |

## gp\_interconnect\_proxy\_addresses

Sets the proxy ports that Greenplum Database uses when the server configuration parameter `gp_interconnect_type` is set to `proxy`. Otherwise, this parameter is ignored. The default value is an empty string ("").

When the `gp_interconnect_type` parameter is set to `proxy`, You must specify a proxy port for the master, standby master, and all primary and mirror segment instances in this format:

```
<db_id>:<cont_id>:<seg_address>:<port>[, ... ]
```

For the master, standby master, and segment instance, the first three fields, `db_id`, `cont_id`, and `seg_address` can be found in the `gp_segment_configuration` catalog table. The fourth field, `port`, is the proxy port for the Greenplum master or a segment instance.

- `db_id` is the `dbid` column in the catalog table.
- `cont_id` is the `content` column in the catalog table.
- `seg_address` is the IP address or hostname corresponding to the `address` column in the catalog table.
- `port` is the TCP/IP port for the segment instance proxy that you specify.

**Important:** If a segment instance hostname is bound to a different IP address at runtime, you must run `gpstop -U` to re-load the `gp_interconnect_proxy_addresses` value.

You must specify the value as a single-quoted string. This `gpconfig` command sets the value for `gp_interconnect_proxy_addresses` as a single-quoted string. The Greenplum system consists of a master and a single segment instance.

```
gpconfig --skipvalidation -c gp_interconnect_proxy_addresses -v "'1:-1:192.168.180.50:35432,2:0:192.168.180.54:35000'"
```

For an example of setting `gp_interconnect_proxy_addresses`, see [Configuring Proxies for the Greenplum Interconnect](#).

| Value Range                           | Default | Set Classifications   |
|---------------------------------------|---------|-----------------------|
| string (maximum length - 16384 bytes) |         | local, system, reload |

## gp\_interconnect\_queue\_depth

Sets the amount of data per-peer to be queued by the Greenplum Database interconnect on receivers (when data is received but no space is available to receive it the data will be dropped, and the transmitter will need to resend it) for the default UDPIFC interconnect. Increasing the depth from its default value will cause the system to use more memory, but may increase performance. It is reasonable to set this value between 1 and 10. Queries with data skew potentially perform better with an increased queue depth. Increasing this may radically increase the amount of memory used by the system.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| 1-2048      | 4       | master, session, reload |

## gp\_interconnect\_setup\_timeout

Specifies the amount of time, in seconds, that Greenplum Database waits for the interconnect to complete setup before it times out.

| Value Range      | Default                | Set Classifications     |
|------------------|------------------------|-------------------------|
| 0 - 7200 seconds | 7200 seconds (2 hours) | master, session, reload |

## gp\_interconnect\_snd\_queue\_depth

Sets the amount of data per-peer to be queued by the default UDPIFC interconnect on senders. Increasing the depth from its default value will cause the system to use more memory, but may increase performance. Reasonable values for this parameter are between 1 and 4. Increasing the value might radically increase the amount of memory used by the system.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| 1 - 4096    | 2       | master, session, reload |

## gp\_interconnect\_transmit\_timeout

Specifies the amount of time, in seconds, that Greenplum Database waits for network transmission of interconnect traffic to complete before it times out.

| Value Range      | Default               | Set Classifications     |
|------------------|-----------------------|-------------------------|
| 1 - 7200 seconds | 3600 seconds (1 hour) | master, session, reload |

## gp\_interconnect\_type

Sets the networking protocol used for Greenplum Database interconnect traffic. UDPIFC specifies using UDP with flow control for interconnect traffic, and is the only value supported.

UDPIFC (the default) specifies using UDP with flow control for interconnect traffic. Specify the interconnect flow control method with [gp\\_interconnect\\_fc\\_method](#).

With TCP as the interconnect protocol, Greenplum Database has an upper limit of 1000 segment instances - less than that if the query workload involves complex, multi-slice queries.

The `PROXY` value specifies using the TCP protocol, and when running queries, using a proxy for Greenplum interconnect communication between the master instance and segment instances and between two segment instances. When this parameter is set to `PROXY`, you must specify the proxy ports for the master and segment instances with the server configuration parameter [gp\\_interconnect\\_proxy\\_addresses](#). For information about configuring and using proxies with the Greenplum interconnect, see [Configuring Proxies for the Greenplum Interconnect](#).

| Value Range        | Default | Set Classifications    |
|--------------------|---------|------------------------|
| UDPIFC, TCP, PROXY | UDPIFC  | local, session, reload |

## gp\_log\_format

Specifies the format of the server log files. If using *gp\_toolkit* administrative schema, the log files must be in CSV format.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| csv         | csv     | local, system, restart |
| text        |         |                        |

## gp\_max\_local\_distributed\_cache

Sets the maximum number of distributed transaction log entries to cache in the backend process memory of a segment instance.

The log entries contain information about the state of rows that are being accessed by an SQL statement. The information is used to determine which rows are visible to an SQL transaction when running multiple simultaneous SQL statements in an MVCC environment. Caching distributed transaction log entries locally improves transaction processing speed by improving performance of the row visibility determination process.

The default value is optimal for a wide variety of SQL processing environments.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| integer     | 1024    | local, system, restart |

## gp\_max\_packet\_size

Sets the tuple-serialization chunk size for the Greenplum Database interconnect.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| 512-65536   | 8192    | master, system, reload |

## gp\_max\_plan\_size

Specifies the total maximum uncompressed size of a query execution plan multiplied by the number of Motion operators (slices) in the plan. If the size of the query plan exceeds the value, the query is cancelled and an error is returned. A value of 0 means that the size of the plan is not monitored.

You can specify a value in **kB**, **MB**, or **GB**. The default unit is **kB**. For example, a value of **200** is 200kB. A value of **1GB** is the same as **1024MB** or **1048576kB**.

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| integer     | 0       | master, superuser, session, reload |

## gp\_max\_slices

Specifies the maximum number of slices (portions of a query plan that are run on segment instances) that can be generated by a query. If the query generates more than the specified number of slices, Greenplum Database returns an error and does not run the query. The default value is 0, no maximum value.

Running a query that generates a large number of slices might affect Greenplum Database performance. For example, a query that contains **UNION** or **UNION ALL** operators over several complex views can generate a large number of slices. You can run **EXPLAIN ANALYZE** on the query to view slice statistics for the query.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| 0 - INT_MAX | 0       | master, session, reload |

## gp\_motion\_cost\_per\_row

Sets the Postgres Planner cost estimate for a Motion operator to transfer a row from one segment to another, measured as a fraction of the cost of a sequential page fetch. If 0, then the value used is two times the value of *cpu\_tuple\_cost*.

| Value Range    | Default | Set Classifications     |
|----------------|---------|-------------------------|
| floating point | 0       | master, session, reload |

## gp\_recursive\_cte

Controls the availability of the `RECURSIVE` keyword in the `WITH` clause of a `SELECT [INTO]` command, or a `DELETE`, `INSERT` or `UPDATE` command. The keyword allows a subquery in the `WITH` clause of a command to reference itself. The default value is `true`, the `RECURSIVE` keyword is allowed in the `WITH` clause of a command.

For information about the `RECURSIVE` keyword, see the [SELECT command](#) and [WITH Queries \(Common Table Expressions\)](#).

The parameter can be set for a database system, an individual database, or a session or query.

**Note:** This parameter was previously named `gp_recursive_cte_prototype`, but has been renamed to reflect the current status of the implementation.

| Value Range | Default | Set Classifications      |
|-------------|---------|--------------------------|
| Boolean     | true    | master, session, restart |

## gp\_reject\_percent\_threshold

For single row error handling on COPY and external table SELECTs, sets the number of rows processed before `SEGMENT REJECT LIMIT n PERCENT` starts calculating.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| 1- <i>n</i> | 300     | master, session, reload |

## gp\_reraise\_signal

If enabled, will attempt to dump core if a fatal server error occurs.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_resgroup\_memory\_policy

**Note:** The `gp_resgroup_memory_policy` server configuration parameter is enforced only when resource group-based resource management is active.

Used by a resource group to manage memory allocation to query operators.

When set to `auto`, Greenplum Database uses resource group memory limits to distribute memory across query operators, allocating a fixed size of memory to non-memory-intensive operators and the rest to memory-intensive operators.

When you specify `eager_free`, Greenplum Database distributes memory among operators more optimally by re-allocating memory released by operators that have completed their processing to operators in a later query stage.

| Value Range      | Default    | Set Classifications              |
|------------------|------------|----------------------------------|
| auto, eager_free | eager_free | local, system, superuser, reload |

## gp\_resource\_group\_bypass

**Note:** The `gp_resource_group_bypass` server configuration parameter is enforced only when resource group-based resource management is active.

Activates or deactivates the enforcement of resource group concurrent transaction limits on Greenplum Database resources. The default value is `false`, which enforces resource group transaction limits. Resource groups manage resources such as CPU, memory, and the number of concurrent transactions that are used by queries and external components such as PL/Container.

You can set this parameter to `true` to bypass resource group concurrent transaction limitations so that a query can run immediately. For example, you can set the parameter to `true` for a session to run a system catalog query or a similar query that requires a minimal amount of resources.

When you set this parameter to `true` and a run a query, the query runs in this environment:

- The query runs inside a resource group. The resource group assignment for the query does not change.
- The query memory quota is approximately 10 MB per query. The memory is allocated from resource group shared memory or global shared memory. The query fails if there is not enough shared memory available to fulfill the memory allocation request.

This parameter can be set for a session. The parameter cannot be set within a transaction or a function.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| Boolean     | false   | local, session, reload |

## gp\_resource\_group\_cpu\_ceiling\_enforcement

Enables the Ceiling Enforcement mode when assigning CPU resources by Percentage. When deactivated, the Elastic mode will be used.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| Boolean     | false   | local, system, restart |

## gp\_resource\_group\_cpu\_limit

**Note:** The `gp_resource_group_cpu_limit` server configuration parameter is enforced only when resource group-based resource management is active.

Identifies the maximum percentage of system CPU resources to allocate to resource groups on each Greenplum Database segment node.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| 0.1 - 1.0   | 0.9     | local, system, restart |

## gp\_resource\_group\_enable\_recalculate\_query\_mem

**Note:** The `gp_resource_group_enable_recalculate_query_mem` server configuration parameter is enforced only when resource group-based resource management is active.

Specifies whether or not Greenplum Database recalculates the maximum amount of memory to allocate on a segment host per query running in a resource group. The default value is `false`, Greenplum database calculates the maximum per-query memory on a segment host based on the memory configuration and the number of primary segments on the master host. When set to `true`, Greenplum Database recalculates the maximum per-query memory on a segment host based on the memory and the number of primary segments configured for that segment host.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | false   | master, session, reload |

## gp\_resource\_group\_memory\_limit

**Note:** The `gp_resource_group_memory_limit` server configuration parameter is enforced only when resource group-based resource management is active.

Identifies the maximum percentage of system memory resources to allocate to resource groups on each Greenplum Database segment node.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| 0.1 - 1.0   | 0.7     | local, system, restart |

**Note:** When resource group-based resource management is active, the memory allotted to a segment host is equally shared by active primary segments. Greenplum Database assigns memory to primary segments when the segment takes the primary role. The initial memory allotment to a primary segment does not change, even in a failover situation. This may result in a segment host utilizing more memory than the `gp_resource_group_memory_limit` setting permits.

For example, suppose your Greenplum Database cluster is utilizing the default `gp_resource_group_memory_limit` of `0.7` and a segment host named `seghost1` has 4 primary segments and 4 mirror segments. Greenplum Database assigns each primary segment on `seghost1` ( $0.7 / 4 = 0.175\%$ ) of overall system memory. If failover occurs and two mirrors on `seghost1` fail over to become primary segments, each of the original 4 primaries retain their memory allotment of `0.175`, and the two new primary segments are each allotted ( $0.7 / 6 = 0.116\%$ ) of system memory. `seghost1`'s overall memory allocation in this scenario is

$$0.7 + (0.116 * 2) = 0.932\%$$

which is above the percentage configured in the `gp_resource_group_memory_limit` setting.

## gp\_resource\_group\_queuing\_timeout

**Note:** The `gp_resource_group_queuing_timeout` server configuration parameter is enforced only when resource group-based resource management is active.

Cancel a transaction queued in a resource group that waits longer than the specified number of milliseconds. The time limit applies separately to each transaction. The default value is zero;

transactions are queued indefinitely and never time out.

| Value Range                        | Default     | Set Classifications     |
|------------------------------------|-------------|-------------------------|
| 0 - <code>INT_MAX</code> millisecs | 0 millisecs | master, session, reload |

## gp\_resource\_manager

Identifies the resource management scheme currently enabled in the Greenplum Database cluster. The default scheme is to use resource queues. For information about Greenplum Database resource management, see [Managing Resources](#).

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| group       | queue   | local, system, restart |
| queue       |         |                        |

## gp\_resqueue\_memory\_policy

**Note:** The `gp_resqueue_memory_policy` server configuration parameter is enforced only when resource queue-based resource management is active.

Enables Greenplum memory management features. The distribution algorithm `eager_free` takes advantage of the fact that not all operators run at the same time (in Greenplum Database 4.2 and later). The query plan is divided into stages and Greenplum Database eagerly frees memory allocated to a previous stage at the end of that stage's execution, then allocates the eagerly freed memory to the new stage.

When set to `none`, memory management is the same as in Greenplum Database releases prior to 4.1.

When set to `auto`, query memory usage is controlled by `statement_mem` and resource queue memory limits.

| Value Range                         | Default                 | Set Classifications    |
|-------------------------------------|-------------------------|------------------------|
| none, auto, <code>eager_free</code> | <code>eager_free</code> | local, session, reload |

## gp\_resqueue\_priority

**Note:** The `gp_resqueue_priority` server configuration parameter is enforced only when resource queue-based resource management is active.

Activates or deactivates query prioritization. When this parameter is deactivated, existing priority settings are not evaluated at query run time.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| Boolean     | on      | local, system, restart |

## gp\_resqueue\_priority\_cpucore\_per\_segment

**Note:** The `gp_resqueue_priority_cpucores_per_segment` server configuration parameter is enforced only when resource queue-based resource management is active.

Specifies the number of CPU units allocated to each segment instance on a segment host. If the segment is configured with primary-mirror segment instance pairs, use the number of primary segment instances on the host in the calculation. Include any CPU core that is available to the operating system, including virtual CPU cores, in the total number of available cores.

For example, if a Greenplum Database cluster has 10-core segment hosts that are configured with four primary segments, set the value to 2.5 on each segment host (10 divided by 4). A master host typically has only a single running master instance, so set the value on the master and standby maaster hosts to reflect the usage of all available CPU cores, in this case 10.

Incorrect settings can result in CPU under-utilization or query prioritization not working as designed.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| 0.1 - 512.0 | 4       | local, system, restart |

## gp\_resqueue\_priority\_sweeper\_interval

**Note:** The `gp_resqueue_priority_sweeper_interval` server configuration parameter is enforced only when resource queue-based resource management is active.

Specifies the interval at which the sweeper process evaluates current CPU usage. When a new statement becomes active, its priority is evaluated and its CPU share determined when the next interval is reached.

| Value Range    | Default | Set Classifications    |
|----------------|---------|------------------------|
| 500 - 15000 ms | 1000    | local, system, restart |

## gp\_retrieve\_conn

A session that you initiate with `PGOPTIONS='-c gp_retrieve_conn=true'` is a retrieve session. You use a retrieve session to retrieve query result tuples from a specific endpoint instantiated for a parallel retrieve cursor.

The default value is `false`.

| Value Range | Default | Set Classifications |
|-------------|---------|---------------------|
| Boolean     | false   | read only           |

## gp\_role

The role of this server process is set to `dispatch` for the master and `execute` for a segment.

| Value Range | Default | Set Classifications |
|-------------|---------|---------------------|
| dispatch    |         | read only           |
| execute     |         |                     |
| utility     |         |                     |

## gp\_safefswritesize

Specifies a minimum size for safe write operations to append-optimized tables in a non-mature file system. When a number of bytes greater than zero is specified, the append-optimized writer adds padding data up to that number in order to prevent data corruption due to file system errors. Each non-mature file system has a known safe write size that must be specified here when using Greenplum Database with that type of file system. This is commonly set to a multiple of the extent size of the file system; for example, Linux ext3 is 4096 bytes, so a value of 32768 is commonly used.

| Value Range | Default | Set Classifications   |
|-------------|---------|-----------------------|
| integer     | 0       | local, system, reload |

## gp\_segment\_connect\_timeout

Time that the Greenplum interconnect will try to connect to a segment instance over the network before timing out. Controls the network connection timeout between master and primary segments, and primary to mirror segment replication processes.

| Value Range                                 | Default | Set Classifications    |
|---|---------|------------------------|
| Any valid time expression (number and unit) | 3min    | local, session, reload |

## gp\_segments\_for\_planner

Sets the number of primary segment instances for the Postgres Planner to assume in its cost and size estimates. If 0, then the value used is the actual number of primary segments. This variable affects the Postgres Planner's estimates of the number of rows handled by each sending and receiving process in Motion operators.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| 0-n         | 0       | master, session, reload |

## gp\_server\_version

Reports the version number of the server as a string. A version modifier argument might be appended to the numeric portion of the version string, example: *5.0.0 beta*.

| Value Range                    | Default | Set Classifications |
|--------------------------------|---------|---------------------|
| String. Examples: <i>5.0.0</i> | n/a     | read only           |

## gp\_server\_version\_num

Reports the version number of the server as an integer. The number is guaranteed to always be increasing for each version and can be used for numeric comparisons. The major version is represented as is, the minor and patch versions are zero-padded to always be double digit wide.

| Value Range   | Default | Set Classifications |
|---|---------|---------------------|
| <i>Mmmpp</i> where <i>M</i> is the major version, <i>mm</i> is the minor version zero-padded and <i>pp</i> is the patch version zero-padded. Example: 50000 | n/a     | read only           |

## gp\_session\_id

A system assigned ID number for a client session. Starts counting from 1 when the master instance is first started.

| Value Range | Default | Set Classifications |
|-------------|---------|---------------------|
| 1- <i>n</i> | 14      | read only           |

## gp\_set\_proc\_affinity

If enabled, when a Greenplum server process (postmaster) is started it will bind to a CPU.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, system, restart |

## gp\_set\_read\_only

Set to on to deactivate writes to the database. Any in progress transactions must finish before read-only mode takes affect.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, system, restart |

## gp\_statistics\_pullup\_from\_child\_partition

Enables the use of statistics from child tables when planning queries on the parent table by the Postgres Planner.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## gp\_statistics\_use\_fkeys

When enabled, the Postgres Planner will use the statistics of the referenced column in the parent table when a column is foreign key reference to another table instead of the statistics of the

column itself.

**Note:** This parameter is deprecated and will be removed in a future Greenplum Database release.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## gp\_use\_legacy\_hashops

For a table that is defined with a `DISTRIBUTED BY key\column` clause, this parameter controls the hash algorithm that is used to distribute table data among segment instances. The default value is `false`, use the jump consistent hash algorithm.

Setting the value to `true` uses the modulo hash algorithm that is compatible with Greenplum Database 5.x and earlier releases.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | false   | master, session, reload |

## gp\_vmem\_idle\_resource\_timeout

If a database session is idle for longer than the time specified, the session will free system resources (such as shared memory), but remain connected to the database. This allows more concurrent connections to the database at one time.

| Value Range                                 | Default | Set Classifications     |
|---|---------|-------------------------|
| Any valid time expression (number and unit) | 18s     | master, session, reload |

## gp\_vmem\_protect\_limit

**Note:** The `gp_vmem_protect_limit` server configuration parameter is enforced only when resource queue-based resource management is active.

Sets the amount of memory (in number of MBs) that all `postgres` processes of an active segment instance can consume. If a query causes this limit to be exceeded, memory will not be allocated and the query will fail. Note that this is a local parameter and must be set for every segment in the system (primary and mirrors). When setting the parameter value, specify only the numeric value. For example, to specify 4096MB, use the value `4096`. Do not add the units `MB` to the value.

To prevent over-allocation of memory, these calculations can estimate a safe `gp_vmem_protect_limit` value.

First calculate the value of `gp_vmem`. This is the Greenplum Database memory available on a host.

- If the total system memory is less than 256 GB, use this formula:

$$gp\_vmem = ((SWAP + RAM) - (7.5GB + 0.05 * RAM)) / 1.7$$

- If the total system memory is equal to or greater than 256 GB, use this formula:

```
gp_vmem = ((SWAP + RAM) - (7.5GB + 0.05 * RAM)) / 1.17
```

where SWAP is the host swap space and RAM is the RAM on the host in GB.

Next, calculate the `max_acting_primary_segments`. This is the maximum number of primary segments that can be running on a host when mirror segments are activated due to a failure. With mirrors arranged in a 4-host block with 8 primary segments per host, for example, a single segment host failure would activate two or three mirror segments on each remaining host in the failed host's block. The `max_acting_primary_segments` value for this configuration is 11 (8 primary segments plus 3 mirrors activated on failure).

This is the calculation for `gp_vmem_protect_limit`. The value should be converted to MB.

```
gp_vmem_protect_limit = <gp_vmem> / <acting_primary_segments>
```

For scenarios where a large number of workfiles are generated, this is the calculation for `gp_vmem` that accounts for the workfiles.

- If the total system memory is less than 256 GB:

```
<gp_vmem> = (((<SWAP> + <RAM>) - (7.5GB + 0.05 * <RAM> - (300KB * <total_#_workfiles>))) / 1.7
```

- If the total system memory is equal to or greater than 256 GB:

```
<gp_vmem> = (((<SWAP> + <RAM>) - (7.5GB + 0.05 * <RAM> - (300KB * <total_#_workfiles>))) / 1.17
```

For information about monitoring and managing workfile usage, see the *Greenplum Database Administrator Guide*.

Based on the `gp_vmem` value you can calculate the value for the `vm.overcommit_ratio` operating system kernel parameter. This parameter is set when you configure each Greenplum Database host.

```
vm.overcommit_ratio = (<RAM> - (0.026 * <gp_vmem>)) / <RAM>
```

**Note:** The default value for the kernel parameter `vm.overcommit_ratio` in Red Hat Enterprise Linux is 50.

For information about the kernel parameter, see the *Greenplum Database Installation Guide*.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| integer     | 8192    | local, system, restart |

## gp\_vmem\_protect\_segworker\_cache\_limit

If a query executor process consumes more than this configured amount, then the process will not be cached for use in subsequent queries after the process completes. Systems with lots of connections or idle processes may want to reduce this number to free more memory on the segments. Note that this is a local parameter and must be set for every segment.

| Value Range         | Default | Set Classifications    |
|---------------------|---------|------------------------|
| number of megabytes | 500     | local, system, restart |

## gp\_workfile\_compression

Specifies whether the temporary files created, when a hash aggregation or hash join operation spills to disk, are compressed.

If your Greenplum Database installation uses serial ATA (SATA) disk drives, enabling compression might help to avoid overloading the disk subsystem with IO operations.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## gp\_workfile\_limit\_files\_per\_query

Sets the maximum number of temporary spill files (also known as workfiles) allowed per query per segment. Spill files are created when running a query that requires more memory than it is allocated. The current query is terminated when the limit is exceeded.

Set the value to 0 (zero) to allow an unlimited number of spill files. master session reload

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| integer     | 100000  | master, session, reload |

## gp\_workfile\_limit\_per\_query

Sets the maximum disk size an individual query is allowed to use for creating temporary spill files at each segment. The default value is 0, which means a limit is not enforced.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| kilobytes   | 0       | master, session, reload |

## gp\_workfile\_limit\_per\_segment

Sets the maximum total disk size that all running queries are allowed to use for creating temporary spill files at each segment. The default value is 0, which means a limit is not enforced.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| kilobytes   | 0       | local, system, restart |

## gpperfmon\_port

Controls the time (in seconds) that Greenplum Database waits before returning an error when Greenplum Database is attempting to connect or write to a `gpfdist` server and `gpfdist` does not respond. The default value is 300 (5 minutes). A value of 0 deactivates the timeout.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| integer     | 8888    | master, system, restart |

## ignore\_checksum\_failure

Only has effect if [data\\_checksums](#) is enabled.

Greenplum Database uses checksums to prevent loading data that has been corrupted in the file system into memory managed by database processes.

By default, when a checksum verify error occurs when reading a heap data page, Greenplum Database generates an error and prevents the page from being loaded into managed memory. When [ignore\\_checksum\\_failure](#) is set to on and a checksum verify failure occurs, Greenplum Database generates a warning, and allows the page to be read into managed memory. If the page is then updated it is saved to disk and replicated to the mirror. If the page header is corrupt an error is reported even if this option is enabled.

**Warning:** Setting [ignore\\_checksum\\_failure](#) to on may propagate or hide data corruption or lead to other serious problems. However, if a checksum failure has already been detected and the page header is uncorrupted, setting [ignore\\_checksum\\_failure](#) to on may allow you to bypass the error and recover undamaged tuples that may still be present in the table.

The default setting is off, and it can only be changed by a superuser.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| Boolean     | off     | local, session, reload |

## integer\_datetimes

Reports whether PostgreSQL was built with support for 64-bit-integer dates and times.

| Value Range | Default | Set Classifications |
|-------------|---------|---------------------|
| Boolean     | on      | read only           |

## IntervalStyle

Sets the display format for interval values. The value *sql\_standard* produces output matching SQL standard interval literals. The value *postgres* produces output matching PostgreSQL releases prior to 8.4 when the [DateStyle](#) parameter was set to ISO.

The value *postgres\_verbose* produces output matching Greenplum releases prior to 3.3 when the [DateStyle](#) parameter was set to non-ISO output.

The value *iso\_8601* will produce output matching the time interval *format with designators* defined in section 4.4.3.2 of ISO 8601. See the [PostgreSQL 9.4 documentation](#) for more information.

| Value Range      | Default  | Set Classifications     |
|------------------|----------|-------------------------|
| postgres         | postgres | master, session, reload |
| postgres_verbose |          |                         |
| sql_standard     |          |                         |
| iso_8601         |          |                         |

## join\_collapse\_limit

The Postgres Planner will rewrite explicit inner `JOIN` constructs into lists of `FROM` items whenever a list of no more than this many items in total would result. By default, this variable is set the same as `from_collapse_limit`, which is appropriate for most uses. Setting it to 1 prevents any reordering of inner JOINS. Setting this variable to a value between 1 and `from_collapse_limit` might be useful to trade off planning time against the quality of the chosen plan (higher values produce better plans).

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| 1-n         | 20      | master, session, reload |

## krb\_caseins\_users

Sets whether Kerberos user names should be treated case-insensitively. The default is case sensitive (off).

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| Boolean     | off     | master, system, reload |

## krb\_server\_keyfile

Sets the location of the Kerberos server key file.

| Value Range        | Default | Set Classifications     |
|--------------------|---------|-------------------------|
| path and file name | unset   | master, system, restart |

## lc\_collate

Reports the locale in which sorting of textual data is done. The value is determined when the Greenplum Database array is initialized.

| Value Range        | Default | Set Classifications |
|--------------------|---------|---------------------|
| <system dependent> |         | read only           |

## lc\_ctype

Reports the locale that determines character classifications. The value is determined when the Greenplum Database array is initialized.

| Value Range        | Default | Set Classifications |
|--------------------|---------|---------------------|
| <system dependent> |         | read only           |

## lc\_messages

Sets the language in which messages are displayed. The locales available depends on what was installed with your operating system - use *locale -a* to list available locales. The default value is inherited from the execution environment of the server. On some systems, this locale category does not exist. Setting this variable will still work, but there will be no effect. Also, there is a chance that no translated messages for the desired language exist. In that case you will continue to see the English messages.

| Value Range        | Default | Set Classifications    |
|--------------------|---------|------------------------|
| <system dependent> |         | local, session, reload |

## lc\_monetary

Sets the locale to use for formatting monetary amounts, for example with the *to\_char* family of functions. The locales available depends on what was installed with your operating system - use *locale -a* to list available locales. The default value is inherited from the execution environment of the server.

| Value Range        | Default | Set Classifications    |
|--------------------|---------|------------------------|
| <system dependent> |         | local, session, reload |

## lc\_numeric

Sets the locale to use for formatting numbers, for example with the *to\_char* family of functions. The locales available depends on what was installed with your operating system - use *locale -a* to list available locales. The default value is inherited from the execution environment of the server.

| Value Range        | Default | Set Classifications    |
|--------------------|---------|------------------------|
| <system dependent> |         | local, system, restart |

## lc\_time

This parameter currently does nothing, but may in the future.

| Value Range        | Default | Set Classifications    |
|--------------------|---------|------------------------|
| <system dependent> |         | local, system, restart |

## listen\_addresses

Specifies the TCP/IP address(es) on which the server is to listen for connections from client applications - a comma-separated list of host names and/or numeric IP addresses. The special entry \* corresponds to all available IP interfaces. If the list is empty, only UNIX-domain sockets can connect.

| Value Range  | Default | Set Classifications     |
|--|---------|-------------------------|
| localhost, host names, IP addresses, * (all available IP interfaces) | *       | master, system, restart |

## local\_preload\_libraries

Comma separated list of shared library files to preload at the start of a client session.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
|             |         | local, system, restart |

## lock\_timeout

Abort any statement that waits longer than the specified number of milliseconds while attempting to acquire a lock on a table, index, row, or other database object. The time limit applies separately to each lock acquisition attempt. The limit applies both to explicit locking requests (such as `LOCK TABLE` or `SELECT FOR UPDATE`) and to implicitly-acquired locks. If `log_min_error_statement` is set to `ERROR` or lower, Greenplum Database logs the statement that timed out. A value of zero (the default) turns off this lock wait monitoring.

Unlike `statement_timeout`, this timeout can only occur while waiting for locks. Note that if `statement_timeout` is nonzero, it is rather pointless to set `lock_timeout` to the same or larger value, since the statement timeout would always trigger first.

Greenplum Database uses the `deadlock_timeout` and `gp_global_deadlock_detector_period` to trigger local and global deadlock detection. Note that if `lock_timeout` is turned on and set to a value smaller than these deadlock detection timeouts, Greenplum Database will abort a statement before it would ever trigger a deadlock check in that session.

**Note:** Setting `lock_timeout` in `postgresql.conf` is not recommended because it would affect all sessions

| Value Range                        | Default     | Set Classifications     |
|------------------------------------|-------------|-------------------------|
| 0 - <code>INT_MAX</code> millisecs | 0 millisecs | master, session, reload |

## log\_autostats

Logs information about automatic `ANALYZE` operations related to `gp_autostats_mode` and `gp_autostats_on_change_threshold`.

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| Boolean     | off     | master, session, reload, superuser |

## log\_connections

This outputs a line to the server log detailing each successful connection. Some client programs, like psql, attempt to connect twice while determining if a password is required, so duplicate "connection received" messages do not always indicate a problem.

| Value Range | Default | Set Classifications   |
|-------------|---------|-----------------------|
| Boolean     | off     | local, system, reload |

## log\_disconnections

This outputs a line in the server log at termination of a client session, and includes the duration of the session.

| Value Range | Default | Set Classifications   |
|-------------|---------|-----------------------|
| Boolean     | off     | local, system, reload |

## log\_dispatch\_stats

When set to "on," this parameter adds a log message with verbose information about the dispatch of the statement.

| Value Range | Default | Set Classifications   |
|-------------|---------|-----------------------|
| Boolean     | off     | local, system, reload |

## log\_duration

Causes the duration of every completed statement which satisfies *log\_statement* to be logged.

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| Boolean     | off     | master, session, reload, superuser |

## log\_error\_verbosity

Controls the amount of detail written in the server log for each message that is logged.

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| TERSE       | DEFAULT | master, session, reload, superuser |
| DEFAULT     |         |                                    |
| VERBOSE     |         |                                    |

## log\_executor\_stats

For each query, write performance statistics of the query executor to the server log. This is a crude profiling instrument. Cannot be enabled together with *log\_statement\_stats*.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| Boolean     | off     | local, system, restart |

## log\_file\_mode

On Unix systems this parameter sets the permissions for log files when *logging\_collector* is enabled. The parameter value is expected to be a numeric mode specified in the format accepted by the *chmod* and *umask* system calls.

| Value Range  | Default | Set Classifications   |
|--|---------|-----------------------|
| numeric UNIX file permission mode (as accepted by the <i>chmod</i> or <i>umask</i> commands) | 0600    | local, system, reload |

## log\_hostname

By default, connection log messages only show the IP address of the connecting host. Turning on this option causes logging of the IP address and host name of the Greenplum Database master. Note that depending on your host name resolution setup this might impose a non-negligible performance penalty.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| Boolean     | off     | master, system, reload |

## log\_min\_duration\_statement

Logs the statement and its duration on a single log line if its duration is greater than or equal to the specified number of milliseconds. Setting this to 0 will print all statements and their durations. -1 deactivates the feature. For example, if you set it to 250 then all SQL statements that run 250ms or longer will be logged. Enabling this option can be useful in tracking down unoptimized queries in your applications.

| Value Range                   | Default | Set Classifications                |
|-------------------------------|---------|------------------------------------|
| number of milliseconds, 0, -1 | -1      | master, session, reload, superuser |

## log\_min\_error\_statement

Controls whether or not the SQL statement that causes an error condition will also be recorded in the server log. All SQL statements that cause an error of the specified level or higher are logged. The default is ERROR. To effectively turn off logging of failing statements, set this parameter to PANIC.

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| DEBUG5      | ERROR   | master, session, reload, superuser |
| DEBUG4      |         |                                    |
| DEBUG3      |         |                                    |
| DEBUG2      |         |                                    |
| DEBUG1      |         |                                    |
| INFO        |         |                                    |
| NOTICE      |         |                                    |
| WARNING     |         |                                    |
| ERROR       |         |                                    |
| FATAL       |         |                                    |
| PANIC       |         |                                    |

---

## log\_min\_messages

Controls which message levels are written to the server log. Each level includes all the levels that follow it. The later the level, the fewer messages are sent to the log.

If the Greenplum Database PL/Container extension is installed. This parameter also controls the PL/Container log level. For information about the extension, see [PL/pgSQL Language](#).

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| DEBUG5      | WARNING | master, session, reload, superuser |
| DEBUG4      |         |                                    |
| DEBUG3      |         |                                    |
| DEBUG2      |         |                                    |
| DEBUG1      |         |                                    |
| INFO        |         |                                    |
| NOTICE      |         |                                    |
| WARNING     |         |                                    |
| LOG         |         |                                    |
| ERROR       |         |                                    |
| FATAL       |         |                                    |
| PANIC       |         |                                    |

## log\_parser\_stats

For each query, write performance statistics of the query parser to the server log. This is a crude profiling instrument. Cannot be enabled together with *log\_statement\_stats*.

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| Boolean     | off     | master, session, reload, superuser |

## log\_planner\_stats

For each query, write performance statistics of the Postgres Planner to the server log. This is a crude profiling instrument. Cannot be enabled together with *log\_statement\_stats*.

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| Boolean     | off     | master, session, reload, superuser |

## log\_rotation\_age

Determines the amount of time Greenplum Database writes messages to the active log file. When this amount of time has elapsed, the file is closed and a new log file is created. Set to zero to deactivate time-based creation of new log files.

| Value Range                                 | Default | Set Classifications    |
|---|---------|------------------------|
| Any valid time expression (number and unit) | 1d      | local, system, restart |

## log\_rotation\_size

Determines the size of an individual log file that triggers rotation. When the log file size is equal to or greater than this size, the file is closed and a new log file is created. Set to zero to deactivate size-based creation of new log files.

The maximum value is INT\_MAX/1024. If an invalid value is specified, the default value is used. INT\_MAX is the largest value that can be stored as an integer on your system.

| Value Range         | Default | Set Classifications    |
|---------------------|---------|------------------------|
| number of kilobytes | 1048576 | local, system, restart |

## log\_statement

Controls which SQL statements are logged. DDL logs all data definition commands like CREATE, ALTER, and DROP commands. MOD logs all DDL statements, plus INSERT, UPDATE, DELETE, TRUNCATE, and COPY FROM. PREPARE and EXPLAIN ANALYZE statements are also logged if their contained command is of an appropriate type.

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| NONE        | ALL     | master, session, reload, superuser |
| DDL         |         |                                    |
| MOD         |         |                                    |
| ALL         |         |                                    |

## log\_statement\_stats

For each query, write total performance statistics of the query parser, planner, and executor to the server log. This is a crude profiling instrument.

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| Boolean     | off     | master, session, reload, superuser |

## log\_temp\_files

Controls logging of temporary file names and sizes. Temporary files can be created for sorts, hashes, temporary query results and spill files. A log entry is made in `log` for each temporary file when it is deleted. Depending on the source of the temporary files, the log entry could be created on either the master and/or segments. A `log_temp_files` value of zero logs all temporary file information, while positive values log only files whose size is greater than or equal to the specified number of kilobytes. The default setting is `-1`, which deactivates logging. Only superusers can change this setting.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| Integer     | -1      | local, session, reload |

## log\_timezone

Sets the time zone used for timestamps written in the log. Unlike `TimeZone`, this value is system-wide, so that all sessions will report timestamps consistently. The default is `unknown`, which means to use whatever the system environment specifies as the time zone.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| string      | unknown | local, system, restart |

## log\_truncate\_on\_rotation

Truncates (overwrites), rather than appends to, any existing log file of the same name. Truncation will occur only when a new file is being opened due to time-based rotation. For example, using this setting in combination with a `log_filename` such as `gpseg#-%H.log` would result in generating twenty-four hourly log files and then cyclically overwriting them. When off, pre-existing files will be appended to in all cases.

| Value Range | Default | Set Classifications   |
|-------------|---------|-----------------------|
| Boolean     | off     | local, system, reload |

## maintenance\_work\_mem

Specifies the maximum amount of memory to be used in maintenance operations, such as `VACUUM` and `CREATE INDEX`. It defaults to 16 megabytes (16MB). Larger settings might improve performance for vacuuming and for restoring database dumps.

| Value Range | Default | Set Classifications   |
|-------------|---------|-----------------------|
| Integer     | 16      | local, system, reload |

## max\_appendonly\_tables

Sets the maximum number of concurrent transactions that can write to or update append-optimized tables. Transactions that exceed the maximum return an error.

Operations that are counted are `INSERT`, `UPDATE`, `COPY`, and `VACUUM` operations. The limit is only for in-progress transactions. Once a transaction ends (either aborted or committed), it is no longer counted against this limit.

**Note:** Greenplum Database limits the maximum number of concurrent inserts into an append-only table to 127.

For operations against a partitioned table, each subpartition (child table) that is an append-optimized table and is changed counts as a single table towards the maximum. For example, a partitioned table `p_tbl` is defined with three subpartitions that are append-optimized tables `p_tbl_ao1`, `p_tbl_ao2`, and `p_tbl_ao3`. An `INSERT` or `UPDATE` command against the partitioned table `p_tbl` that changes append-optimized tables `p_tbl_ao1` and `p_tbl_ao2` is counted as two transactions.

Increasing the limit allocates more shared memory on the master host at server start.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| integer > 0 | 10000   | master, system, restart |

## max\_connections

The maximum number of concurrent connections to the database server. In a Greenplum Database system, user client connections go through the Greenplum master instance only. Segment instances should allow 3-10 times the amount as the master. When you increase this parameter, [max\\_prepared\\_transactions](#) must be increased as well. For more information about limiting concurrent connections, see "Configuring Client Authentication" in the *Greenplum Database Administrator Guide*.

Increasing this parameter may cause Greenplum Database to request more shared memory. See [shared\\_buffers](#) for information about Greenplum server instance shared memory buffers.

| Value Range  | Default                          | Set Classifications    |
|--------------|----------------------------------|------------------------|
| 10 - 8388607 | 250 on master<br>750 on segments | local, system, restart |

## max\_files\_per\_process

Sets the maximum number of simultaneously open files allowed to each server subprocess. If the kernel is enforcing a safe per-process limit, you don't need to worry about this setting. Some platforms such as BSD, the kernel will allow individual processes to open many more files than the system can really support.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| integer     | 1000    | local, system, restart |

## max\_function\_args

Reports the maximum number of function arguments.

| Value Range | Default | Set Classifications |
|-------------|---------|---------------------|
| integer     | 100     | read only           |

## max\_identifier\_length

Reports the maximum identifier length.

| Value Range | Default | Set Classifications |
|-------------|---------|---------------------|
| integer     | 63      | read only           |

## max\_index\_keys

Reports the maximum number of index keys.

| Value Range | Default | Set Classifications |
|-------------|---------|---------------------|
| integer     | 32      | read only           |

## max\_locks\_per\_transaction

The shared lock table is created with room to describe locks on *max\_locks\_per\_transaction* \* (*max\_connections* + *max\_prepared\_transactions*) objects, so no more than this many distinct objects can be locked at any one time. This is not a hard limit on the number of locks taken by any one transaction, but rather a maximum average value. You might need to raise this value if you have clients that touch many different tables in a single transaction.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| integer     | 128     | local, system, restart |

## max\_prepared\_transactions

Sets the maximum number of transactions that can be in the prepared state simultaneously. Greenplum uses prepared transactions internally to ensure data integrity across the segments. This value must be at least as large as the value of [max\\_connections](#) on the master. Segment instances should be set to the same value as the master.

| Value Range | Default         | Set Classifications    |
|-------------|-----------------|------------------------|
| integer     | 250 on master   | local, system, restart |
|             | 250 on segments |                        |

## max\_resource\_portals\_per\_transaction

**Note:** The [max\\_resource\\_portals\\_per\\_transaction](#) server configuration parameter is enforced only when resource queue-based resource management is active.

Sets the maximum number of simultaneously open user-declared cursors allowed per transaction. Note that an open cursor will hold an active query slot in a resource queue. Used for resource management.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| integer     | 64      | master, system, restart |

## max\_resource\_queues

**Note:** The [max\\_resource\\_queues](#) server configuration parameter is enforced only when resource queue-based resource management is active.

Sets the maximum number of resource queues that can be created in a Greenplum Database system. Note that resource queues are system-wide (as are roles) so they apply to all databases in

the system.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| integer     | 9       | master, system, restart |

## max\_slot\_wal\_keep\_size

Sets the maximum size in megabytes of Write-Ahead Logging (WAL) files on disk per segment instance that can be reserved when Greenplum streams data to the mirror segment instance or standby master to keep it synchronized with the corresponding primary segment instance or master. The default is -1, Greenplum can retain an unlimited amount of WAL files on disk.

If the file size exceeds the maximum size, the files are released and are available for deletion. A mirror or standby may no longer be able to continue replication due to removal of required WAL files.

**WARNING:** If `max_slot_wal_keep_size` is set to a non-default value for acting primaries, full and incremental recovery of their mirrors may not be possible. Depending on the workload on the primary running concurrently with a full recovery, the recovery may fail with a missing WAL error. Therefore, you must ensure that `max_slot_wal_keep_size` is set to the default of -1 or a high enough value before running full recovery. Similarly, depending on how behind the downed mirror is, an incremental recovery of it may fail with a missing WAL complaint. In this case, full recovery would be the only recourse.

| Value Range | Default | Set Classifications   |
|-------------|---------|-----------------------|
| Integer     | -1      | local, system, reload |

## max\_stack\_depth

Specifies the maximum safe depth of the server's execution stack. The ideal setting for this parameter is the actual stack size limit enforced by the kernel (as set by `ulimit -s` or local equivalent), less a safety margin of a megabyte or so. Setting the parameter higher than the actual kernel limit will mean that a runaway recursive function can crash an individual backend process.

| Value Range         | Default | Set Classifications    |
|---------------------|---------|------------------------|
| number of kilobytes | 2MB     | local, session, reload |

## max\_statement\_mem

Sets the maximum memory limit for a query. Helps avoid out-of-memory errors on a segment host during query processing as a result of setting `statement_mem` too high.

Taking into account the configuration of a single segment host, calculate `max_statement_mem` as follows:

```
(segghost_physical_memory) / (average_number_concurrent_queries)
```

When changing both `max_statement_mem` and `statement_mem`, `max_statement_mem` must be changed first, or listed first in the `postgresql.conf` file.

| Value Range         | Default | Set Classifications                |
|---------------------|---------|------------------------------------|
| number of kilobytes | 2000MB  | master, session, reload, superuser |

## memory\_spill\_ratio

**Note:** The `memory_spill_ratio` server configuration parameter is enforced only when resource group-based resource management is active.

Sets the memory usage threshold percentage for memory-intensive operators in a transaction. When a transaction reaches this threshold, it spills to disk.

The default `memory_spill_ratio` percentage is the value defined for the resource group assigned to the currently active role. You can set `memory_spill_ratio` at the session level to selectively set this limit on a per-query basis. For example, if you have a specific query that spills to disk and requires more memory, you may choose to set a larger `memory_spill_ratio` to increase the initial memory allocation.

You can specify an integer percentage value from 0 to 100 inclusive. If you specify a value of 0, Greenplum Database uses the `statement_mem` server configuration parameter value to control the initial query operator memory amount.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| 0 - 100     | 20      | master, session, reload |

## optimizer

Activates or deactivates GPORCA when running SQL queries. The default is `on`. If you deactivate GPORCA, Greenplum Database uses only the Postgres Planner.

GPORCA co-exists with the Postgres Planner. With GPORCA enabled, Greenplum Database uses GPORCA to generate an execution plan for a query when possible. If GPORCA cannot be used, then the Postgres Planner is used.

The optimizer parameter can be set for a database system, an individual database, or a session or query.

For information about the Postgres Planner and GPORCA, see [Querying Data](#) in the *Greenplum Database Administrator Guide*.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## optimizer\_analyze\_root\_partition

For a partitioned table, controls whether the `ROOTPARTITION` keyword is required to collect root partition statistics when the `ANALYZE` command is run on the table. GPORCA uses the root partition statistics when generating a query plan. The Postgres Planner does not use these statistics.

The default setting for the parameter is `on`, the `ANALYZE` command can collect root partition statistics without the `ROOTPARTITION` keyword. Root partition statistics are collected when you run

`ANALYZE` on the root partition, or when you run `ANALYZE` on a child leaf partition of the partitioned table and the other child leaf partitions have statistics. When the value is `off`, you must run `ANALYZE ROOTPARTITION` to collect root partition statistics.

When the value of the server configuration parameter `optimizer` is `on` (the default), the value of this parameter should also be `on`. For information about collecting table statistics on partitioned tables, see [ANALYZE](#).

For information about the Postgres Planner and GPORCA, see [Querying Data](#) in the *Greenplum Database Administrator Guide*.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## optimizer\_array\_expansion\_threshold

When GPORCA is enabled (the default) and is processing a query that contains a predicate with a constant array, the `optimizer_array_expansion_threshold` parameter limits the optimization process based on the number of constants in the array. If the array in the query predicate contains more than the number elements specified by parameter, GPORCA deactivates the transformation of the predicate into its disjunctive normal form during query optimization.

The default value is 100.

For example, when GPORCA is running a query that contains an `IN` clause with more than 100 elements, GPORCA does not transform the predicate into its disjunctive normal form during query optimization to reduce optimization time consume less memory. The difference in query processing can be seen in the filter condition for the `IN` clause of the query `EXPLAIN` plan.

Changing the value of this parameter changes the trade-off between a shorter optimization time and lower memory consumption, and the potential benefits from constraint derivation during query optimization, for example conflict detection and partition elimination.

The parameter can be set for a database system, an individual database, or a session or query.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Integer > 0 | 25      | master, session, reload |

## optimizer\_control

Controls whether the server configuration parameter `optimizer` can be changed with `SET`, the `RESET` command, or the Greenplum Database utility `gpconfig`. If the `optimizer_control` parameter value is `on`, users can set the `optimizer` parameter. If the `optimizer_control` parameter value is `off`, the `optimizer` parameter cannot be changed.

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| Boolean     | on      | master, session, reload, superuser |

## optimizer\_cost\_model

When GPORCA is enabled (the default), this parameter controls the cost model that GPORCA chooses for bitmap scans used with bitmap indexes or with btree indexes on AO tables.

- `legacy` - preserves the calibrated cost model used by GPORCA in Greenplum Database releases 6.13 and earlier
- `calibrated` - improves cost estimates for indexes
- `experimental` - reserved for future experimental cost models; currently equivalent to the `calibrated` model

The default cost model, `calibrated`, is more likely to choose a faster bitmap index with nested loop joins instead of hash joins.

| Value Range  | Default    | Set Classifications     |
|--------------|------------|-------------------------|
| legacy       | calibrated | master, session, reload |
| calibrated   |            |                         |
| experimental |            |                         |

## optimizer\_cte\_inlining\_bound

When GPORCA is enabled (the default), this parameter controls the amount of inlining performed for common table expression (CTE) queries (queries that contain a `WHERE` clause). The default value, 0, deactivates inlining.

The parameter can be set for a database system, an individual database, or a session or query.

| Value Range  | Default | Set Classifications     |
|--------------|---------|-------------------------|
| Decimal >= 0 | 0       | master, session, reload |

## optimizer\_dpe\_stats

When GPORCA is enabled (the default) and this parameter is `true` (the default), GPORCA derives statistics that allow it to more accurately estimate the number of rows to be scanned during dynamic partition elimination.

The parameter can be set for a database system, an individual database, or a session or query.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | true    | master, session, reload |

## optimizer\_enable\_associativity

When GPORCA is enabled (the default), this parameter controls whether the join associativity transform is enabled during query optimization. The transform analyzes join orders. For the default value `off`, only the GPORCA dynamic programming algorithm for analyzing join orders is enabled. The join associativity transform largely duplicates the functionality of the newer dynamic programming algorithm.

If the value is `on`, GPORCA can use the associativity transform during query optimization.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see [About GPORCA](#) in the *Greenplum Database Administrator Guide*.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## optimizer\_enable\_dml

When GPORCA is enabled (the default) and this parameter is `true` (the default), GPORCA attempts to run DML commands such as `INSERT`, `UPDATE`, and `DELETE`. If GPORCA cannot run the command, Greenplum Database falls back to the Postgres Planner.

When set to `false`, Greenplum Database always falls back to the Postgres Planner when performing DML commands.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see [About GPORCA](#) in the *Greenplum Database Administrator Guide*.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | true    | master, session, reload |

## optimizer\_enable\_indexonlyscan

When GPORCA is enabled (the default) and this parameter is `true` (the default), GPORCA can generate index-only scan plan types for B-tree indexes. GPORCA accesses the index values only, not the data blocks of the relation. This provides a query execution performance improvement, particularly when the table has been vacuumed, has wide columns, and GPORCA does not need to fetch any data blocks (for example, they are visible).

When deactivated (`false`), GPORCA does not generate index-only scan plan types.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see [About GPORCA](#) in the *Greenplum Database Administrator Guide*.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | true    | master, session, reload |

## optimizer\_enable\_master\_only\_queries

When GPORCA is enabled (the default), this parameter allows GPORCA to run catalog queries that run only on the Greenplum Database master. For the default value `off`, only the Postgres Planner can run catalog queries that run only on the Greenplum Database master.

The parameter can be set for a database system, an individual database, or a session or query.

**Note:** Enabling this parameter decreases performance of short running catalog queries. To avoid this issue, set this parameter only for a session or a query.

For information about GPORCA, see [About GPORCA](#) in the *Greenplum Database Administrator Guide*.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## optimizer\_enable\_multiple\_distinct\_aggs

When GPORCA is enabled (the default), this parameter allows GPORCA to support Multiple Distinct Qualified Aggregates, such as `SELECT count(DISTINCT a), sum(DISTINCT b) FROM foo`. This parameter is deactivated by default because its plan is generally suboptimal in comparison to the plan generated by the Postgres planner.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see [About GPORCA](#) in the *Greenplum Database Administrator Guide*.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## optimizer\_enable\_orderedagg

When GPORCA is enabled (the default), this parameter determines whether or not GPORCA generates a query plan for ordered aggregates. This parameter is deactivated by default; GPORCA does not generate a plan for a query that includes an ordered aggregate, and the query falls back to the Postgres Planner.

You can set this parameter for a database system, an individual database, or a session or query.

## optimizer\_enable\_replicated\_table

When GPORCA is enabled (the default), this parameter controls GPORCA's behavior when it encounters DML operations on a replicated table.

The default value is `on`, GPORCA attempts to plan and execute operations on replicated tables. When `off`, GPORCA immediately falls back to the Postgres Planner when it detects replicated table operations.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see [About GPORCA](#) in the *Greenplum Database Administrator Guide*.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## optimizer\_force\_agg\_skew\_avoidance

When GPORCA is enabled (the default), this parameter affects the query plan alternatives that GPORCA considers when 3 stage aggregate plans are generated. When the value is `true`, the default, GPORCA considers only 3 stage aggregate plans where the intermediate aggregation uses the `GROUP BY` and `DISTINCT` columns for distribution to reduce the effects of processing skew.

If the value is `false`, GPORCA can also consider a plan that uses `GROUP BY` columns for distribution. These plans might perform poorly when processing skew is present.

For information about GPORCA, see [About GPORCA](#) in the *Greenplum Database Administrator Guide*.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | true    | master, session, reload |

## optimizer\_force\_comprehensive\_join\_implementation

When GPORCA is enabled (the default), this parameter affects its consideration of nested loop join and hash join alternatives.

The default value is `false`, GPORCA does not consider nested loop join alternatives when a hash join is available, which significantly improves optimization performance for most queries. When set to `true`, GPORCA will explore nested loop join alternatives even when a hash join is possible.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | false   | master, session, reload |

## optimizer\_force\_multistage\_agg

For the default settings, GPORCA is enabled and this parameter is `false`, GPORCA makes a cost-based choice between a one- or two-stage aggregate plan for a scalar distinct qualified aggregate. When `true`, GPORCA chooses a multi-stage aggregate plan when such a plan alternative is generated.

The parameter can be set for a database system, an individual database, or a session or query.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | true    | master, session, reload |

## optimizer\_force\_three\_stage\_scalar\_dqa

For the default settings, GPORCA is enabled and this parameter is `true`, GPORCA chooses a plan with multistage aggregates when such a plan alternative is generated. When the value is `false`, GPORCA makes a cost based choice rather than a heuristic choice.

The parameter can be set for a database system, an individual database, or a session, or query.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | true    | master, session, reload |

## optimizer\_join\_arity\_for\_associativity\_commutativity

The value is an optimization hint to limit the number of join associativity and join commutativity transformations explored during query optimization. The limit controls the alternative plans that GPORCA considers during query optimization. For example, the default value of 18 is an optimization hint for GPORCA to stop exploring join associativity and join commutativity transformations when an n-ary join operator has more than 18 children during optimization.

For a query with a large number of joins, specifying a lower value improves query performance by limiting the number of alternate query plans that GPORCA evaluates. However, setting the value too low might cause GPORCA to generate a query plan that performs sub-optimally.

This parameter has no effect when the `optimizer_join_order` parameter is set to `query` or `greedy`.

This parameter can be set for a database system or a session.

| Value Range | Default | Set Classifications   |
|-------------|---------|-----------------------|
| integer > 0 | 18      | local, system, reload |

## optimizer\_join\_order

When GPORCA is enabled (the default), this parameter sets the join enumeration algorithm:

- `query` - Uses the join order specified in the query.
- `greedy` - Evaluates the join order specified in the query and alternatives based on minimum cardinalities of the relations in the joins.
- `exhaustive` - Applies transformation rules to find and evaluate up to a configurable threshold number (`optimizer_join_order_threshold`, default 10) of n-way inner joins, and then changes to and uses the `greedy` method beyond that. While planning time drops significantly at that point, plan quality and execution time may get worse.
- `exhaustive2` - Operates with an emphasis on generating join orders that are suitable for dynamic partition elimination. This algorithm applies transformation rules to find and evaluate n-way inner and outer joins. When evaluating very large joins with more than `optimizer_join_order_threshold` (default 10) tables, this algorithm employs a gradual transition to the `greedy` method; planning time goes up smoothly as the query gets more complicated, and plan quality and execution time only gradually degrade. `exhaustive2` provides a good trade-off between planning time and execution time for many queries.

Setting this parameter to `query` or `greedy` can generate a suboptimal query plan. However, if the administrator is confident that a satisfactory plan is generated with the `query` or `greedy` setting, query optimization time may be improved by setting the parameter to the lower optimization level.

When you set this parameter to `query` or `greedy`, GPORCA ignores the `optimizer_join_order_threshold` parameter.

This parameter can be set for an individual database, a session, or a query.

| Value Range | Default    | Set Classifications     |
|-------------|------------|-------------------------|
| query       | exhaustive | master, session, reload |
| greedy      |            |                         |
| exhaustive  |            |                         |
| exhaustive2 |            |                         |

## optimizer\_join\_order\_threshold

When GPORCA is enabled (the default), this parameter sets the maximum number of join children for which GPORCA will use the dynamic programming-based join ordering algorithm. This threshold restricts the search effort for a join plan to reasonable limits.

GPORCA examines the `optimizer_join_order_threshold` parameter when `optimizer_join_order` is set to `exhaustive` or `exhaustive2`. GPORCA ignores this parameter when `optimizer_join_order` is set to `query` or `greedy`.

You can set this value for a single query or for an entire session.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| 0 - 12      | 10      | master, session, reload |

## optimizer\_mdcache\_size

Sets the maximum amount of memory on the Greenplum Database master that GPORCA uses to cache query metadata (optimization data) during query optimization. The memory limit session based. GPORCA caches query metadata during query optimization with the default settings: GPORCA is enabled and `optimizer_metadata_caching` is `on`.

The default value is 16384 (16MB). This is an optimal value that has been determined through performance analysis.

You can specify a value in KB, MB, or GB. The default unit is KB. For example, a value of 16384 is 16384KB. A value of 1GB is the same as 1024MB or 1048576KB. If the value is 0, the size of the cache is not limited.

This parameter can be set for a database system, an individual database, or a session or query.

| Value Range  | Default | Set Classifications     |
|--------------|---------|-------------------------|
| Integer >= 0 | 16384   | master, session, reload |

## optimizer\_metadata\_caching

When GPORCA is enabled (the default), this parameter specifies whether GPORCA caches query metadata (optimization data) in memory on the Greenplum Database master during query optimization. The default for this parameter is `on`, enable caching. The cache is session based.

When a session ends, the cache is released. If the amount of query metadata exceeds the cache size, then old, unused metadata is evicted from the cache.

If the value is `off`, GPORCA does not cache metadata during query optimization.

This parameter can be set for a database system, an individual database, or a session or query.

The server configuration parameter `optimizer_mdcache_size` controls the size of the query metadata cache.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## optimizer\_minidump

GPORCA generates minidump files to describe the optimization context for a given query. The information in the file is not in a format that can be easily used for debugging or troubleshooting. The minidump file is located under the master data directory and uses the following naming format:

```
Minidump_date_time.mdp
```

The minidump file contains this query related information:

- Catalog objects including data types, tables, operators, and statistics required by GPORCA
- An internal representation (DXL) of the query
- An internal representation (DXL) of the plan produced by GPORCA
- System configuration information passed to GPORCA such as server configuration parameters, cost and statistics configuration, and number of segments
- A stack trace of errors generated while optimizing the query

Setting this parameter to `ALWAYS` generates a minidump for all queries. Set this parameter to `ONERROR` to minimize total optimization time.

For information about GPORCA, see [About GPORCA](#) in the *Greenplum Database Administrator Guide*.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| ONERROR     | ONERROR | master, session, reload |
| ALWAYS      |         |                         |

## optimizer\_nestloop\_factor

This parameter adds a costing factor to GPORCA to prioritize hash joins instead of nested loop joins during query optimization. The default value of 1024 was chosen after evaluating numerous workloads with uniformly distributed data. 1024 should be treated as the practical upper bound setting for this parameter. If you find the GPORCA selects hash joins more often than it should, reduce the value to shift the costing factor in favor of nested loop joins.

The parameter can be set for a database system, an individual database, or a session or query.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| INT_MAX > 1 | 1024    | master, session, reload |

## optimizer\_parallel\_union

When GPORCA is enabled (the default), `optimizer_parallel_union` controls the amount of parallelization that occurs for queries that contain a `UNION` or `UNION ALL` clause.

When the value is `off`, the default, GPORCA generates a query plan where each child of an `APPEND(UNION)` operator is in the same slice as the `APPEND` operator. During query execution, the children are run in a sequential manner.

When the value is `on`, GPORCA generates a query plan where a redistribution motion node is under an `APPEND(UNION)` operator. During query execution, the children and the parent `APPEND` operator are on different slices, allowing the children of the `APPEND(UNION)` operator to run in parallel on segment instances.

The parameter can be set for a database system, an individual database, or a session or query.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| boolean     | off     | master, session, reload |

## optimizer\_penalize\_skew

When GPORCA is enabled (the default), this parameter allows GPORCA to penalize the local cost of a HashJoin with a skewed Redistribute Motion as child to favor a Broadcast Motion during query optimization. The default value is `true`.

GPORCA determines there is skew for a Redistribute Motion when the NDV (number of distinct values) is less than the number of segments.

The parameter can be set for a database system, an individual database, or a session or query.

For information about GPORCA, see [About GPORCA](#) in the *Greenplum Database Administrator Guide*.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | true    | master, session, reload |

## optimizer\_print\_missing\_stats

When GPORCA is enabled (the default), this parameter controls the display of table column information about columns with missing statistics for a query. The default value is `true`, display the column information to the client. When the value is `false`, the information is not sent to the client.

The information is displayed during query execution, or with the `EXPLAIN` or `EXPLAIN ANALYZE` commands.

The parameter can be set for a database system, an individual database, or a session.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | true    | master, session, reload |

## optimizer\_print\_optimization\_stats

When GPORCA is enabled (the default), this parameter enables logging of GPORCA query optimization statistics for various optimization stages for a query. The default value is off, do not log optimization statistics. To log the optimization statistics, this parameter must be set to on and the parameter `client_min_messages` must be set to log.

- `set optimizer_print_optimization_stats = on;`
- `set client_min_messages = 'log';`

The information is logged during query execution, or with the `EXPLAIN` or `EXPLAIN ANALYZE` commands.

This parameter can be set for a database system, an individual database, or a session or query.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## optimizer\_sort\_factor

When GPORCA is enabled (the default), `optimizer_sort_factor` controls the cost factor to apply to sorting operations during query optimization. The default value `1` specifies the default sort cost factor. The value is a ratio of increase or decrease from the default factor. For example, a value of `2.0` sets the cost factor at twice the default, and a value of `0.5` sets the factor at half the default.

The parameter can be set for a database system, an individual database, or a session or query.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Decimal > 0 | 1       | master, session, reload |

## optimizer\_use\_gpdb\_allocators

When GPORCA is enabled (the default) and this parameter is `true` (the default), GPORCA uses Greenplum Database memory management when running queries. When set to `false`, GPORCA uses GPORCA-specific memory management. Greenplum Database memory management allows for faster optimization, reduced memory usage during optimization, and improves GPORCA support of vmem limits when compared to GPORCA-specific memory management.

For information about GPORCA, see [About GPORCA](#) in the *Greenplum Database Administrator Guide*.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | true    | master, system, restart |

## optimizer\_xform\_bind\_threshold

When GPORCA is enabled (the default), this parameter controls the maximum number of bindings per transform that GPORCA produces per group expression. Setting this parameter limits the number of alternatives that GPORCA creates, in many cases reducing the optimization time and overall memory usage of queries that include deeply nested expressions.

The default value is 0, GPORCA produces an unlimited set of bindings.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| 0 - INT_MAX | 0       | master, session, reload |

## password\_encryption

When a password is specified in CREATE USER or ALTER USER without writing either ENCRYPTED or UNENCRYPTED, this option determines whether the password is to be encrypted.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## password\_hash\_algorithm

Specifies the cryptographic hash algorithm that is used when storing an encrypted Greenplum Database user password. The default algorithm is MD5.

For information about setting the password hash algorithm to protect user passwords, see [Protecting Passwords in Greenplum Database](#).

| Value Range   | Default | Set Classifications                |
|---------------|---------|------------------------------------|
| MD5           | MD5     | master, session, reload, superuser |
| SHA-256       |         |                                    |
| SCRAM-SHA-256 |         |                                    |

## plan\_cache\_mode

Prepared statements (either explicitly prepared or implicitly generated, for example by PL/pgSQL) can be run using *custom* or *generic* plans. Custom plans are created for each execution using its specific set of parameter values, while generic plans do not rely on the parameter values and can be re-used across executions. The use of a generic plan saves planning time, but if the ideal plan depends strongly on the parameter values, then a generic plan might be inefficient. The choice between these options is normally made automatically, but it can be overridden by setting the `plan_cache_mode` parameter. If the prepared statement has no parameters, a generic plan is always used.

The allowed values are `auto` (the default), `force_custom_plan` and `force_generic_plan`. This setting is considered when a cached plan is to be run, not when it is prepared. For more information see [PREPARE](#).

The parameter can be set for a database system, an individual database, a session, or a query.

| Value Range        | Default | Set Classifications     |
|--------------------|---------|-------------------------|
| auto               | auto    | master, session, reload |
| force_custom_plan  |         |                         |
| force_generic_plan |         |                         |

## pljava\_classpath

A colon (:) separated list of jar files or directories containing jar files needed for PL/Java functions. The full path to the jar file or directory must be specified, except the path can be omitted for jar files in the `$GPHOME/lib/postgresql/java` directory. The jar files must be installed in the same locations on all Greenplum hosts and readable by the `gpadmin` user.

The `pljava_classpath` parameter is used to assemble the PL/Java classpath at the beginning of each user session. Jar files added after a session has started are not available to that session.

If the full path to a jar file is specified in `pljava_classpath` it is added to the PL/Java classpath. When a directory is specified, any jar files the directory contains are added to the PL/Java classpath. The search does not descend into subdirectories of the specified directories. If the name of a jar file is included in `pljava_classpath` with no path, the jar file must be in the `$GPHOME/lib/postgresql/java` directory.

**Note:** Performance can be affected if there are many directories to search or a large number of jar files.

If `pljava_classpath_insecure` is `false`, setting the `pljava_classpath` parameter requires superuser privilege. Setting the classpath in SQL code will fail when the code is run by a user without superuser privilege. The `pljava_classpath` parameter must have been set previously by a superuser or in the `postgresql.conf` file. Changing the classpath in the `postgresql.conf` file requires a reload (`gpstop -u`).

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| string      |         | master, session, reload, superuser |

## pljava\_classpath\_insecure

Controls whether the server configuration parameter `pljava_classpath` can be set by a user without Greenplum Database superuser privileges. When `true`, `pljava_classpath` can be set by a regular user. Otherwise, `pljava_classpath` can be set only by a database superuser. The default is `false`.

**Warning:** Enabling this parameter exposes a security risk by giving non-administrator database users the ability to run unauthorized Java methods.

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| Boolean     | false   | master, session, reload, superuser |

## pljava\_statement\_cache\_size

Sets the size in KB of the JRE MRU (Most Recently Used) cache for prepared statements.

| Value Range         | Default | Set Classifications               |
|---------------------|---------|-----------------------------------|
| number of kilobytes | 10      | master, system, reload, superuser |

## pljava\_release\_lingering\_savepoints

If true, lingering savepoints used in PL/Java functions will be released on function exit. If false, savepoints will be rolled back.

| Value Range | Default | Set Classifications               |
|-------------|---------|-----------------------------------|
| Boolean     | true    | master, system, reload, superuser |

## pljava\_vmoptions

Defines the startup options for the Java VM. The default value is an empty string ("").

| Value Range | Default | Set Classifications               |
|-------------|---------|-----------------------------------|
| string      |         | master, system, reload, superuser |

## port

The database listener port for a Greenplum instance. The master and each segment has its own port. Port numbers for the Greenplum system must also be changed in the [gp\\_segment\\_configuration](#) catalog. You must shut down your Greenplum Database system before changing port numbers.

| Value Range           | Default | Set Classifications    |
|-----------------------|---------|------------------------|
| any valid port number | 5432    | local, system, restart |

## quote\_all\_identifiers

Ensures that all identifiers are quoted, even if they are not keywords, when the database generates SQL. See also the `--quote-all-identifiers` option of [pg\\_dump](#) and [pg\\_dumpall](#).

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| Boolean     | false   | local, session, reload |

## random\_page\_cost

Sets the estimate of the cost of a nonsequentially fetched disk page for the Postgres Planner. This is measured as a multiple of the cost of a sequential page fetch. A higher value makes it more likely a sequential scan will be used, a lower value makes it more likely an index scan will be used.

| Value Range    | Default | Set Classifications     |
|----------------|---------|-------------------------|
| floating point | 100     | master, session, reload |

## readable\_external\_table\_timeout

When an SQL query reads from an external table, the parameter value specifies the amount of time in seconds that Greenplum Database waits before cancelling the query when data stops being returned from the external table.

The default value of 0, specifies no time out. Greenplum Database does not cancel the query.

If queries that use gpfdist run a long time and then return the error "intermittent network connectivity issues", you can specify a value for `readable_external_table_timeout`. If no data is returned by gpfdist for the specified length of time, Greenplum Database cancels the query.

| Value Range  | Default | Set Classifications    |
|--------------|---------|------------------------|
| integer >= 0 | 0       | master, system, reload |

## repl\_catchup\_within\_range

For Greenplum Database master mirroring, controls updates to the active master. If the number of WAL segment files that have not been processed by the `walsender` exceeds this value, Greenplum Database updates the active master.

If the number of segment files does not exceed the value, Greenplum Database blocks updates to the to allow the `walsender` process the files. If all WAL segments have been processed, the active master is updated.

| Value Range | Default | Set Classifications               |
|-------------|---------|-----------------------------------|
| 0 - 64      | 1       | master, system, reload, superuser |

## wal\_sender\_timeout

For Greenplum Database master mirroring, sets the maximum time in milliseconds that the `walsender` process on the active master waits for a status message from the `walreceiver` process on the standby master. If a message is not received, the `walsender` logs an error message.

The `wal_receiver_status_interval` controls the interval between `walreceiver` status messages.

| Value Range | Default               | Set Classifications               |
|-------------|-----------------------|-----------------------------------|
| 0 - INT_MAX | 60000 ms (60 seconds) | master, system, reload, superuser |

## resource\_cleanup\_gangs\_on\_wait

**Note:** The `resource_cleanup_gangs_on_wait` server configuration parameter is enforced only when resource queue-based resource management is active.

If a statement is submitted through a resource queue, clean up any idle query executor worker processes before taking a lock on the resource queue.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## resource\_select\_only

**Note:** The `resource_select_only` server configuration parameter is enforced only when resource queue-based resource management is active.

Sets the types of queries managed by resource queues. If set to on, then `SELECT`, `SELECT INTO`, `CREATE TABLE AS SELECT`, and `DECLARE CURSOR` commands are evaluated. If set to off `INSERT`, `UPDATE`, and `DELETE` commands will be evaluated as well.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, system, restart |

## runaway\_detector\_activation\_percent

For queries that are managed by resource queues or resource groups, this parameter determines when Greenplum Database terminates running queries based on the amount of memory the queries are using. A value of 100 deactivates the automatic termination of queries based on the percentage of memory that is utilized.

Either the resource queue or the resource group management scheme can be active in Greenplum Database; both schemes cannot be active at the same time. The server configuration parameter `gp_resource_manager` controls which scheme is active.

**When resource queues are enabled** - This parameter sets the percent of utilized Greenplum Database vmem memory that triggers the termination of queries. If the percentage of vmem memory that is utilized for a Greenplum Database segment exceeds the specified value, Greenplum Database terminates queries managed by resource queues based on memory usage, starting with the query consuming the largest amount of memory. Queries are terminated until the percentage of utilized vmem is below the specified percentage.

Specify the maximum vmem value for active Greenplum Database segment instances with the server configuration parameter `gp_vmem_protect_limit`.

For example, if vmem memory is set to 10GB, and this parameter is 90 (90%), Greenplum Database starts terminating queries when the utilized vmem memory exceeds 9 GB.

For information about resource queues, see [Using Resource Queues](#).

**When resource groups are enabled** - This parameter sets the percent of utilized resource group global shared memory that triggers the termination of queries that are managed by resource groups that are configured to use the `vmtracker` memory auditor, such as `admin_group` and `default_group`. For information about memory auditors, see [Memory Auditor](#).

Resource groups have a global shared memory pool when the sum of the `MEMORY_LIMIT` attribute values configured for all resource groups is less than 100. For example, if you have 3 resource

groups configured with `memory_limit` values of 10 , 20, and 30, then global shared memory is 40% = 100% - (10% + 20% + 30%). See [Global Shared Memory](#).

If the percentage of utilized global shared memory exceeds the specified value, Greenplum Database terminates queries based on memory usage, selecting from queries managed by the resource groups that are configured to use the `vmtracker` memory auditor. Greenplum Database starts with the query consuming the largest amount of memory. Queries are terminated until the percentage of utilized global shared memory is below the specified percentage.

For example, if global shared memory is 10GB, and this parameter is 90 (90%), Greenplum Database starts terminating queries when the utilized global shared memory exceeds 9 GB.

For information about resource groups, see [Using Resource Groups](#).

| Value Range          | Default | Set Classifications    |
|----------------------|---------|------------------------|
| percentage (integer) | 90      | local, system, restart |

## search\_path

Specifies the order in which schemas are searched when an object is referenced by a simple name with no schema component. When there are objects of identical names in different schemas, the one found first in the search path is used. The system catalog schema, `pg_catalog`, is always searched, whether it is mentioned in the path or not. When objects are created without specifying a particular target schema, they will be placed in the first schema listed in the search path. The current effective value of the search path can be examined via the SQL function `current_schema()`. `current_schema()` shows how the requests appearing in `search_path` were resolved.

| Value Range                            | Default                    | Set Classifications     |
|--|----------------------------|-------------------------|
| a comma-separated list of schema names | <code>\$user,public</code> | master, session, reload |

## seq\_page\_cost

For the Postgres Planner, sets the estimate of the cost of a disk page fetch that is part of a series of sequential fetches.

| Value Range    | Default | Set Classifications     |
|----------------|---------|-------------------------|
| floating point | 1       | master, session, reload |

## server\_encoding

Reports the database encoding (character set). It is determined when the Greenplum Database array is initialized. Ordinarily, clients need only be concerned with the value of `client_encoding`.

| Value Range        | Default | Set Classifications |
|--------------------|---------|---------------------|
| <system dependent> | UTF8    | read only           |

## server\_version

Reports the version of PostgreSQL that this release of Greenplum Database is based on.

| Value Range | Default | Set Classifications |
|-------------|---------|---------------------|
| string      | 9.4.20  | read only           |

## server\_version\_num

Reports the version of PostgreSQL that this release of Greenplum Database is based on as an integer.

| Value Range | Default | Set Classifications |
|-------------|---------|---------------------|
| integer     | 90420   | read only           |

## shared\_buffers

Sets the amount of memory a Greenplum Database segment instance uses for shared memory buffers. This setting must be at least 128KB and at least 16KB times [max\\_connections](#).

Each Greenplum Database segment instance calculates and attempts to allocate certain amount of shared memory based on the segment configuration. The value of [shared\\_buffers](#) is significant portion of this shared memory calculation, but is not all it. When setting [shared\\_buffers](#), the values for the operating system parameters [SHMMAX](#) or [SHMALL](#) might also need to be adjusted.

The operating system parameter [SHMMAX](#) specifies maximum size of a single shared memory allocation. The value of [SHMMAX](#) must be greater than this value:

```
`shared_buffers` + <other_seg_shmem>
```

The value of [other\\_seg\\_shmem](#) is the portion the Greenplum Database shared memory calculation that is not accounted for by the [shared\\_buffers](#) value. The [other\\_seg\\_shmem](#) value will vary based on the segment configuration.

With the default Greenplum Database parameter values, the value for [other\\_seg\\_shmem](#) is approximately 111MB for Greenplum Database segments and approximately 79MB for the Greenplum Database master.

The operating system parameter [SHMALL](#) specifies the maximum amount of shared memory on the host. The value of [SHMALL](#) must be greater than this value:

```
(<num_instances_per_host> * ( `shared_buffers` + <other_seg_shmem> )) + <other_app_shared_mem>
```

The value of [other\\_app\\_shared\\_mem](#) is the amount of shared memory that is used by other applications and processes on the host.

When shared memory allocation errors occur, possible ways to resolve shared memory allocation issues are to increase [SHMMAX](#) or [SHMALL](#), or decrease [shared\\_buffers](#) or [max\\_connections](#).

See the *Greenplum Database Installation Guide* for information about the Greenplum Database values for the parameters [SHMMAX](#) and [SHMALL](#).

| Value Range                            | Default | Set Classifications    |
|--|---------|------------------------|
| integer > 16K * <i>max_connections</i> | 125MB   | local, system, restart |

## shared\_preload\_libraries

A comma-separated list of shared libraries that are to be preloaded at server start. PostgreSQL procedural language libraries can be preloaded in this way, typically by using the syntax '*\$libdir/plXXX*' where XXX is pgsq, perl, tcl, or python. By preloading a shared library, the library startup time is avoided when the library is first used. If a specified library is not found, the server will fail to start.

**Note:** When you add a library to *shared\_preload\_libraries*, be sure to retain any previous setting of the parameter.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
|             |         | local, system, restart |

## ssl

Enables SSL connections.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, system, restart |

## ssl\_ciphers

Specifies a list of SSL ciphers that are allowed to be used on secure connections. *ssl\_ciphers* overrides any ciphers string specified in */etc/openssl.cnf*. The default value *ALL:!ADH:!LOW:!EXP:!MD5:@STRENGTH* enables all ciphers except for ADH, LOW, EXP, and MD5 ciphers, and prioritizes ciphers by their strength.

**Note:** With TLS 1.2 some ciphers in MEDIUM and HIGH strength still use NULL encryption (no encryption for transport), which the default *ssl\_ciphers* string allows. To bypass NULL ciphers with TLS 1.2 use a string such as *TLSv1.2:!eNULL:!aNULL*.

See the openssl manual page for a list of supported ciphers.

| Value Range | Default                           | Set Classifications     |
|-------------|-----------------------------------|-------------------------|
| string      | ALL:!ADH:!LOW:!EXP:!MD5:@STRENGTH | master, system, restart |

## standard\_conforming\_strings

Determines whether ordinary string literals ('...') treat backslashes literally, as specified in the SQL standard. The default value is on. Turn this parameter off to treat backslashes in string literals as escape characters instead of literal backslashes. Applications may check this parameter to determine how string literals are processed. The presence of this parameter can also be taken as an indication that the escape string syntax (E'...') is supported.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | on      | master, session, reload |

## statement\_mem

Allocates segment host memory per query. The amount of memory allocated with this parameter cannot exceed `max_statement_mem` or the memory limit on the resource queue or resource group through which the query was submitted. If additional memory is required for a query, temporary spill files on disk are used.

*If you are using resource groups to control resource allocation in your Greenplum Database cluster:*

- Greenplum Database uses `statement_mem` to control query memory usage when the resource group `MEMORY_SPILL_RATIO` is set to 0.
- You can use the following calculation to estimate a reasonable `statement_mem` value:

```
rg_perseg_mem = ((RAM * (vm.overcommit_ratio / 100) + SWAP) * gp_resource_group
_memory_limit) / num_active_primary_segments
statement_mem = rg_perseg_mem / max_expected_concurrent_queries
```

*If you are using resource queues to control resource allocation in your Greenplum Database cluster:*

- When `gp_resqueue_memory_policy` = auto, `statement_mem` and resource queue memory limits control query memory usage.
- You can use the following calculation to estimate a reasonable `statement_mem` value for a wide variety of situations:

```
( <gp_vmem_protect_limit>GB * .9 ) / <max_expected_concurrent_queries>
```

For example, with a `gp_vmem_protect_limit` set to 8192MB (8GB) and assuming a maximum of 40 concurrent queries with a 10% buffer, you would use the following calculation to determine the `statement_mem` value:

```
(8GB * .9) / 40 = .18GB = 184MB
```

When changing both `max_statement_mem` and `statement_mem`, `max_statement_mem` must be changed first, or listed first in the `postgresql.conf` file.

| Value Range         | Default | Set Classifications     |
|---------------------|---------|-------------------------|
| number of kilobytes | 128MB   | master, session, reload |

## statement\_timeout

Abort any statement that takes over the specified number of milliseconds. 0 turns off the limitation.

| Value Range            | Default | Set Classifications     |
|------------------------|---------|-------------------------|
| number of milliseconds | 0       | master, session, reload |

## stats\_queue\_level

**Note:** The `stats_queue_level` server configuration parameter is enforced only when resource queue-based resource management is active.

Collects resource queue statistics on database activity.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## superuser\_reserved\_connections

Determines the number of connection slots that are reserved for Greenplum Database superusers.

| Value Range                      | Default | Set Classifications    |
|----------------------------------|---------|------------------------|
| integer < <i>max_connections</i> | 10      | local, system, restart |

## tcp\_keepalives\_count

How many keepalives may be lost before the connection is considered dead. A value of 0 uses the system default. If TCP\_KEEPCNT is not supported, this parameter must be 0.

Use this parameter for all connections that are not between a primary and mirror segment.

| Value Range               | Default | Set Classifications    |
|---------------------------|---------|------------------------|
| number of lost keepalives | 0       | local, system, restart |

## tcp\_keepalives\_idle

Number of seconds between sending keepalives on an otherwise idle connection. A value of 0 uses the system default. If TCP\_KEEPIIDLE is not supported, this parameter must be 0.

Use this parameter for all connections that are not between a primary and mirror segment.

| Value Range       | Default | Set Classifications    |
|-------------------|---------|------------------------|
| number of seconds | 0       | local, system, restart |

## tcp\_keepalives\_interval

How many seconds to wait for a response to a keepalive before retransmitting. A value of 0 uses the system default. If TCP\_KEEPIINTVL is not supported, this parameter must be 0.

Use this parameter for all connections that are not between a primary and mirror segment.

| Value Range       | Default | Set Classifications    |
|-------------------|---------|------------------------|
| number of seconds | 0       | local, system, restart |

## temp\_buffers

Sets the maximum memory, in blocks, to allow for temporary buffers by each database session. These are session-local buffers used only for access to temporary tables. The setting can be changed within individual sessions, but only up until the first use of temporary tables within a session. The cost of setting a large value in sessions that do not actually need a lot of temporary buffers is only a buffer descriptor for each block, or about 64 bytes, per increment. However if a buffer is actually used, an additional 32768 bytes will be consumed.

You can set this parameter to the number of 32K blocks (for example, `1024` to allow 32MB for buffers), or specify the maximum amount of memory to allow (for example `'48MB'` for 1536 blocks). The `gpconfig` utility and `SHOW` command report the maximum amount of memory allowed for temporary buffers.

| Value Range | Default     | Set Classifications     |
|-------------|-------------|-------------------------|
| integer     | 1024 (32MB) | master, session, reload |

## temp\_tablespaces

Specifies tablespaces in which to create temporary objects (temp tables and indexes on temp tables) when a `CREATE` command does not explicitly specify a tablespace. These tablespaces can also include temporary files for purposes such as large data set sorting.

The value is a comma-separated list of tablespace names. When the list contains more than one tablespace name, Greenplum chooses a random list member each time it creates a temporary object. An exception applies within a transaction, where successively created temporary objects are placed in successive tablespaces from the list. If the selected element of the list is an empty string, Greenplum automatically uses the default tablespace of the current database instead.

When setting `temp_tablespaces` interactively, avoid specifying a nonexistent tablespace, or a tablespace for which the user does not have `CREATE` privileges. For non-superusers, a superuser must `GRANT` them the `CREATE` privilege on the temp tablespace. When using a previously set value (for example a value in `postgresql.conf`), nonexistent tablespaces are ignored, as are tablespaces for which the user lacks `CREATE` privilege.

The default value is an empty string, which results in all temporary objects being created in the default tablespace of the current database.

See also [default\\_tablespace](#).

| Value Range                  | Default | Set Classifications     |
|------------------------------|---------|-------------------------|
| one or more tablespace names | unset   | master, session, reload |

## TimeZone

Sets the time zone for displaying and interpreting time stamps. The default is to use whatever the system environment specifies as the time zone. See [Date/Time Keywords](#) in the PostgreSQL documentation.

| Value Range            | Default | Set Classifications |
|------------------------|---------|---------------------|
| time zone abbreviation |         | local, restart      |

## timezone\_abbreviations

Sets the collection of time zone abbreviations that will be accepted by the server for date time input. The default is `Default`, which is a collection that works in most of the world. `Australia` and `India`, and other collections can be defined for a particular installation. Possible values are names of configuration files stored in `$GPHOME/share/postgresql/timezonesets/`.

To configure Greenplum Database to use a custom collection of timezones, copy the file that contains the timezone definitions to the directory `$GPHOME/share/postgresql/timezonesets/` on the Greenplum Database master and segment hosts. Then set value of the server configuration parameter `timezone_abbreviations` to the file. For example, to use a file `custom` that contains the default timezones and the WIB (Waktu Indonesia Barat) timezone.

1. Copy the file `Default` from the directory `$GPHOME/share/postgresql/timezonesets/` the file `custom`. Add the WIB timezone information from the file `Asia.txt` to the `custom`.
2. Copy the file `custom` to the directory `$GPHOME/share/postgresql/timezonesets/` on the Greenplum Database master and segment hosts.
3. Set value of the server configuration parameter `timezone_abbreviations` to `custom`.
4. Reload the server configuration file (`gpstop -u`).

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| string      | Default | master, session, reload |

## track\_activities

Enables the collection of information on the currently executing command of each session, along with the time when that command began execution. The default value is `true`. Only superusers can change this setting. See the `pg_stat_activity` view.

**Note:** Even when enabled, this information is not visible to all users, only to superusers and the user owning the session being reported on, so it should not represent a security risk.

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| Boolean     | true    | master, session, reload, superuser |

## track\_activity\_query\_size

Sets the maximum length limit for the query text stored in `query` column of the system catalog view `pg_stat_activity`. The minimum length is 1024 characters.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| integer     | 1024    | local, system, restart |

## track\_counts

Enables the collection of information on the currently executing command of each session, along with the time at which that command began execution.

| Value Range | Default | Set Classifications                |
|-------------|---------|------------------------------------|
| Boolean     | true    | master, session, reload, superuser |

## transaction\_isolation

Sets the current transaction's isolation level.

| Value Range    | Default        | Set Classifications     |
|----------------|----------------|-------------------------|
| read committed | read committed | master, session, reload |
| serializable   |                |                         |

## transaction\_read\_only

Sets the current transaction's read-only status.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## transform\_null\_equals

When on, expressions of the form `expr = NULL` (or `NULL = expr`) are treated as `expr IS NULL`, that is, they return true if `expr` evaluates to the null value, and false otherwise. The correct SQL-spec-compliant behavior of `expr = NULL` is to always return null (unknown).

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## unix\_socket\_directories

Specifies the directory of the UNIX-domain socket on which the server is to listen for connections from client applications. Multiple sockets can be created by listing multiple directories separated by commas.

**Important:** Do not change the value of this parameter. The default location is required for Greenplum Database utilities.

| Value Range    | Default | Set Classifications    |
|----------------|---------|------------------------|
| directory path | 0777    | local, system, restart |

## unix\_socket\_group

Sets the owning group of the UNIX-domain socket. By default this is an empty string, which uses the default group for the current user.

| Value Range     | Default | Set Classifications    |
|-----------------|---------|------------------------|
| UNIX group name | unset   | local, system, restart |

## unix\_socket\_permissions

Sets the access permissions of the UNIX-domain socket. UNIX-domain sockets use the usual UNIX file system permission set. Note that for a UNIX-domain socket, only write permission matters.

| Value Range  | Default | Set Classifications    |
|--|---------|------------------------|
| numeric UNIX file permission mode (as accepted by the <i>chmod</i> or <i>umask</i> commands) | 0777    | local, system, restart |

## update\_process\_title

Enables updating of the process title every time a new SQL command is received by the server. The process title is typically viewed by the *ps* command.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| Boolean     | on      | local, session, reload |

## vacuum\_cost\_delay

The length of time that the process will sleep when the cost limit has been exceeded. 0 deactivates the cost-based vacuum delay feature.

| Value Range                           | Default | Set Classifications    |
|---------------------------------------|---------|------------------------|
| milliseconds < 0 (in multiples of 10) | 0       | local, session, reload |

## vacuum\_cost\_limit

The accumulated cost that will cause the vacuuming process to sleep.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| integer > 0 | 200     | local, session, reload |

## vacuum\_cost\_page\_dirty

The estimated cost charged when vacuum modifies a block that was previously clean. It represents the extra I/O required to flush the dirty block out to disk again.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| integer > 0 | 20      | local, session, reload |

## vacuum\_cost\_page\_hit

The estimated cost for vacuuming a buffer found in the shared buffer cache. It represents the cost to lock the buffer pool, lookup the shared hash table and scan the content of the page.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| integer > 0 | 1       | local, session, reload |

## vacuum\_cost\_page\_miss

The estimated cost for vacuuming a buffer that has to be read from disk. This represents the effort to lock the buffer pool, lookup the shared hash table, read the desired block in from the disk and scan its content.

| Value Range | Default | Set Classifications    |
|-------------|---------|------------------------|
| integer > 0 | 10      | local, session, reload |

## vacuum\_freeze\_min\_age

Specifies the cutoff age (in transactions) that `VACUUM` should use to decide whether to replace transaction IDs with *FrozenXID* while scanning a table.

For information about `VACUUM` and transaction ID management, see "Managing Data" in the *Greenplum Database Administrator Guide* and the [PostgreSQL documentation](#).

| Value Range             | Default  | Set Classifications    |
|-------------------------|----------|------------------------|
| integer 0-1000000000000 | 50000000 | local, session, reload |

## validate\_previous\_free\_tid

Enables a test that validates the free tuple ID (TID) list. The list is maintained and used by Greenplum Database. Greenplum Database determines the validity of the free TID list by ensuring the previous free TID of the current free tuple is a valid free tuple. The default value is `true`, enable the test.

If Greenplum Database detects a corruption in the free TID list, the free TID list is rebuilt, a warning is logged, and a warning is returned by queries for which the check failed. Greenplum Database attempts to run the queries.

**Note:** If a warning is returned, please contact VMware Support.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | true    | master, session, reload |

## verify\_gpfdists\_cert

When a Greenplum Database external table is defined with the `gpfdists` protocol to use SSL security, this parameter controls whether SSL certificate authentication is enabled.

Regardless of the setting of this server configuration parameter, Greenplum Database always encrypts data that you read from or write to an external table that specifies the `gpfdists` protocol.

The default is `true`, SSL authentication is enabled when Greenplum Database communicates with the `gpfdist` utility to either read data from or write data to an external data source.

The value `false` deactivates SSL certificate authentication. These SSL exceptions are ignored:

- The self-signed SSL certificate that is used by `gpfdist` is not trusted by Greenplum Database.
- The host name contained in the SSL certificate does not match the host name that is running `gpfdist`.

You can set the value to `false` to deactivate authentication when testing the communication between the Greenplum Database external table and the `gpfdist` utility that is serving the external data.

**Warning:** Deactivating SSL certificate authentication exposes a security risk by not validating the `gpfdists` SSL certificate.

For information about the `gpfdists` protocol, see [gpfdists:// Protocol](#). For information about running the `gpfdist` utility, see [gpfdist](#).

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | true    | master, session, reload |

## vmem\_process\_interrupt

Enables checking for interrupts before reserving vmem memory for a query during Greenplum Database query execution. Before reserving further vmem for a query, check if the current session for the query has a pending query cancellation or other pending interrupts. This ensures more responsive interrupt processing, including query cancellation requests. The default is `off`.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| Boolean     | off     | master, session, reload |

## wait\_for\_replication\_threshold

When Greenplum Database segment mirroring is enabled, specifies the maximum amount of Write-Ahead Logging (WAL)-based records (in KB) written by a transaction on the primary segment instance before the records are written to the mirror segment instance for replication. As the default, Greenplum Database writes the records to the mirror segment instance when a checkpoint occurs or the `wait_for_replication_threshold` value is reached.

A value of 0 deactivates the check for the amount of records. The records are written to the mirror segment instance only after a checkpoint occurs.

If you set the value to 0, database performance issues might occur under heavy loads that perform long transactions that do not perform a checkpoint operation.

| Value Range        | Default | Set Classifications    |
|--------------------|---------|------------------------|
| 0 - MAX-INT / 1024 | 1024    | master, system, reload |

## wal\_keep\_segments

For Greenplum Database master mirroring, sets the maximum number of processed WAL segment files that are saved by the by the active Greenplum Database master if a checkpoint operation occurs.

The segment files are used to synchronize the active master on the standby master.

| Value Range | Default | Set Classifications               |
|-------------|---------|-----------------------------------|
| integer     | 5       | master, system, reload, superuser |

## wal\_receiver\_status\_interval

For Greenplum Database master mirroring, sets the interval in seconds between `walreceiver` process status messages that are sent to the active master. Under heavy loads, the time might be longer.

The value of `wal_sender_timeout` controls the time that the `walsender` process waits for a `walreceiver` message.

| Value Range             | Default | Set Classifications               |
|-------------------------|---------|-----------------------------------|
| integer 0- INT_MAX/1000 | 10 sec  | master, system, reload, superuser |

## writable\_external\_table\_bufsize

Size of the buffer that Greenplum Database uses for network communication, such as the `gpfdist` utility and external web tables (that use http). Valid units are `KB` (as in `128KB`), `MB`, `GB`, and `TB`. Greenplum Database stores data in the buffer before writing the data out. For information about `gpfdist`, see the *Greenplum Database Utility Guide*.

| Value Range                        | Default | Set Classifications    |
|------------------------------------|---------|------------------------|
| integer 32 - 131072 (32KB - 128MB) | 64      | local, session, reload |

## xid\_stop\_limit

The number of transaction IDs prior to the ID where transaction ID wraparound occurs. When this limit is reached, Greenplum Database stops creating new transactions to avoid data loss due to transaction ID wraparound.

| Value Range                | Default   | Set Classifications    |
|----------------------------|-----------|------------------------|
| integer 10000000 - INT_MAX | 100000000 | local, system, restart |

## xid\_warn\_limit

The number of transaction IDs prior to the limit specified by `xid_stop_limit`. When Greenplum Database reaches this limit, it issues a warning to perform a VACUUM operation to avoid data loss due to transaction ID wraparound.

| Value Range                | Default   | Set Classifications    |
|----------------------------|-----------|------------------------|
| integer 10000000 - INT_MAX | 500000000 | local, system, restart |

## xmlbinary

Specifies how binary values are encoded in XML data. For example, when `bytea` values are converted to XML. The binary data can be converted to either base64 encoding or hexadecimal encoding. The default is base64.

The parameter can be set for a database system, an individual database, or a session.

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| base64      | base64  | master, session, reload |
| hex         |         |                         |

## xmloption

Specifies whether XML data is to be considered as an XML document (`document`) or XML content fragment (`content`) for operations that perform implicit parsing and serialization. The default is `content`.

This parameter affects the validation performed by `xml_is_well_formed()`. If the value is `document`, the function checks for a well-formed XML document. If the value is `content`, the function checks for a well-formed XML content fragment.

**Note:** An XML document that contains a document type declaration (DTD) is not considered a valid XML content fragment. If `xmloption` set to `content`, XML that contains a DTD is not considered valid XML.

To cast a character string that contains a DTD to the `xml` data type, use the `xmlparse` function with the `document` keyword, or change the `xmloption` value to `document`.

The parameter can be set for a database system, an individual database, or a session. The SQL command to set this option for a session is also available in Greenplum Database.

```
SET XML OPTION { DOCUMENT | CONTENT }
```

| Value Range | Default | Set Classifications     |
|-------------|---------|-------------------------|
| document    | content | master, session, reload |
| content     |         |                         |

## Greenplum Database Utility Guide

Reference information for Greenplum Database utility programs.

- **About the Greenplum Database Utilities**  
General information about using the Greenplum Database utility programs.
- **Utility Reference**  
The command-line utilities provided with Greenplum Database.
- **Additional Supplied Programs**  
Additional programs available in the Greenplum Database installation.

## About the Greenplum Database Utilities

General information about using the Greenplum Database utility programs.

Parent topic: [Greenplum Database Utility Guide](#)

## Referencing IP Addresses

When you reference IPv6 addresses in Greenplum Database utility programs, or when you use numeric IP addresses instead of hostnames in any management utility, always enclose the IP address in brackets. When specifying an IP address at the command line, the best practice is to escape any brackets or enclose them in single quotes. For example, use either:

```
\[2620:0:170:610::11\]
```

Or:

```
'[2620:0:170:610::11]'
```

## Running Backend Server Programs

Greenplum Database has modified certain PostgreSQL backend server programs to handle the parallelism and distribution of a Greenplum Database system. You access these programs only through the Greenplum Database management tools and utilities. *Do not run these programs directly.*

The following table identifies certain PostgreSQL backend server programs and the Greenplum Database utility command to run instead.

| PostgreSQL Program Name | Description  | Use Instead                |
|-------------------------|--|----------------------------|
| <code>initdb</code>     | This program is called by <code>gpinitssystem</code> when initializing a Greenplum Database array. It is used internally to create the individual segment instances and the master instance. | <code>gpinitssystem</code> |
| <code>ipcclean</code>   | Not used in Greenplum Database   | N/A                        |

| PostgreSQL Program Name     | Description   | Use Instead  |
|-----------------------------|---|--|
| <code>pg_basebackup</code>  | This program makes a binary copy of a single database instance. Greenplum Database uses it for tasks such as creating a standby master instance, or recovering a mirror segment when a full copy is needed. Do not use this utility to back up Greenplum Database segment instances because it does not produce MPP-consistent backups. | <code>gpinitstandby</code> , [ <code>gprecoverseg</code> ] ( <a href="#">ref/gprecoverseg.html</a> )   |
| <code>pg_controldata</code> | Not used in Greenplum Database  | <code>gpstate</code>   |
| <code>pg_ctl</code>         | This program is called by <code>gpstart</code> and <code>gpstop</code> when starting or stopping a Greenplum Database array. It is used internally to stop and start the individual segment instances and the master instance in parallel and with the correct options.   | <code>gpstart</code> , <code>gpstop</code>   |
| <code>pg_resetxlog</code>   | DO NOT USE<br><br><b>Warning:</b> This program might cause data loss or cause data to become unavailable. If this program is used, the Tanzu Greenplum cluster is not supported. The cluster must be reinitialized and restored by the customer.  | N/A  |
| <code>postgres</code>       | The <code>postgres</code> executable is the actual PostgreSQL server process that processes queries.  | The main <code>postgres</code> process (postmaster) creates other <code>postgres</code> subprocesses and <code>postgres</code> session as needed to handle client connections.                                   |
| <code>postmaster</code>     | <code>postmaster</code> starts the <code>postgres</code> database server listener process that accepts client connections. In Greenplum Database, a <code>postgres</code> database listener process runs on the Greenplum master Instance and on each Segment Instance.   | In Greenplum Database, you use <code>gpstart</code> and <code>gpstop</code> to start all postmasters ( <code>postgres</code> processes) in the system at once in the correct order and with the correct options. |

## Utility Reference

The command-line utilities provided with Greenplum Database.

Greenplum Database uses the standard PostgreSQL client and server programs and provides additional management utilities for administering a distributed Greenplum Database DBMS.

Several utilities are installed when you install the Greenplum Database server. These utilities reside in `$GPHOME/bin`. Other utilities must be downloaded from VMware Tanzu Network and installed separately. These include:

- The [Tanzu Greenplum Backup and Restore](#) utilities.
- The [Tanzu Greenplum Copy Utility](#).
- The [Tanzu Greenplum Streaming Server](#) utilities.

Additionally, the [Tanzu Clients](#) package is a separate download from VMware Tanzu Network that includes selected utilities from the Greenplum Database server installation that you can install on a client system.

Greenplum Database provides the following utility programs. Superscripts identify those utilities that require separate downloads, as well as those utilities that are also installed with the Client and Loader Tools Packages. (See the Note following the table.) All utilities are installed when you install the Greenplum Database server, unless specifically identified by a superscript.

- analyzedb
- clusterdb
- createdb<sup>3</sup>
- createuser<sup>3</sup>
- dropdb<sup>3</sup>
- dropuser<sup>3</sup>

**Note:**

<sup>1</sup> The utility program can be obtained from the *Greenplum Backup and Restore* tile on [VMware Tanzu Network](#).

<sup>2</sup> The utility program can be obtained from the *Greenplum Data Copy Utility* tile on [VMware Tanzu Network](#).

<sup>3</sup> The utility program is also installed with the *Greenplum Client and Loader Tools Package* for Linux and Windows. You can obtain these packages from the Greenplum Database *Greenplum Clients* filegroup on [VMware Tanzu Network](#).

<sup>4</sup> The utility program is also installed with the *Greenplum Client and Loader Tools Package* for Linux. You can obtain the most up-to-date version of the *Greenplum Streaming Server* from [VMware Tanzu Network](#).

## analyzedb

A utility that performs [ANALYZE](#) operations on tables incrementally and concurrently. For append optimized tables, analyzedb updates statistics only if the statistics are not current.

## Synopsis

```
analyzedb -d <dbname>
  { -s <schema> |
  { -t <schema>.<table>
    [ -i <col1>[,<col2>, ...] |
      -x <col1>[,<col2>, ...] ] } |
  { -f | --file} <config-file> }
  [ -l | --list ]
  [ --gen_profile_only ]
  [ -p <parallel-level> ]
  [ --full ]
  [ --skip_root_stats ]
  [ --skip_orca_root_stats ]
  [ -v | --verbose ]
  [ -a ]

analyzedb { --clean_last | --clean_all }
analyzedb --version
analyzedb { -? | -h | --help }
```

## Description

The analyzedb utility updates statistics on table data for the specified tables in a Greenplum database incrementally and concurrently.

While performing [ANALYZE](#) operations, analyzedb creates a snapshot of the table metadata and stores it on disk on the master host. An [ANALYZE](#) operation is performed only if the table has been modified. If a table or partition has not been modified since the last time it was analyzed, analyzedb automatically skips the table or partition because it already contains up-to-date statistics.

- For append optimized tables, analyzedb updates statistics incrementally, if the statistics are not current. For example, if table data is changed after statistics were collected for the table. If there are no statistics for the table, statistics are collected.
- For heap tables, statistics are always updated.

Specify the `--full` option to update append-optimized table statistics even if the table statistics are current.

By default, analyzedb creates a maximum of 5 concurrent sessions to analyze tables in parallel. For each session, analyzedb issues an [ANALYZE](#) command to the database and specifies different table names. The `-p` option controls the maximum number of concurrent sessions.

### Partitioned Append-Optimized Tables

For a partitioned, append-optimized table, analyzedb checks the partitioned table root partition and leaf partitions. If needed, the utility updates statistics for non-current partitions and the root partition. For information about how statistics are collected for partitioned tables, see [ANALYZE](#).

`analyzedb` must sample additional partitions within a partitioned table when it encounters a stale partition, even when statistics are already collected. Consider it a best practice to run `analyzedb` on

the root partition any time that you add a new partition(s) to a partitioned table. This operation both analyzes the child leaf partitions in parallel and merges any updated statistics into the root partition.

## Notes

The `analyze` utility updates append optimized table statistics if the table has been modified by DML or DDL commands, including `INSERT`, `DELETE`, `UPDATE`, `CREATE TABLE`, `ALTER TABLE` and `TRUNCATE`. The utility determines if a table has been modified by comparing catalog metadata of tables with the previous snapshot of metadata taken during a previous `analyze` operation. The snapshots of table metadata are stored as state files in the directory

`db_analyze/<db_name>/<timestamp>` in the Greenplum Database master data directory.

The utility preserves old snapshot information from the past 8 days, and the 3 most recent state directories regardless of age, while all other directories are automatically removed. You can also specify the `--clean_last` or `--clean_all` option to remove state files generated by `analyze`.

If you do not specify a table, set of tables, or schema, the `analyze` utility collects the statistics as needed on all system catalog tables and user-defined tables in the database.

External tables are not affected by `analyze`.

Table names that contain spaces are not supported.

Running the `ANALYZE` command on a table, not using the `analyze` utility, does not update the table metadata that the `analyze` utility uses to determine whether table statistics are up to date.

## Options

`--clean_last`

Remove the state files generated by last `analyze` operation. All other options except `-d` are ignored.

`--clean_all`

Remove all the state files generated by `analyze`. All other options except `-d` are ignored.

`-d dbname`

Specifies the name of the database that contains the tables to be analyzed. If this option is not specified, the database name is read from the environment variable `PGDATABASE`. If `PGDATABASE` is not set, the user name specified for the connection is used.

`-f config-file | --file config-file`

Text file that contains a list of tables to be analyzed. A relative file path from current directory can be specified.

The file lists one table per line. Table names must be qualified with a schema name.

Optionally, a list of columns can be specified using the `-i` or `-x`. No other options are allowed in the file. Other options such as `--full` must be specified on the command line.

Only one of the options can be used to specify the files to be analyzed: `-f` or `--file`, `-t`, or `-s`.

When performing `ANALYZE` operations on multiple tables, `analyze` creates concurrent sessions to analyze tables in parallel. The `-p` option controls the maximum number of concurrent sessions.

In the following example, the first line performs an ANALYZE operation on the table `public.nation`, the second line performs an ANALYZE operation only on the columns `l_shipdate` and `l_receiptdate` in the table `public.lineitem`.

```
public.nation
public.lineitem -i l_shipdate,l_receiptdate
```

`--full`

Perform an ANALYZE operation on all the specified tables. The operation is performed even if the statistics are up to date.

`--gen_profile_only`

Update the `analyzedb` snapshot of table statistics information without performing any ANALYZE operations. If other options specify tables or a schema, the utility updates the snapshot information only for the specified tables.

Specify this option if the ANALYZE command was run on database tables and you want to update the `analyzedb` snapshot for the tables.

`-i col1,col2, ...`

Optional. Must be specified with the `-t` option. For the table specified with the `-t` option, collect statistics only for the specified columns.

Only `-i`, or `-x` can be specified. Both options cannot be specified.

`-l | --list`

Lists the tables that would have been analyzed with the specified options. The ANALYZE operations are not performed.

`-p parallel-level`

The number of tables that are analyzed in parallel. parallel level can be an integer between 1 and 10, inclusive. Default value is 5.

`--skip_root_stats`

This option is no longer used, you may remove it from your scripts.

`--skip_orca_root_stats`

**Note:** Do not use this option if GPORCA is enabled.

Use this option if you find that ANALYZE ROOTPARTITION commands take a very long time to complete.

**Warning:** After you run `analyzedb` with this option, subsequent `analyzedb` executions will not update root partition statistics except when changes have been made to the table.

`-s schema`

Specify a schema to analyze. All tables in the schema will be analyzed. Only a single schema name can be specified on the command line.

Only one of the options can be used to specify the files to be analyzed: `-f` or `--file`, `-t`, or `-s`.

`-t schema.table`

Collect statistics only on `schema.table`. The table name must be qualified with a schema name. Only a single table name can be specified on the command line. You can specify the `-f` option to specify multiple tables in a file or the `-s` option to specify all the tables in a schema.

Only one of these options can be used to specify the files to be analyzed: `-f` or `--file`, `-t`, or `-s`.

`-x col1,col2, ...`

Optional. Must be specified with the `-t` option. For the table specified with the `-t` option, exclude statistics collection for the specified columns. Statistics are collected only on the columns that are not listed.

Only `-i`, or `-x` can be specified. Both options cannot be specified.

`-a`

Quiet mode. Do not prompt for user confirmation.

`-h | -? | --help`

Displays the online help.

`-v | --verbose`

If specified, sets the logging level to verbose to write additional information the log file and to the command line during command execution. The information includes a list of all the tables to be analyzed (including child leaf partitions of partitioned tables). Output also includes the duration of each `ANALYZE` operation.

`--version`

Displays the version of this utility.

## Examples

An example that collects statistics only on a set of table columns. In the database `mytest`, collect statistics on the columns `shipdate` and `receiptdate` in the table `public.orders`:

```
analyzedb -d mytest -t public.orders -i shipdate,receiptdate
```

An example that collects statistics on a table and exclude a set of columns. In the database `mytest`, collect statistics on the table `public.foo`, and do not collect statistics on the columns `bar` and `test2`.

```
analyzedb -d mytest -t public.foo -x bar,test2
```

An example that specifies a file that contains a list of tables. This command collect statistics on the tables listed in the file `analyze-tables` in the database named `mytest`.

```
analyzedb -d mytest -f analyze-tables
```

If you do not specify a table, set of tables, or schema, the `analyzedb` utility collects the statistics as needed on all catalog tables and user-defined tables in the specified database. This command refreshes table statistics on the system catalog tables and user-defined tables in the database `mytest`.

```
analyzedb -d mytest
```

You can create a PL/Python function to run the `analyzedb` utility as a Greenplum Database function. This example `CREATE FUNCTION` command creates a user defined PL/Python function that runs the `analyzedb` utility and displays output on the command line. Specify `analyzedb` options as the function parameter.

```

CREATE OR REPLACE FUNCTION analyzedb(params TEXT)
  RETURNS VOID AS
$BODY$
  import subprocess
  cmd = ['analyzedb', '-a' ] + params.split()
  p = subprocess.Popen(cmd, stdout=subprocess.PIPE, stderr=subprocess.STDOUT)

  # verbose output of process
  for line in iter(p.stdout.readline, ''):
    plpy.info(line);

  p.wait()
$BODY$
LANGUAGE plpythonu VOLATILE;

```

When this `SELECT` command is run by the `gpadmin` user, the `analyzedb` utility performs an analyze operation on the table `public.mytable` that is in the database `mytest`.

```
SELECT analyzedb('-d mytest -t public.mytable') ;
```

**Note:** To create a PL/Python function, the PL/Python procedural language must be registered as a language in the database. For example, this `CREATE LANGUAGE` command run as `gpadmin` registers PL/Python as an untrusted language:

```
CREATE LANGUAGE plpythonu;
```

## See Also

[ANALYZE](#)

## clusterdb

Reclusters tables that were previously clustered with `CLUSTER`.

## Synopsis

```

clusterdb [<connection-option> ...] [--verbose | -v] [--table | -t <table>] [[--dbname
| -d] <dbname>

clusterdb [<connection-option> ...] [--all | -a] [--verbose | -v]

clusterdb -? | --help

clusterdb -V | --version

```

## Description

To cluster a table means to physically reorder a table on disk according to an index so that index scan operations can access data on disk in a somewhat sequential order, thereby improving index seek performance for queries that use that index.

The `clusterdb` utility will find any tables in a database that have previously been clustered with the `CLUSTER` SQL command, and clusters them again on the same index that was last used. Tables that have never been clustered are not affected.

`clusterdb` is a wrapper around the SQL command `CLUSTER`. Although clustering a table in this way is supported in Greenplum Database, it is not recommended because the `CLUSTER` operation itself is extremely slow.

If you do need to order a table in this way to improve your query performance, use a `CREATE TABLE AS` statement to reorder the table on disk rather than using `CLUSTER`. If you do 'cluster' a table in this way, then `clusterdb` would not be relevant.

## Options

`-a` | `--all`

Cluster all databases.

`[-d] dbname` |  `[--dbname=]dbname`

Specifies the name of the database to be clustered. If this is not specified, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

`-e` | `--echo`

Echo the commands that `clusterdb` generates and sends to the server.

`-q` | `--quiet`

Do not display a response.

`-t table` | `--table=table`

Cluster the named table only. Multiple tables can be clustered by writing multiple `-t` switches.

`-v` | `--verbose`

Print detailed information during processing.

`-V` | `--version`

Print the `clusterdb` version and exit.

`-?` | `--help`

Show help about `clusterdb` command line arguments, and exit.

### Connection Options

`-h host` | `--host=host`

The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to `localhost`.

`-p port` | `--port=port`

The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to `5432`.

`-U username` | `--username=username`

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

`-w` | `--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will

fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W | --password`

Force a password prompt.

`--maintenance-db=dbname`

Specifies the name of the database to connect to discover what other databases should be clustered. If not specified, the `postgres` database will be used, and if that does not exist, `template1` will be used.

## Examples

To cluster the database `test`:

```
clusterdb test
```

To cluster a single table `foo` in a database named `xyzyz`:

```
clusterdb --table foo xyzyz
```

## See Also

[CLUSTER](#)

## createdb

Creates a new database.

## Synopsis

```
createdb [<connection-option> ...] [<option> ...] [<dbname> ['<description>']]

createdb -? | --help

createdb -V | --version
```

## Description

`createdb` creates a new database in a Greenplum Database system.

Normally, the database user who runs this command becomes the owner of the new database.

However, a different owner can be specified via the `-o` option, if the executing user has appropriate privileges.

`createdb` is a wrapper around the SQL command [CREATE DATABASE](#) .

## Options

`dbname`

The name of the database to be created. The name must be unique among all other databases in the Greenplum system. If not specified, reads from the environment variable `PGDATABASE`, then `PGUSER` or defaults to the current system user.

description

A comment to be associated with the newly created database. Descriptions containing white space must be enclosed in quotes.

`-D tablespace | --tablespace=tablespace`

Specifies the default tablespace for the database. (This name is processed as a double-quoted identifier.)

`-e echo`

Echo the commands that `createdb` generates and sends to the server.

`-E encoding | --encoding encoding`

Character set encoding to use in the new database. Specify a string constant (such as `'UTF8'`), an integer encoding number, or `DEFAULT` to use the default encoding. See the Greenplum Database Reference Guide for information about supported character sets.

`-l locale | --locale locale`

Specifies the locale to be used in this database. This is equivalent to specifying both `--lc-collate` and `--lc-ctype`.

`--lc-collate locale`

Specifies the `LC_COLLATE` setting to be used in this database.

`--lc-ctype locale`

Specifies the `LC_CTYPE` setting to be used in this database.

`-O owner | --owner=owner`

The name of the database user who will own the new database. Defaults to the user running this command. (This name is processed as a double-quoted identifier.)

`-T template | --template=template`

The name of the template from which to create the new database. Defaults to `template1`. (This name is processed as a double-quoted identifier.)

`-V | --version`

Print the `createdb` version and exit.

`-? | --help`

Show help about `createdb` command line arguments, and exit.

The options `-D`, `-l`, `-E`, `-O`, and `-T` correspond to options of the underlying SQL command `CREATE DATABASE`; see `CREATE DATABASE` in the *Greenplum Database Reference Guide* for more information about them.

### Connection Options

`-h host | --host=host`

The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to `localhost`.

`-p port | --port=port`

The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

`-U username | --username=username`

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

`-w | --no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W | --password`

Force a password prompt.

`--maintenance-db=dbname`

Specifies the name of the database to connect to when creating the new database. If not specified, the `postgres` database will be used; if that does not exist (or if it is the name of the new database being created), `template1` will be used.

## Examples

To create the database `test` using the default options:

```
createdb test
```

To create the database `demo` using the Greenplum master on host `gpmaster`, port `54321`, using the `LATIN1` encoding scheme:

```
createdb -p 54321 -h gpmaster -E LATIN1 demo
```

## See Also

[CREATE DATABASE](#), [dropdb](#)

## createuser

Creates a new database role.

## Synopsis

```
createuser [<connection-option> ...] [<role_attribute> ...] [-e] <role_name>

createuser -? | --help

createuser -V | --version
```

## Description

`createuser` creates a new Greenplum Database role. You must be a superuser or have the `CREATEROLE` privilege to create new roles. You must connect to the database as a superuser to create new superusers.

Superusers can bypass all access permission checks within the database, so superuser privileges should not be granted lightly.

`createuser` is a wrapper around the SQL command `CREATE ROLE`.

## Options

### role\_name

The name of the role to be created. This name must be different from all existing roles in this Greenplum Database installation.

### -c number | --connection-limit=number

Set a maximum number of connections for the new role. The default is to set no limit.

### -d | --createdb

The new role will be allowed to create databases.

### -D | --no-createdb

The new role will not be allowed to create databases. This is the default.

### -e | --echo

Echo the commands that `createuser` generates and sends to the server.

### -E | --encrypted

Encrypts the role's password stored in the database. If not specified, the default password behavior is used.

### -i | --inherit

The new role will automatically inherit privileges of roles it is a member of. This is the default.

### -I | --no-inherit

The new role will not automatically inherit privileges of roles it is a member of.

### --interactive

Prompt for the user name if none is specified on the command line, and also prompt for whichever of the options `-d/-D`, `-r/-R`, `-s/-S` is not specified on the command line.

### -l | --login

The new role will be allowed to log in to Greenplum Database. This is the default.

### -L | --no-login

The new role will not be allowed to log in (a group-level role).

### -N | --unencrypted

Does not encrypt the role's password stored in the database. If not specified, the default password behavior is used.

### -P | --pwprompt

If given, `createuser` will issue a prompt for the password of the new role. This is not necessary if you do not plan on using password authentication.

### -r | --createrole

The new role will be allowed to create new roles (`CREATEROLE` privilege).

### -R | --no-createrole

The new role will not be allowed to create new roles. This is the default.

### -s | --superuser

The new role will be a superuser.

### -S | --no-superuser

The new role will not be a superuser. This is the default.

### -V | --version

Print the `createuser` version and exit.

### --replication

The new user will have the `REPLICATION` privilege, which is described more fully in the documentation for `CREATE ROLE`.

### --no-replication

The new user will not have the `REPLICATION` privilege, which is described more fully in the documentation for `CREATE ROLE`.

`-? | --help`

Show help about `createuser` command line arguments, and exit.

### Connection Options

`-h host | --host=host`

The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to `localhost`.

`-p port | --port=port`

The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to `5432`.

`-U username | --username=username`

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

`-w | --no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W | --password`

Force a password prompt.

## Examples

To create a role `joe` on the default database server:

```
$ createuser joe
```

To create a role `joe` on the default database server with prompting for some additional attributes:

```
$ createuser --interactive joe
Shall the new role be a superuser? (y/n) **n**
Shall the new role be allowed to create databases? (y/n) **n**
Shall the new role be allowed to create more new roles? (y/n) **n**
CREATE ROLE
```

To create the same role `joe` using connection options, with attributes explicitly specified, and taking a look at the underlying command:

```
createuser -h masterhost -p 54321 -S -D -R -e joe
CREATE ROLE joe NOSUPERUSER NOCREATEDB NOCREATEROLE INHERIT
LOGIN;
CREATE ROLE
```

To create the role `joe` as a superuser, and assign password `admin123` immediately:

```
createuser -P -s -e joe
Enter password for new role: admin123
Enter it again: admin123
```

```
CREATE ROLE joe PASSWORD 'admin123' SUPERUSER CREATEDB
CREATEROLE INHERIT LOGIN;
CREATE ROLE
```

In the above example, the new password is not actually echoed when typed, but we show what was typed for clarity. However the password will appear in the echoed command, as illustrated if the `-e` option is used.

[CREATE ROLE, dropuser](#)

## dropdb

Removes a database.

## Synopsis

```
dropdb [<connection-option> ...] [-e] [-i] <dbname>

dropdb -? | --help

dropdb -V | --version
```

## Description

`dropdb` destroys an existing database. The user who runs this command must be a superuser or the owner of the database being dropped.

`dropdb` is a wrapper around the SQL command `DROP DATABASE`. See the *Greenplum Database Reference Guide* for information about `DROP DATABASE`.

## Options

`dbname`

The name of the database to be removed.

`-e | --echo`

Echo the commands that `dropdb` generates and sends to the server.

`-i | --interactive`

Issues a verification prompt before doing anything destructive.

`-V | --version`

Print the `dropdb` version and exit.

`--if-exists`

Do not throw an error if the database does not exist. A notice is issued in this case.

`-? | --help`

Show help about `dropdb` command line arguments, and exit.

## Connection Options

`-h host | --host=host`

The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to `localhost`.

`-p port | --port=port`

The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to `5432`.

`-U username | --username=username`

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

`-w | --no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W | --password`

Force a password prompt.

`--maintenance-db=dbname`

Specifies the name of the database to connect to in order to drop the target database. If not specified, the `postgres` database will be used; if that does not exist (or if it is the name of the database being dropped), `template1` will be used.

## Examples

To destroy the database named `demo` using default connection parameters:

```
dropdb demo
```

To destroy the database named `demo` using connection options, with verification, and a peek at the underlying command:

```
dropdb -p 54321 -h masterhost -i -e demo
Database "demo" will be permanently deleted.
Are you sure? (y/n) y
DROP DATABASE "demo"
DROP DATABASE
```

## dropuser

Removes a database role.

## Synopsis

```
dropuser [<connection-option> ...] [-e] [-i] <role_name>
```

```
dropuser -? | --help
dropuser -V | --version
```

## Description

`dropuser` removes an existing role from Greenplum Database. Only superusers and users with the `CREATEROLE` privilege can remove roles. To remove a superuser role, you must yourself be a superuser.

`dropuser` is a wrapper around the SQL command `DROP ROLE`.

## Options

`role_name`

The name of the role to be removed. You will be prompted for a name if not specified on the command line and the `-i/--interactive` option is used.

`-e | --echo`

Echo the commands that `dropuser` generates and sends to the server.

`-i | --interactive`

Prompt for confirmation before actually removing the role, and prompt for the role name if none is specified on the command line.

`--if-exists`

Do not throw an error if the user does not exist. A notice is issued in this case.

`-V | --version`

Print the `dropuser` version and exit.

`-? | --help`

Show help about `dropuser` command line arguments, and exit.

### Connection Options

`-h host | --host=host`

The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to localhost.

`-p port | --port=port`

The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

`-U username | --username=username`

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

`-w | --no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W | --password`

Force a password prompt.

## Examples

To remove the role `joe` using default connection options:

```
dropuser joe
DROP ROLE
```

To remove the role `joe` using connection options, with verification, and a peek at the underlying command:

```
dropuser -p 54321 -h masterhost -i -e joe
Role "joe" will be permanently removed.
Are you sure? (y/n) y
DROP ROLE "joe"
DROP ROLE
```

## gpactivatestandby

Activates a standby master host and makes it the active master for the Greenplum Database system.

## Synopsis

```
gpactivatestandby [-d <standby_master_datadir>] [-f] [-a] [-q]
                  [-l <logfile_directory>]

gpactivatestandby -v

gpactivatestandby -? | -h | --help
```

## Description

The `gpactivatestandby` utility activates a backup, standby master host and brings it into operation as the active master instance for a Greenplum Database system. The activated standby master effectively becomes the Greenplum Database master, accepting client connections on the master port.

When you initialize a standby master, the default is to use the same port as the active master. For information about the master port for the standby master, see [gpinitstandby](#).

You must run this utility from the master host you are activating, not the failed master host you are deactivating. Running this utility assumes you have a standby master host configured for the system (see [gpinitstandby](#)).

The utility will perform the following steps:

- Stops the synchronization process (`walreceiver`) on the standby master

- Updates the system catalog tables of the standby master using the logs
- Activates the standby master to be the new active master for the system
- Restarts the Greenplum Database system with the new master host

A backup, standby Greenplum master host serves as a 'warm standby' in the event of the primary Greenplum master host becoming non-operational. The standby master is kept up to date by transaction log replication processes (the `walsender` and `walreceiver`), which run on the primary master and standby master hosts and keep the data between the primary and standby master hosts synchronized.

If the primary master fails, the log replication process is shutdown, and the standby master can be activated in its place by using the `gpactivestandby` utility. Upon activation of the standby master, the replicated logs are used to reconstruct the state of the Greenplum master host at the time of the last successfully committed transaction.

In order to use `gpactivestandby` to activate a new primary master host, the master host that was previously serving as the primary master cannot be running. The utility checks for a `postmaster.pid` file in the data directory of the deactivated master host, and if it finds it there, it will assume the old master host is still active. In some cases, you may need to remove the `postmaster.pid` file from the deactivated master host data directory before running `gpactivestandby` (for example, if the deactivated master host process was terminated unexpectedly).

After activating a standby master, run `ANALYZE` to update the database query statistics. For example:

```
psql <dbname> -c 'ANALYZE;'
```

After you activate the standby master as the primary master, the Greenplum Database system no longer has a standby master configured. You might want to specify another host to be the new standby with the `gpinitstandby` utility.

## Options

`-a` (do not prompt)

Do not prompt the user for confirmation.

`-d` `standby_master_datadir`

The absolute path of the data directory for the master host you are activating.

If this option is not specified, `gpactivestandby` uses the value of the `MASTER_DATA_DIRECTORY` environment variable setting on the master host you are activating. If this option is specified, it overrides any setting of `MASTER_DATA_DIRECTORY`.

If a directory cannot be determined, the utility returns an error.

`-f` (force activation)

Use this option to force activation of the backup master host. Use this option only if you are sure that the standby and primary master hosts are consistent.

`-l` `logfile_directory`

The directory to write the log file. Defaults to `~/gpAdminLogs`.

`-q` (no screen output)

Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

`-v` (show utility version)

Displays the version, status, last updated date, and check sum of this utility.

`-? | -h | --help` (help)

Displays the online help.

## Example

Activate the standby master host and make it the active master instance for a Greenplum Database system (run from backup master host you are activating):

```
gpactivatestandby -d /gpdata
```

## See Also

## gpaddmirrors

Adds mirror segments to a Greenplum Database system that was initially configured without mirroring.

## Synopsis

```
gpaddmirrors [-p <port_offset>] [-m <datadir_config_file> [-a]] [-s]
  [-d <master_data_directory>] [-b <segment_batch_size>] [-B <batch_size>] [-l <logfile_directory>]
  [-v] [--hba-hostnames <boolean>]

gpaddmirrors -i <mirror_config_file> [-a] [-d <master_data_directory>]
  [-b <segment_batch_size>] [-B <batch_size>] [-l <logfile_directory>] [-v]

gpaddmirrors -o output_sample_mirror_config> [-s] [-m <datadir_config_file>]

gpaddmirrors -?

gpaddmirrors --version
```

## Description

The `gpaddmirrors` utility configures mirror segment instances for an existing Greenplum Database system that was initially configured with primary segment instances only. The utility will create the mirror instances and begin the online replication process between the primary and mirror segment instances. Once all mirrors are synchronized with their primaries, your Greenplum Database system is fully data redundant.

**Important:** During the online replication process, Greenplum Database should be in a quiescent state, workloads and other queries should not be running.

By default, the utility will prompt you for the file system location(s) where it will create the mirror segment data directories. If you do not want to be prompted, you can pass in a file containing the file system locations using the `-m` option.

The mirror locations and ports must be different than your primary segment data locations and ports.

The utility creates a unique data directory for each mirror segment instance in the specified location using the predefined naming convention. There must be the same number of file system locations declared for mirror segment instances as for primary segment instances. It is OK to specify the same directory name multiple times if you want your mirror data directories created in the same location, or you can enter a different data location for each mirror. Enter the absolute path. For example:

```
Enter mirror segment data directory location 1 of 2 > /gpdb/mirror
Enter mirror segment data directory location 2 of 2 > /gpdb/mirror
```

OR

```
Enter mirror segment data directory location 1 of 2 > /gpdb/m1
Enter mirror segment data directory location 2 of 2 > /gpdb/m2
```

Alternatively, you can run the `gpaddmirrors` utility and supply a detailed configuration file using the `-i` option. This is useful if you want your mirror segments on a completely different set of hosts than your primary segments. The format of the mirror configuration file is:

```
<contentID>|<address>|<port>|<data_dir>
```

Where `<contentID>` is the segment instance content ID, `<address>` is the host name or IP address of the segment host, `<port>` is the communication port, and `<data_dir>` is the segment instance data directory.

For example:

```
0|sdw1-1|60000|/gpdata/m1/gp0
1|sdw1-1|60001|/gpdata/m2/gp1
```

The `gp_segment_configuration` system catalog table can help you determine your current primary segment configuration so that you can plan your mirror segment configuration. For example, run the following query:

```
=# SELECT dbid, content, address as host_address, port, datadir
FROM gp_segment_configuration
ORDER BY dbid;
```

If you are creating mirrors on alternate mirror hosts, the new mirror segment hosts must be pre-installed with the Greenplum Database software and configured exactly the same as the existing primary segment hosts.

You must make sure that the user who runs `gpaddmirrors` (the `gpadmin` user) has permissions to write to the data directory locations specified. You may want to create these directories on the segment hosts and `chown` them to the appropriate user before running `gpaddmirrors`.

**Note:** This utility uses secure shell (SSH) connections between systems to perform its tasks. In large Greenplum Database deployments, cloud deployments, or deployments with a large number of segments per host, this utility may exceed the host's maximum threshold for unauthenticated connections. Consider updating the SSH `MaxStartups` configuration parameter to increase this threshold. For more information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

## Options

-a (do not prompt)

Run in quiet mode - do not prompt for information. Must supply a configuration file with either `-m` or `-i` if this option is used.

-b `segment_batch_size`

The maximum number of segments per host to operate on in parallel. Valid values are 1 to 128. If not specified, the utility will start recovering up to 64 segments in parallel on each host.

-B `batch_size`

The number of hosts to work on in parallel. If not specified, the utility will start working on up to 16 hosts in parallel. Valid values are 1 to 64.

-d `master_data_directory`

The master data directory. If not specified, the value set for `$MASTER_DATA_DIRECTORY` will be used.

--hba-hostnames boolean

Optional. Controls whether this utility uses IP addresses or host names in the `pg_hba.conf` file when updating this file with addresses that can connect to Greenplum Database. When set to 0 -- the default value -- this utility uses IP addresses when updating this file. When set to 1, this utility uses host names when updating this file. For consistency, use the same value that was specified for `HBA_HOSTNAMES` when the Greenplum Database system was initialized. For information about how Greenplum Database resolves host names in the `pg_hba.conf` file, see [Configuring Client Authentication](#).

-i `mirror_config_file`

A configuration file containing one line for each mirror segment you want to create. You must have one mirror segment instance listed for each primary segment in the system. The format of this file is as follows (as per attributes in the `gp_segment_configuration` catalog table):

```
<contentID>|<address>|<port>|<data_dir>
```

: Where `<contentID>` is the segment instance content ID, `<address>` is the hostname or IP address of the segment host, `<port>` is the communication port, and `<data_dir>` is the segment instance data directory. For information about using a hostname or IP address, see [Specifying Hosts using Hostnames or IP Addresses](#). Also, see [Using Host Systems with Multiple NICs](#).

-l `logfile_directory`

The directory to write the log file. Defaults to `~/gpAdminLogs`.

-m `datadir_config_file`

A configuration file containing a list of file system locations where the mirror data directories will be created. If not supplied, the utility prompts you for locations. Each line in the file specifies a mirror data directory location. For example:

```
/gpdata/m1
/gpdata/m2
/gpdata/m3
/gpdata/m4
```

**-o output\_sample\_mirror\_config**

If you are not sure how to lay out the mirror configuration file used by the **-i** option, you can run `gpaddmirrors` with this option to generate a sample mirror configuration file based on your primary segment configuration. The utility will prompt you for your mirror segment data directory locations (unless you provide these in a file using **-m**). You can then edit this file to change the host names to alternate mirror hosts if necessary.

**-p port\_offset**

Optional. This number is used to calculate the database ports used for mirror segments. The default offset is 1000. Mirror port assignments are calculated as follows:

```
primary_port + offset = mirror_database_port
```

For example, if a primary segment has port 50001, then its mirror will use a database port of 51001, by default.

**-s (spread mirrors)**

Spreads the mirror segments across the available hosts. The default is to group a set of mirror segments together on an alternate host from their primary segment set. Mirror spreading will place each mirror on a different host within the Greenplum Database array. Spreading is only allowed if there is a sufficient number of hosts in the array (number of hosts is greater than the number of segment instances per host).

**-v (verbose)**

Sets logging output to verbose.

**--version (show utility version)**

Displays the version of this utility.

**-? (help)**

Displays the online help.

## Specifying Hosts using Hostnames or IP Addresses

When specifying a mirroring configuration using the `gpaddmirrors` option **-i**, you can specify either a hostname or an IP address for the `<address>` value.

- If you specify a hostname, the resolution of the hostname to an IP address should be done locally for security. For example, you should use entries in a local `/etc/hosts` file to map the hostname to an IP address. The resolution of a hostname to an IP address should not be performed by an external service such as a public DNS server. You must stop the Greenplum system before you change the mapping of a hostname to a different IP address.
- If you specify an IP address, the address should not be changed after the initial configuration. When segment mirroring is enabled, replication from the primary to the

mirror segment will fail if the IP address changes from the configured value. For this reason, you should use a hostname when enabling mirroring using the `-i` option unless you have a specific requirement to use IP addresses.

When enabling a mirroring configuration that adds hosts to the Greenplum system, `gpaddmirrors` populates the `gp_segment_configuration` catalog table with the mirror segment instance information. Greenplum Database uses the address value of the `gp_segment_configuration` catalog table when looking up host systems for Greenplum interconnect (internal) communication between the master and segment instances and between segment instances, and for other internal communication.

## Using Host Systems with Multiple NICs

If hosts systems are configured with multiple NICs, you can initialize a Greenplum Database system to use each NIC as a Greenplum host system. You must ensure that the host systems are configured with sufficient resources to support all the segment instances being added to the host. Also, if you enable segment mirroring, you must ensure that the Greenplum system configuration supports failover if a host system fails. For information about Greenplum Database mirroring schemes, see [Segment Mirroring Configurations](#).

For example, this is a segment instance configuration for a simple Greenplum system. The segment host `gp6m` is configured with two NICs, `gp6m-1` and `gp6m-2`, where the Greenplum Database system uses `gp6m-1` for the master segment and `gp6m-2` for segment instances.

```
select content, role, port, hostname, address from gp_segment_configuration ;
```

| content | role | port  | hostname | address |
|---------|------|-------|----------|---------|
| -1      | p    | 5432  | gp6m     | gp6m-1  |
| 0       | p    | 40000 | gp6m     | gp6m-2  |
| 0       | m    | 50000 | gp6s     | gp6s    |
| 1       | p    | 40000 | gp6s     | gp6s    |
| 1       | m    | 50000 | gp6m     | gp6m-2  |

(5 rows)

## Examples

Add mirroring to an existing Greenplum Database system using the same set of hosts as your primary data. Calculate the mirror database ports by adding 100 to the current primary segment port numbers:

```
$ gpaddmirrors -p 100
```

Generate a sample mirror configuration file with the `-o` option to use with `gpaddmirrors -i`:

```
$ gpaddmirrors -o /home/gpadmin/sample_mirror_config
```

Add mirroring to an existing Greenplum Database system using a different set of hosts from your primary data:

```
$ gpaddmirrors -i mirror_config_file
```

Where `mirror_config_file` looks something like this:

```
0|sdw1-1|52001|/gpdata/m1/gp0
1|sdw1-2|52002|/gpdata/m2/gp1
2|sdw2-1|52001|/gpdata/m1/gp2
3|sdw2-2|52002|/gpdata/m2/gp3
```

## See Also

[gpinitssystem](#), [gpinitstandby](#), [gpactivatestandby](#)

## gpcheckcat

The `gpcheckcat` utility tests Greenplum Database catalog tables for inconsistencies.

The utility is in `$GPHOME/bin/lib`.

## Synopsis

```
gpcheckcat [ <options> ] [ <dbname> ]

Options:
  -g <dir>
  -p <port>
  -s <test_name | 'test_name1, test_name2 [, ...]'\>
  -P <password>
  -U <user_name>
  -S {none | only}
  -O
  -R <test_name | 'test_name1, test_name2 [, ...]'\>
  -C <catalog_name>
  -B <parallel_processes>
  -v
  -A

gpcheckcat -l

gpcheckcat -? | --help
```

## Description

The `gpcheckcat` utility runs multiple tests that check for database catalog inconsistencies. Some of the tests cannot be run concurrently with other workload statements or the results will not be usable. Restart the database in restricted mode when running `gpcheckcat`, otherwise `gpcheckcat` might report inconsistencies due to ongoing database operations rather than the actual number of inconsistencies. If you run `gpcheckcat` without stopping database activity, run it with `-O` option.

**Note:** Any time you run the utility, it checks for and deletes orphaned, temporary database schemas (temporary schemas without a session ID) in the specified databases. The utility displays the results of the orphaned, temporary schema check on the command line and also logs the results.

Catalog inconsistencies are inconsistencies that occur between Greenplum Database system tables. In general, there are three types of inconsistencies:

- Inconsistencies in system tables at the segment level. For example, an inconsistency between a system table that contains table data and a system table that contains column data. As another, a system table that contains duplicates in a column that should to be unique.
- Inconsistencies between same system table across segments. For example, a system table is missing row on one segment, but other segments have this row. As another example, the values of specific row column data are different across segments, such as table owner or table access privileges.
- Inconsistency between a catalog table and the filesystem. For example, a file exists in database directory, but there is no entry for it in the `pg_class` table.

## Options

-A

Run `gpcheckcat` on all databases in the Greenplum Database installation.

-B <parallel\_processes>

The number of processes to run in parallel.

The `gpcheckcat` utility attempts to determine the number of simultaneous processes (the batch size) to use. The utility assumes it can use a buffer with a minimum of 20MB for each process. The maximum number of parallel processes is the number of Greenplum Database segment instances. The utility displays the number of parallel processes that it uses when it starts checking the catalog. **Note:** The utility might run out of memory if the number of errors returned exceeds the buffer size. If an out of memory error occurs, you can lower the batch size with the `-B` option. For example, if the utility displays a batch size of 936 and runs out of memory, you can specify `-B 468` to run 468 processes in parallel.

-C catalog\_table

Run cross consistency, foreign key, and ACL tests for the specified catalog table.

-g data\_directory

Generate SQL scripts to fix catalog inconsistencies. The scripts are placed in `data_directory`.

-l

List the `gpcheckcat` tests.

-O

Run only the `gpcheckcat` tests that can be run in online (not restricted) mode.

-p port

This option specifies the port that is used by the Greenplum Database.

-P password

The password of the user connecting to Greenplum Database.

-R test\_name | 'test\_name1,test\_name2 [, ...]'

Specify one or more tests to run. Specify multiple tests as a comma-delimited list of test names enclosed in quotes.

Some tests can be run only when Greenplum Database is in restricted mode.

These are the tests that can be performed:

`acl` - Cross consistency check for access control privileges

`aoseg_table` - Check that the vertical partition information (`vpinfo`) on segment instances is consistent with `pg_attribute` (checks only append-optimized, column storage tables in the database)

`duplicate` - Check for duplicate entries

`foreign_key` - Check foreign keys

`inconsistent` - Cross consistency check for master segment inconsistency

`missing_extraneous` - Cross consistency check for missing or extraneous entries

`owner` - Check table ownership that is inconsistent with the master database

`orphaned_toast_tables` - Check for orphaned TOAST tables.

**Note:** There are several ways a TOAST table can become orphaned where a repair script cannot be generated and a manual catalog change is required. One way is if the `reltoastrelid` entry in `pg_class` points to an incorrect TOAST table (a TOAST table mismatch). Another way is if both the `reltoastrelid` in `pg_class` is missing and the `pg_depend` entry is missing (a double orphan TOAST table). If a manual catalog change is needed, `gpcheckcat` will display detailed steps you can follow to update the catalog. Contact VMware Support if you need help with the catalog change.

`part_integrity` - Check `pg_partition` branch integrity, partition with OIDs, partition distribution policy

`part_constraint` - Check constraints on partitioned tables

`unique_index_violation` - Check tables that have columns with the unique index constraint for duplicate entries

`dependency` - Check for dependency on non-existent objects (restricted mode only)

`distribution_policy` - Check constraints on randomly distributed tables (restricted mode only)

`namespace` - Check for schemas with a missing schema definition (restricted mode only)

`pgclass` - Check `pg_class` entry that does not have any corresponding `pg_attribute` entry (restricted mode only)

`-S test_name | 'test_name1, test_name2 [, ...]'`

Specify one or more tests to skip. Specify multiple tests as a comma-delimited list of test names enclosed in quotes.

`-S {none | only}`

Specify this option to control the testing of catalog tables that are shared across all databases in the Greenplum Database installation, such as `pg_database`.

The value `none` deactivates testing of shared catalog tables. The value `only` tests only the shared catalog tables.

`-U user_name`

The user connecting to Greenplum Database.

`-? | --help`

Displays the online help.

-v (verbose)

Displays detailed information about the tests that are performed.

## Notes

The utility identifies tables with missing attributes and displays them in various locations in the output and in a non-standardized format. The utility also displays a summary list of tables with missing attributes in the format `<database>. <schema>. <table>. <segment_id>` after the output information is displayed.

If `gpcheckcat` detects inconsistent OID (Object ID) information, it generates one or more verification files that contain an SQL query. You can run the SQL query to see details about the OID inconsistencies and investigate the inconsistencies. The files are generated in the directory where `gpcheckcat` is invoked.

This is the format of the file:

```
gpcheckcat.verify.dbname.catalog\_table\_name.test\_name.TIMESTAMP.sql
```

This is an example verification filename created by `gpcheckcat` when it detects inconsistent OID (Object ID) information in the catalog table `pg_type` in the database `mydb`:

```
gpcheckcat.verify.mydb.pg_type.missing_extraneous.20150420102715.sql
```

This is an example query from a verification file:

```
SELECT *
FROM (
  SELECT relname, oid FROM pg_class WHERE reltype
    IN (1305822,1301043,1301069,1301095)
  UNION ALL
  SELECT relname, oid FROM gp_dist_random('pg_class') WHERE reltype
    IN (1305822,1301043,1301069,1301095)
) alltyprelids
GROUP BY relname, oid ORDER BY count(*) desc ;
```

## gpcheckperf

Verifies the baseline hardware performance of the specified hosts.

## Synopsis

```
gpcheckperf -d <test_directory> [-d <test_directory> ...]
  {-f <hostfile_gpcheckperf> | -h <hostname> [-h hostname ...]}
  [-r ds] [-B <block_size>] [-S <file_size>] [-D] [-v|-V]

gpcheckperf -d <temp_directory>
  {-f <hostfile_gpchecknet> | -h <hostname> [-h hostname ...]}
  [ -r n|N|M [--duration <time>] [--netperf] ] [-D] [-v | -V]

gpcheckperf -?
```

```
gpcheckperf --version
```

## Description

The `gpcheckperf` utility starts a session on the specified hosts and runs the following performance tests:

- **Disk I/O Test (dd test)** — To test the sequential throughput performance of a logical disk or file system, the utility uses the `dd` command, which is a standard UNIX utility. It times how long it takes to write and read a large file to and from disk and calculates your disk I/O performance in megabytes (MB) per second. By default, the file size that is used for the test is calculated at two times the total random access memory (RAM) on the host. This ensures that the test is truly testing disk I/O and not using the memory cache.
- **Memory Bandwidth Test (stream)** — To test memory bandwidth, the utility uses the `STREAM` benchmark program to measure sustainable memory bandwidth (in MB/s). This tests that your system is not limited in performance by the memory bandwidth of the system in relation to the computational performance of the CPU. In applications where the data set is large (as in Greenplum Database), low memory bandwidth is a major performance issue. If memory bandwidth is significantly lower than the theoretical bandwidth of the CPU, then it can cause the CPU to spend significant amounts of time waiting for data to arrive from system memory.
- **Network Performance Test (gpnetbench\*)** — To test network performance (and thereby the performance of the Greenplum Database interconnect), the utility runs a network benchmark program that transfers a 5 second stream of data from the current host to each remote host included in the test. The data is transferred in parallel to each remote host and the minimum, maximum, average and median network transfer rates are reported in megabytes (MB) per second. If the summary transfer rate is slower than expected (less than 100 MB/s), you can run the network test serially using the `-r n` option to obtain per-host results. To run a full-matrix bandwidth test, you can specify `-r M` which will cause every host to send and receive data from every other host specified. This test is best used to validate if the switch fabric can tolerate a full-matrix workload.

To specify the hosts to test, use the `-f` option to specify a file containing a list of host names, or use the `-h` option to name single host names on the command-line. If running the network performance test, all entries in the host file must be for network interfaces within the same subnet. If your segment hosts have multiple network interfaces configured on different subnets, run the network test once for each subnet.

You must also specify at least one test directory (with `-d`). The user who runs `gpcheckperf` must have write access to the specified test directories on all remote hosts. For the disk I/O test, the test directories should correspond to your segment data directories (primary and/or mirrors). For the memory bandwidth and network tests, a temporary directory is required for the test program files.

Before using `gpcheckperf`, you must have a trusted host setup between the hosts involved in the performance test. You can use the utility `gpssh-exkeys` to update the known host files and exchange public keys between hosts if you have not done so already. Note that `gpcheckperf` calls to `gpssh` and `gpscp`, so these Greenplum utilities must also be in your `$PATH`.

## Options

### -B block\_size

Specifies the block size (in KB or MB) to use for disk I/O test. The default is 32KB, which is the same as the Greenplum Database page size. The maximum block size is 1 MB.

### -d test\_directory

For the disk I/O test, specifies the file system directory locations to test. You must have write access to the test directory on all hosts involved in the performance test. You can use the `-d` option multiple times to specify multiple test directories (for example, to test disk I/O of your primary and mirror data directories).

### -d temp\_directory

For the network and stream tests, specifies a single directory where the test program files will be copied for the duration of the test. You must have write access to this directory on all hosts involved in the test.

### -D (display per-host results)

Reports performance results for each host for the disk I/O tests. The default is to report results for just the hosts with the minimum and maximum performance, as well as the total and average performance of all hosts.

### --duration time

Specifies the duration of the network test in seconds (s), minutes (m), hours (h), or days (d). The default is 15 seconds.

### -f hostfile\_gpcheckperf

For the disk I/O and stream tests, specifies the name of a file that contains one host name per host that will participate in the performance test. The host name is required, and you can optionally specify an alternate user name and/or SSH port number per host. The syntax of the host file is one host per line as follows:

```
[<username>@]<hostname>[:<ssh_port>]
```

### -f hostfile\_gpchecknet

For the network performance test, all entries in the host file must be for host addresses within the same subnet. If your segment hosts have multiple network interfaces configured on different subnets, run the network test once for each subnet. For example (a host file containing segment host address names for interconnect subnet 1):

```
sdw1-1
sdw2-1
sdw3-1
```

### -h hostname

Specifies a single host name (or host address) that will participate in the performance test. You can use the `-h` option multiple times to specify multiple host names.

### --netperf

Specifies that the `netperf` binary should be used to perform the network test instead of the Greenplum network test. To use this option, you must download `netperf` from <https://github.com/HewlettPackard/netperf> and install it into `$GPHOME/bin/lib` on all Greenplum hosts (master and segments).

### -r ds{n|N|M}

Specifies which performance tests to run. The default is `dsn`:

- Disk I/O test (`d`)
- Stream test (`s`)
- Network performance test in sequential (`n`), parallel (`N`), or full-matrix (`M`) mode. The optional `--duration` option specifies how long (in seconds) to run the network test. To use the parallel (`N`) mode, you must run the test on an even number of hosts.

If you would rather use `netperf` (<https://github.com/HewlettPackard/netperf>) instead of the Greenplum network test, you can download it and install it into `$GPHOME/bin/lib` on all Greenplum hosts (master and segments). You would then specify the optional `--netperf` option to use the `netperf` binary instead of the default `gpnetbench*` utilities.

`-S file_size`

Specifies the total file size to be used for the disk I/O test for all directories specified with `-d`. `file_size` should equal two times total RAM on the host. If not specified, the default is calculated at two times the total RAM on the host where `gpcheckperf` is run. This ensures that the test is truly testing disk I/O and not using the memory cache. You can specify sizing in KB, MB, or GB.

`-v (verbose) | -V (very verbose)`

Verbose mode shows progress and status messages of the performance tests as they are run. Very verbose mode shows all output messages generated by this utility.

`--version`

Displays the version of this utility.

`-? (help)`

Displays the online help.

## Examples

Run the disk I/O and memory bandwidth tests on all the hosts in the file `host_file` using the test directory of `/data1` and `/data2`:

```
$ gpcheckperf -f hostfile_gpcheckperf -d /data1 -d /data2 -r ds
```

Run only the disk I/O test on the hosts named `sdw1` and `sdw2` using the test directory of `/data1`. Show individual host results and run in verbose mode:

```
$ gpcheckperf -h sdw1 -h sdw2 -d /data1 -r d -D -v
```

Run the parallel network test using the test directory of `/tmp`, where `hostfile_gpchecknet_ic*` specifies all network interface host address names within the same interconnect subnet:

```
$ gpcheckperf -f hostfile_gpchecknet_ic1 -r N -d /tmp
$ gpcheckperf -f hostfile_gpchecknet_ic2 -r N -d /tmp
```

Run the same test as above, but use `netperf` instead of the Greenplum network test (note that `netperf` must be installed in `$GPHOME/bin/lib` on all Greenplum hosts):

```
$ gpcheckperf -f hostfile_gpchecknet_ic1 -r N --netperf -d /tmp
$ gpcheckperf -f hostfile_gpchecknet_ic2 -r N --netperf -d /tmp
```

## See Also

[gpssh](#), [gpscp](#)

## gpconfig

Sets server configuration parameters on all segments within a Greenplum Database system.

## Synopsis

```
gpconfig -c <param_name> -v <value> [-m <master_value> | --masteronly]
| -r <param_name> [--masteronly]
| -l
| [--skipvalidation] [--verbose] [--debug]

gpconfig -s <param_name> [--file | --file-compare] [--verbose] [--debug]

gpconfig --help
```

## Description

The `gpconfig` utility allows you to set, unset, or view configuration parameters from the `postgresql.conf` files of all instances (master, segments, and mirrors) in your Greenplum Database system. When setting a parameter, you can also specify a different value for the master if necessary. For example, parameters such as `max_connections` require a different setting on the master than what is used for the segments. If you want to set or unset a global or master only parameter, use the `--masteronly` option.

**Note:** For configuration parameters of vartype `string`, you may not pass values enclosed in single quotes to `gpconfig -c`.

`gpconfig` can only be used to manage certain parameters. For example, you cannot use it to set parameters such as `port`, which is required to be distinct for every segment instance. Use the `-l` (list) option to see a complete list of configuration parameters supported by `gpconfig`.

When `gpconfig` sets a configuration parameter in a segment `postgresql.conf` file, the new parameter setting always displays at the bottom of the file. When you use `gpconfig` to remove a configuration parameter setting, `gpconfig` comments out the parameter in all segment `postgresql.conf` files, thereby restoring the system default setting. For example, if you use `gpconfig` to remove (comment out) a parameter and later add it back (set a new value), there will be two instances of the parameter; one that is commented out, and one that is enabled and inserted at the bottom of the `postgresql.conf` file.

After setting a parameter, you must restart your Greenplum Database system or reload the `postgresql.conf` files in order for the change to take effect. Whether you require a restart or a reload depends on the parameter.

For more information about the server configuration parameters, see the *Greenplum Database Reference Guide*.

To show the currently set values for a parameter across the system, use the `-s` option.

`gpconfig` uses the following environment variables to connect to the Greenplum Database master instance and obtain system configuration information:

- `PGHOST`
- `PGPORT`
- `PGUSER`
- `PGPASSWORD`
- `PGDATABASE`

## Options

`-c | --change param_name`

Changes a configuration parameter setting by adding the new setting to the bottom of the `postgresql.conf` files.

`-v | --value value`

The value to use for the configuration parameter you specified with the `-c` option. By default, this value is applied to all segments, their mirrors, the master, and the standby master.

The utility correctly quotes the value when adding the setting to the `postgresql.conf` files.

To set the value to an empty string, enter empty single quotes (`''`).

`-m | --mastervalue master_value`

The master value to use for the configuration parameter you specified with the `-c` option. If specified, this value only applies to the master and standby master. This option can only be used with `-v`.

`--masteronly`

When specified, `gpconfig` will only edit the master `postgresql.conf` file.

`-r | --remove param_name`

Removes a configuration parameter setting by commenting out the entry in the `postgresql.conf` files.

`-l | --list`

Lists all configuration parameters supported by the `gpconfig` utility.

`-s | --show param_name`

Shows the value for a configuration parameter used on all instances (master and segments) in the Greenplum Database system. If there is a difference in a parameter value among the instances, the utility displays an error message. Running `gpconfig` with the `-s` option reads parameter values directly from the database, and not the `postgresql.conf` file. If you are using `gpconfig` to set configuration parameters across all segments, then running `gpconfig -s` to verify the changes, you might still see the previous (old) values. You must reload the configuration files (`gpstop -u`) or restart the system (`gpstop -r`) for changes to take effect.

`--file`

For a configuration parameter, shows the value from the `postgresql.conf` file on all instances (master and segments) in the Greenplum Database system. If there is a difference in a

parameter value among the instances, the utility displays a message. Must be specified with the `-s` option.

For example, the configuration parameter `statement_mem` is set to 64MB for a user with the `ALTER ROLE` command, and the value in the `postgresql.conf` file is 128MB. Running the command `gpconfig -s statement_mem --file` displays 128MB. The command `gpconfig -s statement_mem` run by the user displays 64MB.

Not valid with the `--file-compare` option.

#### `--file-compare`

For a configuration parameter, compares the current Greenplum Database value with the value in the `postgresql.conf` files on hosts (master and segments). The values in the `postgresql.conf` files represent the value when Greenplum Database is restarted.

If the values are not the same, the utility displays the values from all hosts. If all hosts have the same value, the utility displays a summary report.

Not valid with the `--file` option.

#### `--skipvalidation`

Overrides the system validation checks of `gpconfig` and allows you to operate on any server configuration parameter, including hidden parameters and restricted parameters that cannot be changed by `gpconfig`. When used with the `-l` option (list), it shows the list of restricted parameters.

**Warning:** Use extreme caution when setting configuration parameters with this option.

#### `--verbose`

Displays additional log information during `gpconfig` command execution.

#### `--debug`

Sets logging output to debug level.

#### `-? | -h | --help`

Displays the online help.

## Examples

Set the `max_connections` setting to 100 on all segments and 10 on the master:

```
gpconfig -c max_connections -v 100 -m 10
```

These examples shows the syntax required due to bash shell string processing.

```
gpconfig -c search_path -v '"$user",public'
gpconfig -c dynamic_library_path -v '$libdir'
```

The configuration parameters are added to the `postgresql.conf` file.

```
search_path='"$user",public'
dynamic_library_path='$libdir'
```

Comment out all instances of the `default_statistics_target` configuration parameter, and restore the system default:

```
gpconfig -r default_statistics_target
```

List all configuration parameters supported by `gpconfig`:

```
gpconfig -l
```

Show the values of a particular configuration parameter across the system:

```
gpconfig -s max_connections
```

## See Also

[gpstop](#)

## gpcopy

The `gpcopy` utility copies objects from databases in a source Greenplum Database system to databases in a destination Greenplum Database system.

**Note:** The `gpcopy` utility is available as a separate download for the commercial release of Tanzu Greenplum. See the [Tanzu Greenplum Copy Utility Documentation](#).

## gpdeletesystem

Deletes a Greenplum Database system that was initialized using `gpinitssystem`.

## Synopsis

```
gpdeletesystem [-d <master_data_directory>] [-B <parallel_processes>]
  [-f] [-l <logfile_directory>] [-D]

gpdeletesystem -?

gpdeletesystem -v
```

## Description

The `gpdeletesystem` utility performs the following actions:

- Stop all `postgres` processes (the segment instances and master instance).
- Deletes all data directories.

Before running `gpdeletesystem`:

- Move any backup files out of the master and segment data directories.
- Make sure that Greenplum Database is running.
- If you are currently in a segment data directory, change directory to another location. The utility fails with an error when run from within a segment data directory.

This utility will not uninstall the Greenplum Database software.

## Options

**-d** master\_data\_directory

Specifies the master host data directory. If this option is not specified, the setting for the environment variable `MASTER_DATA_DIRECTORY` is used. If this option is specified, it overrides any setting of `MASTER_DATA_DIRECTORY`. If `master_data_directory` cannot be determined, the utility returns an error.

**-B** parallel\_processes

The number of segments to delete in parallel. If not specified, the utility will start up to 60 parallel processes depending on how many segment instances it needs to delete.

**-f** (force)

Force a delete even if backup files are found in the data directories. The default is to not delete Greenplum Database instances if backup files are present.

**-l** logfile\_directory

The directory to write the log file. Defaults to `~/gpAdminLogs`.

**-D** (debug)

Sets logging level to debug.

**-?** (help)

Displays the online help.

**-v** (show utility version)

Displays the version, status, last updated date, and check sum of this utility.

## Examples

Delete a Greenplum Database system:

```
gpdeletesystem -d /gpdata/gp-1
```

Delete a Greenplum Database system even if backup files are present:

```
gpdeletesystem -d /gpdata/gp-1 -f
```

## See Also

[gpinitssystem](#)

## gpexpand

Expands an existing Greenplum Database across new hosts in the system.

## Synopsis

```
gpexpand [{-f|--hosts-file} <hosts_file>]
         | {-i|--input} <input_file> [-B <batch_size>]
         | [{-d | --duration} <hh:mm:ss> | {-e|--end} '<YYYY-MM-DD hh:mm:ss>']
         [-a|--analyze]
```

```

    [-n <parallel_processes>]
    | {-r|--rollback}
    | {-c|--clean}
    [-v|--verbose] [-s|--silent]
    [{-t|--tardir} <directory> ]
    [-S|--simple-progress ]

gpexpand -? | -h | --help

gpexpand --version

```

## Prerequisites

- You are logged in as the Greenplum Database superuser (`gpadmin`).
- The new segment hosts have been installed and configured as per the existing segment hosts. This involves:
  - Configuring the hardware and OS
  - Installing the Greenplum software
  - Creating the `gpadmin` user account
  - Exchanging SSH keys.
- Enough disk space on your segment hosts to temporarily hold a copy of your largest table.
- When redistributing data, Greenplum Database must be running in production mode. Greenplum Database cannot be running in restricted mode or in master mode. The `gpstart` options `-R` or `-m` cannot be specified to start Greenplum Database.

**Note:** These utilities cannot be run while `gpexpand` is performing segment initialization.

- `gpbackup`
- `gpcheckcat`
- `gpconfig`
- `gppkg`
- `gprestore`

**Important:** When expanding a Greenplum Database system, you must deactivate Greenplum interconnect proxies before adding new hosts and segment instances to the system, and you must update the `gp_interconnect_proxy_addresses` parameter with the newly-added segment instances before you re-enable interconnect proxies. For information about Greenplum interconnect proxies, see [Configuring Proxies for the Greenplum Interconnect](#).

For information about preparing a system for expansion, see [Expanding a Greenplum System](#) in the *Greenplum Database Administrator Guide*.

## Description

The `gpexpand` utility performs system expansion in two phases: segment instance initialization and then table data redistribution.

In the initialization phase, `gpexpand` runs with an input file that specifies data directories, dbid values, and other characteristics of the new segment instances. You can create the input file manually, or by following the prompts in an interactive interview.

If you choose to create the input file using the interactive interview, you can optionally specify a file containing a list of expansion system hosts. If your platform or command shell limits the length of the list of hostnames that you can type when prompted in the interview, specifying the hosts with `-f` may be mandatory.

In addition to initializing the segment instances, the initialization phase performs these actions:

- Creates an expansion schema named `gpexpand` in the postgres database to store the status of the expansion operation, including detailed status for tables.

In the table data redistribution phase, `gpexpand` redistributes table data to rebalance the data across the old and new segment instances.

**Note:** Data redistribution should be performed during low-use hours. Redistribution can be divided into batches over an extended period.

To begin the redistribution phase, run `gpexpand` with either the `-d` (duration) or `-e` (end time) options, or with no options. If you specify an end time or duration, then the utility redistributes tables in the expansion schema until the specified end time or duration is reached. If you specify no options, then the utility redistribution phase continues until all tables in the expansion schema are reorganized. Each table is reorganized using `ALTER TABLE` commands to rebalance the tables across new segments, and to set tables to their original distribution policy. If `gpexpand` completes the reorganization of all tables, it displays a success message and ends.

**Note:** This utility uses secure shell (SSH) connections between systems to perform its tasks. In large Greenplum Database deployments, cloud deployments, or deployments with a large number of segments per host, this utility may exceed the host's maximum threshold for unauthenticated connections. Consider updating the SSH `MaxStartups` and `MaxSessions` configuration parameters to increase this threshold. For more information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

## Options

`-a` | `--analyze`

Run `ANALYZE` to update the table statistics after expansion. The default is to not run `ANALYZE`.

`-B` `batch_size`

Batch size of remote commands to send to a given host before making a one-second pause. Default is `16`. Valid values are 1-128.

The `gpexpand` utility issues a number of setup commands that may exceed the host's maximum threshold for unauthenticated connections as defined by `MaxStartups` in the SSH daemon configuration. The one-second pause allows authentications to be completed before `gpexpand` issues any more commands.

The default value does not normally need to be changed. However, it may be necessary to reduce the maximum number of commands if `gpexpand` fails with connection errors such as `'ssh_exchange_identification: Connection closed by remote host.'`

`-c` | `--clean`

Remove the expansion schema.

`-d | --duration hh:mm:ss`

Duration of the expansion session from beginning to end.

`-e | --end 'YYYY-MM-DD hh:mm:ss'`

Ending date and time for the expansion session.

`-f | --hosts-file filename`

Specifies the name of a file that contains a list of new hosts for system expansion. Each line of the file must contain a single host name.

This file can contain hostnames with or without network interfaces specified. The `gpexpand` utility handles either case, adding interface numbers to end of the hostname if the original nodes are configured with multiple network interfaces.

**Note:** The Greenplum Database segment host naming convention is `sdwN` where `sdw` is a prefix and `N` is an integer. For example, `sdw1`, `sdw2` and so on. For hosts with multiple interfaces, the convention is to append a dash (-) and number to the host name. For example, `sdw1-1` and `sdw1-2` are the two interface names for host `sdw1`.

For information about using a hostname or IP address, see [Specifying Hosts using Hostnames or IP Addresses](#). Also, see [Using Host Systems with Multiple NICs](#).

`-i | --input input_file`

Specifies the name of the expansion configuration file, which contains one line for each segment to be added in the format of:

```
hostname|address|port|datadir|dbid|content|preferred_role
```

`-n parallel_processes`

The number of tables to redistribute simultaneously. Valid values are 1 - 96.

Each table redistribution process requires two database connections: one to alter the table, and another to update the table's status in the expansion schema. Before increasing `-n`, check the current value of the server configuration parameter `max_connections` and make sure the maximum connection limit is not exceeded.

`-r | --rollback`

Roll back a failed expansion setup operation.

`-s | --silent`

Runs in silent mode. Does not prompt for confirmation to proceed on warnings.

`-S | --simple-progress`

If specified, the `gpexpand` utility records only the minimum progress information in the Greenplum Database table `gpexpand.expansion_progress`. The utility does not record the relation size information and status information in the table `gpexpand.status_detail`.

Specifying this option can improve performance by reducing the amount of progress information written to the `gpexpand` tables.

`[-t | --tardir] directory`

The fully qualified path to a directory on segment hosts where the `gpexpand` utility copies a temporary tar file. The file contains Greenplum Database files that are used to create segment instances. The default directory is the user home directory.

`-v | --verbose`

Verbose debugging output. With this option, the utility will output all DDL and DML used to expand the database.

--version

Display the utility's version number and exit.

-? | -h | --help

Displays the online help.

## Specifying Hosts using Hostnames or IP Addresses

When expanding a Greenplum Database system, you can specify either a hostname or an IP address for the value.

- If you specify a hostname, the resolution of the hostname to an IP address should be done locally for security. For example, you should use entries in a local `/etc/hosts` file to map a hostname to an IP address. The resolution of a hostname to an IP address should not be performed by an external service such as a public DNS server. You must stop the Greenplum system before you change the mapping of a hostname to a different IP address.
- If you specify an IP address, the address should not be changed after the initial configuration. When segment mirroring is enabled, replication from the primary to the mirror segment will fail if the IP address changes from the configured value. For this reason, you should use a hostname when expanding a Greenplum Database system unless you have a specific requirement to use IP addresses.

When expanding a Greenplum system, `gpexpand` populates `gp_segment_configuration` catalog table with the new segment instance information. Greenplum Database uses the `address` value of the `gp_segment_configuration` catalog table when looking up host systems for Greenplum interconnect (internal) communication between the master and segment instances and between segment instances, and for other internal communication.

## Using Host Systems with Multiple NICs

If host systems are configured with multiple NICs, you can expand a Greenplum Database system to use each NIC as a Greenplum host system. You must ensure that the host systems are configured with sufficient resources to support all the segment instances being added to the host. Also, if you enable segment mirroring, you must ensure that the expanded Greenplum system configuration supports failover if a host system fails. For information about Greenplum Database mirroring schemes, see [GUID-best\\_practices-ha.html#topic\\_ngz\\_qf4\\_tt](#).

For example, this is a `gpexpand` configuration file for a simple Greenplum system. The segment host `gp6s1` and `gp6s2` are configured with two NICs, `-s1` and `-s2`, where the Greenplum Database system uses each NIC as a host system.

```
gp6s1-s2|gp6s1-s2|40001|/data/data1/gpseg2|6|2|p
gp6s2-s1|gp6s2-s1|50000|/data/mirror1/gpseg2|9|2|m
gp6s2-s1|gp6s2-s1|40000|/data/data1/gpseg3|7|3|p
gp6s1-s2|gp6s1-s2|50001|/data/mirror1/gpseg3|8|3|m
```

## Examples

Run `gpexpand` with an input file to initialize new segments and create the expansion schema in the postgres database:

```
$ gpexpand -i input_file
```

Run `gpexpand` for sixty hours maximum duration to redistribute tables to new segments:

```
$ gpexpand -d 60:00:00
```

## gpfdist

Serves data files to or writes data files out from Greenplum Database segments.

## Synopsis

```
gpfdist [-d <directory>] [-p <http_port>] [-P <last_http_port>] [-l <log_file>]
  [-t <timeout>] [-S] [-w <time>] [-v | -V] [-s] [-m <max_length>]
  [--ssl <certificate_path> [--sslclean <wait_time>] ]
  [-c <config.yml>]

gpfdist -? | --help

gpfdist --version
```

## Description

`gpfdist` is Greenplum Database parallel file distribution program. It is used by readable external tables and `gpload` to serve external table files to all Greenplum Database segments in parallel. It is used by writable external tables to accept output streams from Greenplum Database segments in parallel and write them out to a file.

**Note:** `gpfdist` and `gpload` are compatible only with the Greenplum Database major version in which they are shipped. For example, a `gpfdist` utility that is installed with Greenplum Database 4.x cannot be used with Greenplum Database 5.x or 6.x.

In order for `gpfdist` to be used by an external table, the `LOCATION` clause of the external table definition must specify the external table data using the `gpfdist://` protocol (see the Greenplum Database command `CREATE EXTERNAL TABLE`).

**Note:** If the `--ssl` option is specified to enable SSL security, create the external table with the `gpfdists://` protocol.

The benefit of using `gpfdist` is that you are guaranteed maximum parallelism while reading from or writing to external tables, thereby offering the best performance as well as easier administration of external tables.

For readable external tables, `gpfdist` parses and serves data files evenly to all the segment instances in the Greenplum Database system when users `SELECT` from the external table. For writable external tables, `gpfdist` accepts parallel output streams from the segments when users `INSERT` into the external table, and writes to an output file.

**Note:** When `gpfdist` reads data and encounters a data formatting error, the error message includes a row number indicating the location of the formatting error. `gpfdist` attempts to capture the row that contains the error. However, `gpfdist` might not capture the exact row for some formatting errors.

For readable external tables, if load files are compressed using `gzip`, `bzip2`, or `zstd` (have a `.gz`, `.bz2`, or `.zst` file extension), `gpfdist` uncompresses the data while loading the data (on the fly). For writable external tables, `gpfdist` compresses the data using `gzip` if the target file has a `.gz` extension, `bzip` if the target file has a `.bz2` extension, or `zstd` if the target file has a `.zst` extension.

**Note:** Compression is not supported for readable and writeable external tables when the `gpfdist` utility runs on Windows platforms.

When reading or writing data with the `gpfdist` or `gpfdists` protocol, Greenplum Database includes `X-GP-PROTO` in the HTTP request header to indicate that the request is from Greenplum Database. The utility rejects HTTP requests that do not include `X-GP-PROTO` in the request header.

Most likely, you will want to run `gpfdist` on your ETL machines rather than the hosts where Greenplum Database is installed. To install `gpfdist` on another host, simply copy the utility over to that host and add `gpfdist` to your `$PATH`.

**Note:** When using IPv6, always enclose the numeric IP address in brackets.

## Options

`-d` directory

The directory from which `gpfdist` will serve files for readable external tables or create output files for writable external tables. If not specified, defaults to the current directory.

`-l` log\_file

The fully qualified path and log file name where standard output messages are to be logged.

`-p` http\_port

The HTTP port on which `gpfdist` will serve files. Defaults to 8080.

`-P` last\_http\_port

The last port number in a range of HTTP port numbers (`http_port` to `last_http_port`, inclusive) on which `gpfdist` will attempt to serve files. `gpfdist` serves the files on the first port number in the range to which it successfully binds.

`-t` timeout

Sets the time allowed for Greenplum Database to establish a connection to a `gpfdist` process. Default is 5 seconds. Allowed values are 2 to 7200 seconds (2 hours). May need to be increased on systems with a lot of network traffic.

`-m` max\_length

Sets the maximum allowed data row length in bytes. Default is 32768. Should be used when user data includes very wide rows (or when `line too long` error message occurs). Should not be used otherwise as it increases resource allocation. Valid range is 32K to 256MB. (The upper limit is 1MB on Windows systems.)

**Note:** Memory issues might occur if you specify a large maximum row length and run a large number of `gpfdist` concurrent connections. For example, setting this value to the maximum of 256MB with 96 concurrent `gpfdist` processes requires approximately 24GB of memory  $((96 + 1) \times 246\text{MB})$ .

-S

Enables simplified logging. When this option is specified, only messages with `WARN` level and higher are written to the `gpfdist` log file. `INFO` level messages are not written to the log file. If this option is not specified, all `gpfdist` messages are written to the log file.

You can specify this option to reduce the information written to the log file.

-S (use `O_SYNC`)

Opens the file for synchronous I/O with the `O_SYNC` flag. Any writes to the resulting file descriptor block `gpfdist` until the data is physically written to the underlying hardware.

-w time

Sets the number of seconds that Greenplum Database delays before closing a target file such as a named pipe. The default value is 0, no delay. The maximum value is 7200 seconds (2 hours).

For a Greenplum Database with multiple segments, there might be a delay between segments when writing data from different segments to the file. You can specify a time to wait before Greenplum Database closes the file to ensure all the data is written to the file.

--ssl certificate\_path

Adds SSL encryption to data transferred with `gpfdist`. After running `gpfdist` with the `--ssl certificate_path` option, the only way to load data from this file server is with the `gpfdist://` protocol. For information on the `gpfdist://` protocol, see "Loading and Unloading Data" in the *Greenplum Database Administrator Guide*.

The location specified in `certificate_path` must contain the following files:

- The server certificate file, `server.crt`
- The server private key file, `server.key`
- The trusted certificate authorities, `root.crt`

The root directory (`/`) cannot be specified as `certificate_path`.

--sslclean wait\_time

When the utility is run with the `--ssl` option, sets the number of seconds that the utility delays before closing an SSL session and cleaning up the SSL resources after it completes writing data to or from a Greenplum Database segment. The default value is 0, no delay. The maximum value is 500 seconds. If the delay is increased, the transfer speed decreases.

In some cases, this error might occur when copying large amounts of data: `gpfdist server closed connection`. To avoid the error, you can add a delay, for example `--sslclean 5`.

-c config.yaml

Specifies rules that `gpfdist` uses to select a transform to apply when loading or extracting data. The `gpfdist` configuration file is a YAML 1.1 document.

For information about the file format, see [Configuration File Format](#) in the *Greenplum Database Administrator Guide*. For information about configuring data transformation with

`gpfdist`, see [Transforming External Data with gpfdist and gpload](#) in the *Greenplum Database Administrator Guide*.

This option is not available on Windows platforms.

`-v` (verbose)

Verbose mode shows progress and status messages.

`-V` (very verbose)

Verbose mode shows all output messages generated by this utility.

`-?` (help)

Displays the online help.

`--version`

Displays the version of this utility.

## Notes

The server configuration parameter `verify_gpfdists_cert` controls whether SSL certificate authentication is enabled when Greenplum Database communicates with the `gpfdist` utility to either read data from or write data to an external data source. You can set the parameter value to `false` to deactivate authentication when testing the communication between the Greenplum Database external table and the `gpfdist` utility that is serving the external data. If the value is `false`, these SSL exceptions are ignored:

- The self-signed SSL certificate that is used by `gpfdist` is not trusted by Greenplum Database.
- The host name contained in the SSL certificate does not match the host name that is running `gpfdist`.

**Warning:** Deactivating SSL certificate authentication exposes a security risk by not validating the `gpfdists` SSL certificate.

You can set the server configuration parameter `gpfdist_retry_timeout` to control the time that Greenplum Database waits before returning an error when a `gpfdist` server does not respond while Greenplum Database is attempting to write data to `gpfdist`. The default is 300 seconds (5 minutes).

If the `gpfdist` utility hangs with no read or write activity occurring, you can generate a core dump the next time a hang occurs to help debug the issue. Set the environment variable `GPFDIST_WATCHDOG_TIMER` to the number of seconds of no activity to wait before `gpfdist` is forced to exit. When the environment variable is set and `gpfdist` hangs, the utility is stopped after the specified number of seconds, creates a core dump, and sends relevant information to the log file.

This example sets the environment variable on a Linux system so that `gpfdist` exits after 300 seconds (5 minutes) of no activity.

```
export GPFDIST_WATCHDOG_TIMER=300
```

## Examples

To serve files from a specified directory using port 8081 (and start `gpfdist` in the background):

```
gpfdist -d /var/load_files -p 8081 &
```

To start `gpfdist` in the background and redirect output and errors to a log file:

```
gpfdist -d /var/load_files -p 8081 -l /home/gpadmin/log &
```

To stop `gpfdist` when it is running in the background:

--First find its process id:

```
ps ax | grep gpfdist
```

--Then stop the process, for example:

```
kill 3456
```

## gpinitstandby

Adds and/or initializes a standby master host for a Greenplum Database system.

## Synopsis

```
gpinitstandby { -s <standby_hostname> [-P port] | -r | -n } [-a] [-q]
  [-D] [-S <standby_data_directory>] [-l <logfile_directory>]
  [--hba-hostnames <boolean>]

gpinitstandby -v

gpinitstandby -?
```

## Description

The `gpinitstandby` utility adds a backup, standby master instance to your Greenplum Database system. If your system has an existing standby master instance configured, use the `-r` option to remove it before adding the new standby master instance.

Before running this utility, make sure that the Greenplum Database software is installed on the standby master host and that you have exchanged SSH keys between the hosts. It is recommended that the master port is set to the same port number on the master host and the standby master host.

This utility should be run on the currently active *primary* master host. See the *Greenplum Database Installation Guide* for instructions.

The utility performs the following steps:

- Updates the Greenplum Database system catalog to remove the existing standby master information (if the `-r` option is supplied)
- Updates the Greenplum Database system catalog to add the new standby master instance information
- Edits the `pg_hba.conf` file of the Greenplum Database master to allow access from the newly added standby master
- Sets up the standby master instance on the alternate master host
- Starts the synchronization process

A backup, standby master instance serves as a 'warm standby' in the event of the primary master becoming non-operational. The standby master is kept up to date by transaction log replication processes (the `walsender` and `walreceiver`), which run on the primary master and standby master hosts and keep the data between the primary and standby master instances synchronized. If the primary master fails, the log replication process is shut down, and the standby master can be activated in its place by using the `gpactivatestandby` utility. Upon activation of the standby master, the replicated logs are used to reconstruct the state of the master instance at the time of the last successfully committed transaction.

The activated standby master effectively becomes the Greenplum Database master, accepting client connections on the master port and performing normal master operations such as SQL command processing and resource management.

**Important:** If the `gpinitstandby` utility previously failed to initialize the standby master, you must delete the files in the standby master data directory before running `gpinitstandby` again. The standby master data directory is not cleaned up after an initialization failure because it contains log files that can help in determining the reason for the failure.

If an initialization failure occurs, a summary report file is generated in the standby host directory `/tmp`. The report file lists the directories on the standby host that require clean up.

## Options

`-a` (do not prompt)

Do not prompt the user for confirmation.

`-D` (debug)

Sets logging level to debug.

`--hba-hostnames` boolean

Optional. Controls whether this utility uses IP addresses or host names in the `pg_hba.conf` file when updating this file with addresses that can connect to Greenplum Database. When set to 0 -- the default value -- this utility uses IP addresses when updating this file. When set to 1, this utility uses host names when updating this file. For consistency, use the same value that was specified for `HBA_HOSTNAMES` when the Greenplum Database system was initialized. For information about how Greenplum Database resolves host names in the `pg_hba.conf` file, see [Configuring Client Authentication](#).

`-l logfile_directory`

The directory to write the log file. Defaults to `~/gpAdminLogs`.

`-n` (restart standby master)

Specify this option to start a Greenplum Database standby master that has been configured but has stopped for some reason.

**-P port**

This option specifies the port that is used by the Greenplum Database standby master. The default is the same port used by the active Greenplum Database master.

If the Greenplum Database standby master is on the same host as the active master, the ports must be different. If the ports are the same for the active and standby master and the host is the same, the utility returns an error.

**-q (no screen output)**

Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

**-r (remove standby master)**

Removes the currently configured standby master instance from your Greenplum Database system.

**-s standby\_hostname**

The host name of the standby master host.

**-S standby\_data\_directory**

The data directory to use for a new standby master. The default is the same directory used by the active master.

If the standby master is on the same host as the active master, a different directory must be specified using this option.

**-v (show utility version)**

Displays the version, status, last updated date, and checksum of this utility.

**-? (help)**

Displays the online help.

## Examples

Add a standby master instance to your Greenplum Database system and start the synchronization process:

```
gpinitstandby -s host09
```

Start an existing standby master instance and synchronize the data with the current primary master instance:

```
gpinitstandby -n
```

**Note:** Do not specify the `-n` and `-s` options in the same command.

Add a standby master instance to your Greenplum Database system specifying a different port:

```
gpinitstandby -s myhost -P 2222
```

If you specify the same host name as the active Greenplum Database master, you must also specify a different port number with the `-P` option and a standby data directory with the `-S` option.

Remove the existing standby master from your Greenplum system configuration:

```
gpinitstandby -r
```

## See Also

## gpinitssystem

Initializes a Greenplum Database system using configuration parameters specified in the `gpinitssystem_config` file.

## Synopsis

```
gpinitssystem -c <cluster_configuration_file>
               [-h <hostfile_gpinitssystem>]
               [-B <parallel_processes>]
               [-p <postgresql_conf_param_file>]
               [-s <standby_master_host>
                 [-P <standby_master_port>]
                 [-S <standby_master_datadir> | --standby_datadir=<standby_master_datad
ir>]]
               [--ignore-warnings]
               [-m <number> | --max_connections=number]
               [-b <size> | --shared_buffers=<size>]
               [-n <locale> | --locale=<locale>] [--lc-collate=<locale>]
               [--lc-ctype=<locale>] [--lc-messages=<locale>]
               [--lc-monetary=<locale>] [--lc-numeric=<locale>]
               [--lc-time=<locale>] [-e <password> | --su_password=<password>]
               [--mirror-mode={group|spread}] [-a] [-q] [-l <logfile_directory>] [-D]
               [-I <input_configuration_file>]
               [-O <output_configuration_file>]

gpinitssystem -v | --version

gpinitssystem -? | --help
```

## Description

The `gpinitssystem` utility creates a Greenplum Database instance or writes an input configuration file using the values defined in a cluster configuration file and any command-line options that you provide. See [Initialization Configuration File Format](#) for more information about the configuration file. Before running this utility, make sure that you have installed the Greenplum Database software on all the hosts in the array.

With the `<-O output_configuration_file>` option, `gpinitssystem` writes all provided configuration information to the specified output file. This file can be used with the `-I` option to create a new cluster or re-create a cluster from a backed up configuration. See [Initialization Configuration File Format](#) for more information.

In a Greenplum Database DBMS, each database instance (the master instance and all segment instances) must be initialized across all of the hosts in the system in such a way that they can all

work together as a unified DBMS. The `gpinitssystem` utility takes care of initializing the Greenplum master and each segment instance, and configuring the system as a whole.

Before running `gpinitssystem`, you must set the `$GPHOME` environment variable to point to the location of your Greenplum Database installation on the master host and exchange SSH keys between all host addresses in the array using `gpssh-exkeys`.

This utility performs the following tasks:

- Verifies that the parameters in the configuration file are correct.
- Ensures that a connection can be established to each host address. If a host address cannot be reached, the utility will exit.
- Verifies the locale settings.
- Displays the configuration that will be used and prompts the user for confirmation.
- Initializes the master instance.
- Initializes the standby master instance (if specified).
- Initializes the primary segment instances.
- Initializes the mirror segment instances (if mirroring is configured).
- Configures the Greenplum Database system and checks for errors.
- Starts the Greenplum Database system.

**Note:** This utility uses secure shell (SSH) connections between systems to perform its tasks. In large Greenplum Database deployments, cloud deployments, or deployments with a large number of segments per host, this utility may exceed the host's maximum threshold for unauthenticated connections. Consider updating the SSH `MaxStartups` and `MaxSessions` configuration parameters to increase this threshold. For more information about SSH configuration options, refer to the SSH documentation for your Linux distribution.

## Options

-a

Do not prompt the user for confirmation.

-B parallel\_processes

The number of segments to create in parallel. If not specified, the utility will start up to 4 parallel processes at a time.

-c cluster\_configuration\_file

Required. The full path and filename of the configuration file, which contains all of the defined parameters to configure and initialize a new Greenplum Database system. See [Initialization Configuration File Format](#) for a description of this file. You must provide either the `-c <cluster_configuration_file>` option or the `-I <input_configuration_file>` option to `gpinitssystem`.

-D

Sets log output level to debug.

-h hostfile\_gpinitssystem

Optional. The full path and filename of a file that contains the host addresses of your segment hosts. If not specified on the command line, you can specify the host file using the

`MACHINE_LIST_FILE` parameter in the `gpinitssystem_config` file.

`-I input_configuration_file`

The full path and filename of an input configuration file, which defines the Greenplum Database host systems, the master instance and segment instances on the hosts, using the `QD_PRIMARY_ARRAY`, `PRIMARY_ARRAY`, and `MIRROR_ARRAY` parameters. The input configuration file is typically created by using `gpinitssystem` with the `-O output\_configuration\_file` option. Edit those parameters in order to initialize a new cluster or re-create a cluster from a backed up configuration. You must provide either the `-c <cluster_configuration_file>` option or the `-I <input_configuration_file>` option to `gpinitssystem`.

`--ignore-warnings`

Controls the value returned by `gpinitssystem` when warnings or an error occurs. The utility returns 0 if system initialization completes without warnings. If only warnings occur, system initialization completes and the system is operational.

With this option, `gpinitssystem` also returns 0 if warnings occurred during system initialization, and returns a non-zero value if a fatal error occurs.

If this option is not specified, `gpinitssystem` returns 1 if initialization completes with warnings, and returns value of 2 or greater if a fatal error occurs.

See the `gpinitssystem` log file for warning and error messages.

`-n locale | --locale=locale`

Sets the default locale used by Greenplum Database. If not specified, the default locale is `en_US.utf8`. A locale identifier consists of a language identifier and a region identifier, and optionally a character set encoding. For example, `sv_SE` is Swedish as spoken in Sweden, `en_US` is U.S. English, and `fr_CA` is French Canadian. If more than one character set can be useful for a locale, then the specifications look like this: `en_US.UTF-8` (locale specification and character set encoding). On most systems, the command `locale` will show the locale environment settings and `locale -a` will show a list of all available locales.

`--lc-collate=locale`

Similar to `--locale`, but sets the locale used for collation (sorting data). The sort order cannot be changed after Greenplum Database is initialized, so it is important to choose a collation locale that is compatible with the character set encodings that you plan to use for your data. There is a special collation name of `C` or `POSIX` (byte-order sorting as opposed to dictionary-order sorting). The `C` collation can be used with any character encoding.

`--lc-ctype=locale`

Similar to `--locale`, but sets the locale used for character classification (what character sequences are valid and how they are interpreted). This cannot be changed after Greenplum Database is initialized, so it is important to choose a character classification locale that is compatible with the data you plan to store in Greenplum Database.

`--lc-messages=locale`

Similar to `--locale`, but sets the locale used for messages output by Greenplum Database. The current version of Greenplum Database does not support multiple locales for output messages (all messages are in English), so changing this setting will not have any effect.

`--lc-monetary=locale`

Similar to `--locale`, but sets the locale used for formatting currency amounts.

`--lc-numeric=locale`

Similar to `--locale`, but sets the locale used for formatting numbers.

`--lc-time=locale`

Similar to `--locale`, but sets the locale used for formatting dates and times.

`-l logfile_directory`

The directory to write the log file. Defaults to `~/gpAdminLogs`.

`-m number | --max_connections=number`

Sets the maximum number of client connections allowed to the master. The default is 250.

`-O output_configuration_file`

Optional, used during new cluster initialization. This option writes the `cluster_configuration_file` information (used with `-c`) to the specified `output_configuration_file`. This file defines the Greenplum Database members using the `QD_PRIMARY_ARRAY`, `PRIMARY_ARRAY`, and `MIRROR_ARRAY` parameters. Use this file as a template for the `-I input_configuration_file` option. See [Examples](#) for more information.

`-p postgresql_conf_param_file`

Optional. The name of a file that contains `postgresql.conf` parameter settings that you want to set for Greenplum Database. These settings will be used when the individual master and segment instances are initialized. You can also set parameters after initialization using the `gpconfig` utility.

`-q`

Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

`-b size | --shared_buffers=size`

Sets the amount of memory a Greenplum server instance uses for shared memory buffers. You can specify sizing in kilobytes (kB), megabytes (MB) or gigabytes (GB). The default is 125MB.

`-s standby_master_host`

Optional. If you wish to configure a backup master instance, specify the host name using this option. The Greenplum Database software must already be installed and configured on this host.

`-P standby_master_port`

If you configure a standby master instance with `-s`, specify its port number using this option. The default port is the same as the master port. To run the standby and master on the same host, you must use this option to specify a different port for the standby. The Greenplum Database software must already be installed and configured on the standby host.

`-S standby_master_datadir | --standby_dir=standby_master_datadir`

If you configure a standby master host with `-s`, use this option to specify its data directory. If you configure a standby on the same host as the master instance, the master and standby must have separate data directories.

`-e superuser_password | --su_password=superuser_password`

Use this option to specify the password to set for the Greenplum Database superuser account (such as `gpadmin`). If this option is not specified, the default password `gparray` is assigned to the superuser account. You can use the `ALTER ROLE` command to change the password at a later time.

Recommended security best practices:

- Do not use the default password option for production environments.
- Change the password immediately after installation.

`--mirror-mode={groups|spread}`

Use this option to specify the placement of mirror segment instances on the segment hosts. The default, `group`, groups the mirror segments for all of a host's primary segments on a single alternate host. `spread` spreads mirror segments for the primary segments on a host across different hosts in the Greenplum Database array. Spreading is only allowed if the number of hosts is greater than the number of segment instances per host. See [Overview of Segment Mirroring](#) for information about Greenplum Database mirroring strategies.

`-v | --version`

Print the `gpinitssystem` version and exit.

`-? | --help`

Show help about `gpinitssystem` command line arguments, and exit.

## Initialization Configuration File Format

`gpinitssystem` requires a cluster configuration file with the following parameters defined. An example initialization configuration file can be found in `$GPHOME/docs/cli_help/gpconfigs/gpinitssystem_config`.

To avoid port conflicts between Greenplum Database and other applications, the Greenplum Database port numbers should not be in the range specified by the operating system parameter `net.ipv4.ip_local_port_range`. For example, if `net.ipv4.ip_local_port_range = 10000 65535`, you could set Greenplum Database base port numbers to these values.

```
PORT_BASE = 6000
MIRROR_PORT_BASE = 7000
```

**ARRAY\_NAME**

**Required.** A name for the cluster you are configuring. You can use any name you like. Enclose the name in quotes if the name contains spaces.

**MACHINE\_LIST\_FILE**

**Optional.** Can be used in place of the `-h` option. This specifies the file that contains the list of the segment host address names that comprise the Greenplum Database system. The master host is assumed to be the host from which you are running the utility and should not be included in this file. If your segment hosts have multiple network interfaces, then this file would include all addresses for the host. Give the absolute path to the file.

**SEG\_PREFIX**

**Required.** This specifies a prefix that will be used to name the data directories on the master and segment instances. The naming convention for data directories in a Greenplum Database system is `SEG_PREFIXnumber` where `number` starts with 0 for segment instances (the master is always -1). So for example, if you choose the prefix `gpseg`, your master instance data directory would be named `gpseg-1`, and the segment instances would be named `gpseg0`, `gpseg1`, `gpseg2`, `gpseg3`, and so on.

**PORT\_BASE**

**Required.** This specifies the base number by which primary segment port numbers are calculated. The first primary segment port on a host is set as `PORT_BASE`, and then incremented by one for each additional primary segment on that host. Valid values range from 1 through 65535.

**DATA\_DIRECTORY**

**Required.** This specifies the data storage location(s) where the utility will create the primary segment data directories. The number of locations in the list dictate the number of primary segments that will get created per physical host (if multiple addresses for a host are listed in the host file, the number of segments will be spread evenly across the specified interface addresses). It is OK to list the same data storage area multiple times if you want your data directories created in the same location. The user who runs `gpinitssystem` (for example, the `gpadmin` user) must have permission to write to these directories. For example, this will create six primary segments per host:

```
declare -a DATA_DIRECTORY=(/data1/primary /data1/primary
/data1/primary /data2/primary /data2/primary /data2/primary)
```

#### MASTER\_HOSTNAME

**Required.** The host name of the master instance. This host name must exactly match the configured host name of the machine (run the `hostname` command to determine the correct hostname).

#### MASTER\_DIRECTORY

**Required.** This specifies the location where the data directory will be created on the master host. You must make sure that the user who runs `gpinitssystem` (for example, the `gpadmin` user) has permissions to write to this directory.

#### MASTER\_PORT

**Required.** The port number for the master instance. This is the port number that users and client connections will use when accessing the Greenplum Database system.

#### TRUSTED\_SHELL

**Required.** The shell the `gpinitssystem` utility uses to run commands on remote hosts. Allowed values are `ssh`. You must set up your trusted host environment before running the `gpinitssystem` utility (you can use `gpssh-exkeys` to do this).

#### CHECK\_POINT\_SEGMENTS

**Required.** Maximum distance between automatic write ahead log (WAL) checkpoints, in log file segments (each segment is normally 16 megabytes). This will set the `checkpoint_segments` parameter in the `postgresql.conf` file for each segment instance in the Greenplum Database system.

#### ENCODING

**Required.** The character set encoding to use. This character set must be compatible with the `--locale` settings used, especially `--lc-collate` and `--lc-ctype`. Greenplum Database supports the same character sets as PostgreSQL.

#### DATABASE\_NAME

**Optional.** The name of a Greenplum Database database to create after the system is initialized. You can always create a database later using the `CREATE DATABASE` command or the `createdb` utility.

#### MIRROR\_PORT\_BASE

**Optional.** This specifies the base number by which mirror segment port numbers are calculated. The first mirror segment port on a host is set as `MIRROR_PORT_BASE`, and then incremented by one for each additional mirror segment on that host. Valid values range from 1 through 65535 and cannot conflict with the ports calculated by `PORT_BASE`.

#### MIRROR\_DATA\_DIRECTORY

**Optional.** This specifies the data storage location(s) where the utility will create the mirror segment data directories. There must be the same number of data directories declared for mirror segment instances as for primary segment instances (see the `DATA_DIRECTORY` parameter). The user who runs `gpinitssystem` (for example, the `gpadmin` user) must have permission to write to these directories. For example:

```
declare -a MIRROR_DATA_DIRECTORY=(/data1/mirror
/data1/mirror /data1/mirror /data2/mirror /data2/mirror
/data2/mirror)
```

#### QD\_PRIMARY\_ARRAY, PRIMARY\_ARRAY, MIRROR\_ARRAY

**Required** when using `input_configuration` file with `-I` option. These parameters specify the Greenplum Database master host, the primary segment, and the mirror segment hosts respectively. During new cluster initialization, use the `gpinitssystem -O output\_configuration\_file` to populate `QD_PRIMARY_ARRAY`, `PRIMARY_ARRAY`, `MIRROR_ARRAY`.

To initialize a new cluster or re-create a cluster from a backed up configuration, edit these values in the input configuration file used with the `gpinitssystem -I input\_configuration\_file` option. Use one of the following formats to specify the host information:

```
<hostname>~<address>~<port>~<data_directory>/<seg_prefix<segment_id>~<dbid>~<content_id>
```

OR

```
<host>~<port>~<data_directory>/<seg_prefix<segment_id>~<dbid>~<content_id>
```

The first format populates the `hostname` and `address` fields in the `gp_segment_configuration` catalog table with the hostname and address values provided in the input configuration file. The second format populates `hostname` and `address` fields with the same value, derived from host.

The Greenplum Database master always uses the value `-1` for the segment ID and content ID. For example, `seg_prefix<segment_id>` and `dbid` values for `QD_PRIMARY_ARRAY` use `-1` to indicate the master instance:

```
QD_PRIMARY_ARRAY=mdw~mdw~5432~/gpdata/master/gpseg-1~1~-1
declare -a PRIMARY_ARRAY=(
sdw1~sdw1~4000~/gpdata/data1/gpseg0~2~0
sdw1~sdw1~40001~/gpdata/data2/gpseg1~3~1
sdw2~sdw2~4000~/gpdata/data1/gpseg2~4~2
sdw2~sdw2~40001~/gpdata/data2/gpseg3~5~3
)
declare -a MIRROR_ARRAY=(
sdw2~sdw2~5000~/gpdata/mirror1/gpseg0~6~0
sdw2~sdw2~50001~/gpdata/mirror2/gpseg1~7~1
sdw1~sdw1~5000~/gpdata/mirror1/gpseg2~8~2
sdw1~sdw1~50001~/gpdata/mirror2/gpseg3~9~3
)
```

To re-create a cluster using a known Greenplum Database system configuration, you can edit the segment and content IDs to match the values of the system.

## HEAP\_CHECKSUM

**Optional.** This parameter specifies if checksums are enabled for heap data. When enabled, checksums are calculated for heap storage in all databases, enabling Greenplum Database to detect corruption in the I/O system. This option is set when the system is initialized and cannot be changed later.

The `HEAP_CHECKSUM` option is on by default and turning it off is strongly discouraged. If you set this option to off, data corruption in storage can go undetected and make recovery much more difficult.

To determine if heap checksums are enabled in a Greenplum Database system, you can query the `data_checksums` server configuration parameter with the `gpconfig` management utility:

```
$ gpconfig -s data_checksums
```

## HBA\_HOSTNAMES

**Optional.** This parameter controls whether `gpinitssystem` uses IP addresses or host names in the `pg_hba.conf` file when updating the file with addresses that can connect to Greenplum Database. The default value is `0`, the utility uses IP addresses when updating the file. When initializing a Greenplum Database system, specify `HBA_HOSTNAMES=1` to have the utility use host names in the `pg_hba.conf` file.

For information about how Greenplum Database resolves host names in the `pg_hba.conf` file, see [Configuring Client Authentication](#).

# Specifying Hosts using Hostnames or IP Addresses

When initializing a Greenplum Database system with `gpinitssystem`, you can specify segment hosts using either hostnames or IP addresses. For example, you can use hostnames or IP addresses in the file specified with the `-h` option.

- If you specify a hostname, the resolution of the hostname to an IP address should be done locally for security. For example, you should use entries in a local `/etc/hosts` file to map a hostname to an IP address. The resolution of a hostname to an IP address should not be performed by an external service such as a public DNS server. You must stop the Greenplum system before you change the mapping of a hostname to a different IP address.
- If you specify an IP address, the address should not be changed after the initial configuration. When segment mirroring is enabled, replication from the primary to the mirror segment will fail if the IP address changes from the configured value. For this reason, you should use a hostname when initializing a Greenplum Database system unless you have a specific requirement to use IP addresses.

When initializing the Greenplum Database system, `gpinitssystem` uses the initialization information to populate the `gp_segment_configuration` catalog table and adds hosts to the `pg_hba.conf` file. By default, the host IP address is added to the file. Specify the `gpinitssystem` configuration file parameter `HBA_HOSTNAMES=1` to add hostnames to the file.

Greenplum Database uses the `address` value of the `gp_segment_configuration` catalog table when looking up host systems for Greenplum interconnect (internal) communication between the master

and segment instances and between segment instances, and for other internal communication.

## Examples

Initialize a Greenplum Database system by supplying a cluster configuration file and a segment host address file, and set up a spread mirroring (`--mirror-mode=spread`) configuration:

```
$ gpinitssystem -c gpinitssystem_config -h hostfile_gpinitssystem --mirror-mode=spread
```

Initialize a Greenplum Database system and set the superuser remote password:

```
$ gpinitssystem -c gpinitssystem_config -h hostfile_gpinitssystem --su-password=myspassword
```

Initialize a Greenplum Database system with an optional standby master host:

```
$ gpinitssystem -c gpinitssystem_config -h hostfile_gpinitssystem -s host09
```

Initialize a Greenplum Database system and write the provided configuration to an output file, for example `cluster_init.config`:

```
$ gpinitssystem -c gpinitssystem_config -h hostfile_gpinitssystem -O cluster_init.config
```

The output file uses the `QD_PRIMARY_ARRAY` and `PRIMARY_ARRAY` parameters to define master and segment hosts:

```
TRUSTED_SHELL=ssh
CHECK_POINT_SEGMENTS=8
ENCODING=UNICODE
SEG_PREFIX=gpseg
HEAP_CHECKSUM=on
HBA_HOSTNAMES=0
QD_PRIMARY_ARRAY=mdw~mdw.local~5433~/data/master1/gpseg-1~1~-1
declare -a PRIMARY_ARRAY=(
mdw~mdw.local~6001~/data/primary1/gpseg0~2~0
)
declare -a MIRROR_ARRAY=(
mdw~mdw.local~7001~/data/mirror1/gpseg0~3~0
)
```

Initialize a Greenplum Database using an input configuration file (a file that defines the Greenplum Database cluster) using `QD_PRIMARY_ARRAY` and `PRIMARY_ARRAY` parameters:

```
$ gpinitssystem -I cluster_init.config
```

The following example uses a host system configured with multiple NICs. If host systems are configured with multiple NICs, you can initialize a Greenplum Database system to use each NIC as a Greenplum host system. You must ensure that the host systems are configured with sufficient resources to support all the segment instances being added to the host. Also, if high availability is enabled, you must ensure that the Greenplum system configuration supports failover if a host system fails. For information about Greenplum Database mirroring schemes, see [GUID-best\\_practices-ha.html#topic\\_ngz\\_qf4\\_tt](#).

For this simple master and segment instance configuration, the host system `gp6m` is configured with two NICs `gp6m-1` and `gp6m-2`. In the configuration, the `QD_PRIMARY_ARRAY` parameter defines the master segment using `gp6m-1`. The `PRIMARY_ARRAY` and `MIRROR_ARRAY` parameters use `gp6m-2` to define a primary and mirror segment instance.

```
QD_PRIMARY_ARRAY=gp6m~gp6m-1~5432~/data/master/gpseg-1~1~-1
declare -a PRIMARY_ARRAY=(
gp6m~gp6m-2~40000~/data/data1/gpseg0~2~0
gp6s~gp6s~40000~/data/data1/gpseg1~3~1
)
declare -a MIRROR_ARRAY=(
gp6s~gp6s~50000~/data/mirror1/gpseg0~4~0
gp6m~gp6m-2~50000~/data/mirror1/gpseg1~5~1
)
```

## gpload

Runs a load job as defined in a YAML formatted control file.

## Synopsis

```
gpload -f <control_file> [-l <log_file>] [-h <hostname>] [-p <port>]
[-U <username>] [-d <database>] [-W] [--gpfdist_timeout <seconds>]
[--no_auto_trans] [--max_retries <retry_times>] [[-v | -V] [-q]] [-D]

gpload -?

gpload --version
```

## Requirements

The client machine where `gpload` is run must have the following:

- The `gpfdist` parallel file distribution program installed and in your `$PATH`. This program is located in `$GPHOME/bin` of your Greenplum Database server installation.
- Network access to and from all hosts in your Greenplum Database array (master and segments).
- Network access to and from the hosts where the data to be loaded resides (ETL servers).

## Description

`gpload` is a data loading utility that acts as an interface to the Greenplum Database external table parallel loading feature. Using a load specification defined in a YAML formatted control file, `gpload` runs a load by invoking the Greenplum Database parallel file server (`gpfdist`), creating an external

table definition based on the source data defined, and running an `INSERT`, `UPDATE` or `MERGE` operation to load the source data into the target table in the database.

**Note:** `gpfdist` is compatible only with the Greenplum Database major version in which it is shipped. For example, a `gpfdist` utility that is installed with Greenplum Database 4.x cannot be used with Greenplum Database 5.x or 6.x.

**Note:** The Greenplum Database 5.22 and later `gpload` for Linux is compatible with Greenplum Database 6.x. The Greenplum Database 6.x `gpload` for both Linux and Windows is compatible with Greenplum 5.x.

**Note:** `MERGE` and `UPDATE` operations are not supported if the target table column name is a reserved keyword, has capital letters, or includes any character that requires quotes (" ") to identify the column.

The operation, including any SQL commands specified in the `SQL` collection of the YAML control file (see [Control File Format](#)), are performed as a single transaction to prevent inconsistent data when performing multiple, simultaneous load operations on a target table.

## Options

`-f control_file`

Required. A YAML file that contains the load specification details. See [Control File Format](#).

`--gpfdist_timeout seconds`

Sets the timeout for the `gpfdist` parallel file distribution program to send a response. Enter a value from 0 to 30 seconds (entering "0" to deactivates timeouts). Note that you might need to increase this value when operating on high-traffic networks.

`-l log_file`

Specifies where to write the log file. Defaults to `~/gpAdminLogs/gpload_YYYYMMDD`. For more information about the log file, see [Log File Format](#).

`--no_auto_trans`

Specify `--no_auto_trans` to deactivate processing the load operation as a single transaction if you are performing a single load operation on the target table.

By default, `gpload` processes each load operation as a single transaction to prevent inconsistent data when performing multiple, simultaneous operations on a target table.

`-q` (no screen output)

Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

`-D` (debug mode)

Check for error conditions, but do not run the load.

`-v` (verbose mode)

Show verbose output of the load steps as they are run.

`-V` (very verbose mode)

Shows very verbose output.

`-?` (show help)

Show help, then exit.

`--version`

Show the version of this utility, then exit.

## Connection Options

### -d database

The database to load into. If not specified, reads from the load control file, the environment variable `$PGDATABASE` or defaults to the current system user name.

### -h hostname

Specifies the host name of the machine on which the Greenplum Database master database server is running. If not specified, reads from the load control file, the environment variable `$PGHOST` or defaults to `localhost`.

### -p port

Specifies the TCP port on which the Greenplum Database master database server is listening for connections. If not specified, reads from the load control file, the environment variable `$PGPORT` or defaults to 5432.

### --max\_retries retry\_times

Specifies the maximum number of times `gpload` attempts to connect to Greenplum Database after a connection timeout. The default value is 0, do not attempt to connect after a connection timeout. A negative integer, such as -1, specifies an unlimited number of attempts.

### -U username

The database role name to connect as. If not specified, reads from the load control file, the environment variable `$PGUSER` or defaults to the current system user name.

### -W (force password prompt)

Force a password prompt. If not specified, reads the password from the environment variable `$PGPASSWORD` or from a password file specified by `$PGPASSFILE` or in `~/.pgpass`. If these are not set, then `gpload` will prompt for a password even if `-w` is not supplied.

## Control File Format

The `gpload` control file uses the [YAML 1.1](#) document format and then implements its own schema for defining the various steps of a Greenplum Database load operation. The control file must be a valid YAML document.

The `gpload` program processes the control file document in order and uses indentation (spaces) to determine the document hierarchy and the relationships of the sections to one another. The use of white space is significant. White space should not be used simply for formatting purposes, and tabs should not be used at all.

The basic structure of a load control file is:

```

```

## VERSION

Optional. The version of the `gpload` control file schema. The current version is 1.0.0.1.

## DATABASE

Optional. Specifies which database in the Greenplum Database system to connect to. If not specified, defaults to `$PGDATABASE` if set or the current system user name. You can also specify the database on the command line using the `-d` option.

## USER

Optional. Specifies which database role to use to connect. If not specified, defaults to the current user or `$PGUSER` if set. You can also specify the database role on the command line using the `-U` option.

If the user running `gpload` is not a Greenplum Database superuser, then the appropriate rights must be granted to the user for the load to be processed. See the *Greenplum Database Reference Guide* for more information.

#### HOST

Optional. Specifies Greenplum Database master host name. If not specified, defaults to localhost or `$PGHOST` if set. You can also specify the master host name on the command line using the `-h` option.

#### PORT

Optional. Specifies Greenplum Database master port. If not specified, defaults to 5432 or `$PGPORT` if set. You can also specify the master port on the command line using the `-p` option.

#### GPLOAD

Required. Begins the load specification section. A `GPLOAD` specification must have an `INPUT` and an `OUTPUT` section defined.

#### INPUT

Required. Defines the location and the format of the input data to be loaded. `gpload` will start one or more instances of the `gpfdist` file distribution program on the current host and create the required external table definition(s) in Greenplum Database that point to the source data. Note that the host from which you run `gpload` must be accessible over the network by all Greenplum Database hosts (master and segments).

#### SOURCE

Required. The `SOURCE` block of an `INPUT` specification defines the location of a source file. An `INPUT` section can have more than one `SOURCE` block defined. Each `SOURCE` block defined corresponds to one instance of the `gpfdist` file distribution program that will be started on the local machine. Each `SOURCE` block defined must have a `FILE` specification.

For more information about using the `gpfdist` parallel file server and single and multiple `gpfdist` instances, see [Loading and Unloading Data](#).

#### LOCAL\_HOSTNAME

Optional. Specifies the host name or IP address of the local machine on which `gpload` is running. If this machine is configured with multiple network interface cards (NICs), you can specify the host name or IP of each individual NIC to allow network traffic to use all NICs simultaneously. The default is to use the local machine's primary host name or IP only.

#### PORT

Optional. Specifies the specific port number that the `gpfdist` file distribution program should use. You can also supply a `PORT_RANGE` to select an available port from the specified range. If both `PORT` and `PORT_RANGE` are defined, then `PORT` takes precedence. If neither `PORT` or `PORT_RANGE` are defined, the default is to select an available port between 8000 and 9000.

If multiple host names are declared in `LOCAL_HOSTNAME`, this port number is used for all hosts. This configuration is desired if you want to use all NICs to load the same file or set of files in a given directory location.

#### PORT\_RANGE

Optional. Can be used instead of `PORT` to supply a range of port numbers from which `gpload` can choose an available port for this instance of the `gpfdist` file distribution program.

#### FILE

Required. Specifies the location of a file, named pipe, or directory location on the local file system that contains data to be loaded. You can declare more than one file so long as the data is of the same format in all files specified.

If the files are compressed using `gzip` or `bzip2` (have a `.gz` or `.bz2` file extension), the files will be uncompressed automatically (provided that `gunzip` or `bunzip2` is in your path).

When specifying which source files to load, you can use the wildcard character (`*`) or other C-style pattern matching to denote multiple files. The files specified are assumed to be relative to the current directory from which `gpload` is run (or you can declare an absolute path).

#### SSL

Optional. Specifies usage of SSL encryption. If `SSL` is set to `true`, `gpload` starts the `gpfdist` server with the `--ssl` option and uses the `gpfdist://` protocol.

#### CERTIFICATES\_PATH

Required when `SSL` is `true`; cannot be specified when `SSL` is `false` or unspecified. The location specified in `CERTIFICATES_PATH` must contain the following files:

- The server certificate file, `server.crt`
- The server private key file, `server.key`
- The trusted certificate authorities, `root.crt`

The root directory (`/`) cannot be specified as `CERTIFICATES_PATH`.

#### FULLY\_QUALIFIED\_DOMAIN\_NAME

Optional. Specifies whether `gpload` resolve hostnames to the fully qualified domain name (FQDN) or the local hostname. If the value is set to `true`, names are resolved to the FQDN. If the value is set to `false`, resolution is to the local hostname. The default is `false`.

A fully qualified domain name might be required in some situations. For example, if the Greenplum Database system is in a different domain than an ETL application that is being accessed by `gpload`.

#### COLUMNS

Optional. Specifies the schema of the source data file(s) in the format of `field\_name:data\_type`. The `DELIMITER` character in the source file is what separates two data value fields (columns). A row is determined by a line feed character (`0x0a`).

If the input `COLUMNS` are not specified, then the schema of the output `TABLE` is implied, meaning that the source data must have the same column order, number of columns, and data format as the target table.

The default source-to-target mapping is based on a match of column names as defined in this section and the column names in the target `TABLE`. This default mapping can be overridden using the `MAPPING` section.

**TRANSFORM**

Optional. Specifies the name of the input transformation passed to `gpload`. For information about XML transformations, see "Loading and Unloading Data" in the *Greenplum Database Administrator Guide*.

**TRANSFORM\_CONFIG**

Required when `TRANSFORM` is specified. Specifies the location of the transformation configuration file that is specified in the `TRANSFORM` parameter, above.

**MAX\_LINE\_LENGTH**

Optional. An integer that specifies the maximum length of a line in the XML transformation data passed to `gpload`.

**FORMAT**

Optional. Specifies the format of the source data file(s) - either plain text (`TEXT`) or comma separated values (`CSV`) format. Defaults to `TEXT` if not specified. For more information about the format of the source data, see [Loading and Unloading Data](#).

**DELIMITER**

Optional. Specifies a single ASCII character that separates columns within each row (line) of data. The default is a tab character in `TEXT` mode, a comma in `CSV` mode. You can also specify a non-printable ASCII character or a non-printable unicode character, for example: `"\x1B"` or `"\u001B"`. The escape string syntax, `E'<character-code>`, is also supported for non-printable characters. The ASCII or unicode character must be enclosed in single quotes. For example: `E'\x1B'` or `E'\u001B'`.

**ESCAPE**

Specifies the single character that is used for C escape sequences (such as `\n`, `\t`, `\100`, and so on) and for escaping data characters that might otherwise be taken as row or column delimiters. Make sure to choose an escape character that is not used anywhere in your actual column data. The default escape character is a `\` (backslash) for text-formatted files and a `"` (double quote) for csv-formatted files, however it is possible to specify another character to represent an escape. It is also possible to deactivate escaping in text-formatted files by specifying the value `'OFF'` as the escape value. This is very useful for data such as text-formatted web log data that has many embedded backslashes that are not intended to be escapes.

**NEWLINE**

Specifies the type of newline used in your data files, one of:

- LF (Line feed, 0x0A)
- CR (Carriage return, 0x0D)
- CRLF (Carriage return plus line feed, 0x0D 0x0A).

If not specified, Greenplum Database detects the newline type by examining the first row of data that it receives, and uses the first newline type that it encounters.

**NULL\_AS**

Optional. Specifies the string that represents a null value. The default is `\N` (backslash-N) in `TEXT` mode, and an empty value with no quotations in `CSV` mode. You might prefer an empty string even in `TEXT` mode for cases where you do not want to distinguish nulls from empty strings. Any source data item that matches this string will be considered a null value.

**FILL\_MISSING\_FIELDS**

Optional. The default value is `false`. When reading a row of data that has missing trailing field values (the row of data has missing data fields at the end of a line or row), Greenplum Database returns an error.

If the value is `true`, when reading a row of data that has missing trailing field values, the values are set to `NULL`. Blank rows, fields with a `NOT NULL` constraint, and trailing delimiters on a line will still report an error.

See the `FILL MISSING FIELDS` clause of the `CREATE EXTERNAL TABLE` command.

#### FORCE\_NOT\_NULL

Optional. In CSV mode, processes each specified column as though it were quoted and hence not a `NULL` value. For the default null string in CSV mode (nothing between two delimiters), this causes missing values to be evaluated as zero-length strings.

#### QUOTE

Required when `FORMAT` is `CSV`. Specifies the quotation character for `CSV` mode. The default is double-quote (`"`).

#### HEADER

Optional. Specifies that the first line in the data file(s) is a header row (contains the names of the columns) and should not be included as data to be loaded. If using multiple data source files, all files must have a header row. The default is to assume that the input files do not have a header row.

#### ENCODING

Optional. Character set encoding of the source data. Specify a string constant (such as `'SQL_ASCII'`), an integer encoding number, or `'DEFAULT'` to use the default client encoding. If not specified, the default client encoding is used. For information about supported character sets, see the *Greenplum Database Reference Guide*.

**Note:** If you *change* the `ENCODING` value in an existing `gpload` control file, you must manually drop any external tables that were creating using the previous `ENCODING` configuration. `gpload` does not drop and recreate external tables to use the new `ENCODING` if `REUSE_TABLES` is set to `true`.

#### ERROR\_LIMIT

Optional. Enables single row error isolation mode for this load operation. When enabled, input rows that have format errors will be discarded provided that the error limit count is not reached on any Greenplum Database segment instance during input processing. If the error limit is not reached, all good rows will be loaded and any error rows will either be discarded or captured as part of error log information. The default is to cancel the load operation on the first error encountered. Note that single row error isolation only applies to data rows with format errors; for example, extra or missing attributes, attributes of a wrong data type, or invalid client encoding sequences. Constraint errors, such as primary key violations, will still cause the load operation to be cancelled if encountered. For information about handling load errors, see [Loading and Unloading Data](#).

#### LOG\_ERRORS

Optional when `ERROR_LIMIT` is declared. Value is either `true` or `false`. The default value is `false`. If the value is `true`, rows with formatting errors are logged internally

when running in single row error isolation mode. You can examine formatting errors with the Greenplum Database built-in SQL function `gp_read_error_log('<table_name>')`. If formatting errors are detected when loading data, `gpload` generates a warning message with the name of the table that contains the error information similar to this message.

```
<timestamp>|WARN|1 bad row, please use GPDB built-in function gp_read_error_log
('table-name')
to access the detailed error row
```

: If `LOG_ERRORS: true` is specified, `REUSE_TABLES: true` must be specified to retain the formatting errors in Greenplum Database error logs. If `REUSE_TABLES: true` is not specified, the error information is deleted after the `gpload` operation. Only summary information about formatting errors is returned. You can delete the formatting errors from the error logs with the Greenplum Database function `gp_truncate_error_log()`.

**Note:** When `gpfdist` reads data and encounters a data formatting error, the error message includes a row number indicating the location of the formatting error. `gpfdist` attempts to capture the row that contains the error. However, `gpfdist` might not capture the exact row for some formatting errors.

For more information about handling load errors, see "Loading and Unloading Data" in the *Greenplum Database Administrator Guide*. For information about the `gp_read_error_log()` function, see the [CREATE EXTERNAL TABLE](#) command.

#### EXTERNAL

Optional. Defines the schema of the external table database objects created by `gpload`.

The default is to use the Greenplum Database `search_path`.

#### : SCHEMA

Required when `EXTERNAL` is declared. The name of the schema of the external table. If the schema does not exist, an error is returned.

If `%` (percent character) is specified, the schema of the table name specified by `TABLE` in the `OUTPUT` section is used. If the table name does not specify a schema, the default schema is used.

#### OUTPUT

Required. Defines the target table and final data column values that are to be loaded into the database.

#### TABLE

Required. The name of the target table to load into.

#### MODE

Optional. Defaults to `INSERT` if not specified. There are three available load modes:

**INSERT** - Loads data into the target table using the following method:

```
INSERT INTO <target_table> SELECT * FROM <input_data>;
```

**UPDATE** - Updates the `UPDATE_COLUMNS` of the target table where the rows have `MATCH_COLUMNS` attribute values equal to those of the input data, and the optional `UPDATE_CONDITION` is true. `UPDATE` is not supported if the target table column name is a reserved keyword, has capital letters, or includes any character that requires quotes (" ") to identify the column.

**MERGE** - Inserts new rows and updates the `UPDATE_COLUMNS` of existing rows where `FOOBAR` attribute values are equal to those of the input data, and the optional `MATCH_COLUMNS` is true. New rows are identified when the `MATCH_COLUMNS` value in the source data does not have a corresponding value in the existing data of the target table. In those cases, the **entire row** from the source file is inserted, not only the `MATCH` and `UPDATE` columns. If there are multiple new `MATCH_COLUMNS` values that are the same, only one new row for that value will be inserted. Use `UPDATE_CONDITION` to filter out the rows to discard. `MERGE` is not supported if the target table column name is a reserved keyword, has capital letters, or includes any character that requires quotes (" ") to identify the column.

#### MATCH\_COLUMNS

Required if `MODE` is `UPDATE` or `MERGE`. Specifies the column(s) to use as the join condition for the update. The attribute value in the specified target column(s) must be equal to that of the corresponding source data column(s) in order for the row to be updated in the target table.

#### UPDATE\_COLUMNS

Required if `MODE` is `UPDATE` or `MERGE`. Specifies the column(s) to update for the rows that meet the `MATCH_COLUMNS` criteria and the optional `UPDATE_CONDITION`.

#### UPDATE\_CONDITION

Optional. Specifies a Boolean condition (similar to what you would declare in a `WHERE` clause) that must be met in order for a row in the target table to be updated.

#### MAPPING

Optional. If a mapping is specified, it overrides the default source-to-target column mapping. The default source-to-target mapping is based on a match of column names as defined in the source `COLUMNS` section and the column names of the target `TABLE`. A mapping is specified as either:

```
<target_column_name>: <source_column_name>
```

or

```
<target_column_name>: '<expression>'
```

Where `<expression>` is any expression that you would specify in the `SELECT` list of a query, such as a constant value, a column reference, an operator invocation, a function call, and so on.

#### PRELOAD

Optional. Specifies operations to run prior to the load operation. Right now the only preload operation is `TRUNCATE`.

#### TRUNCATE

Optional. If set to true, `gpload` will remove all rows in the target table prior to loading it. Default is false.

#### REUSE\_TABLES

Optional. If set to true, `gpload` will not drop the external table objects and staging table objects it creates. These objects will be reused for future load operations that use the same load specifications. This improves performance of trickle loads (ongoing small loads to the same target table).

If `LOG_ERRORS: true` is specified, `REUSE_TABLES: true` must be specified to retain the formatting errors in Greenplum Database error logs. If `REUSE_TABLES: true` is not specified, formatting error information is deleted after the `gpload` operation.

If the `<external_table_name>` exists, the utility uses the existing table. The utility returns an error if the table schema does not match the `OUTPUT` table schema.

#### STAGING\_TABLE

Optional. Specify the name of the temporary external table that is created during a `gpload` operation. The external table is used by `gpfdist`. `REUSE_TABLES: true` must also be specified. If `REUSE_TABLES` is false or not specified, `STAGING_TABLE` is ignored. By default, `gpload` creates a temporary external table with a randomly generated name.

If `external_table_name` contains a period (`.`), `gpload` returns an error. If the table exists, the utility uses the table. The utility returns an error if the existing table schema does not match the `OUTPUT` table schema.

The utility uses the value of `SCHEMA` in the `EXTERNAL` section as the schema for `<external_table_name>`. If the `SCHEMA` value is `%`, the schema for `<external_table_name>` is the same as the schema of the target table, the schema of `TABLE` in the `OUTPUT` section.

If `SCHEMA` is not set, the utility searches for the table (using the schemas in the database `search_path`). If the table is not found, `external_table_name` is created in the default `PUBLIC` schema.

`gpload` creates the staging table using the distribution key(s) of the target table as the distribution key(s) for the staging table. If the target table was created `DISTRIBUTED RANDOMLY`, `gpload` uses `MATCH_COLUMNS` as the staging table's distribution key(s).

#### FAST\_MATCH

Optional. If set to true, `gpload` only searches the database for matching external table objects when reusing external tables. The utility does not check the external table column names and column types in the catalog table `pg_attribute` to ensure that the table can be used for a `gpload` operation. Set the value to true to improve `gpload` performance when reusing external table objects and the database catalog table `pg_attribute` contains a large number of rows. The utility returns an error and quits if the column definitions are not compatible.

The default value is false, the utility checks the external table definition column names and column types.

`REUSE_TABLES: true` must also be specified. If `REUSE_TABLES` is false or not specified and `FAST_MATCH: true` is specified, `gpload` returns a warning message.

#### SQL

Optional. Defines SQL commands to run before and/or after the load operation. You can specify multiple `BEFORE` and/or `AFTER` commands. List commands in the order of desired execution.

**BEFORE**

Optional. An SQL command to run before the load operation starts. Enclose commands in quotes.

**AFTER**

Optional. An SQL command to run after the load operation completes. Enclose commands in quotes.

## Log File Format

Log files output by `gpload` have the following format:

```
<timestamp>|<level>|<message>
```

Where `<timestamp>` takes the form: `YYYY-MM-DD HH:MM:SS`, level is one of `DEBUG`, `LOG`, `INFO`, `ERROR`, and message is a normal text message.

Some `INFO` messages that may be of interest in the log files are (where `#` corresponds to the actual number of seconds, units of data, or failed rows):

```
INFO|running time: <#.##> seconds
INFO|transferred <#.##> kB of <#.##> kB.
INFO|gpload succeeded
INFO|gpload succeeded with warnings
INFO|gpload failed
INFO|1 bad row
INFO|<#> bad rows
```

## Notes

If your database object names were created using a double-quoted identifier (delimited identifier), you must specify the delimited name within single quotes in the `gpload` control file. For example, if you create a table as follows:

```
CREATE TABLE "MyTable" ("MyColumn" text);
```

Your YAML-formatted `gpload` control file would refer to the above table and column names as follows:

```
- COLUMNS:
  - "MyColumn": text
OUTPUT:
  - TABLE: public."MyTable"
```

If the YAML control file contains the `ERROR_TABLE` element that was available in Greenplum Database 4.3.x, `gpload` logs a warning stating that `ERROR_TABLE` is not supported, and load errors are handled as if the `LOG_ERRORS` and `REUSE_TABLE` elements were set to `true`. Rows with formatting errors are logged internally when running in single row error isolation mode.

## Examples

Run a load job as defined in `my_load.yml`:

```
gpload -f my_load.yml
```

Example load control file:

```
---
VERSION: 1.0.0.1
DATABASE: ops
USER: gpadmin
HOST: mdw-1
PORT: 5432
Gpload:
  INPUT:
    - SOURCE:
      LOCAL_HOSTNAME:
        - etl1-1
        - etl1-2
        - etl1-3
        - etl1-4
      PORT: 8081
      FILE:
        - /var/load/data/*
    - COLUMNS:
      - name: text
      - amount: float4
      - category: text
      - descr: text
      - date: date
    - FORMAT: text
    - DELIMITER: '|'
    - ERROR_LIMIT: 25
    - LOG_ERRORS: true
  OUTPUT:
    - TABLE: payables.expenses
    - MODE: INSERT
  PRELOAD:
    - REUSE_TABLES: true
  SQL:
    - BEFORE: "INSERT INTO audit VALUES('start', current_timestamp)"
    - AFTER: "INSERT INTO audit VALUES('end', current_timestamp)"
```

## gplogfilter

Searches through Greenplum Database log files for specified entries.

## Synopsis

```
gplogfilter [<timestamp_options>] [<pattern_options>]
            [<output_options>] [<input_options>] [<input_file>]

gplogfilter --help
```

```
gplogfilter --version
```

## Description

The `gplogfilter` utility can be used to search through a Greenplum Database log file for entries matching the specified criteria. If an input file is not supplied, then `gplogfilter` will use the `$MASTER_DATA_DIRECTORY` environment variable to locate the Greenplum master log file in the standard logging location. To read from standard input, use a dash (-) as the input file name. Input files may be compressed using `gzip`. In an input file, a log entry is identified by its timestamp in `YYYY-MM-DD [hh:mm[:ss]]` format.

You can also use `gplogfilter` to search through all segment log files at once by running it through the `gpssh` utility. For example, to display the last three lines of each segment log file:

```
gpssh -f seg_host_file
=> source /usr/local/greenplum-db/greenplum_path.sh
=> gplogfilter -n 3 /gpdata/*/log/gpdb*.csv
```

By default, the output of `gplogfilter` is sent to standard output. Use the `-o` option to send the output to a file or a directory. If you supply an output file name ending in `.gz`, the output file will be compressed by default using maximum compression. If the output destination is a directory, the output file is given the same name as the input file.

## Options

### Timestamp Options

`-b datetime` | `--begin=datetime`

Specifies a starting date and time to begin searching for log entries in the format of `YYYY-MM-DD [hh:mm[:ss]]`.

If a time is specified, the date and time must be enclosed in either single or double quotes. This example encloses the date and time in single quotes:

```
gplogfilter -b '2013-05-23 14:33'
```

`-e datetime` | `--end=datetime`

Specifies an ending date and time to stop searching for log entries in the format of `YYYY-MM-DD [hh:mm[:ss]]`.

If a time is specified, the date and time must be enclosed in either single or double quotes. This example encloses the date and time in single quotes:

```
gplogfilter -e '2013-05-23 14:33'
```

`-d<time>` | `--duration=<time>`

Specifies a time duration to search for log entries in the format of `[hh] [:mm[:ss]]`. If used without either the `-b` or `-e` option, will use the current time as a basis.

## Pattern Matching Options

-c i [ignore] | r [expect] | --case=i [ignore] | r [expect]

Matching of alphabetic characters is case sensitive by default unless preceded by the `--case=ignore` option.

-C 'string' | --columns='string'

Selects specific columns from the log file. Specify the desired columns as a comma-delimited string of column numbers beginning with 1, where the second column from left is 2, the third is 3, and so on. See "Viewing the Database Server Log Files" in the *Greenplum Database Administrator Guide* for details about the log file format and for a list of the available columns and their associated number.

-f 'string' | --find='string'

Finds the log entries containing the specified string.

-F 'string' | --nofind='string'

Rejects the log entries containing the specified string.

-m regex | --match=regex

Finds log entries that match the specified Python regular expression. See <https://docs.python.org/library/re.html> for Python regular expression syntax.

-M regex | --nomatch=regex

Rejects log entries that match the specified Python regular expression. See <https://docs.python.org/library/re.html> for Python regular expression syntax.

-t | --trouble

Finds only the log entries that have `ERROR:`, `FATAL:`, or `PANIC:` in the first line.

## Output Options

-n <integer> | --tail=<integer>

Limits the output to the last <integer> of qualifying log entries found.

-s <offset> [limit] | --slice=<offset> [limit]

From the list of qualifying log entries, returns the <limit> number of entries starting at the <offset> entry number, where an <offset> of zero (0) denotes the first entry in the result set and an <offset> of any number greater than zero counts back from the end of the result set.

-o <output\_file> | --out=<output\_file>

Writes the output to the specified file or directory location instead of `STDOUT`.

-z 0-9 | --zip=0-9

Compresses the output file to the specified compression level using `gzip`, where 0 is no compression and 9 is maximum compression. If you supply an output file name ending in `.gz`, the output file will be compressed by default using maximum compression.

-a | --append

If the output file already exists, appends to the file instead of overwriting it.

## Input Options

input\_file

The name of the input log file(s) to search through. If an input file is not supplied, `gplogfilter` will use the `$MASTER_DATA_DIRECTORY` environment variable to locate the Greenplum Database master log file. To read from standard input, use a dash (-) as the input file name.

-u | --unzip

Uncompress the input file using `gunzip`. If the input file name ends in `.gz`, it will be uncompressed by default.

`--help`

Displays the online help.

`--version`

Displays the version of this utility.

## Examples

Display the last three error messages in the master log file:

```
gplogfilter -t -n 3
```

Display all log messages in the master log file timestamped in the last 10 minutes:

```
gplogfilter -d :10
```

Display log messages in the master log file containing the string `|con6 cmd11|`:

```
gplogfilter -f '|con6 cmd11|'
```

Using `gpssh`, run `gplogfilter` on the segment hosts and search for log messages in the segment log files containing the string `con6` and save output to a file.

```
gpssh -f seg_hosts_file -e 'source
/usr/local/greenplum-db/greenplum_path.sh ; gplogfilter -f
con6 /gpdata/*/log/gpdb*.csv' > seglog.out
```

## See Also

[gpssh](#), [gpscp](#)

## gpmapproduce

Runs Greenplum MapReduce jobs as defined in a YAML specification document.

## Synopsis

```
gpmapproduce -f <config.yaml> [dbname [<username>]]
  [-k <name=value> | --key <name=value>]
  [-h <hostname> | --host <hostname>] [-p <port> | --port <port>]
  [-U <username> | --username <username>] [-W] [-v]

gpmapproduce -x | --explain

gpmapproduce -X | --explain-analyze

gpmapproduce -V | --version

gpmapproduce -h | --help
```

## Requirements

The following are required prior to running this program:

- You must have your MapReduce job defined in a YAML file. See [gmapreduce.yaml](#) for more information about the format of, and keywords supported in, the Greenplum MapReduce YAML configuration file.
- You must be a Greenplum Database superuser to run MapReduce jobs written in untrusted Perl or Python.
- You must be a Greenplum Database superuser to run MapReduce jobs with `EXEC` and `FILE` inputs.
- You must be a Greenplum Database superuser to run MapReduce jobs with `GPFDIST` input unless the user has the appropriate rights granted.

## Description

**MapReduce** is a programming model developed by Google for processing and generating large data sets on an array of commodity servers. Greenplum MapReduce allows programmers who are familiar with the MapReduce paradigm to write map and reduce functions and submit them to the Greenplum Database parallel engine for processing.

`gmapreduce` is the Greenplum MapReduce program. You configure a Greenplum MapReduce job via a YAML-formatted configuration file that you pass to the program for execution by the Greenplum Database parallel engine. The Greenplum Database system distributes the input data, runs the program across a set of machines, handles machine failures, and manages the required inter-machine communication.

## Options

`-f config.yaml`

Required. The YAML file that contains the Greenplum MapReduce job definitions. Refer to [gmapreduce.yaml](#) for the format and content of the parameters that you specify in this file.

`-? | --help`

Show help, then exit.

`-V | --version`

Show version information, then exit.

`-v | --verbose`

Show verbose output.

`-x | --explain`

Do not run MapReduce jobs, but produce explain plans.

`-X | --explain-analyze`

Run MapReduce jobs and produce explain-analyze plans.

`-k | --keyname=value`

Sets a YAML variable. A value is required. Defaults to "key" if no variable name is specified.

### Connection Options

`-h host | --host host`

Specifies the host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to `localhost`.

`-p port | --port port`

Specifies the TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to `5432`.

`-U username | --username username`

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system user name.

`-W | --password`

Force a password prompt.

## Examples

Run a MapReduce job as defined in `my_mrjob.yaml` and connect to the database `mydatabase`:

```
gmprepareduce -f my_mrjob.yaml mydatabase
```

## Description

You specify the input, map and reduce tasks, and the output for the Greenplum MapReduce `gpmapreduce` program in a YAML-formatted configuration file. (This reference page uses the name `gpmapreduce.yaml` when referring to this file; you may choose your own name for the file.)

The `gpmapreduce` utility processes the YAML configuration file in order, using indentation (spaces) to determine the document hierarchy and the relationships between the sections. The use of white space in the file is significant.

## Keys and Values

### VERSION

Required. The version of the Greenplum MapReduce YAML specification. Current supported versions are 1.0.0.1, 1.0.0.2, and 1.0.0.3.

### DATABASE

Optional. Specifies which database in Greenplum to connect to. If not specified, defaults to the default database or `$PGDATABASE` if set.

### USER

Optional. Specifies which database role to use to connect. If not specified, defaults to the current user or `$PGUSER` if set. You must be a Greenplum superuser to run functions written in untrusted Python and Perl. Regular database users can run functions written in trusted Perl. You also must be a database superuser to run MapReduce jobs that contain `FILE`, `GPFDIST` and `EXEC` input types.

### HOST

Optional. Specifies Greenplum master host name. If not specified, defaults to localhost or `$PGHOST` if set.

### PORT

Optional. Specifies Greenplum master port. If not specified, defaults to 5432 or `$PGPORT` if set.

### DEFINE

Required. A sequence of definitions for this MapReduce document. The `DEFINE` section must have at least one `INPUT` definition.

### INPUT

Required. Defines the input data. Every MapReduce document must have at least one input defined. Multiple input definitions are allowed in a document, but each input definition can specify only one of these access types: a file, a `gpfdist` file reference, a table in the database, an SQL command, or an operating system command. See `` for information about this reference.

### NAME

A name for this input. Names must be unique with regards to the names of other objects in this MapReduce job (such as map function, task, reduce function and output names). Also, names cannot conflict with existing objects in the database (such as tables, functions or views).

### FILE

A sequence of one or more input files in the format: `seghostname:/path/to/filename`. You must be a Greenplum Database superuser to run MapReduce jobs with `FILE` input. The file must reside on a Greenplum segment host.

#### GPFDIST

A sequence identifying one or more running `gpfdist` file servers in the format: `hostname[:port]/file_pattern`. You must be a Greenplum Database superuser to run MapReduce jobs with `GPFDIST` input.

#### TABLE

The name of an existing table in the database.

#### QUERY

A SQL `SELECT` command to run within the database.

#### EXEC

An operating system command to run on the Greenplum segment hosts. The command is run by all segment instances in the system by default. For example, if you have four segment instances per segment host, the command will be run four times on each host. You must be a Greenplum Database superuser to run MapReduce jobs with `EXEC` input.

#### COLUMNS

Optional. Columns are specified as: `column_name``[``data_type``]`. If not specified, the default is `value text`. The `DELIMITER` character is what separates two data value fields (columns). A row is determined by a line feed character (0x0a).

#### FORMAT

Optional. Specifies the format of the data - either delimited text (`TEXT`) or comma separated values (`CSV`) format. If the data format is not specified, defaults to `TEXT`.

#### DELIMITER

Optional for `FILE`, `GPFDIST` and `EXEC` inputs. Specifies a single character that separates data values. The default is a tab character in `TEXT` mode, a comma in `CSV` mode. The delimiter character must only appear between any two data value fields. Do not place a delimiter at the beginning or end of a row.

#### ESCAPE

Optional for `FILE`, `GPFDIST` and `EXEC` inputs. Specifies the single character that is used for C escape sequences (such as `\n`, `\t`, `\100`, and so on) and for escaping data characters that might otherwise be taken as row or column delimiters. Make sure to choose an escape character that is not used anywhere in your actual column data. The default escape character is a `\` (backslash) for text-formatted files and a `"` (double quote) for csv-formatted files, however it is possible to specify another character to represent an escape. It is also possible to deactivate escaping by specifying the value `'OFF'` as the escape value. This is very useful for data such as text-formatted web log data that has many embedded backslashes that are not intended to be escapes.

#### NULL

Optional for `FILE`, `GPFDIST` and `EXEC` inputs. Specifies the string that represents a null value. The default is `\N` in `TEXT` format, and an empty value with no quotations in `CSV` format. You might prefer an empty string even in `TEXT` mode for cases where you do not want to distinguish nulls from empty strings. Any input data item that matches this string will be considered a null value.

#### QUOTE

Optional for [FILE](#), [GPFDIST](#) and [EXEC](#) inputs. Specifies the quotation character for [CSV](#) formatted files. The default is a double quote ("). In [CSV](#) formatted files, data value fields must be enclosed in double quotes if they contain any commas or embedded new lines. Fields that contain double quote characters must be surrounded by double quotes, and the embedded double quotes must each be represented by a pair of consecutive double quotes. It is important to always open and close quotes correctly in order for data rows to be parsed correctly.

#### ERROR\_LIMIT

If the input rows have format errors they will be discarded provided that the error limit count is not reached on any Greenplum segment instance during input processing. If the error limit is not reached, all good rows will be processed and any error rows discarded.

#### ENCODING

Character set encoding to use for the data. Specify a string constant (such as `'SQL_ASCII'`), an integer encoding number, or [DEFAULT](#) to use the default client encoding. See [Character Set Support](#) for more information.

#### OUTPUT

Optional. Defines where to output the formatted data of this MapReduce job. If output is not defined, the default is [STDOUT](#) (standard output of the client). You can send output to a file on the client host or to an existing table in the database.

#### NAME

A name for this output. The default output name is [STDOUT](#). Names must be unique with regards to the names of other objects in this MapReduce job (such as map function, task, reduce function and input names). Also, names cannot conflict with existing objects in the database (such as tables, functions or views).

#### FILE

Specifies a file location on the MapReduce client machine to output data in the format:  
`/path/to/filename.`

#### TABLE

Specifies the name of a table in the database to output data. If this table does not exist prior to running the MapReduce job, it will be created using the distribution policy specified with [KEYS](#).

#### KEYS

Optional for [TABLE](#) output. Specifies the column(s) to use as the Greenplum Database distribution key. If the [EXECUTE](#) task contains a [REDUCE](#) definition, then the [REDUCE](#) keys will be used as the table distribution key by default. Otherwise, the first column of the table will be used as the distribution key.

#### MODE

Optional for [TABLE](#) output. If not specified, the default is to create the table if it does not already exist, but error out if it does exist. Declaring [APPEND](#) adds output data to an existing table (provided the table schema matches the output format) without removing any existing data. Declaring [REPLACE](#) will drop the table if it exists and then recreate it. Both [APPEND](#) and [REPLACE](#) will create a new table if one does not exist.

#### MAP

Required. Each [MAP](#) function takes data structured in (`key, value`) pairs, processes each pair, and generates zero or more output (`key, value`) pairs. The Greenplum MapReduce framework then collects all pairs with the same key from all output lists

and groups them together. This output is then passed to the **REDUCE** task, which is comprised of **TRANSITION | CONSOLIDATE | FINALIZE** functions. There is one predefined **MAP** function named **IDENTITY** that returns (**key, value**) pairs unchanged. Although (**key, value**) are the default parameters, you can specify other prototypes as needed.

#### TRANSITION | CONSOLIDATE | FINALIZE

**TRANSITION**, **CONSOLIDATE** and **FINALIZE** are all component pieces of **REDUCE**. A **TRANSITION** function is required. **CONSOLIDATE** and **FINALIZE** functions are optional. By default, all take **state** as the first of their input **PARAMETERS**, but other prototypes can be defined as well.

A **TRANSITION** function iterates through each value of a given key and accumulates values in a **state** variable. When the transition function is called on the first value of a key, the **state** is set to the value specified by **INITIALIZE** of a **REDUCE** job (or the default state value for the data type). A transition takes two arguments as input; the current state of the key reduction, and the next value, which then produces a new **state**.

If a **CONSOLIDATE** function is specified, **TRANSITION** processing is performed at the segment-level before redistributing the keys across the Greenplum interconnect for final aggregation (two-phase aggregation). Only the resulting **state** value for a given key is redistributed, resulting in lower interconnect traffic and greater parallelism. **CONSOLIDATE** is handled like a **TRANSITION**, except that instead of `(state + value) => state`, it is `(state + state) => state`.

If a **FINALIZE** function is specified, it takes the final **state** produced by **CONSOLIDATE** (if present) or **TRANSITION** and does any final processing before emitting the final result. **TRANSITION** and **CONSOLIDATE** functions cannot return a set of values. If you need a **REDUCE** job to return a set, then a **FINALIZE** is necessary to transform the final state into a set of output values.

#### NAME

Required. A name for the function. Names must be unique with regards to the names of other objects in this MapReduce job (such as function, task, input and output names). You can also specify the name of a function built-in to Greenplum Database. If using a built-in function, do not supply **LANGUAGE** or a **FUNCTION** body.

#### FUNCTION

Optional. Specifies the full body of the function using the specified **LANGUAGE**. If **FUNCTION** is not specified, then a built-in database function corresponding to **NAME** is used.

#### LANGUAGE

Required when **FUNCTION** is used. Specifies the implementation language used to interpret the function. This release has language support for **perl**, **python**, and **C**. If calling a built-in database function, **LANGUAGE** should not be specified.

#### LIBRARY

Required when **LANGUAGE** is **C** (not allowed for other language functions). To use this attribute, **VERSION** must be 1.0.0.2. The specified library file must be installed prior to running the MapReduce job, and it must exist in the same file system location on all Greenplum hosts (master and segments).

#### PARAMETERS

Optional. Function input parameters. The default type is `text`.

`MAP` default - `key text, value text`

`TRANSITION` default - `state text, value text`

`CONSOLIDATE` default - `state1 text, state2 text` (must have exactly two input parameters of the same data type)

`FINALIZE` default - `state text` (single parameter only)

## RETURNS

Optional. The default return type is `text`.

`MAP` default - `key text, value text`

`TRANSITION` default - `state text` (single return value only)

`CONSOLIDATE` default - `state text` (single return value only)

`FINALIZE` default - `value text`

## OPTIMIZE

Optional optimization parameters for the function:

`STRICT` - function is not affected by `NULL` values

`IMMUTABLE` - function will always return the same value for a given input

## MODE

Optional. Specifies the number of rows returned by the function.

`MULTI` - returns 0 or more rows per input record. The return value of the function must be an array of rows to return, or the function must be written as an iterator using `yield` in Python or `return_next` in Perl. `MULTI` is the default mode for `MAP` and `FINALIZE` functions.

`SINGLE` - returns exactly one row per input record. `SINGLE` is the only mode supported for `TRANSITION` and `CONSOLIDATE` functions. When used with `MAP` and `FINALIZE` functions, `SINGLE` mode can provide modest performance improvement.

## REDUCE

Required. A `REDUCE` definition names the `TRANSITION | CONSOLIDATE | FINALIZE` functions that comprise the reduction of `(key, value)` pairs to the final result set. There are also several predefined `REDUCE` jobs you can run, which all operate over a column named `value`:

`IDENTITY` - returns `(key, value)` pairs unchanged

`SUM` - calculates the sum of numeric data

`AVG` - calculates the average of numeric data

`COUNT` - calculates the count of input data

`MIN` - calculates minimum value of numeric data

`MAX` - calculates maximum value of numeric data

**NAME**

Required. The name of this **REDUCE** job. Names must be unique with regards to the names of other objects in this MapReduce job (function, task, input and output names). Also, names cannot conflict with existing objects in the database (such as tables, functions or views).

**TRANSITION**

Required. The name of the **TRANSITION** function.

**CONSOLIDATE**

Optional. The name of the **CONSOLIDATE** function.

**FINALIZE**

Optional. The name of the **FINALIZE** function.

**INITIALIZE**

Optional for **text** and **float** data types. Required for all other data types. The default value for text is `' '`. The default value for float is `0.0`. Sets the initial **state** value of the **TRANSITION** function.

**KEYS**

Optional. Defaults to `[key, *]`. When using a multi-column reduce it may be necessary to specify which columns are key columns and which columns are value columns. By default, any input columns that are not passed to the **TRANSITION** function are key columns, and a column named **key** is always a key column even if it is passed to the **TRANSITION** function. The special indicator `*` indicates all columns not passed to the **TRANSITION** function. If this indicator is not present in the list of keys then any unmatched columns are discarded.

**TASK**

Optional. A **TASK** defines a complete end-to-end **INPUT/MAP/REDUCE** stage within a Greenplum MapReduce job pipeline. It is similar to **EXECUTE** except it is not immediately run. A task object can be called as **INPUT** to further processing stages.

**NAME**

Required. The name of this task. Names must be unique with regards to the names of other objects in this MapReduce job (such as map function, reduce function, input and output names). Also, names cannot conflict with existing objects in the database (such as tables, functions or views).

**SOURCE**

The name of an **INPUT** or another **TASK**.

**MAP**

Optional. The name of a **MAP** function. If not specified, defaults to **IDENTITY**.

**REDUCE**

Optional. The name of a **REDUCE** function. If not specified, defaults to **IDENTITY**.

**EXECUTE**

Required. **EXECUTE** defines the final **INPUT/MAP/REDUCE** stage within a Greenplum MapReduce job pipeline.

**RUN**

**SOURCE**

Required. The name of an **INPUT** or **TASK**.

**TARGET**

Optional. The name of an **OUTPUT**. The default output is **STDOUT**.

**MAP**

Optional. The name of a **MAP** function. If not specified, defaults to **IDENTITY**.

**REDUCE**

Optional. The name of a **REDUCE** function. Defaults to **IDENTITY**.

[gmapreduce](#)

## gpmemreport

Interprets the output created by the [gpmemwatcher](#) utility and generates output files in a readable format.

## Synopsis

```
gpmemreport [<GZIP_FILE>] [[-s <START>] | [--start= <START>]] [[-e <END>] | [--end= <END>]]

gpmemreport --version

gpmemreport -h | --help
```

## Description

The [gpmemreport](#) utility helps interpret the output file created by the [gpmemwatcher](#) utility.

When running [gpmemreport](#) against the [.gz](#) files generated by [gpmemwatcher](#), it generates a series of files, where each file corresponds to a 60 second period of data collected by [gpmemwatcher](#) converted into a readable format.

## Options

**-s** | **--start** start\_time

Indicates the start of the reporting period. Timestamp format must be `'%Y-%m-%d %H:%M:%S'`.

**-e** | **--end** end\_time

Indicates the end of the reporting period. Timestamp format must be `'%Y-%m-%d %H:%M:%S'`.

**--version**

Displays the version of this utility.

**-h** | **--help**

Displays the online help.

## Examples

### Example 1: Extract all the files generated by [gpmemwatcher](#) for the Greenplum master

Locate the output [.gz](#) file from [gpmemwatcher](#) and run [gpmemreport](#) against it:

```
$ gpmemreport mdw.ps.out.gz
>>>21:11:19:15:37:18<<<

>>>21:11:19:15:38:18<<<

>>>21:11:19:15:39:18<<<
```

Check that the generated files are listed under the current directory:

```
$ ls -thrl
-rw-rw-r--. 1 gpadmin gpadmin 1.2K Nov 19 15:50 20211119-153718
-rw-rw-r--. 1 gpadmin gpadmin 1.2K Nov 19 15:50 20211119-153818
-rw-rw-r--. 1 gpadmin gpadmin 1.2K Nov 19 15:50 20211119-153918
```

### Example 2: Extract the files generated by `gpmemwatcher` for the Greenplum master starting after a certain timestamp

Locate the output `.gz` file from `gpmemwatcher` and run `gpmemreport` against it, indicating the start time as `2021-11-19 15:38:00`:

```
$ gpmemreport mdw.ps.out.gz --start='2021-11-19 15:38:00'
>>>21:11:19:15:37:18<<<

>>>21:11:19:15:38:18<<<

>>>21:11:19:15:39:18<<<
```

Check under the current directory that only the selected timestamp files are listed:

```
$ ls -thrl
-rw-rw-r--. 1 gpadmin gpadmin 1.2K Nov 19 15:50 20211119-153818
-rw-rw-r--. 1 gpadmin gpadmin 1.2K Nov 19 15:50 20211119-153918
```

## See Also

[gpmemwatcher](#)

## gpmemwatcher

Tracks the memory usage of each process in a Greenplum Database cluster.

## Synopsis

```
gpmemwatcher [-f | --host_file <hostfile>]

gpmemwatcher --stop [-f | --host_file <hostfile>]

gpmemwatcher --version

gpmemwatcher -h | --help
```

## Description

The `gpmemwatcher` utility is a daemon that runs on all servers of a Greenplum Database cluster. It tracks the memory usage of each process by collecting the output of the `ps` command every 60 seconds. It is a low impact process that only consumes 4 MB of memory. It will generate approximately 30 MB of data over a 24-hour period.

You may use this utility if Greenplum Database is reporting `Out of memory` errors and causing segments to go down or queries to fail. You collect the memory usage information of one or multiple servers within the Greenplum Database cluster with `gpmemwatcher` and then use `gpmemreport` to analyze the files collected.

## Options

`-f | --host_file hostfile`

Indicates the hostfile input file that lists the hosts from which the utility should collect memory usage information. The file must include the hostnames and a working directory that exists on each one of the hosts. For example:

```
mdw:/home/gpadmin/gpmemwatcher_dir/working
sdw1:/home/gpadmin/gpmemwatcher_dir/working
sdw2:/home/gpadmin/gpmemwatcher_dir/working
sdw3:/home/gpadmin/gpmemwatcher_dir/working
sdw4:/home/gpadmin/gpmemwatcher_dir/working
```

`--stop`

Stops all the `gpmemwatcher` processes, generates `.gz` data files in the current directory, and removes all the work files from all the hosts.

`--version`

Displays the version of this utility.

`-h | --help`

Displays the online help.

## Examples

### Example 1: Start the utility specifying the list of hosts from which to collect the information

Create the file `/home/gpadmin/hostmap.txt` that contains the following:

```
mdw:/home/gpadmin/gpmemwatcher_dir/working
sdw1:/home/gpadmin/gpmemwatcher_dir/working
sdw2:/home/gpadmin/gpmemwatcher_dir/working
sdw3:/home/gpadmin/gpmemwatcher_dir/working
sdw4:/home/gpadmin/gpmemwatcher_dir/working
```

Make sure that the path `/home/gpadmin/gpmemwatcher_dir/working` exists on all hosts.

Start the utility:

```
$ gpmemwatcher -f /home/gpadmin/hostmap.txt
```

**Example 2: Stop utility and dump the resulting into a .gz file**

Stop the utility you started in Example 1:

```
$ gpmemwatcher -f /home/gpadmin/hostmap.txt --stop
```

The results .gz files will be dumped into the directory where you are running the command:

```
$ [gpadmin@gpdb-m]$ ls -thrl
-rw-rw-r--. 1 gpadmin gpadmin 2.8K Nov 19 15:17 mdw.ps.out.gz
-rw-rw-r--. 1 gpadmin gpadmin 2.8K Nov 19 15:17 sdw1.ps.out.gz
-rw-rw-r--. 1 gpadmin gpadmin 2.8K Nov 19 15:17 sdw2.ps.out.gz
-rw-rw-r--. 1 gpadmin gpadmin 2.8K Nov 19 15:17 sdw3.ps.out.gz
-rw-rw-r--. 1 gpadmin gpadmin 2.8K Nov 19 15:17 sdw4.ps.out.gz
```

[gpmemreport](#)

## gpmovemirrors

Moves mirror segment instances to new locations.

## Synopsis

```
gpmovemirrors -i <move_config_file> [-d <master_data_directory>]
               [-l <logfile_directory>] [-b <segment_batch_size>]
               [-B <batch_size>] [-v] [--hba-hostnames <boolean>]

gpmovemirrors -?

gpmovemirrors --version
```

## Description

The `gpmovemirrors` utility moves mirror segment instances to new locations. You may want to move mirrors to new locations to optimize distribution or data storage.

By default, the utility will prompt you for the file system location(s) where it will move the mirror segment data directories.

You must make sure that the user who runs `gpmovemirrors` (the `gpadmin` user) has permissions to write to the data directory locations specified. You may want to create these directories on the segment hosts and `chown` them to the appropriate user before running `gpmovemirrors`.

## Options

`-b segment_batch_size`

The maximum number of segments per host to operate on in parallel. Valid values are 1 to 128. If not specified, the utility will start recovering up to 64 segments in parallel on each host.

**-B batch\_size**

The number of hosts to work on in parallel. If not specified, the utility will start working on up to 16 hosts in parallel. Valid values are 1 to 64.

**-d master\_data\_directory**

The master data directory. If not specified, the value set for `$MASTER_DATA_DIRECTORY` will be used.

**--hba-hostnames boolean**

Optional. Controls whether this utility uses IP addresses or host names in the `pg_hba.conf` file when updating this file with addresses that can connect to Greenplum Database. When set to 0 -- the default value -- this utility uses IP addresses when updating this file. When set to 1, this utility uses host names when updating this file. For consistency, use the same value that was specified for `HBA_HOSTNAMES` when the Greenplum Database system was initialized. For information about how Greenplum Database resolves host names in the `pg_hba.conf` file, see [Configuring Client Authentication](#).

**-i move\_config\_file**

A configuration file containing information about which mirror segments to move, and where to move them.

You must have one mirror segment listed for each primary segment in the system. Each line inside the configuration file has the following format (as per attributes in the `gp_segment_configuration` catalog table):

```
<old_address>|<port>|<data_dir> <new_address>|<port>|<data_dir>
```

: Where `<old_address>` and `<new_address>` are the host names or IP addresses of the segment hosts, `<port>` is the communication port, and `<data_dir>` is the segment instance data directory.

**-l logfile\_directory**

The directory to write the log file. Defaults to `~/gpAdminLogs`.

**-v (verbose)**

Sets logging output to verbose.

**--version (show utility version)**

Displays the version of this utility.

**-? (help)**

Displays the online help.

## Examples

Moves mirrors from an existing Greenplum Database system to a different set of hosts:

```
$ gpmoveerrors -i move_config_file
```

Where the `move_config_file` looks something like this:

```
sdw2|50000|/data2/mirror/gpseg0 sdw3|50000|/data/mirror/gpseg0
sdw2|50001|/data2/mirror/gpseg1 sdw4|50001|/data/mirror/gpseg1
sdw3|50002|/data2/mirror/gpseg2 sdw1|50002|/data/mirror/gpseg2
```

## gpmt

GPMT (Greenplum Magic Tool) provides a set of diagnostic utilities to troubleshoot and resolve common supportability issues, along with a consistent method for gathering information required by VMware Support.

## Synopsis

```
gpmt <tool> [<tool_options> ...]

gpmt -hostfile <file>

gpmt -help

gpmt -verbose
```

## Tools

### Greenplum

#### [analyze\\_session](#)

Collect information from a hung Greenplum Database session for remote analysis.

#### [catalogbackup](#)

For VMware Support use only. Back up catalog prior to performing catalog repairs.

#### [gp\\_log\\_collector](#)

Basic Greenplum Database log collection utility.

#### [storage\\_rca\\_collector](#)

Collect storage-related artifacts.

#### [gpcheckcat](#)

For VMware Support use only. Greenplum Database gpcheckcat log analysis.

#### [gpcheckup](#)

For VMware Support use only. Greenplum Database Health Check.

#### [gpstatscheck](#)

Check for missing stats on objects used in a query.

#### [packcore](#)

Package core files into single tarball for remote analysis.

#### [primarymirror\\_lengths](#)

For VMware Support use only. Check whether primary and mirror AO and AOCO refiles are the correct lengths.

#### [tablecollect](#)

For VMware Support use only. Collect data and index files for data corruption RCA.

### Miscellaneous

#### [hostfile](#)

Generate hostfiles for use with other tools.

#### [replcheck](#)

Check whether tool is replicated to all hosts.

replicate

Replicate tool to all hosts.

version

Display the GPMT version.

## Global Options

-hostfile

Limit the hosts where the tool will be run.

-help

Display the online help.

-verbose

Print verbose log messages.

## Examples

### Display gpmt version

```
gpmt version
```

### Collect a core file

```
gpmt packcore -cmd collect -core core.1234
```

### Show help for a specific tool

```
gpmt gp_log_collector -help
```

## gpmt analyze\_session

This tool traces busy processes associated with a Greenplum Database session. The information collected can be used by VMware Support for root cause analysis on hung sessions.

## Usage

```
gpmt analyze_session [-session <session_id> ] [-master-dir <directory>]
[-segment-dir <directory>]
```

## Options

-session

Greenplum session ID which is referenced in `pg_stat_activity`.

-master-dir

Working directory for master process.

-segment-dir

Working directory for segment processes.

-free-space

Free space threshold which will exit log collection if reached. Default value is 10%.

-a

Answer Yes to all prompts.

## Examples

Collect process information for a given Greenplum Database session id:

```
gpmt analyze_session -session 12345
```

The tool prompt gives a high-level list of only the servers that are running busy processes and how processes are distributed across the Greenplum hosts. This gives an idea of what hosts are busier than others, which might be caused by processing skew or other environmental issue with the affected hosts.

Note: `lsof`, `strace`, `pstack`, `gcore`, `gdb` must be installed on all hosts. `gcore` will perform a memory dump of the Greenplum process and the size could be anywhere from 300MB to several Gigabytes. Isolating which hosts to collect using the `gpmt` global option `-hostfile` to limit the collection size.

## gpmt gp\_log\_collector

This tool collects Greenplum and system log files, along with the relevant configuration parameters, and generates a file which can be provided to VMware Customer Support for diagnosis of errors or system failures.

## Usage

```
gpmt gp_log_collector [-failed-segs | -c <ID1, ID2, ...>| -hostfile <file> | -h <host1, host2, ...>]
[ -start <YYYY-MM-DD> ] [ -end <YYYY-MM-DD> ]
[ -dir <path> ] [ -segdir <path> ] [ -a ] [-skip-master] [-with-gpbackup] [-with-gptext]
[-with-gptext-only] [-with-pxf] [-with-pxf-only] [-with-gpupgrade]
```

## Options

-failed-segs

The tool scans `gp_configuration_history` to identify when a segment fails over to their mirrors or simply fails without explanation. The relevant content ID logs will be collected.

-free-space

Free space threshold which will exit log collection if reached. Default value is 10%.

-c

Comma separated list of content IDs to collect logs from.

-hostfile

Hostfile with a list of hostnames to collect logs from.

-h

Comma separated list of hostnames to collect logs from.

-start

- Start date for logs to collect (defaults to current date).
- end  
End date for logs to collect (defaults to current date).
- dir  
Working directory (defaults to current directory).
- segdir  
Segment temporary directory (defaults to /tmp).
- a  
Answer Yes to all prompts.
- skip-master  
When running `gp_log_collector`, the generated tarball can be very large. Use this option to skip Greenplum Master log collection when only Greenplum Segment logs are required.
- with-gpbackup  
Beginning with Greenplum 6.22, this option enables you to collect logs related to backup and restore.

With this option, `gpmt` collects these log files from `$GPADMIN_HOME/gpAdminLogs`:

- `gpbackup_.log`
- `gpbackup_helper_.log`
- `gpbackup_plugin .log`
- `gprestore_.log`

These are collected from the provided `--backup-dir` or default backup directory:

- `gpbackup__config.yaml`
- `gpbackup__metadata.sql`
- `gpbackup__report`
- `gpbackup__toc.yaml`
- `gprestore__report`
- `gpbackup__report`

Also, the `pg_log` file is collected from the master and segment hosts.

- with-gptext  
Collect all GPText logs along with Greenplum logs.
- with-gptext-only  
Collect only GPText logs.
- with-pxf  
Collect all PXF logs along with Greenplum logs.
- with-pxf-only  
Collect only PXF logs.
- with-gpupgrade  
Collect all `gpupgrade` logs along with Greenplum logs.

**Note:** Hostnames provided through `-hostfile` or `-h` must match the hostname column in `gp_segment_configuration`.

The tool also collects the following information:

| Source                                | Files and outputs   |
|---------------------------------------|---|
| Database parameters                   | <ul style="list-style-type: none"> <li>• <code>version</code></li> <li>• <code>uptime</code></li> <li>• <code>pg_resqueue</code></li> <li>• <code>pg_resgroup_config</code></li> <li>• <code>pg_database</code></li> <li>• <code>gp_segment_configuration</code></li> <li>• <code>gp_configuration_history</code></li> <li>• Initialization timestamp</li> </ul>                                  |

**NOTE:** Some commands might not be able to be run if user does not have the correct permissions.

## Examples

Collect Greenplum master and segment logs listed in a hostfile from today:

```
gpmt gp_log_collector -hostfile ~/gpconfig/hostfile
```

Collect logs for any segments marked down from 21-03-2016 until today:

```
gpmt gp_log_collector -failed-segs -start 2016-03-21
```

Collect logs from host `sdw2.gpdb.local` between 2016-03-21 and 2016-03-23:

```
gpmt gp_log_collector -failed-segs -start 2016-03-21 -end 2016-03-21
```

Collect only GPText logs for all segments, without any Greenplum logs:

```
gpmt gp_log_collector -with-gptext-only
```

## storage\_rca\_collector

This tool collects storage-related table data and generates an output file which can be provided to VMware Customer Support for diagnosis of storage-related errors or system failures.

## Usage

```
storage_rca_collector [-db <database> ] [-t <table> ] | -c <ID1,ID2,...> ] [-dir <path> ] [-a] [-translog ]
```

## Options

- db  
The database name.
- t  
The table name.
- c  
Comma separated list of content IDs to collect logs from.
- dir  
The output directory. Defaults to the current directory.
- a  
Answer Yes to all prompts.
- translog  
Specifies that the tool should collect transaction log data.

The tool also collects the following information:

- Output from:
  - pg\_class
  - pg\_stat\_last\_operation
  - gp\_distributed\_log
  - pg\_appendonly
- Data from transaction logs, if you call this tool with the `-translog` option
- AOCO data for a given appendonly, column-oriented table
- AO data for a given appendonly table

**NOTE:** some commands might not be able to be run if the user does not have correct permissions.

## Examples

Collect storage root cause analysis artifacts only for master, database `postgres`, and table `test_table`:

```
gpmt storage_rca_collector -db postgres -t test_table
```

Collect storage root cause analysis artifacts for primary segment with contentid [0,1], database `postgres`, and table `test_table`:

```
gpmt storage_rca_collector -db postgres -c 0,1 -t test_table
```

Collect storage root cause analysis artifacts for primary segment with contentid [0,1], database `postgres`, and table `test_table`, with prompt deactivated:

```
gpmt storage_rca_collector -db postgres -c 0,1 -t test_table -a
```

Collect storage rca artifacts for primary segment with contentid [0,1], database `postgres`, and table `test_table` and also collect transaction logs:

```
gpmt storage_rca_collector -db postgres -c 0,1 -t test_table -transLog
```

Collect storage rca artifacts for primary segment with contentid [0,1], database `postgres` and table `test_table` and output to a specified directory location.

```
gpmt storage_rca_collector -db postgres -c 0,1 -t test_table -dir <dir>
```

**Note:** Output files follow the naming convention `<database name>_<dbid>_<artifact name>`.

## gpmt gpstatscheck

This tool can be used to verify if all tables involved in a query have optimal statistics. When a query is running slower than expected, it is possible that outdated or invalid statistics on the tables involved in the query are causing the slowness. This can happen if new data has been loaded into the table but `analyze` was never run, so the database is using wrong statistics when generating the query plan.

## Usage

```
gpmt gpstatscheck -f <query-file>
[-p <port>] [-d <database>]
```

## Options

- f  
File containing the query to analyze.
- p  
Database port.
- d  
Database where the query is being run.

## Examples

Run the query in `query1.sql` in database `Postgres` and check for missing stats.

```
gpmt gpstatscheck -f query1.sql -d postgres
```

If invalid statistics are detected the tool will generate a script listing the suggested commands to run. For example:

```
$ cat gpstatscheck_20160926_134946.sql
ANALYZE public.nums;
```

You can then run the provided script against the affected database:

```
$ psql -p 5432 -d postgres -f gpstatscheck_20160926_134946.sql
```

## gpmt packcore

This tool collects all the necessary files and generates a script that runs the `gdb` command to create a core file readable by an external host. Use this command when VMware Support needs to collect core files generated by the Greenplum processes.

## Usage

```
gpmt packcore collect -core <corefile> [-binary <binary> ]
[-keep_tmp_dir] [-ignore_missing]
```

## Options

- core  
Corefile name.
- binary  
Binary name that generated the core file.
- keep\_tmp\_dir  
Do not delete the temporary directory.
- ignore\_missing  
Ignore missing libraries.

## Examples

Collect core info for `core.1234` for binary `/usr/local/greenplum-db/bin/postgres`.

```
gpmt packcore -cmd collect -core core.1234 -binary /usr/local/greenplum-db/bin/postgre
s
```

## gppkg

Installs Greenplum Database extensions in `.gppkg` format, such as PL/Java, PL/R, PostGIS, and MADlib, along with their dependencies, across an entire cluster.

## Synopsis

```
gppkg [-i <package> | -u <package> | -r <name>-<version> | -c]
      [-d <master_data_directory>] [-a] [-v]

gppkg --migrate <GPHOME_old> <GPHOME_new> [-a] [-v]

gppkg [-q | --query] <query_option>

gppkg -? | --help | -h

gppkg --version
```

## Description

The Greenplum Package Manager (`gppkg`) utility installs Greenplum Database extensions, along with any dependencies, on all hosts across a cluster. It will also automatically install extensions on new hosts in the case of system expansion and segment recovery.

**Note:** After a major upgrade to Greenplum Database, you must download and install all `gppkg` extensions again.

Examples of database extensions and packages software that are delivered using the Greenplum Package Manager are:

- PL/Java
- PL/R
- PostGIS
- MADlib

## Options

`-a` (do not prompt)

Do not prompt the user for confirmation.

`-c` | `--clean`

Reconciles the package state of the cluster to match the state of the master host. Running this option after a failed or partial install/uninstall ensures that the package installation state is consistent across the cluster.

`-d` `master_data_directory`

The master data directory. If not specified, the value set for `$MASTER_DATA_DIRECTORY` will be used.

`-i` `package` | `--install=package`

Installs the given package. This includes any pre/post installation steps and installation of any dependencies.

`--migrate` `GPHOME_old` `GPHOME_new`

Migrates packages from a separate `$GPHOME`. Carries over packages from one version of Greenplum Database to another.

For example: `gppkg --migrate /usr/local/greenplum-db-<old-version> /usr/local/greenplum-db-<new-version>`

**Note:** In general, it is best to avoid using the `--migrate` option, and packages should be reinstalled, not migrated. See [Upgrading from 6.x to a Newer 6.x Release](#).

When migrating packages, these requirements must be met.

- At least the master instance of the destination Greenplum Database must be started (the instance installed in `GPHOME_new`). Before running the `gppkg` command start the Greenplum Database master with the command `gpstart -m`.
- Run the `gppkg` utility from the `GPHOME_new` installation. The migration destination installation directory.

`-q | --query query_option`

Provides information specified by `query_option` about the installed packages. Only one `query_option` can be specified at a time. The following table lists the possible values for `query_option`. `<package_file>` is the name of a package.

| query_option                             | Returns   |
|--|---|
| <code>&lt;package_file&gt;</code>        | Whether the specified package is installed.                           |
| <code>--info &lt;package_file&gt;</code> | The name, version, and other information about the specified package. |
| <code>--list &lt;package_file&gt;</code> | The file contents of the specified package.                           |
| <code>--all</code>                       | List of all installed packages.                                       |

`-r name-version | --remove=name-version`

Removes the specified package.

`-u package | --update=package`

Updates the given package.

**Warning:** The process of updating a package includes removing all previous versions of the system objects related to the package. For example, previous versions of shared libraries are removed. After the update process, a database function will fail when it is called if the function references a package file that has been removed.

`--version` (show utility version)

Displays the version of this utility.

`-v | --verbose`

Sets the logging level to verbose.

`-? | -h | --help`

Displays the online help.

## gprecoverseg

Recovers a primary or mirror segment instance that has been marked as down (if mirroring is enabled).

## Synopsis

```

gprecoverseg [[-p <new_recover_host>[,...]] | -i <recover_config_file>] [-d <master_data_directory>]
    [-b <segment_batch_size>] [-B <batch_size>] [-F [-s]] [-a] [-q]
    [--hba-hostnames <boolean>]
    [--no-progress] [-l <logfile_directory>]

gprecoverseg -r

gprecoverseg -o <output_recover_config_file>
    [-p <new_recover_host>[,...]]

gprecoverseg -? | -h | --help

gprecoverseg -v | --verbose

gprecoverseg --version

```

## Description

In a system with mirrors enabled, the `gprecoverseg` utility reactivates a failed segment instance and identifies the changed database files that require resynchronization. Once `gprecoverseg` completes this process, the system goes into `Not in Sync` mode until the recovered segment is brought up to date. The system is online and fully operational during resynchronization.

During an incremental recovery (the `-F` option is not specified), if `gprecoverseg` detects a segment instance with mirroring deactivated in a system with mirrors activated, the utility reports that mirroring is deactivated for the segment, does not attempt to recover that segment instance, and continues the recovery process.

A segment instance can fail for several reasons, such as a host failure, network failure, or disk failure. When a segment instance fails, its status is marked as `d` (down) in the Greenplum Database system catalog, and its mirror is activated in `Not in Sync` mode. In order to bring the failed segment instance back into operation again, you must first correct the problem that made it fail in the first place, and then recover the segment instance in Greenplum Database using `gprecoverseg`.

**Note:** If incremental recovery was not successful and the down segment instance data is not corrupted, contact VMware Support.

Segment recovery using `gprecoverseg` requires that you have an active mirror to recover from. For systems that do not have mirroring enabled, or in the event of a double fault (a primary and mirror pair both down at the same time) — you must take manual steps to recover the failed segment instances and then perform a system restart to bring the segments back online. For example, this command restarts a system.

```
gpstop -r
```

By default, a failed segment is recovered in place, meaning that the system brings the segment back online on the same host and data directory location on which it was originally configured. In this case, use the following format for the recovery configuration file (using `-i`).

```
<failed_host_address>|<port>|<data_directory>
```

In some cases, this may not be possible (for example, if a host was physically damaged and cannot be recovered). In this situation, `gprecoverseg` allows you to recover failed segments to a completely new host (using `-p`), on an alternative data directory location on your remaining live segment hosts (using `-s`), or by supplying a recovery configuration file (using `-i`) in the following format. The word `<SPACE>` indicates the location of a required space. Do not add additional spaces.

```
<failed_host_address>|<port>|<data_directory><SPACE>
<recovery_host_address>|<port>|<data_directory>
```

See the `-i` option below for details and examples of a recovery configuration file.

The `gp_segment_configuration` system catalog table can help you determine your current segment configuration so that you can plan your mirror recovery configuration. For example, run the following query:

```
=# SELECT dbid, content, address, port, datadir
   FROM gp_segment_configuration
   ORDER BY dbid;
```

The new recovery segment host must be pre-installed with the Greenplum Database software and configured exactly the same as the existing segment hosts. A spare data directory location must exist on all currently configured segment hosts and have enough disk space to accommodate the failed segments.

The recovery process marks the segment as up again in the Greenplum Database system catalog, and then initiates the resynchronization process to bring the transactional state of the segment up-to-date with the latest changes. The system is online and available during `Not in Sync` mode.

## Options

`-a` (do not prompt)

Do not prompt the user for confirmation.

`-b segment_batch_size`

The maximum number of segments per host to operate on in parallel. Valid values are `1` to `128`. If not specified, the utility will start recovering up to 64 segments in parallel on each host.

`-B batch_size`

The number of hosts to work on in parallel. If not specified, the utility will start working on up to 16 hosts in parallel. Valid values are `1` to `64`.

`-d master_data_directory`

Optional. The master host data directory. If not specified, the value set for `$MASTER_DATA_DIRECTORY` will be used.

`-F` (full recovery)

Optional. Perform a full copy of the active segment instance in order to recover the failed segment. The default is to only copy over the incremental changes that occurred while the segment was down.

**Warning:** A full recovery deletes the data directory of the down segment instance before copying the data from the active (current primary) segment instance. Before performing a full

recovery, ensure that the segment failure did not cause data corruption and that any host segment disk issues have been fixed.

Also, for a full recovery, the utility does not restore custom files that are stored in the segment instance data directory even if the custom files are also in the active segment instance. You must restore the custom files manually. For example, when using the `gpfdists` protocol (`gpfdist` with SSL encryption) to manage external data, client certificate files are required in the segment instance `$PGDATA/gpfdists` directory. These files are not restored. For information about configuring `gpfdists`, see [Encrypting gpfdist Connections](#).

Use the `-s` option to output a new line once per second for each segment. Alternatively, use the `--no-progress` option to completely deactivate progress reports.

`--hba-hostnames` boolean

Optional. Controls whether this utility uses IP addresses or host names in the `pg_hba.conf` file when updating this file with addresses that can connect to Greenplum Database. When set to 0 -- the default value -- this utility uses IP addresses when updating this file. When set to 1, this utility uses host names when updating this file. For consistency, use the same value that was specified for `HBA_HOSTNAMES` when the Greenplum Database system was initialized. For information about how Greenplum Database resolves host names in the `pg_hba.conf` file, see [Configuring Client Authentication](#).

`-i recover_config_file`

Specifies the name of a file with the details about failed segments to recover.

Each line in the config file specifies a segment to recover. This line can have one of two formats. In the event of in-place (incremental) recovery, enter one group of pipe-delimited fields in the line. For example:

```
failedAddress|failedPort|failedDataDirectory
```

For recovery to a new location, enter two groups of fields separated by a space in the line. The required space is indicated by `<SPACE>`. Do not add additional spaces.

```
failedAddress|failedPort|failedDataDirectory<SPACE>newAddress|
newPort|newDataDirectory
```

**Note:** Lines beginning with `#` are treated as comments and ignored.

## Examples

### In-place (incremental) recovery of a single mirror

```
sdw1-1|50001|/data1/mirror/gpseg16
```

### Recovery of a single mirror to a new host

```
sdw1-1|50001|/data1/mirror/gpseg16<SPACE>sdw4-1|50001|/data1/recover1/gpseg16
```

## Obtaining a Sample File

You can use the `-o` option to output a sample recovery configuration file to use as a starting point. The output file lists the currently invalid segments and their default recovery location. This file format can be used with the `-i` option for in-place (incremental) recovery.

`-l logfile_directory`

The directory to write the log file. Defaults to `~/gpAdminLogs`.

`-o output_recover_config_file`

Specifies a file name and location to output a sample recovery configuration file. This file can be edited to supply alternate recovery locations if needed. The following example outputs the default recovery configuration file:

```
$ gprecoverseg -o /home/gpadmin/recover_config_file
```

`-p new_recover_host[,...]`

Specifies a new host outside of the currently configured Greenplum Database array on which to recover invalid segments.

The new host must have the Greenplum Database software installed and configured, and have the same hardware and OS configuration as the current segment hosts (same OS version, locales, `gpadmin` user account, data directory locations created, ssh keys exchanged, number of network interfaces, network interface naming convention, and so on). Specifically, the Greenplum Database binaries must be installed, the new host must be able to connect password-less with all segments including the Greenplum master, and any other Greenplum Database specific OS configuration parameters must be applied.

**Note:** In the case of multiple failed segment hosts, you can specify the hosts to recover with a comma-separated list. However, it is strongly recommended to recover one host at a time. If you must recover more than one host at a time, then it is critical to ensure that a double fault scenario does not occur, in which both the segment primary and corresponding mirror are offline.

`-q` (no screen output)

Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

`-r` (rebalance segments)

After a segment recovery, segment instances may not be returned to the preferred role that they were given at system initialization time. This can leave the system in a potentially unbalanced state, as some segment hosts may have more active segments than is optimal for top system performance. This option rebalances primary and mirror segments by returning them to their preferred roles. All segments must be valid and resynchronized before running `gprecoverseg -r`. If there are any in progress queries, they will be cancelled and rolled back.

`-s` (sequential progress)

Show `pg_basebackup` or `pg_rewind` progress sequentially instead of in-place. Useful when writing to a file, or if a tty does not support escape sequences. The default is to show progress in-place.

`--no-progress`

Suppresses progress reports from the `pg_basebackup` or `pg_rewind` utility. The default is to display progress.

`-v` | `--verbose`

Sets logging output to verbose.

`--version`

Displays the version of this utility.

`-?` | `-h` | `--help`

Displays the online help.

## Examples

### Example 1: Recover Failed Segments in Place

Recover any failed segment instances in place:

```
$ gprecoverseg
```

### Example 2: Rebalance Failed Segments If Not in Preferred Roles

First, verify that all segments are up and running, re synchronization has completed, and there are segments **not** in preferred roles:

```
$ gpstate -e
```

Then, if necessary, rebalance the segments:

```
$ gprecoverseg -r
```

### Example 3: Recover Failed Segments to a Separate Host

Recover any failed segment instances to a newly configured new segment host:

```
$ gprecoverseg -i <recover_config_file>
```

[gpstart](#), [gpstop](#)

## gpreload

Reloads Greenplum Database table data sorting the data based on specified columns.

## Synopsis

```
gpreload -d <database> [-p <port>] {-t | --table-file} <path_to_file> [-a]
gpreload -h
gpreload --version
```

## Description

The `gpreload` utility reloads table data with column data sorted. For tables that were created with the table storage option `appendoptimized=TRUE` and compression enabled, reloading the data with sorted data can improve table compression. You specify a list of tables to be reloaded and the table columns to be sorted in a text file.

Compression is improved by sorting data when the data in the column has a relatively low number of distinct values when compared to the total number of rows.

For a table being reloaded, the order of the columns to be sorted might affect compression. The columns with the fewest distinct values should be listed first. For example, listing state then city would generally result in better compression than listing city then state.

```
public.cust_table: state, city
public.cust_table: city, state
```

For information about the format of the file used with `gpreload`, see the `--table-file` option.

## Notes

To improve reload performance, indexes on tables being reloaded should be removed before reloading the data.

Running the `ANALYZE` command after reloading table data might query performance because of a change in the data distribution of the reloaded data.

For each table, the utility copies table data to a temporary table, truncates the existing table data, and inserts data from the temporary table to the table in the specified sort order. Each table reload is performed in a single transaction.

For a partitioned table, you can reload the data of a leaf child partition. However, data is inserted from the root partition table, which acquires a `ROW EXCLUSIVE` lock on the entire table.

## Options

`-a` (do not prompt)

Optional. If specified, the `gpreload` utility does not prompt the user for confirmation.

`-d` database

The database that contains the tables to be reloaded. The `gpreload` utility connects to the database as the user running the utility.

`-p` port

The Greenplum Database master port. If not specified, the value of the `PGPORT` environment variable is used. If the value is not available, an error is returned.

`{-t | --table-file } path_to_file`

The location and name of file containing list of schema qualified table names to reload and the column names to reorder from the Greenplum Database. Only user defined tables are supported. Views or system catalog tables are not supported.

If indexes are defined on table listed in the file, `gpreload` prompts to continue.

Each line specifies a table name and the list of columns to sort. This is the format of each line in the file:

```
schema.table_name: column [desc] [, column2 [desc] ... ]
```

The table name is followed by a colon ( : ) and then at least one column name. If you specify more than one column, separate the column names with a comma. The columns are sorted

in ascending order. Specify the keyword `desc` after the column name to sort the column in descending order.

Wildcard characters are not supported.

If there are errors in the file, `gppreload` reports the first error and exits. No data is reloaded.

The following example reloads three tables:

```
public.clients: region, state, rep_id desc
public.merchants: region, state
test.lineitem: group, assy, whse
```

In the first table `public.clients`, the data in the `rep_id` column is sorted in descending order. The data in the other columns are sorted in ascending order.

`--version` (show utility version)

Displays the version of this utility.

`-?` (help)

Displays the online help.

## Example

This example command reloads the tables in the database `mytest` that are listed in the file `data-tables.txt`.

```
gppreload -d mytest --table-file data-tables.txt
```

`CREATE TABLE` in the *Greenplum Database Reference Guide*

## gpscp

Copies files between multiple hosts at once.

## Synopsis

```
gpscp { -f <hostfile_gpssh> | -h <hostname> [-h <hostname> ...] }
      [-J <character>] [-v] [[<user>@]<hostname>:]<file_to_copy> [...]
      [[<user>@]<hostname>:]<copy_to_path>

gpscp -?

gpscp --version
```

## Description

The `gpscp` utility allows you to copy one or more files from the specified hosts to other specified hosts in one command using SCP (secure copy). For example, you can copy a file from the Greenplum Database master host to all of the segment hosts at the same time.

To specify the hosts involved in the SCP session, use the `-f` option to specify a file containing a list of host names, or use the `-h` option to name single host names on the command-line. At least one host name (`-h`) or a host file (`-f`) is required. The `-J` option allows you to specify a single character to substitute for the hostname in the `copy from` and `copy to` destination strings. If `-J` is not specified, the default substitution character is an equal sign (=). For example, the following command will copy `.bashrc` from the local host to `/home/gpadmin` on all hosts named in `hostfile_gpssh`:

```
gpscp -f hostfile_gpssh .bashrc =:/home/gpadmin
```

If a user name is not specified in the host list or with `user@` in the file path, `gpscp` will copy files as the currently logged in user. To determine the currently logged in user, do a `whoami` command. By default, `gpscp` goes to `$HOME` of the session user on the remote hosts after login. To ensure the file is copied to the correct location on the remote hosts, it is recommended that you use absolute paths.

Before using `gpscp`, you must have a trusted host setup between the hosts involved in the SCP session. You can use the utility `gpssh-exkeys` to update the known host files and exchange public keys between hosts if you have not done so already.

## Options

`-f hostfile_gpssh`

Specifies the name of a file that contains a list of hosts that will participate in this SCP session. The syntax of the host file is one host per line as follows:

```
<hostname>
```

`-h hostname`

Specifies a single host name that will participate in this SCP session. You can use the `-h` option multiple times to specify multiple host names.

`-J character`

The `-J` option allows you to specify a single character to substitute for the hostname in the `copy from` and `copy to` destination strings. If `-J` is not specified, the default substitution character is an equal sign (=).

`-v (verbose mode)`

Optional. Reports additional messages in addition to the SCP command output.

`file_to_copy`

Required. The file name (or absolute path) of a file that you want to copy to other hosts (or file locations). This can be either a file on the local host or on another named host.

`copy_to_path`

Required. The path where you want the file(s) to be copied on the named hosts. If an absolute path is not used, the file will be copied relative to `$HOME` of the session user. You can also use the equal sign '=' (or another character that you specify with the `-J` option) in place of a hostname. This will then substitute in each host name as specified in the supplied host file (`-f`) or with the `-h` option.

`-? (help)`

Displays the online help.

--version

Displays the version of this utility.

## Examples

Copy the file named `installer.tar` to `/` on all the hosts in the file `hostfile_gpssh`.

```
gpscp -f hostfile_gpssh installer.tar =:/
```

Copy the file named `myfuncs.so` to the specified location on the hosts named `sdw1` and `sdw2`:

```
gpscp -h sdw1 -h sdw2 myfuncs.so =:/usr/local/greenplum-db/lib
```

## See Also

[gpssh](#), [gpssh-exkeys](#)

## gpssh

Provides SSH access to multiple hosts at once.

## Synopsis

```
gpssh { -f <hostfile_gpssh> | -h <hostname> [-h <hostname> ...] } \[-s\] [-e]
      [-d <seconds>] [-t <multiplier>] [-v]
      [<bash_command>]

gpssh -?

gpssh --version
```

## Description

The `gpssh` utility allows you to run bash shell commands on multiple hosts at once using SSH (secure shell). You can run a single command by specifying it on the command-line, or omit the command to enter into an interactive command-line session.

To specify the hosts involved in the SSH session, use the `-f` option to specify a file containing a list of host names, or use the `-h` option to name single host names on the command-line. At least one host name (`-h`) or a host file (`-f`) is required. Note that the current host is **not** included in the session by default — to include the local host, you must explicitly declare it in the list of hosts involved in the session.

Before using `gpssh`, you must have a trusted host setup between the hosts involved in the SSH session. You can use the utility `gpssh-exkeys` to update the known host files and exchange public keys between hosts if you have not done so already.

If you do not specify a command on the command-line, `gpssh` will go into interactive mode. At the `gpssh` command prompt (`=>`), you can enter a command as you would in a regular bash terminal

command-line, and the command will be run on all hosts involved in the session. To end an interactive session, press **CTRL+D** on the keyboard or type `exit` or `quit`.

If a user name is not specified in the host file, `gpssh` will run commands as the currently logged in user. To determine the currently logged in user, do a `whoami` command. By default, `gpssh` goes to `$HOME` of the session user on the remote hosts after login. To ensure commands are run correctly on all remote hosts, you should always enter absolute paths.

If you encounter network timeout problems when using `gpssh`, you can use `-d` and `-t` options or set parameters in the `gpssh.conf` file to control the timing that `gpssh` uses when validating the initial `ssh` connection. For information about the configuration file, see [gpssh Configuration File](#).

## Options

### bash\_command

A bash shell command to run on all hosts involved in this session (optionally enclosed in quotes). If not specified, `gpssh` starts an interactive session.

### -d (delay) seconds

Optional. Specifies the time, in seconds, to wait at the start of a `gpssh` interaction with `ssh`. Default is `0.05`. This option overrides the `delaybeforesend` value that is specified in the `gpssh.conf` configuration file.

Increasing this value can cause a long wait time during `gpssh` startup.

### -e (echo)

Optional. Echoes the commands passed to each host and their resulting output while running in non-interactive mode.

### -f hostfile\_gpssh

Specifies the name of a file that contains a list of hosts that will participate in this SSH session. The syntax of the host file is one host per line.

### -h hostname

Specifies a single host name that will participate in this SSH session. You can use the `-h` option multiple times to specify multiple host names.

### -s

Optional. If specified, before running any commands on the target host, `gpssh` sources the file `greenplum_path.sh` in the directory specified by the `$GPHOME` environment variable.

This option is valid for both interactive mode and single command mode.

### -t multiplier

Optional. A decimal number greater than 0 (zero) that is the multiplier for the timeout that `gpssh` uses when validating the `ssh` prompt. Default is `1`. This option overrides the `prompt_validation_timeout` value that is specified in the `gpssh.conf` configuration file.

Increasing this value has a small impact during `gpssh` startup.

### -v (verbose mode)

Optional. Reports additional messages in addition to the command output when running in non-interactive mode.

### --version

Displays the version of this utility.

### -? (help)

Displays the online help.

## gpssh Configuration File

The `gpssh.conf` file contains parameters that let you adjust the timing that `gpssh` uses when validating the initial `ssh` connection. These parameters affect the network connection before the `gpssh` session runs commands with `ssh`. The location of the file is specified by the environment variable `MASTER_DATA_DIRECTORY`. If the environment variable is not defined or the `gpssh.conf` file does not exist, `gpssh` uses the default values or the values set with the `-d` and `-t` options. For information about the environment variable, see the *Greenplum Database Reference Guide*.

The `gpssh.conf` file is a text file that consists of a `[gpssh]` section and parameters. On a line, the `#` (pound sign) indicates the start of a comment. This is an example `gpssh.conf` file.

```
[gpssh]
delaybeforeseend = 0.05
prompt_validation_timeout = 1.0
sync_retries = 5
```

These are the `gpssh.conf` parameters.

`delaybeforeseend = seconds`

Specifies the time, in seconds, to wait at the start of a `gpssh` interaction with `ssh`. Default is 0.05. Increasing this value can cause a long wait time during `gpssh` startup. The `-d` option overrides this parameter.

`prompt_validation_timeout = multiplier`

A decimal number greater than 0 (zero) that is the multiplier for the timeout that `gpssh` uses when validating the `ssh` prompt. Increasing this value has a small impact during `gpssh` startup. Default is 1. The `-t` option overrides this parameter.

`sync_retries = attempts`

A non-negative integer that specifies the maximum number of times that `gpssh` attempts to connect to a remote Greenplum Database host. The default is 3. If the value is 0, `gpssh` returns an error if the initial connection attempt fails. Increasing the number of attempts also increases the time between retry attempts. This parameter cannot be configured with a command-line option.

The `-t` option also affects the time between retry attempts.

Increasing this value can compensate for slow network performance or segment host performance issues such as heavy CPU or I/O load. However, when a connection cannot be established, an increased value also increases the delay when an error is returned.

## Examples

Start an interactive group SSH session with all hosts listed in the file `hostfile_gpssh`:

```
$ gpssh -f hostfile_gpssh
```

At the `gpssh` interactive command prompt, run a shell command on all the hosts involved in this session.

```
=> ls -a /data/primary/*
```

Exit an interactive session:

```
=> exit
=> quit
```

Start a non-interactive group SSH session with the hosts named `sdw1` and `sdw2` and pass a file containing several commands named `command_file` to `gpssh`:

```
$ gpssh -h sdw1 -h sdw2 -v -e < command_file
```

Run single commands in non-interactive mode on hosts `sdw2` and `localhost`:

```
$ gpssh -h sdw2 -h localhost -v -e 'ls -a /data/primary/*'
$ gpssh -h sdw2 -h localhost -v -e 'echo $GPHOME'
$ gpssh -h sdw2 -h localhost -v -e 'ls -l | wc -l'
```

## gpssh-exkeys

Exchanges SSH public keys between hosts.

## Synopsis

```
gpssh-exkeys -f <hostfile_exkeys> | -h <hostname> [-h <hostname> ...]

gpssh-exkeys -e <hostfile_exkeys> -x <hostfile_gpexpand>

gpssh-exkeys -?

gpssh-exkeys --version
```

## Description

The `gpssh-exkeys` utility exchanges SSH keys between the specified host names (or host addresses). This allows SSH connections between Greenplum hosts and network interfaces without a password prompt. The utility is used to initially prepare a Greenplum Database system for passwordless SSH access, and also to prepare additional hosts for passwordless SSH access when expanding a Greenplum Database system.

Keys are exchanged as the currently logged in user. You run the utility on the master host as the `gpadmin` user (the user designated to own your Greenplum Database installation). Greenplum Database management utilities require that the `gpadmin` user be created on all hosts in the Greenplum Database system, and the utilities must be able to connect as that user to all hosts without a password prompt.

You can also use `gpssh-exkeys` to enable passwordless SSH for additional users, `root`, for example.

The `gpssh-exkeys` utility has the following prerequisites:

- The user must have an account on the master, standby, and every segment host in the Greenplum Database cluster.
- The user must have an `id_rsa` SSH key pair installed on the master host.
- The user must be able to connect with SSH from the master host to every other host machine without entering a password. (This is called "1-*n* passwordless SSH.")

You can enable 1-*n* passwordless SSH using the `ssh-copy-id` command to add the user's public key to each host's `authorized_keys` file. The `gpssh-exkeys` utility enables "*n-n* passwordless SSH," which allows the user to connect with SSH from any host to any other host in the cluster without a password.

To specify the hosts involved in an SSH key exchange, use the `-f` option to specify a file containing a list of host names (recommended), or use the `-h` option to name single host names on the command-line. At least one host name (`-h`) or a host file (`-f`) is required. Note that the local host is included in the key exchange by default.

To specify new expansion hosts to be added to an existing Greenplum Database system, use the `-e` and `-x` options. The `-e` option specifies a file containing a list of existing hosts in the system that have already exchanged SSH keys. The `-x` option specifies a file containing a list of new hosts that need to participate in the SSH key exchange.

The `gpssh-exkeys` utility performs key exchange using the following steps:

- Adds the user's public key to the user's own `authorized_keys` file on the current host.
- Updates the `known_hosts` file of the current user with the host key of each host specified using the `-h`, `-f`, `-e`, and `-x` options.
- Connects to each host using `ssh` and obtains the user's `authorized_keys`, `known_hosts`, and `id_rsa.pub` files.
- Adds keys from the `id_rsa.pub` files obtained from each host to the `authorized_keys` file of the current user.
- Updates the `authorized_keys`, `known_hosts`, and `id_rsa.pub` files on all hosts with new host information (if any).

## Options

`-e` `hostfile_exkeys`

When doing a system expansion, this is the name and location of a file containing all configured host names and host addresses (interface names) for each host in your current Greenplum system (master, standby master, and segments), one name per line without blank lines or extra spaces. Hosts specified in this file cannot be specified in the host file used with `-x`.

`-f` `hostfile_exkeys`

Specifies the name and location of a file containing all configured host names and host addresses (interface names) for each host in your Greenplum system (master, standby master and segments), one name per line without blank lines or extra spaces.

**-h hostname**

Specifies a single host name (or host address) that will participate in the SSH key exchange. You can use the `-h` option multiple times to specify multiple host names and host addresses.

**--version**

Displays the version of this utility.

**-x hostfile\_gpexpand**

When doing a system expansion, this is the name and location of a file containing all configured host names and host addresses (interface names) for each new segment host you are adding to your Greenplum system, one name per line without blank lines or extra spaces. Hosts specified in this file cannot be specified in the host file used with `-e`.

**-? (help)**

Displays the online help.

## Examples

Exchange SSH keys between all host names and addresses listed in the file `hostfile_exkeys`:

```
$ gpssh-exkeys -f hostfile_exkeys
```

Exchange SSH keys between the hosts `sdw1`, `sdw2`, and `sdw3`:

```
$ gpssh-exkeys -h sdw1 -h sdw2 -h sdw3
```

Exchange SSH keys between existing hosts `sdw1`, `sdw2`, and `sdw3`, and new hosts `sdw4` and `sdw5` as part of a system expansion operation:

```
$ cat hostfile_exkeys
mdw
mdw-1
mdw-2
smdw
smdw-1
smdw-2
sdw1
sdw1-1
sdw1-2
sdw2
sdw2-1
sdw2-2
sdw3
sdw3-1
sdw3-2
$ cat hostfile_gpexpand
sdw4
sdw4-1
sdw4-2
sdw5
sdw5-1
sdw5-2
$ gpssh-exkeys -e hostfile_exkeys -x hostfile_gpexpand
```

## gpstart

Starts a Greenplum Database system.

### Synopsis

```
gpstart [-d <master_data_directory>] [-B <parallel_processes>] [-R]
        [-m] [-y] [-a] [-t <timeout_seconds>] [-l <logfile_directory>]
        [--skip-heap-checksum-validation]
        [-v | -q]

gpstart -? | -h | --help

gpstart --version
```

### Description

The `gpstart` utility is used to start the Greenplum Database server processes. When you start a Greenplum Database system, you are actually starting several `postgres` database server listener processes at once (the master and all of the segment instances). The `gpstart` utility handles the startup of the individual instances. Each instance is started in parallel.

As part of the startup process, the utility checks the consistency of heap checksum setting among the Greenplum Database master and segment instances, either enabled or deactivated on all instances. If the heap checksum setting is different among the instances, an error is returned and Greenplum Database does not start. The validation can be deactivated by specifying the option `--skip-heap-checksum-validation`. For more information about heap checksums, see [Enabling High Availability and Data Consistency Features](#) in the *Greenplum Database Administrator Guide*.

**Note:** Before you can start a Greenplum Database system, you must have initialized the system using `gpinitssystem`. Enabling or deactivating heap checksums is set when you initialize the system and cannot be changed after initialization.

If the Greenplum Database system is configured with a standby master, and `gpstart` does not detect it during startup, `gpstart` displays a warning and lets you cancel the startup operation.

- If the `-a` option (deactivate interactive mode prompts) is not specified, `gpstart` displays and logs these messages:

```
Standby host is unreachable, cannot determine whether the standby is currently
acting as the master. Received error: <error>
Continue only if you are certain that the standby is not acting as the master.
```

It also displays this prompt to continue startup:

```
Continue with startup Yy|Nn (default=N):
```

- If the `-a` option is specified, the utility does not start the system. The messages are only logged, and `gpstart` adds this log message:

```
Non interactive mode detected. Not starting the cluster. Start the cluster in i
nteractive mode.
```

If the standby master is not accessible, you can start the system and troubleshoot standby master issues while the system is available.

## Options

-a

Do not prompt the user for confirmation. Deactivates interactive mode.

-B parallel\_processes

The number of segments to start in parallel. If not specified, the utility will start up to 64 parallel processes depending on how many segment instances it needs to start.

-d master\_data\_directory

Optional. The master host data directory. If not specified, the value set for `$MASTER_DATA_DIRECTORY` will be used.

-l logfile\_directory

The directory to write the log file. Defaults to `~/gpAdminLogs`.

-m

Optional. Starts the master instance only, which may be useful for maintenance tasks. This mode only allows connections to the master in utility mode. For example:

```
PGOPTIONS='-c gp_role=utility' psql
```

The consistency of the heap checksum setting on master and segment instances is not checked.

-q

Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

-R

Starts Greenplum Database in restricted mode (only database superusers are allowed to connect).

--skip-heap-checksum-validation

During startup, the utility does not validate the consistency of the heap checksum setting among the Greenplum Database master and segment instances. The default is to ensure that the heap checksum setting is the same on all instances, either enabled or deactivated.

**Warning:** Starting Greenplum Database without this validation could lead to data loss. Use this option to start Greenplum Database only when it is necessary to ignore the heap checksum verification errors to recover data or to troubleshoot the errors.

-t timeout\_seconds

Specifies a timeout in seconds to wait for a segment instance to start up. If a segment instance was shutdown abnormally (due to power failure or killing its `postgres` database listener process, for example), it may take longer to start up due to the database recovery and validation process. If not specified, the default timeout is 600 seconds.

-v

Displays detailed status, progress and error messages output by the utility.

-y

Optional. Do not start the standby master host. The default is to start the standby master host and synchronization process.

-? | -h | --help

Displays the online help.

--version

Displays the version of this utility.

## Examples

Start a Greenplum Database system:

```
gpstart
```

Start a Greenplum Database system in restricted mode (only allow superuser connections):

```
gpstart -R
```

Start the Greenplum master instance only and connect in utility mode:

```
gpstart -m
PGOPTIONS='-c gp_role=utility' psql
```

## See Also

[gpstop](#), [gpinitssystem](#)

## gpstate

Shows the status of a running Greenplum Database system.

## Synopsis

```
gpstate [-d <master_data_directory>] [-B <parallel_processes>]
        [-s | -b | -Q \|| -e\] \[-m \|| -c] [-p] [-i] [-f] [-v | -q] | -x
        [-l <log_directory>]

gpstate -? | -h | --help
```

## Description

The `gpstate` utility displays information about a running Greenplum Database instance. There is additional information you may want to know about a Greenplum Database system, since it is comprised of multiple PostgreSQL database instances (segments) spanning multiple machines. The `gpstate` utility provides additional status information for a Greenplum Database system, such as:

- Which segments are down.
- Master and segment configuration information (hosts, data directories, etc.).
- The ports used by the system.

- A mapping of primary segments to their corresponding mirror segments.

## Options

-b (brief status)

Optional. Display a brief summary of the state of the Greenplum Database system. This is the default option.

-B parallel\_processes

The number of segments to check in parallel. If not specified, the utility will start up to 60 parallel processes depending on how many segment instances it needs to check.

-c (show primary to mirror mappings)

Optional. Display mapping of primary segments to their corresponding mirror segments.

-d master\_data\_directory

Optional. The master data directory. If not specified, the value set for `$MASTER_DATA_DIRECTORY` will be used.

-e (show segments with mirror status issues)

Show details on primary/mirror segment pairs that have potential issues. These issues include:

- Whether any segments are down.
- Whether any primary-mirror segment pairs are out of sync – including information on how many bytes are remaining to sync (as displayed in the `WAL sync remaining bytes` output field).

```
**Note:** `gpstate -e` does not display segment pairs that are in sync.
```

- Whether any primary-mirror segment pairs are not in their preferred roles.

-f (show standby master details)

Display details of the standby master host if configured.

-i (show Greenplum Database version)

Display the Greenplum Database software version information for each instance.

-l logfile\_directory

The directory to write the log file. Defaults to `~/gpAdminLogs`.

-m (list mirrors)

Optional. List the mirror segment instances in the system and their current role.

-p (show ports)

List the port numbers used throughout the Greenplum Database system.

-q (no screen output)

Optional. Run in quiet mode. Except for warning messages, command output is not displayed on the screen. However, this information is still written to the log file.

-Q (quick status)

Optional. Checks segment status in the system catalog on the master host. Does not poll the segments for status.

-s (detailed status)

Optional. Displays detailed status information about the Greenplum Database system.

-v (verbose output)

Optional. Displays error messages and outputs detailed status and progress information.

-x (expand)

Optional. Displays detailed information about the progress and state of a Greenplum system expansion.

-? | -h | --help (help)

Displays the online help.

## Output Field Definitions

The following output fields are reported by `gpstate -s` for the master:

| Output Data                        | Description  |
|------------------------------------|--|
| Master host                        | host name of the master  |
| Master postgres process ID         | PID of the master database listener process                        |
| Master data directory              | file system location of the master data directory                  |
| Master port                        | port of the master <code>postgres</code> database listener process |
| Master current role                | dispatch = regular operating mode<br>utility = maintenance mode    |
| Greenplum array configuration type | Standard = one NIC per host<br>Multi-Home = multiple NICs per host |
| Greenplum initsystem version       | version of Greenplum Database when system was first initialized    |
| Greenplum current version          | current version of Greenplum Database                              |
| Postgres version                   | version of PostgreSQL that Greenplum Database is based on          |
| Greenplum mirroring status         | physical mirroring or none   |
| Master standby                     | host name of the standby master                                    |
| Standby master state               | status of the standby master: active or passive                    |

The following output fields are reported by `gpstate -s` for each primary segment:

| Output Data    | Description  |
|----------------|--|
| Hostname       | system-configured host name  |
| Address        | network address host name (NIC name)                                   |
| Datadir        | file system location of segment data directory                         |
| Port           | port number of segment <code>postgres</code> database listener process |
| Current Role   | current role of a segment: Mirror or Primary                           |
| Preferred Role | role at system initialization time: Mirror or Primary                  |

| Output Data                       | Description   |
|-----------------------------------|---|
| Mirror Status                     | status of a primary/mirror segment pair:<br><br>Synchronized = data is up to date on both<br><br>Not in Sync = the mirror segment has not caught up to the primary segment                        |
| Current write location            | Location where primary segment is writing new logs as they come in  |
| Bytes remaining to send to mirror | Bytes remaining to be sent from primary to mirror   |
| Active PID                        | active process ID of a segment  |
| Master reports status as          | segment status as reported in the system catalog: Up or Down  |
| Database status                   | status of Greenplum Database to incoming requests: Up, Down, or Suspended. A Suspended state means database activity is temporarily paused while a segment transitions from one state to another. |

The following output fields are reported by `gpstate -s` for each mirror segment:

| Output Data                         | Description  |
|-------------------------------------|--|
| Hostname                            | system-configured host name  |
| Address                             | network address host name (NIC name)   |
| Datadir                             | file system location of segment data directory   |
| Port                                | port number of segment <code>postgres</code> database listener process   |
| Current Role                        | current role of a segment: Mirror or Primary   |
| Preferred Role                      | role at system initialization time: Mirror or Primary  |
| Mirror Status                       | status of a primary/mirror segment pair:<br><br>Synchronized = data is up to date on both<br><br>Not in Sync = the mirror segment has not caught up to the primary segment |
| WAL Sent Location                   | Log location up to which the primary segment has sent log data to the mirror   |
| WAL Flush Location                  | Log location up to which the mirror segment has flushed the log data to disk   |
| WAL Replay Location                 | Log location up to which the mirror segment has replayed logs locally  |
| Bytes received but remain to flush  | Difference between flush log location and sent log location  |
| Bytes received but remain to replay | Difference between replay log location and sent log location   |
| Active PID                          | active process ID of a segment   |
| Master reports status as            | segment status as reported in the system catalog: Up or Down   |

| Output Data     | Description   |
|-----------------|---|
| Database status | status of Greenplum Database to incoming requests: Up, Down, or Suspended. A Suspended state means database activity is temporarily paused while a segment transitions from one state to another. |

**Note:** When there is no connection between a primary segment and its mirror, `gpstate -s` displays `Unknown` in the following fields:

- Bytes remaining to send to mirror
- WAL Sent Location
- WAL Flush Location
- WAL Replay Location
- Bytes received but remain to flush
- Bytes received but remain to replay

The following output fields are reported by `gpstate -f` for standby master replication status:

| Output Data      | Description  |
|------------------|--|
| Standby address  | hostname of the standby master   |
| Standby data dir | file system location of the standby master data directory                  |
| Standby port     | port of the standby master <code>postgres</code> database listener process |
| Standby PID      | process ID of the standby master   |
| Standby status   | status of the standby master: Standby host passive                         |
| WAL Sender State | write-ahead log (WAL) streaming state: streaming, startup, backup, catchup |
| Sync state       | WAL sender synchronization state: sync                                     |
| Sent Location    | WAL sender transaction log (xlog) record sent location                     |
| Flush Location   | WAL receiver xlog record flush location                                    |
| Replay Location  | standby xlog record replay location  |

## Examples

Show detailed status information of a Greenplum Database system:

```
gpstate -s
```

Do a quick check for down segments in the master host system catalog:

```
gpstate -Q
```

Show information about mirror segment instances:

```
gpstate -m
```

Show information about the standby master configuration:

```
gpstate -f
```

Display the Greenplum software version information:

```
gpstate -i
```

gpstop --version

gpstop -? | -h | --help
```

## Description

The `gpstop` utility is used to stop the database servers that comprise a Greenplum Database system. When you stop a Greenplum Database system, you are actually stopping several `postgres` database server processes at once (the master and all of the segment instances). The `gpstop` utility handles the shutdown of the individual instances. Each instance is shutdown in parallel.

The default shutdown mode (`-M smart`) waits for current client connections to finish before completing the shutdown. If any connections remain open after the timeout period, or if you interrupt with CTRL-C, `gpstop` lists the open connections and prompts whether to continue waiting for connections to finish, or to perform a fast or immediate shutdown. The default timeout period is 120 seconds and can be changed with the `-t timeout\_seconds` option.

Specify the `-M fast` shutdown mode to roll back all in-progress transactions and terminate any connections before shutting down.

With the `-u` option, the utility uploads changes made to the master `pg_hba.conf` file or to *runtime* configuration parameters in the master `postgresql.conf` file without interruption of service. Note

that any active sessions will not pick up the changes until they reconnect to the database.

## Options

-a

Do not prompt the user for confirmation.

-B parallel\_processes

The number of segments to stop in parallel. If not specified, the utility will start up to 64 parallel processes depending on how many segment instances it needs to stop.

-d master\_data\_directory

Optional. The master host data directory. If not specified, the value set for `$MASTER_DATA_DIRECTORY` will be used.

--host host\_name

The utility shuts down the Greenplum Database segment instances on the specified host to allow maintenance on the host. Each primary segment instance on the host is shut down and the associated mirror segment instance is promoted to a primary segment if the mirror segment is on another host. Mirror segment instances on the host are shut down.

The segment instances are not shut down and the utility returns an error in these cases:

- Segment mirroring is not enabled for the system.
- The master or standby master is on the host.
- Both a primary segment instance and its mirror are on the host.

This option cannot be specified with the `-m`, `-r`, `-u`, or `-y` options.

**Note:** The `gprecoverseg` utility restores segment instances. Run `gprecoverseg` commands to start the segments as mirrors and then to return the segments to their preferred role (primary segments).

-l logfile\_directory

The directory to write the log file. Defaults to `~/gpAdminLogs`.

-m

Optional. Shuts down a Greenplum master instance that was started in maintenance mode.

-M fast

Fast shut down. Any transactions in progress are interrupted and rolled back.

-M immediate

Immediate shut down. Any transactions in progress are cancelled.

This mode kills all `postgres` processes without allowing the database server to complete transaction processing or clean up any temporary or in-process work files.

-M smart

Smart shut down. This is the default shutdown mode. `gpstop` waits for active user connections to disconnect and then proceeds with the shutdown. If any user connections remain open after the timeout period (or if you interrupt by pressing CTRL-C) `gpstop` lists the open user connections and prompts whether to continue waiting for connections to finish, or to perform a fast or immediate shutdown.

-q

Run in quiet mode. Command output is not displayed on the screen, but is still written to the log file.

-r

Restart after shutdown is complete.

-t timeout\_seconds

Specifies a timeout threshold (in seconds) to wait for a segment instance to shutdown. If a segment instance does not shutdown in the specified number of seconds, `gpstop` displays a message indicating that one or more segments are still in the process of shutting down and that you cannot restart Greenplum Database until the segment instance(s) are stopped. This option is useful in situations where `gpstop` is run and there are very large transactions that need to rollback. These large transactions can take over a minute to rollback and surpass the default timeout period of 120 seconds.

-U

This option reloads the `pg_hba.conf` files of the master and segments and the runtime parameters of the `postgresql.conf` files but does not shutdown the Greenplum Database array. Use this option to make new configuration settings active after editing `postgresql.conf` or `pg_hba.conf`. Note that this only applies to configuration parameters that are designated as *runtime* parameters.

-v

Displays detailed status, progress and error messages output by the utility.

-y

Do not stop the standby master process. The default is to stop the standby master.

-? | -h | --help

Displays the online help.

--version

Displays the version of this utility.

## Examples

Stop a Greenplum Database system in smart mode:

```
gpstop
```

Stop a Greenplum Database system in fast mode:

```
gpstop -M fast
```

Stop all segment instances and then restart the system:

```
gpstop -r
```

Stop a master instance that was started in maintenance mode:

```
gpstop -m
```

Reload the `postgresql.conf` and `pg_hba.conf` files after making configuration changes but do not shutdown the Greenplum Database array:

```
gpstop -u
```

## See Also

[gpstart](#)

## pg\_config

Retrieves information about the installed version of Greenplum Database.

## Synopsis

```
pg_config [<option> ...]

pg_config -? | --help

pg_config --version
```

## Description

The `pg_config` utility prints configuration parameters of the currently installed version of Greenplum Database. It is intended, for example, to be used by software packages that want to interface to Greenplum Database to facilitate finding the required header files and libraries. Note that information printed out by `pg_config` is for the Greenplum Database master only.

If more than one option is given, the information is printed in that order, one item per line. If no options are given, all available information is printed, with labels.

## Options

`--bindir`

Print the location of user executables. Use this, for example, to find the `psql` program. This is normally also the location where the `pg_config` program resides.

`--docdir`

Print the location of documentation files.

`--includedir`

Print the location of C header files of the client interfaces.

`--pkgincludedir`

Print the location of other C header files.

`--includedir-server`

Print the location of C header files for server programming.

`--libdir`

Print the location of object code libraries.

`--pkglibdir`

Print the location of dynamically loadable modules, or where the server would search for them. (Other architecture-dependent data files may also be installed in this directory.)

`--localedir`

- Print the location of locale support files.
- `--mandir`  
Print the location of manual pages.
- `--sharedir`  
Print the location of architecture-independent support files.
- `--sysconfdir`  
Print the location of system-wide configuration files.
- `--pgxs`  
Print the location of extension makefiles.
- `--configure`  
Print the options that were given to the configure script when Greenplum Database was configured for building.
- `--cc`  
Print the value of the CC variable that was used for building Greenplum Database. This shows the C compiler used.
- `--cppflags`  
Print the value of the `CPPFLAGS` variable that was used for building Greenplum Database. This shows C compiler switches needed at preprocessing time.
- `--cflags`  
Print the value of the `CFLAGS` variable that was used for building Greenplum Database. This shows C compiler switches.
- `--cflags_sl`  
Print the value of the `CFLAGS_SL` variable that was used for building Greenplum Database. This shows extra C compiler switches used for building shared libraries.
- `--ldflags`  
Print the value of the `LDFLAGS` variable that was used for building Greenplum Database. This shows linker switches.
- `--ldflags_ex`  
Print the value of the `LDFLAGS_EX` variable that was used for building Greenplum Database. This shows linker switches that were used for building executables only.
- `--ldflags_sl`  
Print the value of the `LDFLAGS_SL` variable that was used for building Greenplum Database. This shows linker switches used for building shared libraries only.
- `--libs`  
Print the value of the `LIBS` variable that was used for building Greenplum Database. This normally contains `-l` switches for external libraries linked into Greenplum Database.
- `--version`  
Print the version of Greenplum Database.

## Examples

To reproduce the build configuration of the current Greenplum Database installation, run the following command:

```
eval ./configure 'pg_config --configure'
```

The output of `pg_config --configure` contains shell quotation marks so arguments with spaces are represented correctly. Therefore, using `eval` is required for proper results.

# pg\_dump

Extracts a database into a single script file or other archive file.

## Synopsis

```
pg_dump [<connection-option> ...] [<dump_option> ...] [<dbname>]

pg_dump -? | --help

pg_dump -V | --version
```

## Description

`pg_dump` is a standard PostgreSQL utility for backing up a database, and is also supported in Greenplum Database. It creates a single (non-parallel) dump file. For routine backups of Greenplum Database, it is better to use the Greenplum Database backup utility, `gpbackup`, for the best performance.

Use `pg_dump` if you are migrating your data to another database vendor's system, or to another Greenplum Database system with a different segment configuration (for example, if the system you are migrating to has greater or fewer segment instances). To restore, you must use the corresponding `pg_restore` utility (if the dump file is in archive format), or you can use a client program such as `psql` (if the dump file is in plain text format).

Since `pg_dump` is compatible with regular PostgreSQL, it can be used to migrate data into Greenplum Database. The `pg_dump` utility in Greenplum Database is very similar to the PostgreSQL `pg_dump` utility, with the following exceptions and limitations:

- If using `pg_dump` to backup a Greenplum Database database, keep in mind that the dump operation can take a long time (several hours) for very large databases. Also, you must make sure you have sufficient disk space to create the dump file.
- If you are migrating data from one Greenplum Database system to another, use the `--gp-syntax` command-line option to include the `DISTRIBUTED BY` clause in `CREATE TABLE` statements. This ensures that Greenplum Database table data is distributed with the correct distribution key columns upon restore.

`pg_dump` makes consistent backups even if the database is being used concurrently. `pg_dump` does not block other users accessing the database (readers or writers).

When used with one of the archive file formats and combined with `pg_restore`, `pg_dump` provides a flexible archival and transfer mechanism. `pg_dump` can be used to backup an entire database, then `pg_restore` can be used to examine the archive and/or select which parts of the database are to be restored. The most flexible output file formats are the custom format (`-Fc`) and the directory format (`-Fd`). They allow for selection and reordering of all archived items, support parallel restoration, and are compressed by default. The directory format is the only format that supports parallel dumps.

## Options

`dbname`

Specifies the name of the database to be dumped. If this is not specified, the environment variable `PGDATABASE` is used. If that is not set, the user name specified for the connection is used.

## Dump Options

### -a | --data-only

Dump only the data, not the schema (data definitions). Table data and sequence values are dumped.

This option is similar to, but for historical reasons not identical to, specifying `--section=data`.

### -b | --blobs

Include large objects in the dump. This is the default behavior except when `--schema`, `--table`, or `--schema-only` is specified. The `-b` switch is only useful add large objects to dumps where a specific schema or table has been requested. Note that blobs are considered data and therefore will be included when `--data-only` is used, but not when `--schema-only` is.

**Note:** Greenplum Database does not support the PostgreSQL [large object facility](#) for streaming user data that is stored in large-object structures.

### -c | --clean

Adds commands to the text output file to clean (drop) database objects prior to outputting the commands for creating them. (Restore might generate some harmless error messages, if any objects were not present in the destination database.) Note that objects are not dropped before the dump operation begins, but `DROP` commands are added to the DDL dump output files so that when you use those files to do a restore, the `DROP` commands are run prior to the `CREATE` commands. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

### -C | --create

Begin the output with a command to create the database itself and reconnect to the created database. (With a script of this form, it doesn't matter which database in the destination installation you connect to before running the script.) If `--clean` is also specified, the script drops and recreates the target database before reconnecting to it. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

### -E encoding | --encoding=encoding

Create the dump in the specified character set encoding. By default, the dump is created in the database encoding. (Another way to get the same result is to set the `PGCLIENTENCODING` environment variable to the desired dump encoding.)

### -f file | --file=file

Send output to the specified file. This parameter can be omitted for file-based output formats, in which case the standard output is used. It must be given for the directory output format however, where it specifies the target directory instead of a file. In this case the directory is created by `pg_dump` and must not exist before.

### -F plc|dt | --format=plain|custom|directory|tar

Selects the format of the output. format can be one of the following:

p | plain — Output a plain-text SQL script file (the default).

`c` | `custom` — Output a custom archive suitable for input into `pg_restore`. Together with the directory output format, this is the most flexible output format in that it allows manual selection and reordering of archived items during restore. This format is compressed by default and also supports parallel dumps.

`d` | `directory` — Output a directory-format archive suitable for input into `pg_restore`. This will create a directory with one file for each table and blob being dumped, plus a so-called Table of Contents file describing the dumped objects in a machine-readable format that `pg_restore` can read. A directory format archive can be manipulated with standard Unix tools; for example, files in an uncompressed archive can be compressed with the `gzip` tool. This format is compressed by default.

`t` | `tar` — Output a tar-format archive suitable for input into `pg_restore`. The tar format is compatible with the directory format; extracting a tar-format archive produces a valid directory-format archive. However, the tar format does not support compression. Also, when using tar format the relative order of table data items cannot be changed during restore.

`-j njobs` | `--jobs=njobs`

Run the dump in parallel by dumping `njobs` tables simultaneously. This option reduces the time of the dump but it also increases the load on the database server. You can only use this option with the directory output format because this is the only output format where multiple processes can write their data at the same time.

**Note:** Parallel dumps using `pg_dump` are parallelized only on the query dispatcher (master) node, not across the query executor (segment) nodes as is the case when you use `gpbackup`.

`pg_dump` will open `njobs + 1` connections to the database, so make sure your `max_connections` setting is high enough to accommodate all connections.

Requesting exclusive locks on database objects while running a parallel dump could cause the dump to fail. The reason is that the `pg_dump` master process requests shared locks on the objects that the worker processes are going to dump later in order to make sure that nobody deletes them and makes them go away while the dump is running. If another client then requests an exclusive lock on a table, that lock will not be granted but will be queued waiting for the shared lock of the master process to be released. Consequently, any other access to the table will not be granted either and will queue after the exclusive lock request. This includes the worker process trying to dump the table. Without any precautions this would be a classic deadlock situation. To detect this conflict, the `pg_dump` worker process requests another shared lock using the `NOWAIT` option. If the worker process is not granted this shared lock, somebody else must have requested an exclusive lock in the meantime and there is no way to continue with the dump, so `pg_dump` has no choice but to cancel the dump.

For a consistent backup, the database server needs to support synchronized snapshots, a feature that was introduced in Greenplum Database 6.0. With this feature, database clients can ensure they see the same data set even though they use different connections. `pg_dump -j` uses multiple database connections; it connects to the database once with the master process and once again for each worker job. Without the synchronized snapshot feature, the different worker jobs wouldn't be guaranteed to see the same data in each connection, which could lead to an inconsistent backup.

If you want to run a parallel dump of a pre-6.0 server, you need to make sure that the database content doesn't change from between the time the master connects to the

database until the last worker job has connected to the database. The easiest way to do this is to halt any data modifying processes (DDL and DML) accessing the database before starting the backup. You also need to specify the `--no-synchronized-snapshots` parameter when running `pg_dump -j` against a pre-6.0 Greenplum Database server.

`-n schema | --schema=schema`

Dump only schemas matching the schema pattern; this selects both the schema itself, and all its contained objects. When this option is not specified, all non-system schemas in the target database will be dumped. Multiple schemas can be selected by writing multiple `-n` switches. Also, the schema parameter is interpreted as a pattern according to the same rules used by `psql's \d` commands, so multiple schemas can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards.

Note: When `-n` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected schema(s) may depend upon. Therefore, there is no guarantee that the results of a specific-schema dump can be successfully restored by themselves into a clean database.

**Note:** Non-schema objects such as blobs are not dumped when `-n` is specified. You can add blobs back to the dump with the `--blobs` switch.

`-N schema | --exclude-schema=schema`

Do not dump any schemas matching the schema pattern. The pattern is interpreted according to the same rules as for `-n`. `-N` can be given more than once to exclude schemas matching any of several patterns. When both `-n` and `-N` are given, the behavior is to dump just the schemas that match at least one `-n` switch but no `-N` switches. If `-N` appears without `-n`, then schemas matching `-N` are excluded from what is otherwise a normal dump.

`-o | --oids`

Dump object identifiers (OIDs) as part of the data for every table. Use of this option is not recommended for files that are intended to be restored into Greenplum Database.

`-O | --no-owner`

Do not output commands to set ownership of objects to match the original database. By default, `pg_dump` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created database objects. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-o`. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

`-s | --schema-only`

Dump only the object definitions (schema), not data.

This option is the inverse of `--data-only`. It is similar to, but for historical reasons not identical to, specifying `--section=pre-data --section=post-data`.

(Do not confuse this with the `--schema` option, which uses the word "schema" in a different meaning.)

To exclude table data for only a subset of tables in the database, see `--exclude-table-data`.

`-S username | --superuser=username`

Specify the superuser user name to use when deactivating triggers. This is relevant only if `--disable-triggers` is used. It is better to leave this out, and instead start the resulting script as a superuser.

**Note:** Greenplum Database does not support user-defined triggers.

`-t table | --table=table`

Dump only tables (or views or sequences or foreign tables) matching the table pattern. Specify the table in the format `schema.table`.

Multiple tables can be selected by writing multiple `-t` switches. Also, the table parameter is interpreted as a pattern according to the same rules used by `psql`'s `\d` commands, so multiple tables can also be selected by writing wildcard characters in the pattern. When using wildcards, be careful to quote the pattern if needed to prevent the shell from expanding the wildcards. The `-n` and `-N` switches have no effect when `-t` is used, because tables selected by `-t` will be dumped regardless of those switches, and non-table objects will not be dumped.

**Note:** When `-t` is specified, `pg_dump` makes no attempt to dump any other database objects that the selected table(s) may depend upon. Therefore, there is no guarantee that the results of a specific-table dump can be successfully restored by themselves into a clean database.

Also, `-t` cannot be used to specify a child table partition. To dump a partitioned table, you must specify the parent table name.

`-T table | --exclude-table=table`

Do not dump any tables matching the table pattern. The pattern is interpreted according to the same rules as for `-t`. `-T` can be given more than once to exclude tables matching any of several patterns. When both `-t` and `-T` are given, the behavior is to dump just the tables that match at least one `-t` switch but no `-T` switches. If `-T` appears without `-t`, then tables matching `-T` are excluded from what is otherwise a normal dump.

`-v | --verbose`

Specifies verbose mode. This will cause `pg_dump` to output detailed object comments and start/stop times to the dump file, and progress messages to standard error.

`-V | --version`

Print the `pg_dump` version and exit.

`-x | --no-privileges | --no-acl`

Prevent dumping of access privileges (`GRANT/REVOKE` commands).

`-Z 0..9 | --compress=0..9`

Specify the compression level to use. Zero means no compression. For the custom archive format, this specifies compression of individual table-data segments, and the default is to compress at a moderate level.

For plain text output, setting a non-zero compression level causes the entire output file to be compressed, as though it had been fed through `gzip`; but the default is not to compress. The tar archive format currently does not support compression at all.

`--binary-upgrade`

This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.

`--column-inserts | --attribute-inserts`

Dump data as `INSERT` commands with explicit column names (`INSERT INTO table (column, ...) VALUES ...`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL-based databases. However, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents.

`--disable-dollar-quoting`

This option deactivates the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

`--disable-triggers`

This option is relevant only when creating a data-only dump. It instructs `pg_dump` to include commands to temporarily deactivate triggers on the target tables while the data is reloaded. Use this if you have triggers on the tables that you do not want to invoke during data reload. The commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-s`, or preferably be careful to start the resulting script as a superuser. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

**Note:** Greenplum Database does not support user-defined triggers.

`--exclude-table-data=table`

Do not dump data for any tables matching the table pattern. The pattern is interpreted according to the same rules as for `-t`. `--exclude-table-data` can be given more than once to exclude tables matching any of several patterns. This option is useful when you need the definition of a particular table even though you do not need the data in it.

To exclude data for all tables in the database, see `--schema-only`.

`--if-exists`

Use conditional commands (i.e. add an `IF EXISTS` clause) when cleaning database objects. This option is not valid unless `--clean` is also specified.

`--inserts`

Dump data as `INSERT` commands (rather than `COPY`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL-based databases. However, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents. Note that the restore may fail altogether if you have rearranged column order. The `--column-inserts` option is safe against column order changes, though even slower.

`--lock-wait-timeout=timeout`

Do not wait forever to acquire shared table locks at the beginning of the dump. Instead, fail if unable to lock a table within the specified timeout. Specify timeout as a number of milliseconds.

`--no-security-labels`

Do not dump security labels.

`--no-synchronized-snapshots`

This option allows running `pg_dump -j` against a pre-6.0 Greenplum Database server; see the documentation of the `-j` parameter for more details.

`--no-tablespaces`

Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

This option is only meaningful for the plain-text format. For the archive formats, you can specify the option when you call `pg_restore`.

`--no-unlogged-table-data`

Do not dump the contents of unlogged tables. This option has no effect on whether or not the table definitions (schema) are dumped; it only suppresses dumping the table data. Data in unlogged tables is always excluded when dumping from a standby server.

`--quote-all-identifiers`

Force quoting of all identifiers. This option is recommended when dumping a database from a server whose Greenplum Database major version is different from `pg_dump`'s, or when the output is intended to be loaded into a server of a different major version. By default, `pg_dump` quotes only identifiers that are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using `--quote-all-identifiers` prevents such issues, at the price of a harder-to-read dump script.

`--section=sectionname`

Only dump the named section. The section name can be `pre-data`, `data`, or `post-data`. This option can be specified more than once to select multiple sections. The default is to dump all sections.

The `data` section contains actual table data and sequence values. `post-data` items include definitions of indexes, triggers, rules, and constraints other than validated check constraints. `pre-data` items include all other data definition items.

`--serializable-deferrable`

Use a serializable transaction for the dump, to ensure that the snapshot used is consistent with later database states; but do this by waiting for a point in the transaction stream at which no anomalies can be present, so that there isn't a risk of the dump failing or causing other transactions to roll back with a `serialization_failure`.

This option is not beneficial for a dump which is intended only for disaster recovery. It could be useful for a dump used to load a copy of the database for reporting or other read-only load sharing while the original database continues to be updated. Without it the dump may reflect a state which is not consistent with any serial execution of the transactions eventually committed. For example, if batch processing techniques are used, a batch may show as closed in the dump without all of the items which are in the batch appearing.

This option will make no difference if there are no read-write transactions active when `pg_dump` is started. If read-write transactions are active, the start of the dump may be delayed for an indeterminate length of time. Once running, performance with or without the switch is the same.

**Note:** Because Greenplum Database does not support serializable transactions, the `--serializable-deferrable` option has no effect in Greenplum Database.

`--use-set-session-authorization`

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, may not restore

properly. A dump using `SET SESSION AUTHORIZATION` will require superuser privileges to restore correctly, whereas `ALTER OWNER` requires lesser privileges.

`--gp-syntax | --no-gp-syntax`

Use `--gp-syntax` to dump Greenplum Database syntax in the `CREATE TABLE` statements. This allows the distribution policy (`DISTRIBUTED BY` or `DISTRIBUTED RANDOMLY` clauses) of a Greenplum Database table to be dumped, which is useful for restoring into other Greenplum Database systems. The default is to include Greenplum Database syntax when connected to a Greenplum Database system, and to exclude it when connected to a regular PostgreSQL system.

`--function-oids oids`

Dump the function(s) specified in the oids list of object identifiers.

**Note:** This option is provided solely for use by other administration utilities; its use for any other purpose is not recommended or supported. The behavior of the option may change in future releases without notice.

`--relation-oids oids`

Dump the relation(s) specified in the oids list of object identifiers.

**Note:** This option is provided solely for use by other administration utilities; its use for any other purpose is not recommended or supported. The behavior of the option may change in future releases without notice.

`-? | --help`

Show help about `pg_dump` command line arguments, and exit.

## Connection Options

`-d dbname | --dbname=dbname`

Specifies the name of the database to connect to. This is equivalent to specifying `dbname` as the first non-option argument on the command line.

If this parameter contains an `=` sign or starts with a valid URI prefix (`postgresql://` or `postgres://`), it is treated as a `conninfo` string. See [Connection Strings](#) in the PostgreSQL documentation for more information.

`-h host | --host=host`

The host name of the machine on which the Greenplum Database master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to `localhost`.

`-p port | --port=port`

The TCP port on which the Greenplum Database master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

`-U username | --username=username`

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

`-W | --password`

Force a password prompt.

`-w | --no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file the connection attempt will

fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`--role=rolename`

Specifies a role name to be used to create the dump. This option causes `pg_dump` to issue a `SET ROLE rolename` command after connecting to the database. It is useful when the authenticated user (specified by `-U`) lacks privileges needed by `pg_dump`, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.

## Notes

When a data-only dump is chosen and the option `--disable-triggers` is used, `pg_dump` emits commands to deactivate triggers on user tables before inserting the data and commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs may be left in the wrong state.

The dump file produced by `pg_dump` does not contain the statistics used by the optimizer to make query planning decisions. Therefore, it is wise to run `ANALYZE` after restoring from a dump file to ensure optimal performance.

The database activity of `pg_dump` is normally collected by the statistics collector. If this is undesirable, you can set parameter `track_counts` to false via `PGOPTIONS` or the `ALTER USER` command.

Because `pg_dump` may be used to transfer data to newer versions of Greenplum Database, the output of `pg_dump` can be expected to load into Greenplum Database versions newer than `pg_dump`'s version. `pg_dump` can also dump from Greenplum Database versions older than its own version. However, `pg_dump` cannot dump from Greenplum Database versions newer than its own major version; it will refuse to even try, rather than risk making an invalid dump. Also, it is not guaranteed that `pg_dump`'s output can be loaded into a server of an older major version — not even if the dump was taken from a server of that version. Loading a dump file into an older server may require manual editing of the dump file to remove syntax not understood by the older server. Use of the `--quote-all-identifiers` option is recommended in cross-version cases, as it can prevent problems arising from varying reserved-word lists in different Greenplum Database versions.

## Examples

Dump a database called `mydb` into a SQL-script file:

```
pg_dump mydb > db.sql
```

To reload such a script into a (freshly created) database named `newdb`:

```
psql -d newdb -f db.sql
```

Dump a Greenplum Database in tar file format and include distribution policy information:

```
pg_dump -Ft --gp-syntax mydb > db.tar
```

To dump a database into a custom-format archive file:

```
pg_dump -Fc mydb > db.dump
```

To dump a database into a directory-format archive:

```
pg_dump -Fd mydb -f dumpdir
```

To dump a database into a directory-format archive in parallel with 5 worker jobs:

```
pg_dump -Fd mydb -j 5 -f dumpdir
```

To reload an archive file into a (freshly created) database named `newdb`:

```
pg_restore -d newdb db.dump
```

To dump a single table named `mytab`:

```
pg_dump -t mytab mydb > db.sql
```

To specify an upper-case or mixed-case name in `-t` and related switches, you need to double-quote the name; else it will be folded to lower case. But double quotes are special to the shell, so in turn they must be quoted. Thus, to dump a single table with a mixed-case name, you need something like:

```
pg_dump -t "MixedCaseName" mydb > mytab.sql
```

[pg\\_dumpall](#), [pg\\_restore](#), [psql](#)

## pg\_dumpall

Extracts all databases in a Greenplum Database system to a single script file or other archive file.

## Synopsis

```
pg_dumpall [<connection-option> ...] [<dump_option> ...]
pg_dumpall -? | --help
pg_dumpall -V | --version
```

## Description

`pg_dumpall` is a standard PostgreSQL utility for backing up all databases in a Greenplum Database (or PostgreSQL) instance, and is also supported in Greenplum Database. It creates a single (non-parallel) dump file. For routine backups of Greenplum Database it is better to use the Greenplum Database backup utility, [gppbackup](#), for the best performance.

`pg_dumpall` creates a single script file that contains SQL commands that can be used as input to `psql` to restore the databases. It does this by calling `pg_dump` for each database. `pg_dumpall` also dumps global objects that are common to all databases. (`pg_dump` does not save these objects.) This currently includes information about database users and groups, and access permissions that apply to databases as a whole.

Since `pg_dumpall` reads tables from all databases you will most likely have to connect as a database superuser in order to produce a complete dump. Also you will need superuser privileges to run the saved script in order to be allowed to add users and groups, and to create databases.

The SQL script will be written to the standard output. Use the `[-f | --file]` option or shell operators to redirect it into a file.

`pg_dumpall` needs to connect several times to the Greenplum Database master server (once per database). If you use password authentication it is likely to ask for a password each time. It is convenient to have a `~/.pgpass` file in such cases.

## Options

### Dump Options

`-a | --data-only`

Dump only the data, not the schema (data definitions). This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

`-c | --clean`

Output commands to clean (drop) database objects prior to (the commands for) creating them. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

`-f filename | --file=filename`

Send output to the specified file.

`-g | --globals-only`

Dump only global objects (roles and tablespaces), no databases.

`-o | --oids`

Dump object identifiers (OIDs) as part of the data for every table. Use of this option is not recommended for files that are intended to be restored into Greenplum Database.

`-O | --no-owner`

Do not output commands to set ownership of objects to match the original database. By default, `pg_dump` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created database objects. These statements will fail when the script is run unless it is started by a superuser (or the same user that owns all of the objects in the script). To make a script that can be restored by any user, but will give that user ownership of all the objects, specify `-O`. This option is only meaningful for the plain-text format. For the archive formats, you may specify the option when you call `pg_restore`.

`-r | --roles-only`

Dump only roles, not databases or tablespaces.

`-s | --schema-only`

Dump only the object definitions (schema), not data.

`-S username | --superuser=username`

Specify the superuser user name to use when deactivating triggers. This is relevant only if `--disable-triggers` is used. It is better to leave this out, and instead start the resulting script as a superuser.

**Note:** Greenplum Database does not support user-defined triggers.

`-t | --tablespaces-only`

Dump only tablespaces, not databases or roles.

`-v | --verbose`

Specifies verbose mode. This will cause `[pg\_dump]` (`pg_dump.html`) to output detailed object comments and start/stop times to the dump file, and progress messages to standard error.

`-V | --version`

Print the `pg_dumpall` version and exit.

`-x | --no-privileges | --no-acl`

Prevent dumping of access privileges (`GRANT/REVOKE` commands).

`--binary-upgrade`

This option is for use by in-place upgrade utilities. Its use for other purposes is not recommended or supported. The behavior of the option may change in future releases without notice.

`--column-inserts | --attribute-inserts`

Dump data as `INSERT` commands with explicit column names (`INSERT INTO <table> (<column>, ...) VALUES ...`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL-based databases. Also, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents.

`--disable-dollar-quoting`

This option deactivates the use of dollar quoting for function bodies, and forces them to be quoted using SQL standard string syntax.

`--disable-triggers`

This option is relevant only when creating a data-only dump. It instructs `pg_dumpall` to include commands to temporarily deactivate triggers on the target tables while the data is reloaded. Use this if you have triggers on the tables that you do not want to invoke during data reload. The commands emitted for `--disable-triggers` must be done as superuser. So, you should also specify a superuser name with `-s`, or preferably be careful to start the resulting script as a superuser.

**Note:** Greenplum Database does not support user-defined triggers.

`--inserts`

Dump data as `INSERT` commands (rather than `COPY`). This will make restoration very slow; it is mainly useful for making dumps that can be loaded into non-PostgreSQL-based databases. Also, since this option generates a separate command for each row, an error in reloading a row causes only that row to be lost rather than the entire table contents. Note that the restore may fail altogether if you have rearranged column order. The `--column-inserts` option is safe against column order changes, though even slower.

`--lock-wait-timeout=timeout`

Do not wait forever to acquire shared table locks at the beginning of the dump. Instead, fail if unable to lock a table within the specified timeout. The timeout may be specified in any of the formats accepted by `SET statement_timeout`. Allowed values vary depending on the

server version you are dumping from, but an integer number of milliseconds is accepted by all Greenplum Database versions.

`--no-security-labels`

Do not dump security labels.

`--no-tablespaces`

Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

`--no-unlogged-table-data`

Do not dump the contents of unlogged tables. This option has no effect on whether or not the table definitions (schema) are dumped; it only suppresses dumping the table data.

`--quote-all-identifiers`

Force quoting of all identifiers. This option is recommended when dumping a database from a server whose Greenplum Database major version is different from `pg_dumpall`'s, or when the output is intended to be loaded into a server of a different major version. By default, `pg_dumpall` quotes only identifiers that are reserved words in its own major version. This sometimes results in compatibility issues when dealing with servers of other versions that may have slightly different sets of reserved words. Using `--quote-all-identifiers` prevents such issues, at the price of a harder-to-read dump script.

`--resource-queues`

Dump resource queue definitions.

`--resource-groups`

Dump resource group definitions.

`--use-set-session-authorization`

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards compatible, but depending on the history of the objects in the dump, may not restore properly. A dump using `SET SESSION AUTHORIZATION` will require superuser privileges to restore correctly, whereas `ALTER OWNER` requires lesser privileges.

`--gp-syntax`

Output Greenplum Database syntax in the `CREATE TABLE` statements. This allows the distribution policy (`DISTRIBUTED BY` or `DISTRIBUTED RANDOMLY` clauses) of a Greenplum Database table to be dumped, which is useful for restoring into other Greenplum Database systems.

`--no-gp-syntax`

Do not output the table distribution clauses in the `CREATE TABLE` statements.

`-? | --help`

Show help about `pg_dumpall` command line arguments, and exit.

## Connection Options

`-d connstr | --dbname=connstr`

Specifies parameters used to connect to the server, as a connection string. See [Connection Strings](#) in the PostgreSQL documentation for more information.

The option is called `--dbname` for consistency with other client applications, but because `pg_dumpall` needs to connect to many databases, the database name in the connection string will be ignored. Use the `-1` option to specify the name of the database used to dump global objects and to discover what other databases should be dumped.

`-h host | --host=host`

The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to `localhost`.

`-l dbname | --database=dbname`

Specifies the name of the database in which to connect to dump global objects. If not specified, the `postgres` database is used. If the `postgres` database does not exist, the `template1` database is used.

`-p port | --port=port`

The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

`-U username | --username= username`

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

`-w | --no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W | --password`

Force a password prompt.

`--role=rolename`

Specifies a role name to be used to create the dump. This option causes `pg_dumpall` to issue a `SET ROLE <rolename>` command after connecting to the database. It is useful when the authenticated user (specified by `-U`) lacks privileges needed by `pg_dumpall`, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows dumps to be made without violating the policy.

## Notes

Since `pg_dumpall` calls `pg_dump` internally, some diagnostic messages will refer to `pg_dump`.

Once restored, it is wise to run `ANALYZE` on each database so the query planner has useful statistics. You can also run `vacuumdb -a -z` to vacuum and analyze all databases.

`pg_dumpall` requires all needed tablespace directories to exist before the restore; otherwise, database creation will fail for databases in non-default locations.

## Examples

To dump all databases:

```
pg_dumpall > db.out
```

To reload database(s) from this file, you can use:

```
psql template1 -f db.out
```

To dump only global objects (including resource queues):

```
pg_dumpall -g --resource-queues
```

## See Also

[pg\\_dump](#)

## pg\_restore

Restores a database from an archive file created by [pg\\_dump](#).

## Synopsis

```
pg_restore [<connection-option> ...] [<restore_option> ...] <filename>

pg_restore -? | --help

pg_restore -V | --version
```

## Description

[pg\\_restore](#) is a utility for restoring a database from an archive created by [pg\\_dump](#) in one of the non-plain-text formats. It will issue the commands necessary to reconstruct the database to the state it was in at the time it was saved. The archive files also allow [pg\\_restore](#) to be selective about what is restored, or even to reorder the items prior to being restored.

[pg\\_restore](#) can operate in two modes. If a database name is specified, the archive is restored directly into the database. Otherwise, a script containing the SQL commands necessary to rebuild the database is created and written to a file or standard output. The script output is equivalent to the plain text output format of [pg\\_dump](#). Some of the options controlling the output are therefore analogous to [pg\\_dump](#) options.

[pg\\_restore](#) cannot restore information that is not present in the archive file. For instance, if the archive was made using the "dump data as `INSERT` commands" option, [pg\\_restore](#) will not be able to load the data using `COPY` statements.

## Options

filename

Specifies the location of the archive file (or directory, for a directory-format archive) to be restored. If not specified, the standard input is used.

### Restore Options

-a | --data-only

Restore only the data, not the schema (data definitions). Table data and sequence values are restored, if present in the archive.

This option is similar to, but for historical reasons not identical to, specifying `--section=data`.

`-c | --clean`

Clean (drop) database objects before recreating them. (This might generate some harmless error messages, if any objects were not present in the destination database.)

`-C | --create`

Create the database before restoring into it. If `--clean` is also specified, drop and recreate the target database before connecting to it.

When this option is used, the database named with `-d` is used only to issue the initial `DROP DATABASE` and `CREATE DATABASE` commands. All data is restored into the database name that appears in the archive.

`-d dbname | --dbname=dbname`

Connect to this database and restore directly into this database. This utility, like most other Greenplum Database utilities, also uses the environment variables supported by `libpq`. However it does not read `PGDATABASE` when a database name is not supplied.

`-e | --exit-on-error`

Exit if an error is encountered while sending SQL commands to the database. The default is to continue and to display a count of errors at the end of the restoration.

`-f outfile | --file=outfile`

Specify output file for generated script, or for the listing when used with `-l`. Default is the standard output.

`-F cld|t | --format={custom | directory | tar}`

The format of the archive produced by `pg_dump`. It is not necessary to specify the format, since `pg_restore` will determine the format automatically. Format can be `custom`, `directory`, or `tar`.

`-I index | --index=index`

Restore definition of named index only.

`-j | --number-of-jobs | --jobs=number-of-jobs`

Run the most time-consuming parts of `pg_restore` — those which load data, create indexes, or create constraints — using multiple concurrent jobs. This option can dramatically reduce the time to restore a large database to a server running on a multiprocessor machine.

Each job is one process or one thread, depending on the operating system, and uses a separate connection to the server.

The optimal value for this option depends on the hardware setup of the server, of the client, and of the network. Factors include the number of CPU cores and the disk setup. A good place to start is the number of CPU cores on the server, but values larger than that can also lead to faster restore times in many cases. Of course, values that are too high will lead to decreased performance because of thrashing.

Only the custom archive format is supported with this option. The input file must be a regular file (not, for example, a pipe). This option is ignored when emitting a script rather than connecting directly to a database server. Also, multiple jobs cannot be used together with the option `--single-transaction`.

`-l | --list`

List the contents of the archive. The output of this operation can be used with the `-L` option to restrict and reorder the items that are restored.

`-L list-file | --use-list=list-file`

Restore elements in the list-file only, and in the order they appear in the file. Note that if filtering switches such as `-n` or `-t` are used with `-L`, they will further restrict the items restored.

list-file is normally created by editing the output of a previous `-l` operation. Lines can be moved or removed, and can also be commented out by placing a semicolon (;) at the start of the line. See below for examples.

`-n schema | --schema=schema`

Restore only objects that are in the named schema. This can be combined with the `-t` option to restore just a specific table.

`-O | --no-owner`

Do not output commands to set ownership of objects to match the original database. By default, `pg_restore` issues `ALTER OWNER` or `SET SESSION AUTHORIZATION` statements to set ownership of created schema elements. These statements will fail unless the initial connection to the database is made by a superuser (or the same user that owns all of the objects in the script). With `-o`, any user name can be used for the initial connection, and this user will own all the created objects.

`-P 'function-name(argtype [, ...])' | --function='function-name(argtype [, ...])'`

Restore the named function only. The function name must be enclosed in quotes. Be careful to spell the function name and arguments exactly as they appear in the dump file's table of contents (as shown by the `--list` option).

`-s | --schema-only`

Restore only the schema (data definitions), not data, to the extent that schema entries are present in the archive.

This option is the inverse of `--data-only`. It is similar to, but for historical reasons not identical to, specifying `--section=pre-data --section=post-data`.

(Do not confuse this with the `--schema` option, which uses the word "schema" in a different meaning.)

`-S username | --superuser=username`

Specify the superuser user name to use when deactivating triggers. This is only relevant if `--disable-triggers` is used.

**Note:** Greenplum Database does not support user-defined triggers.

`-t table | --table=table`

Restore definition and/or data of named table only. Multiple tables may be specified with multiple `-t` switches. This can be combined with the `-n` option to specify a schema.

`-T trigger | --trigger=trigger`

Restore named trigger only.

**Note:** Greenplum Database does not support user-defined triggers.

`-v | --verbose`

Specifies verbose mode.

`-V | --version`

Print the `pg_restore` version and exit.

`-x | --no-privileges | --no-acl`

Prevent restoration of access privileges (`GRANT/REVOKE` commands).

`-1 | --single-transaction`

Run the restore as a single transaction. This ensures that either all the commands complete successfully, or no changes are applied.

`--disable-triggers`

This option is relevant only when performing a data-only restore. It instructs `pg_restore` to run commands to temporarily deactivate triggers on the target tables while the data is reloaded. Use this if you have triggers on the tables that you do not want to invoke during data reload. The commands emitted for `--disable-triggers` must be done as superuser. So you should also specify a superuser name with `-s` or, preferably, run `pg_restore` as a superuser.

**Note:** Greenplum Database does not support user-defined triggers.

`--no-data-for-failed-tables`

By default, table data is restored even if the creation command for the table failed (e.g., because it already exists). With this option, data for such a table is skipped. This behavior is useful when the target database may already contain the desired table contents. Specifying this option prevents duplicate or obsolete data from being loaded. This option is effective only when restoring directly into a database, not when producing SQL script output.

`--no-security-labels`

Do not output commands to restore security labels, even if the archive contains them.

`--no-tablespaces`

Do not output commands to select tablespaces. With this option, all objects will be created in whichever tablespace is the default during restore.

`--section=sectionname`

Only restore the named section. The section name can be `pre-data`, `data`, or `post-data`. This option can be specified more than once to select multiple sections.

The default is to restore all sections.

`--use-set-session-authorization`

Output SQL-standard `SET SESSION AUTHORIZATION` commands instead of `ALTER OWNER` commands to determine object ownership. This makes the dump more standards-compatible, but depending on the history of the objects in the dump, it might not restore properly.

`-? | --help`

Show help about `pg_restore` command line arguments, and exit.

## Connection Options

`-h host | --host host`

The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to `localhost`.

`-p port | --port port`

The TCP port on which the Greenplum Database master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to `5432`.

`-U username | --username username`

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

`-w | --no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W | --password`

Force a password prompt.

`--role=rolename`

Specifies a role name to be used to perform the restore. This option causes `pg_restore` to issue a `SET ROLE rolename` command after connecting to the database. It is useful when the authenticated user (specified by `-U`) lacks privileges needed by `pg_restore`, but can switch to a role with the required rights. Some installations have a policy against logging in directly as a superuser, and use of this option allows restores to be performed without violating the policy.

## Notes

If your installation has any local additions to the `template1` database, be careful to load the output of `pg_restore` into a truly empty database; otherwise you are likely to get errors due to duplicate definitions of the added objects. To make an empty database without any local additions, copy from `template0` not `template1`, for example:

```
CREATE DATABASE foo WITH TEMPLATE template0;
```

When restoring data to a pre-existing table and the option `--disable-triggers` is used, `pg_restore` emits commands to deactivate triggers on user tables before inserting the data, then emits commands to re-enable them after the data has been inserted. If the restore is stopped in the middle, the system catalogs may be left in the wrong state.

See also the `pg_dump` documentation for details on limitations of `pg_dump`.

Once restored, it is wise to run `ANALYZE` on each restored table so the query planner has useful statistics.

## Examples

Assume we have dumped a database called `mydb` into a custom-format dump file:

```
pg_dump -Fc mydb > db.dump
```

To drop the database and recreate it from the dump:

```
dropdb mydb
pg_restore -C -d template1 db.dump
```

To reload the dump into a new database called `newdb`. Notice there is no `-C`, we instead connect directly to the database to be restored into. Also note that we clone the new database from `template0` not `template1`, to ensure it is initially empty:

```
createdb -T template0 newdb
pg_restore -d newdb db.dump
```

To reorder database items, it is first necessary to dump the table of contents of the archive:

```
pg_restore -l db.dump > db.list
```

The listing file consists of a header and one line for each item, for example,

```
; Archive created at Mon Sep 14 13:55:39 2009
;   dbname: DBDEMOS
;   TOC Entries: 81
;   Compression: 9
;   Dump Version: 1.10-0
;   Format: CUSTOM
;   Integer: 4 bytes
;   Offset: 8 bytes
;   Dumped from database version: 9.4.24
;   Dumped by pg_dump version: 9.4.24
;
; Selected TOC Entries:
;
3; 2615 2200 SCHEMA - public pasha
1861; 0 0 COMMENT - SCHEMA public pasha
1862; 0 0 ACL - public pasha
317; 1247 17715 TYPE public composite pasha
319; 1247 25899 DOMAIN public domain0 pasha2
```

Semicolons start a comment, and the numbers at the start of lines refer to the internal archive ID assigned to each item. Lines in the file can be commented out, deleted, and reordered. For example:

```
10; 145433 TABLE map_resolutions postgres
;2; 145344 TABLE species postgres
;4; 145359 TABLE nt_header postgres
6; 145402 TABLE species_records postgres
;8; 145416 TABLE ss_old postgres
```

Could be used as input to `pg_restore` and would only restore items 10 and 6, in that order:

```
pg_restore -L db.list db.dump
```

[ -q | --quiet ]
[ -v | --verbose ]
[ {-u | --user}=username ]

pgbouncer [ -V | --version ] | [ -h | --help ]

```

## Description

PgBouncer is a light-weight connection pool manager for Greenplum and PostgreSQL databases. PgBouncer maintains a pool of connections for each database user and database combination. PgBouncer either creates a new database connection for the client or reuses an existing pooled connection for the same user and database. When the client disconnects, PgBouncer returns the connection to the pool for re-use.

PgBouncer supports the standard connection interface shared by PostgreSQL and Greenplum Database. The Greenplum Database client application (for example, `psql`) should connect to the host and port on which PgBouncer is running rather than directly to the Greenplum Database master host and port.

You configure PgBouncer and its access to Greenplum Database via a configuration file. You provide the configuration file name, usually `<pgbouncer.ini>`, when you run the `pgbouncer` command. This file provides location information for Greenplum databases. The `pgbouncer.ini` file also specifies process, connection pool, authorized users, and authentication configuration for PgBouncer, among other configuration options.

By default, the `pgbouncer` process runs as a foreground process. You can optionally start `pgbouncer` as a background (daemon) process with the `-d` option.

The `pgbouncer` process is owned by the operating system user that starts the process. You can optionally specify a different user name under which to start `pgbouncer`.

PgBouncer includes a `psql`-like administration console. Authorized users can connect to a virtual database to monitor and manage PgBouncer. You can manage a PgBouncer daemon process via the admin console. You can also use the console to update and reload the PgBouncer configuration at runtime without stopping and restarting the process.

For additional information about PgBouncer, refer to the [PgBouncer FAQ](#).

## Options

`-d | --daemon`

Run PgBouncer as a daemon (a background process). The default start-up mode is to run as a foreground process.

In daemon mode, setting `pidfile` as well as `logfile` or `syslog` is required. No log messages will be written to `stderr` after going into the background.

To stop a PgBouncer process that was started as a daemon, issue the `SHUTDOWN` command from the PgBouncer administration console.

`-R | --reboot`

Restart PgBouncer using the specified command line arguments. That means connecting to the running process, loading the open sockets from it, and then using them. If there is no active process, boot normally. Non-TLS connections to databases are maintained during restart; TLS connections are dropped.

To restart PgBouncer as a daemon, specify the options `-Rd`.

**Note:** Restart is available only if the operating system supports Unix sockets and the PgBouncer `unix_socket_dir` configuration is not deactivated.

`-q | --quiet`

Run quietly. Do not log to `stderr`. This does not affect logging verbosity, only that `stderr` is not to be used. For use in `init.d` scripts.

`-v | --verbose`

Increase message verbosity. Can be specified multiple times.

`{-u | --user}=<username>`

Assume the identity of username on PgBouncer process start-up.

`-V | --version`

Show the version and exit.

`-h | --help`

Show the command help message and exit.

## See Also

[pgbouncer.ini](#), [pgbouncer-admin](#)

## pgbouncer.ini

PgBouncer configuration file.

## Synopsis

```
[databases]
db = ...

[pgbouncer]
...

[users]
...
```

## Description

You specify PgBouncer configuration parameters and identify user-specific configuration parameters in a configuration file.

The PgBouncer configuration file (typically named `pgbouncer.ini`) is specified in `.ini` format. Files in `.ini` format are composed of sections, parameters, and values. Section names are enclosed in square brackets, for example, `[<section_name>]`. Parameters and values are specified in `key=value` format. Lines beginning with a semicolon (`;`) or pound sign (`#`) are considered comment lines and are ignored.

The PgBouncer configuration file can contain `%include` directives, which specify another file to read and process. This enables you to split the configuration file into separate parts. For example:

```
%include filename
```

If the filename provided is not an absolute path, the file system location is taken as relative to the current working directory.

The PgBouncer configuration file includes the following sections, described in detail below:

- [\[databases\] Section](#)
- [\[pgbouncer\] Section](#)
- [\[users\] Section](#)

## [databases] Section

The `[databases]` section contains `key=value` pairs, where the `key` is a database name and the `value` is a `libpq` connect-string list of `key=value` pairs. Not all features known from `libpq` can be used (service=, `.pgpass`), since the actual `libpq` is not used.

A database name can contain characters `[0-9A-Za-z_.-]` without quoting. Names that contain other characters must be quoted with standard SQL identifier quoting:

- Enclose names in double quotes (`" "`).
- Represent a double-quote within an identifier with two consecutive double quote characters.

The database name `*` is the fallback database. PgBouncer uses the value for this key as a connect string for the requested database. Automatically-created database entries such as these are cleaned up if they remain idle longer than the time specified in `autodb_idle_timeout` parameter.

## Database Connection Parameters

The following parameters may be included in the `value` to specify the location of the database.

`dbname`

The destination database name.

Default: the client-specified database name

`host`

The name or IP address of the Greenplum master host. Host names are resolved at connect time. If DNS returns several results, they are used in a round-robin manner. The DNS result is cached and the `dns_max_ttl` parameter determines when the cache entry expires.

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

Default: not set; the connection is made through a Unix socket

port

The Greenplum Database master port.

Default: 5432

user

If `user=` is set, all connections to the destination database are initiated as the specified user, resulting in a single connection pool for the database.

If the `user=` parameter is not set, PgBouncer attempts to log in to the destination database with the user name passed by the client. In this situation, there will be one pool for each user who connects to the database.

password : If no password is specified here, the password from the `auth_file` or `auth_query` will be used.

auth\_user

Override of the global `auth_user` setting, if specified.

client\_encoding

Ask for specific `client_encoding` from server.

datestyle

Ask for specific `datestyle` from server.

timezone

Ask for specific `timezone` from server.

## Pool Configuration

You can use the following parameters for database-specific pool configuration.

pool\_size

Set the maximum size of pools for this database. If not set, the `default_pool_size` is used.

min\_pool\_size

Set the minimum pool size for this database. If not set, the global `min_pool_size` is used.

reserve\_pool

Set additional connections for this database. If not set, `reserve_pool_size` is used.

connect\_query

Query to be run after a connection is established, but before allowing the connection to be used by any clients. If the query raises errors, they are logged but ignored otherwise.

pool\_mode

Set the pool mode specific to this database. If not set, the default `pool_mode` is used.

max\_db\_connections

Set a database-wide maximum number of PgBouncer connections for this database. The total number of connections for all pools for this database will not exceed this value.

## [pgbouncer] Section

## Generic Settings

### logfile

The location of the log file. For daemonization (`-d`), either this or `syslog` need to be set. The log file is kept open. After log rotation, run `kill -HUP pgbouncer` or run the `RELOAD` command in the PgBouncer Administration Console.

Note that setting `logfile` does not by itself turn off logging to `stderr`. Use the command-line option `-q` or `-d` for that.

Default: not set

### pidfile

The name of the pid file. Without a `pidfile`, you cannot run PgBouncer as a background (daemon) process.

Default: not set

### listen\_addr

Specifies a list of interface addresses where PgBouncer listens for TCP connections. You may also use `*`, which means to listen on all interfaces. If not set, only Unix socket connections are accepted.

Specify addresses numerically (IPv4/IPv6) or by name.

Default: not set

### listen\_port

The port PgBouncer listens on. Applies to both TCP and Unix sockets.

Default: 6432

### unix\_socket\_dir

Specifies the location for the Unix sockets. Applies to both listening socket and server connections. If set to an empty string, Unix sockets are deactivated. A value that starts with `@` specifies that a Unix socket in the abstract namespace should be created.

For online reboot (`-R`) to work, a Unix socket needs to be configured, and it needs to be in the file-system namespace.

Default: `/tmp`

### unix\_socket\_mode

Filesystem mode for the Unix socket. Ignored for sockets in the abstract namespace.

Default: `0777`

### unix\_socket\_group

Group name to use for Unix socket. Ignored for sockets in the abstract namespace.

Default: not set

### user

If set, specifies the Unix user to change to after startup. This works only if PgBouncer is started as root or if it is already running as the given user.

Default: not set

#### auth\_file

The name of the file containing the user names and passwords to load. The file format is the same as the Greenplum Database `pg_auth` file. Refer to the [PgBouncer Authentication File Format](#) for more information.

Default: not set

#### auth\_hba\_file

HBA configuration file to use when `auth_type` is `hba`. Refer to the [Configuring HBA-based Authentication for PgBouncer](#) and [Configuring LDAP-based Authentication for PgBouncer](#) for more information.

Default: not set

#### auth\_type

How to authenticate users.

- `pam`: Use PAM to authenticate users. `auth_file` is ignored. This method is not compatible with databases using the `auth_user` option. The service name reported to PAM is `pgbouncer`. PAM is not supported in the HBA configuration file.
- `hba`: The actual authentication type is loaded from the `auth_hba_file`. This setting allows different authentication methods for different access paths, for example: connections over Unix socket use the `peer` auth method, connections over TCP must use TLS.
- `cert`: Clients must connect with TLS using a valid client certificate. The client's username is taken from `CommonName` field in the certificate.
- `md5`: Use MD5-based password check. `auth_file` may contain both MD5-encrypted or plain-text passwords. If `md5` is configured and a user has a SCRAM secret, then SCRAM authentication is used automatically instead. This is the default authentication method.
- `scram-sha-256`: Use password check with SCRAM-SHA-256. `auth_file` has to contain SCRAM secrets or plain-text passwords.
- `plain`: Clear-text password is sent over wire. *Deprecated*.
- `trust`: No authentication is performed. The username must still exist in the `auth_file`.
- `any`: Like the `trust` method, but the username supplied is ignored. Requires that all databases are configured to log in with a specific user. Additionally, the console database allows any user to log in as `admin`.

#### auth\_query

Query to load a user's password from the database.

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Note that the query is run inside target database, so if a function is used it needs to be installed into each database.

Default: `SELECT username, passwd FROM pg_shadow WHERE username=$1`

#### auth\_user

If `auth_user` is set, any user who is not specified in `auth_file` is authenticated through the `auth_query` query from the `pg_shadow` database view. PgBouncer performs this query as the `auth_user` Greenplum Database user. `auth_user`'s password must be set in the `auth_file`. (If the `auth_user` does not require a password then it does not need to be defined in `auth_file`.)

Direct access to `pg_shadow` requires Greenplum Database administrative privileges. It is preferable to use a non-admin user that calls `SECURITY DEFINER` function instead.

Default: not set

#### pool\_mode

Specifies when a server connection can be reused by other clients.

- `session`: Connection is returned to the pool when the client disconnects. Default.
- `transaction`: Connection is returned to the pool when the transaction finishes.
- `statement`: Connection is returned to the pool when the current query finishes. Transactions spanning multiple statements are disallowed in this mode.

#### max\_client\_conn

Maximum number of client connections allowed. When increased, you should also increase the file descriptor limits. The actual number of file descriptors used is more than `max_client_conn`. The theoretical maximum used, when each user connects with its own username to the server is:

```
max_client_conn + (max pool_size * total databases * total users)
```

If a database user is specified in the connect string, all users connect using the same username. Then the theoretical maximum connections is:

```
max_client_conn + (max pool_size * total databases)
```

The theoretical maximum should be never reached, unless someone deliberately crafts a special load for it. Still, it means you should set the number of file descriptors to a safely high number. Search for `ulimit` in your operating system documentation.

Default: 100

#### default\_pool\_size

The number of server connections to allow per user/database pair. This can be overridden in the per-database configuration.

Default: 20

#### min\_pool\_size

Add more server connections to the pool when it is lower than this number. This improves behavior when the usual load drops and then returns suddenly after a period of total inactivity. The value is effectively capped at the pool size.

Default: 0 (deactivated)

`reserve_pool_size`

The number of additional connections to allow for a pool (see `reserve_pool_timeout`). `0` deactivates.

Default: 0 (deactivated)

`reserve_pool_timeout`

If a client has not been serviced in this many seconds, PgBouncer enables use of additional connections from the reserve pool. `0` deactivates.

Default: 5.0

`max_db_connections`

Do not allow more than this many server connections per database (regardless of user). This considers the PgBouncer database that the client has connected to, not the PostgreSQL database of the outgoing connection.

This can also be set per database in the `[databases]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

`max_user_connections`

Do not allow more than this many server connections per user (regardless of database). This considers the PgBouncer user that is associated with a pool, which is either the user specified for the server connection or in absence of that the user the client has connected as.

This can also be set per user in the `[users]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

`server_round_robin`

By default, PgBouncer reuses server connections in LIFO (last-in, first-out) order, so that a few connections get the most load. This provides the best performance when a single server serves a database. But if there is TCP round-robin behind a database IP, then it is better if PgBouncer also uses connections in that manner to achieve uniform load.

Default: 0

`ignore_startup_parameters`

By default, PgBouncer allows only parameters it can keep track of in startup packets: `client_encoding`, `datestyle`, `timezone`, and `standard_conforming_strings`. All others parameters raise an error. To allow other parameters, specify them here so that PgBouncer knows that they are handled by the admin and it can ignore them.

Default: empty

disable\_pqexec

Deactivates Simple Query protocol (PQexec). Unlike Extended Query protocol, Simple Query protocol allows multiple queries in one packet, which allows some classes of SQL-injection attacks. Deactivating it can improve security. This means that only clients that exclusively use Extended Query protocol will work.

Default: 0

application\_name\_add\_host

Add the client host address and port to the application name setting set on connection start. This helps in identifying the source of bad queries. This logic applies only on start of connection. If `application_name` is later changed with `SET`, PgBouncer does not change it again.

Default: 0

conffile

Show location of the current configuration file. Changing this parameter will result in PgBouncer using another config file for next `RELOAD` / `SIGHUP`.

Default: file from command line

service\_name

Used during win32 service registration.

Default: pgbouncer

job\_name

Alias for `service_name`.

stats\_period

Sets how often the averages shown in various `SHOW` commands are updated and how often aggregated statistics are written to the log (but see `log_stats`). [seconds]

Default: 60

## Log Settings

syslog

Toggles syslog on and off.

Default: 0

syslog\_ident

Under what name to send logs to syslog.

Default: `pgbouncer` (program name)

syslog\_facility

Under what facility to send logs to syslog. Some possibilities are: `auth`, `authpriv`, `daemon`, `user`, `local0-7`.

Default: `daemon`

**log\_connections**

Log successful logins.

Default: 1

**log\_disconnections**

Log disconnections, with reasons.

Default: 1

**log\_pooler\_errors**

Log error messages that the pooler sends to clients.

Default: 1

**log\_stats**

Write aggregated statistics into the log, every `stats_period`. This can be deactivated if external monitoring tools are used to grab the same data from `SHOW` commands.

Default: 1

**verbose**

Increase verbosity. Mirrors the `-v` switch on the command line. Using `-v -v` on the command line is the same as `verbose=2`.

Default: 0

## Console Access Control

**admin\_users**

Comma-separated list of database users that are allowed to connect and run all commands on the PgBouncer Administration Console. Ignored when `auth_type=any`, in which case any username is allowed in as admin.

Default: empty

**stats\_users**

Comma-separated list of database users that are allowed to connect and run read-only queries on the console. This includes all `SHOW` commands except `SHOW FDS`.

Default: empty

## Connection Sanity Checks, Timeouts

**server\_reset\_query**

Query sent to server on connection release, before making it available to other clients. At that moment no transaction is in progress so it should not include `ABORT` or `ROLLBACK`.

The query should clean any changes made to a database session so that the next client gets a connection in a well-defined state. Default is `DISCARD ALL` which cleans everything, but that leaves the next client no pre-cached state. It can be made lighter, e.g. `DEALLOCATE ALL` to just drop prepared statements, if the application does not break when some state is kept around.

**Note:** Greenplum Database does not support `DISCARD ALL`.

When transaction pooling is used, the `server_reset_query` is not used, as clients must not use any session-based features as each transaction ends up in a different connection and thus gets a different session state.

Default: `DISCARD ALL;` (Not supported by Greenplum Database.)

#### `server_reset_query_always`

Whether `server_reset_query` should be run in all pooling modes. When this setting is off (default), the `server_reset_query` will be run only in pools that are in sessions-pooling mode. Connections in transaction-pooling mode should not have any need for reset query.

This setting is for working around broken setups that run applications that use session features over a transaction-pooled PgBouncer. It changes non-deterministic breakage to deterministic breakage: Clients always lose their state after each transaction.

Default: 0

#### `server_check_delay`

How long to keep released connections available for immediate re-use, without running sanity-check queries on it. If 0, then the query is run always.

Default: 30.0

#### `server_check_query`

A simple do-nothing query to test the server connection.

If an empty string, then sanity checking is deactivated.

Default: `SELECT 1;`

#### `server_fast_close`

Disconnect a server in session pooling mode immediately or after the end of the current transaction if it is in “close\_needed” mode (set by `RECONNECT`, `RELOAD` that changes connection settings, or DNS change), rather than waiting for the session end. In statement or transaction pooling mode, this has no effect since that is the default behavior there.

If because of this setting a server connection is closed before the end of the client session, the client connection is also closed. This ensures that the client notices that the session has been interrupted.

This setting makes connection configuration changes take effect sooner if session pooling and long-running sessions are used. The downside is that client sessions are liable to be interrupted by a configuration change, so client applications will need logic to reconnect and reestablish session state. But note that no transactions will be lost, because running transactions are not interrupted, only idle sessions.

Default: 0

#### `server_lifetime`

The pooler will close an unused server connections that has been connected longer than this number of seconds. Setting it to 0 means the connection is to be used only once, then closed. [seconds]

Default: 3600.0

#### server\_idle\_timeout

If a server connection has been idle more than this many seconds it is dropped. If this parameter is set to 0, timeout is deactivated. [seconds]

Default: 600.0

#### server\_connect\_timeout

If connection and login will not finish in this amount of time, the connection will be closed. [seconds]

Default: 15.0

#### server\_login\_retry

If a login fails due to failure from `connect()` or authentication, that pooler waits this much before retrying to connect. [seconds]

Default: 15.0

#### client\_login\_timeout

If a client connects but does not manage to login in this amount of time, it is disconnected. This is needed to avoid dead connections stalling `SUSPEND` and thus online restart. [seconds]

Default: 60.0

#### autodb\_idle\_timeout

If database pools created automatically (via `*`) have been unused this many seconds, they are freed. Their statistics are also forgotten. [seconds]

Default: 3600.0

#### dns\_max\_ttl

How long to cache DNS lookups, in seconds. If a DNS lookup returns several answers, PgBouncer round-robins between them in the meantime. The actual DNS TTL is ignored. [seconds]

Default: 15.0

#### dns\_nxdomain\_ttl

How long error and NXDOMAIN DNS lookups can be cached. [seconds]

Default: 15.0

#### dns\_zone\_check\_period

Period to check if zone serial numbers have changed.

PgBouncer can collect DNS zones from hostnames (everything after first dot) and then periodically check if the zone serial numbers change. If changes are detected, all hostnames in that zone are looked up again. If any host IP changes, its connections are invalidated.

Works only with UDNS and c-ares backend (`--with-udns` or `--with-cares` to configure).

Default: 0.0 (deactivated)

#### resolv\_conf

The location of a custom `resolv.conf` file. This is to allow specifying custom DNS servers and perhaps other name resolution options, independent of the global operating system configuration.

Requires `evdns` ( $\geq 2.0.3$ ) or `c-ares` ( $\geq 1.15.0$ ) backend.

The parsing of the file is done by the DNS backend library, not PgBouncer, so see the library's documentation for details on allowed syntax and directives.

Default: empty (use operating system defaults)

## TLS settings

### `client_tls_sslmode`

TLS mode to use for connections from clients. TLS connections are deactivated by default. When enabled, `client_tls_key_file` and `client_tls_cert_file` must be also configured to set up the key and certificate PgBouncer uses to accept client connections.

- `disable`: Plain TCP. If client requests TLS, it's ignored. Default.
- `allow`: If client requests TLS, it is used. If not, plain TCP is used. If client uses client-certificate, it is not validated.
- `prefer`: Same as `allow`.
- `require`: Client must use TLS. If not, client connection is rejected. If client presents a client-certificate, it is not validated.
- `verify-ca`: Client must use TLS with valid client certificate.
- `verify-full`: Same as `verify-ca`.

### `client_tls_key_file`

Private key for PgBouncer to accept client connections.

Default: not set

### `client_tls_cert_file`

Certificate for private key. Clients can validate it.

Default: unset

### `client_tls_ca_file`

Root certificate to validate client certificates.

Default: unset

### `client_tls_protocols`

Which TLS protocol versions are allowed.

Valid values: are `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`.

Shortcuts: `all` (`tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`), `secure` (`tlsv1.2`, `tlsv1.3`), `legacy` (`all`).

Default: `secure`

### `client_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default/secure`, `compat/legacy`, `insecure/all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

`client_tls_ecdhcurve`

Elliptic Curve name to use for ECDH key exchanges.

Allowed values: `none` (DH is deactivated), `auto` (256-bit ECDH), curve name.

Default: `auto`

`client_tls_dheparams`

DHE key exchange type.

Allowed values: `none` (DH is deactivated), `auto` (2048-bit DH), `legacy` (1024-bit DH).

Default: `auto`

`server_tls_sslmode`

TLS mode to use for connections to Greenplum Database and PostgreSQL servers. TLS connections are deactivated by default.

- `disable`: Plain TCP. TLS is not requested from the server. Default.
- `allow`: If server rejects plain, try TLS. (*PgBouncer Documentation is speculative on this.*)
- `prefer`: TLS connection is always requested first. When connection is refused, plain TCP is used. Server certificate is not validated.
- `require`: Connection must use TLS. If server rejects it, plain TCP is not attempted. Server certificate is not validated.
- `verify-ca`: Connection must use TLS and server certificate must be valid according to `server_tls_ca_file`. The server hostname is not verified against the certificate.
- `verify-full`: Connection must use TLS and the server certificate must be valid according to `server_tls_ca_file`. The server hostname must match the hostname in the certificate.

`server_tls_ca_file`

Root certificate file used to validate Greenplum Database and PostgreSQL server certificates.

Default: `unset`

`server_tls_key_file`

Private key for PgBouncer to authenticate against Greenplum Database or PostgreSQL server.

Default: `not set`

`server_tls_cert_file`

Certificate for private key. Greenplum Database or PostgreSQL servers can validate it.

Default: `not set`

`server_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`); `secure` (`tlsv1.2`, `tlsv1.3`); `legacy` (`all`).

Default: `secure`

`server_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default/secure`, `compat/legacy`, `insecure/all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

## Dangerous Timeouts

Setting the following timeouts can cause unexpected errors.

`query_timeout`

Queries running longer than this (seconds) are canceled. This parameter should be used only with a slightly smaller server-side `statement_timeout`, to apply only for network problems. [seconds]

Default: 0.0 (deactivated)

`query_wait_timeout`

The maximum time, in seconds, queries are allowed to wait for execution. If the query is not assigned to a server during that time, the client is disconnected. This is used to prevent unresponsive servers from grabbing up connections. [seconds]

Default: 120

`client_idle_timeout`

Client connections idling longer than this many seconds are closed. This should be larger than the client-side connection lifetime settings, and only used for network problems. [seconds]

Default: 0.0 (deactivated)

`idle_transaction_timeout`

If client has been in "idle in transaction" state longer than this (seconds), it is disconnected. [seconds]

Default: 0.0 (deactivated)

`suspend_timeout`

How many seconds to wait for buffer flush during `SUSPEND` or reboot (`-R`). A connection is dropped if the flush does not succeed.

Default: 10

## Low-level Network Settings

`pkt_buf`

Internal buffer size for packets. Affects the size of TCP packets sent and general memory usage. Actual `libpq` packets can be larger than this so there is no need to set it large.

Default: 4096

`max_packet_size`

Maximum size for packets that PgBouncer accepts. One packet is either one query or one result set row. A full result set can be larger.

Default: 2147483647

`listen_backlog`

Backlog argument for the `listen(2)` system call. It determines how many new unanswered connection attempts are kept in queue. When the queue is full, further new connection attempts are dropped.

Default: 128

`sbuf_loopcnt`

How many times to process data on one connection, before proceeding. Without this limit, one connection with a big result set can stall PgBouncer for a long time. One loop processes one `pkt_buf` amount of data. 0 means no limit.

Default: 5

`so_reuseport`

Specifies whether to set the socket option `SO_REUSEPORT` on TCP listening sockets. On some operating systems, this allows running multiple PgBouncer instances on the same host listening on the same port and having the kernel distribute the connections automatically. This option is a way to get PgBouncer to use more CPU cores. (PgBouncer is single-threaded and uses one CPU core per instance.)

The behavior in detail depends on the operating system kernel. As of this writing, this setting has the desired effect on (sufficiently recent versions of) Linux, DragonFlyBSD, and FreeBSD. (On FreeBSD, it applies the socket option `SO_REUSEPORT_LB` instead.). Some other operating systems support the socket option but it won't have the desired effect: It will allow multiple processes to bind to the same port but only one of them will get the connections. See your operating system's `setsockopt()` documentation for details.

On systems that don't support the socket option at all, turning this setting on will result in an error.

Each PgBouncer instance on the same host needs different settings for at least `unix_socket_dir` and `pidfile`, as well as `logfile` if that is used. Also note that if you make use of this option, you can no longer connect to a specific PgBouncer instance via TCP/IP, which might have implications for monitoring and metrics collection.

Default: 0

`tcp_defer_accept`

For details on this and other TCP options, please see the `tcp(7)` man page.

Default: 45 on Linux, otherwise 0

tcp\_socket\_buffer

Default: not set

tcp\_keepalive

Turns on basic keepalive with OS defaults.

On Linux, the system defaults are `tcp_keepidle=7200`, `tcp_keepintvl=75`, `tcp_keepcnt=9`. They are probably similar on other operating systems.

Default: 1

tcp\_keepcnt

Default: not set

tcp\_keepidle

Default: not set

tcp\_keepintvl

Default: not set

tcp\_user\_timeout

Sets the `TCP_USER_TIMEOUT` socket option. This specifies the maximum amount of time in milliseconds that transmitted data may remain unacknowledged before the TCP connection is forcibly closed. If set to 0, then the operating system's default is used.

Default: 0

## [users] Section

This section contains `key=value` pairs, where the `key` is a user name and the `value` is a `libpq` connect-string list of `key=value` pairs of configuration settings specific for this user. Only a few settings are available here.

### Pool configuration

pool\_mode

Set the pool mode for all connections from this user. If not set, the database or default `pool_mode` is used.

max\_user\_connection

Configure a maximum for the user (i.e. all pools with the user will not have more than this many server connections).

## Example Configuration Files

### Minimal Configuration

```
[databases]
postgres = host=127.0.0.1 dbname=postgres auth_user=gpadmin

[pgbouncer]
pool_mode = session
listen_port = 6543
listen_addr = 127.0.0.1
auth_type = md5
auth_file = users.txt
```

```
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
stats_users = stat_collector
```

Use connection parameters passed by the client:

```
[databases]
* =

[pgbouncer]
listen_port = 6543
listen_addr = 0.0.0.0
auth_type = trust
auth_file = bouncer/users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
ignore_startup_parameters=options
```

## Database Defaults

```
[databases]

; foodb over unix socket
foodb =

; redirect bardb to bazdb on localhost
bardb = host=127.0.0.1 dbname=bazdb

; access to destination database will go with single user
forcedb = host=127.0.0.1 port=300 user=baz password=foo client_encoding=UNICODE datestyle=ISO
```

Example of a secure function for auth\_query:

```
CREATE OR REPLACE FUNCTION pgbouncer.user_lookup(in i_username text, out uname text, out phash text)
RETURNS record AS $$
BEGIN
    SELECT username, passwd FROM pg_catalog.pg_shadow
    WHERE username = i_username INTO uname, phash;
    RETURN;
END;
$$ LANGUAGE plpgsql SECURITY DEFINER;
REVOKE ALL ON FUNCTION pgbouncer.user_lookup(text) FROM public, pgbouncer;
GRANT EXECUTE ON FUNCTION pgbouncer.user_lookup(text) TO pgbouncer;
```

## pgbouncer-admin

PgBouncer Administration Console.

## Synopsis

```
psql -p <port> pgbouncer
```

## Description

The PgBouncer Administration Console is available via `psql`. Connect to the PgBouncer `<port>` and the virtual database named `pgbouncer` to log in to the console.

Users listed in the `pgbouncer.ini` configuration parameters `admin_users` and `stats_users` have privileges to log in to the PgBouncer Administration Console. When `auth_type=any`, then any user is allowed in as a `stats_user`.

Additionally, the user name `pgbouncer` is allowed to log in without password when the login comes via the Unix socket and the client has same Unix user UID as the running process.

You can control connections between PgBouncer and Greenplum Database from the console. You can also set PgBouncer configuration parameters.

## Options

`-p <port>`

The PgBouncer port number.

## Command Syntax

```
pgbouncer=# SHOW help;
NOTICE:  Console usage
DETAIL:
    SHOW HELP|CONFIG|USERS|DATABASES|POOLS|CLIENTS|SERVERS|VERSION
    SHOW FDS|SOCKETS|ACTIVE_SOCKETS|LISTS|MEM
    SHOW DNS_HOSTS|DNS_ZONES
    SHOW STATS|STATS_TOTALS|STATS_AVERAGES
    SHOW TOTALS
    SET key = arg
    RELOAD
    PAUSE [<db>]
    RESUME [<db>]
    DISABLE <db>
    ENABLE <db>
    RECONNECT [<db>]
    KILL <db>
    SUSPEND
    SHUTDOWN
```

## Administration Commands

The following PgBouncer administration commands control the running `pgbouncer` process.

**PAUSE [<db>]**

If no database is specified, PgBouncer tries to disconnect from all servers, first waiting for all queries to complete. The command will not return before all queries are finished. This command is to be used to prepare to restart the database.

If a database name is specified, PgBouncer pauses only that database.

New client connections to a paused database will wait until a **RESUME** command is invoked.

**DISABLE <db>**

Reject all new client connections on the database.

**ENABLE <db>**

Allow new client connections after a previous **DISABLE** command.

**RECONNECT**

Close each open server connection for the given database, or all databases, after it is released (according to the pooling mode), even if its lifetime is not up yet. New server connections can be made immediately and will connect as necessary according to the pool size settings.

This command is useful when the server connection setup has changed, for example to perform a gradual switchover to a new server. It is not necessary to run this command when the connection string in `pgbouncer.ini` has been changed and reloaded (see **RELOAD**) or when DNS resolution has changed, because then the equivalent of this command will be run automatically. This command is only necessary if something downstream of PgBouncer routes the connections.

After this command is run, there could be an extended period where some server connections go to an old destination and some server connections go to a new destination. This is likely only sensible when switching read-only traffic between read-only replicas, or when switching between nodes of a multimaster replication setup. If all connections need to be switched at the same time, **PAUSE** is recommended instead. To close server connections without waiting (for example, in emergency failover rather than gradual switchover scenarios), also consider **KILL**.

**KILL <db>**

Immediately drop all client and server connections to the named database.

New client connections to a killed database will wait until **RESUME** is called.

**SUSPEND**

All socket buffers are flushed and PgBouncer stops listening for data on them. The command will not return before all buffers are empty. To be used when rebooting PgBouncer online.

New client connections to a suspended database will wait until **RESUME** is called.

**RESUME [<db>]**

Resume work from a previous **KILL**, **PAUSE**, or **SUSPEND** command.

**SHUTDOWN**

The PgBouncer process will exit. To exit from the `psql` command line session, enter `\q`.

**RELOAD**

The PgBouncer process reloads the current configuration file and updates the changeable settings.

PgBouncer notices when a configuration file reload changes the connection parameters of a database definition. An existing server connection to the old destination will be closed when the server connection is next released (according to the pooling mode), and new server connections will immediately use the updated connection parameters

`WAIT_CLOSE [<db>]`

Wait until all server connections, either of the specified database or of all databases, have cleared the “close\_needed” state (see `SHOW SERVERS`). This can be called after a `RECONNECT` or `RELOAD` to wait until the respective configuration change has been fully activated, for example in switchover scripts.

`SET key = value`

Changes the specified configuration setting. See the `SHOW CONFIG;` command.

(Note that this command is run on the PgBouncer admin console and sets PgBouncer settings. A `SET` command run on another database will be passed to the PostgreSQL backend like any other SQL command.)

## SHOW Command

The `SHOW <category>` command displays different types of PgBouncer information. You can specify one of the following categories:

- `CLIENTS`
- `CONFIG`
- `DATABASES`
- `DNS_HOSTS`
- `DNS_ZONES`
- `FDS`
- `LISTS`
- `MEM`
- `POOLS`
- `SERVERS`
- `SOCKETS, ACTIVE_SOCKETS,`
- `STATS`
- `STATS_TOTALS`
- `STATS_AVERAGES`
- `TOTALS`
- `USERS`
- `VERSION`

## CLIENTS

| Column       | Description  |
|--------------|--|
| type         | C, for client.   |
| user         | Client connected user.   |
| database     | Database name.   |
| state        | State of the client connection, one of <code>active</code> or <code>waiting</code> . |
| addr         | IP address of client.  |
| port         | Port client is connected to.   |
| local_addr   | Connection end address on local machine.   |
| local_port   | Connection end port on local machine.  |
| connect_time | Timestamp of connect time.   |
| request_time | Timestamp of latest client request.  |
| wait         | Current Time waiting in seconds.   |
| wait_us      | Microsecond part of the current waiting time.  |
| ptr          | Address of internal object for this connection. Used as unique ID.                   |
| link         | Address of server connection the client is paired with.                              |
| remote_pid   | Process ID, if client connects with Unix socket and the OS supports getting it.      |
| tls          | A string with TLS connection information, or empty if not using TLS.                 |

## CONFIG

Show the current PgBouncer configuration settings, one per row, with the following columns:

| Column     | Description  |
|------------|--|
| key        | Configuration variable name  |
| value      | Configuration value  |
| default    | Configuration default value  |
| changeable | Either <code>yes</code> or <code>no</code> . Shows whether the variable can be changed while running. If <code>no</code> , the variable can be changed only at boot time. Use <code>SET</code> to change a variable at run time. |

## DATABASES

| Column   | Description                                 |
|----------|---|
| name     | Name of configured database entry.          |
| host     | Host pgbouncer connects to.                 |
| port     | Port pgbouncer connects to.                 |
| database | Actual database name pgbouncer connects to. |

| Column              | Description   |
|---------------------|---|
| force_user          | When user is part of the connection string, the connection between pgbouncer and the database server is forced to the given user, whatever the client user. |
| pool_size           | Maximum number of server connections.   |
| min_pool_size       | Minimum number of server connections.   |
| reserve_pool        | The maximum number of additional connections for this database.   |
| pool_mode           | The database's override <code>pool_mode</code> or NULL if the default will be used instead.   |
| max_connections     | Maximum number of allowed connections for this database, as set by <code>max_db_connections</code> , either globally or per-database.                       |
| current_connections | The current number of connections for this database.  |
| paused              | Paused/unpaused state of the database. 1 if this database is currently paused, else 0.  |
| disabled            | Enabled/disabled state of the database. 1 if this database is currently disabled, else 0.   |

## DNS\_HOSTS

Show host names in DNS cache.

| Column   | Description                         |
|----------|-------------------------------------|
| hostname | Host name                           |
| ttd      | How many seconds until next lookup. |
| addrs    | Comma-separated list of addresses.  |

## DNS\_ZONES

Show DNS zones in cache.

| Column   | Description                      |
|----------|----------------------------------|
| zonename | Zone name                        |
| serial   | Current DNS serial number        |
| count    | Hostnames belonging to this zone |

## FDS

`SHOW FDS` is an internal command used for an online restart, for example when upgrading to a new PgBouncer version. It displays a list of file descriptors in use with the internal state attached to them. This command blocks the internal event loop, so it should not be used while PgBouncer is in use.

When the connected user has username "pgbouncer", connects through a Unix socket, and has the same UID as the running process, the actual file descriptors are passed over the connection. This mechanism is used to do an online restart.

| Column   | Description   |
|----------|---|
| fd       | File descriptor numeric value.  |
| task     | One of <code>pooler</code> , <code>client</code> , or <code>server</code> .                         |
| user     | User of the connection using the file descriptor.   |
| database | Database of the connection using the file descriptor.   |
| addr     | IP address of the connection using the file descriptor, <code>unix</code> if a Unix socket is used. |
| port     | Port used by the connection using the file descriptor.  |
| cancel   | Cancel key for this connection.   |
| link     | File descriptor for corresponding server/client. NULL if idle.                                      |

## LISTS

Shows the following PgBouncer internal information, in columns (not rows):

| Item          | Description                                   |
|---------------|---|
| databases     | Count of databases.                           |
| users         | Count of users.                               |
| pools         | Count of pools.                               |
| free_clients  | Count of free clients.                        |
| used_clients  | Count of used clients.                        |
| login_clients | Count of clients in <code>login</code> state. |
| free_servers  | Count of free servers.                        |
| used_servers  | Count of used servers.                        |
| dns_names     | Count of DNS names in the cache.              |
| dns_zones     | Count of DNS zones in the cache.              |
| dns_queries   | Count of in-flight DNS queries.               |
| dns_pending   | not used                                      |

## MEM

Shows low-level information about the current sizes of various internal memory allocations. The information presented is subject to change.

## POOLS

A new pool entry is made for each pair of (database, user).

| Column   | Description    |
|----------|----------------|
| database | Database name. |

| Column        | Description   |
|---------------|---|
| user          | User name.  |
| cl_active     | Client connections that are linked to server connection and can process queries.  |
| cl_waiting    | Client connections that have sent queries but have not yet got a server connection.   |
| cl_cancel_req | Client connections that have not yet forwarded query cancellations to the server.   |
| sv_active     | Server connections that are linked to client.   |
| sv_idle       | Server connections that are unused and immediately usable for client queries.   |
| sv_used       | Server connections that have been idle more than <code>server_check_delay</code> . The <code>server_check_query</code> query must be run on them before they can be used again.   |
| sv_tested     | Server connections that are currently running either <code>server_reset_query</code> or <code>server_check_query</code> .   |
| sv_login      | Server connections currently in the process of logging in.  |
| maxwait       | How long the first (oldest) client in the queue has waited, in seconds. If this begins to increase, the current pool of servers does not handle requests quickly enough. The cause may be either an overloaded server or the <code>pool_size</code> setting is too small. |
| maxwait_us    | Microsecond part of the maximum waiting time.   |
| pool_mode     | The pooling mode in use.  |

## SERVERS

| Column       | Description   |
|--------------|---|
| type         | S, for server.  |
| user         | User name that <code>pgbouncer</code> uses to connect to server.  |
| database     | Database name.  |
| state        | State of the <code>pgbouncer</code> server connection, one of <code>active</code> , <code>idle</code> , <code>used</code> , <code>tested</code> , or <code>new</code> . |
| addr         | IP address of the Greenplum or PostgreSQL server.   |
| port         | Port of the Greenplum or PostgreSQL server.   |
| local_addr   | Connection start address on local machine.  |
| local_port   | Connection start port on local machine.   |
| connect_time | When the connection was made.   |
| request_time | When the last request was issued.   |
| wait         | Current waiting time in seconds.  |

| Column       | Description   |
|--------------|---|
| wait_us      | Microsecond part of the current waiting time.   |
| close_needed | 1 if the connection will be closed as soon as possible, because a configuration file reload or DNS update changed the connection information or <code>RECONNECT</code> was issued.  |
| ptr          | Address of the internal object for this connection. Used as unique ID.  |
| link         | Address of the client connection the server is paired with.   |
| remote_pid   | Pid of backend server process. If the connection is made over Unix socket and the OS supports getting process ID info, it is the OS pid. Otherwise it is extracted from the cancel packet the server sent, which should be PID in case server is PostgreSQL, but it is a random number in case server is another PgBouncer. |
| tls          | A string with TLS connection information, or empty if not using TLS.  |

## SOCKETS, ACTIVE\_SOCKETS

Shows low-level information about sockets or only active sockets. This includes the information shown under `SHOW CLIENTS` and `SHOW SERVERS` as well as other more low-level information.

## STATS

Shows statistics. In this and related commands, the total figures are since process start, the averages are updated every `stats_period`.

| Column            | Description   |
|-------------------|---|
| database          | Statistics are presented per database.  |
| total_xact_count  | Total number of SQL transactions pooled by PgBouncer.   |
| total_query_count | Total number of SQL queries pooled by PgBouncer.  |
| total_received    | Total volume in bytes of network traffic received by <code>pgbouncer</code> .   |
| total_sent        | Total volume in bytes of network traffic sent by <code>pgbouncer</code> .   |
| total_xact_time   | Total number of microseconds spent by PgBouncer when connected to Greenplum Database in a transaction, either idle in transaction or executing queries. |
| total_query_time  | Total number of microseconds spent by <code>pgbouncer</code> when actively connected to the database server.  |
| total_wait_time   | Time spent (in microseconds) by clients waiting for a server.   |
| avg_xact_count    | Average number of transactions per second in the last stat period.  |
| avg_query_count   | Average queries per second in the last stats period.  |
| avg_recv          | Average received (from clients) bytes per second.   |
| avg_sent          | Average sent (to clients) bytes per second.   |

| Column         | Description  |
|----------------|--|
| avg_xact_time  | Average transaction duration in microseconds.                                    |
| avg_query_time | Average query duration in microseconds.  |
| avg_wait_time  | Time spent by clients waiting for a server in microseconds (average per second). |

## STATS\_AVERAGES

Subset of `SHOW STATS` showing the average values for selected statistics (`avg_`)

## STATS\_TOTALS

Subset of `SHOW STATS` showing the total values for selected statistics (`total_`)

## TOTALS

Like `SHOW STATS` but aggregated across all databases.

## USERS

| Column    | Description   |
|-----------|---|
| name      | The user name   |
| pool_mode | The user's override <code>pool_mode</code> , or NULL if the default will be used instead. |

## VERSION

Display PgBouncer version information.

Signals

`SIGHUP` : Reload config. Same as issuing the command `RELOAD` on the console.

`SIGINT` : Safe shutdown. Same as issuing `PAUSE` and `SHUTDOWN` on the console.

`SIGTERM` : Immediate shutdown. Same as issuing `SHUTDOWN` on the console.

`SIGUSR1` : Same as issuing `PAUSE` on the console.

`SIGUSR2` : Same as issuing `RESUME` on the console.

## Libevent Settings

From the Libevent documentation:

```
It is possible to disable support for epoll, kqueue, devpoll, poll or select by
setting the environment variable EVENT_NOEPOLL, EVENT_NOKQUEUE, EVENT_NODEVPOLL,
EVENT_NOPOLL or EVENT_NOSELECT, respectively.
```

By setting the environment variable `EVENT_SHOW_METHOD`, `libevent` displays the kernel notification method that it uses.

## See Also

[pgbouncer](#), [pgbouncer.ini](#)

## plcontainer

The `plcontainer` utility installs Docker images and manages the PL/Container configuration. The utility consists of two sets of commands.

- `image-*` commands manage Docker images on the Greenplum Database system hosts.
- `runtime-*` commands manage the PL/Container configuration file on the Greenplum Database instances. You can add Docker image information to the PL/Container configuration file including the image name, location, and shared folder information. You can also edit the configuration file.

To configure PL/Container to use a Docker image, you install the Docker image on all the Greenplum Database hosts and then add configuration information to the PL/Container configuration.

PL/Container configuration values, such as image names, runtime IDs, and parameter values and names are case sensitive.

## plcontainer Syntax

```
plcontainer [<command>] [-h | --help] [--verbose]
```

Where `<command>` is one of the following.

```
image-add {{-f | --file} <image_file> [-ulc | --use_local_copy]} | {{-u | --URL} <im
age_URL>}
image-delete {-i | --image} <image_name>
image-list

runtime-add {-r | --runtime} <runtime_id>
    {-i | --image} <image_name> {-l | --language} {python | python3 | r}
    [{{-v | --volume} <shared_volume> [{{-v | --volume} <shared_volume>...}}]
    [{{-s | --setting} <param=value> [{{-s | --setting} <param=value> ...}}]
runtime-replace {-r | --runtime} <runtime_id>
    {-i | --image} <image_name> -l {r | python}
    [{{-v | --volume} <shared_volume> [{{-v | --volume} <shared_volume>...}}]
    [{{-s | --setting} <param=value> [{{-s | --setting} <param=value> ...}}]
runtime-show {-r | --runtime} <runtime_id>
runtime-delete {-r | --runtime} <runtime_id>
runtime-edit [{{-e | --editor} <editor>]
runtime-backup {-f | --file} <config_file>
runtime-restore {-f | --file} <config_file>
runtime-verify
```

## plcontainer Commands and Options

## image-add location

Install a Docker image on the Greenplum Database hosts. Specify either the location of the Docker image file on the host or the URL to the Docker image. These are the supported location options:

- **{-f | --file}** `image_file` Specify the file system location of the Docker image tar archive file on the local host. This example specifies an image file in the `gpadmin` user's home directory: `/home/gpadmin/test_image.tar.gz`
- **{-u | --URL}** `image_URL` Specify the URL of the Docker repository and image. This example URL points to a local Docker repository `192.168.0.1:5000/images/mytest_plc_r:devel`

By default, the `image-add` command copies the image to each Greenplum Database segment and standby master host, and installs the image. When you specify an `image_file` and provide the **[-ulc | --use\_local\_copy]** option, `plcontainer` installs the image only on the host on which you run the command.

After installing the Docker image, use the `runtime-add` command to configure PL/Container to use the Docker image.

## image-delete **{-i | --image}** `image_name`

Remove an installed Docker image from all Greenplum Database hosts. Specify the full Docker image name including the tag for example

```
pivotaldata/plcontainer_python_shared:1.0.0
```

## image-list

List the Docker images installed on the host. The command list only the images on the local host, not remote hosts. The command lists all installed Docker images, including images installed with Docker commands.

## runtime-add options

Add configuration information to the PL/Container configuration file on all Greenplum Database hosts. If the specified `runtime_id` exists, the utility returns an error and the configuration information is not added.

These are the supported options:

**{-i | --image}** `docker-image`

Required. Specify the full Docker image name, including the tag, that is installed on the Greenplum Database hosts. For example `pivotaldata/plcontainer_python:1.0.0`.

The utility returns a warning if the specified Docker image is not installed.

The `plcontainer image-list` command displays installed image information including the name and tag (the Repository and Tag columns).

**{-l | --language}** `python | python3 | r`

Required. Specify the PL/Container language type, supported values are `python` (PL/Python using Python 2), `python3` (PL/Python using Python 3) and `r` (PL/R). When adding configuration information for a new runtime, the utility adds a startup command to the configuration based on the language you specify.

Startup command for the Python 2 language.

```
/clientdir/pyclient.sh
```

Startup command for the Python 3 language.

```
/clientdir/pyclient3.sh
```

Startup command for the R language.

```
/clientdir/rclient.sh
```

**{-r | --runtime}** runtime\_id

Required. Add the runtime ID. When adding a `runtime` element in the PL/Container configuration file, this is the value of the `id` element in the PL/Container configuration file. Maximum length is 63 Bytes.

You specify the name in the Greenplum Database UDF on the `# container` line.

**{-s | --setting}** param=value

Optional. Specify a setting to add to the runtime configuration information. You can specify this option multiple times. The setting applies to the runtime configuration specified by the `runtime_id`. The parameter is the XML attribute of the `settings` element in the PL/Container configuration file. These are valid parameters.

- `cpu_share` - Set the CPU limit for each container in the runtime configuration. The default value is 1024. The value is a relative weighting of CPU usage compared to other containers.
- `memory_mb` - Set the memory limit for each container in the runtime configuration. The default value is 1024. The value is an integer that specifies the amount of memory in MB.
- `resource_group_id` - Assign the specified resource group to the runtime configuration. The resource group limits the total CPU and memory resource usage for all containers that share this runtime configuration. You must specify the `groupid` of the resource group. For information about managing PL/Container resources, see [About PL/Container Resource Management](#).
- `roles` - Specify the Greenplum Database roles that are allowed to run a container for the runtime configuration. You can specify a single role name or comma separated lists of role names. The default is no restriction.
- `use_container_logging` - Enable or deactivate Docker logging for the container. The value is either `yes` (activate logging) or `no` (deactivate logging, the default).

The Greenplum Database server configuration parameter `log_min_messages` controls the log level. The default log level is `warning`. For information about PL/Container log information, see [Notes](#).

**{-v | --volume}** shared-volume

Optional. Specify a Docker volume to bind mount. You can specify this option multiple times to define multiple volumes.

The format for a shared volume: `host-dir:container-dir:[rw|ro]`. The information is stored as attributes in the `shared_directory` element of the `runtime` element in the PL/Container configuration file.

- `host-dir` - absolute path to a directory on the host system. The Greenplum Database administrator user (gadmin) must have appropriate access to the directory.
- `container-dir` - absolute path to a directory in the Docker container.
- `[rw|ro]` - read-write or read-only access to the host directory from the container.

When adding configuration information for a new runtime, the utility adds this read-only shared volume information.

```
<greenplum-home>/bin/plcontainer_clients:/clientdir:ro
```

If needed, you can specify other shared directories. The utility returns an error if the specified `container-dir` is the same as the one that is added by the utility, or if you specify multiple shared volumes with the same `container-dir`.

**Warning:** Allowing read-write access to a host directory requires special considerations.

- When specifying read-write access to host directory, ensure that the specified host directory has the correct permissions.
- When running PL/Container user-defined functions, multiple concurrent Docker containers that are running on a host could change data in the host directory. Ensure that the functions support multiple concurrent access to the data in the host directory.

`runtime-backup` **{-f | --file}** `config_file`

Copies the PL/Container configuration file to the specified file on the local host.

`runtime-delete` **{-r | --runtime}** `runtime_id`

Removes runtime configuration information in the PL/Container configuration file on all Greenplum Database instances. The utility returns a message if the specified `runtime_id` does not exist in the file.

`runtime-edit` **{-e | --editor}** `editor`

Edit the XML file `plcontainer_configuration.xml` with the specified editor. The default editor is `vi`.

Saving the file updates the configuration file on all Greenplum Database hosts. If errors exist in the updated file, the utility returns an error and does not update the file.

`runtime-replace` options

Replaces runtime configuration information in the PL/Container configuration file on all Greenplum Database instances. If the `runtime_id` does not exist, the information is added to the configuration file. The utility adds a startup command and shared directory to the configuration.

See [runtime-add](#) for command options and information added to the configuration.

`runtime-restore` **{-f | --file}** `config_file`

Replaces information in the PL/Container configuration file `plcontainer_configuration.xml` on all Greenplum Database instances with the information from the specified file on the local host.

`runtime-show` **[{-r | --runtime} runtime\_id]**

Displays formatted PL/Container runtime configuration information. If a `runtime_id` is not specified, the configuration for all runtime IDs are displayed.

`runtime-verify`

Checks the PL/Container configuration information on the Greenplum Database instances with the configuration information on the master. If the utility finds inconsistencies, you are prompted to replace the remote copy with the local copy. The utility also performs XML validation.

**-h | --help**

Display help text. If specified without a command, displays help for all `plcontainer` commands. If specified with a command, displays help for the command.

**--verbose**

Enable verbose logging for the command.

## Examples

These are examples of common commands to manage PL/Container:

- Install a Docker image on all Greenplum Database hosts. This example loads a Docker image from a file. The utility displays progress information on the command line as the utility installs the Docker image on all the hosts.

```
plcontainer image-add -f plc_newr.tar.gz
```

After installing the Docker image, you add or update a runtime entry in the PL/Container configuration file to give PL/Container access to the Docker image to start Docker containers.

- Install the Docker image only on the local Greenplum Database host:

```
plcontainer image-add -f /home/gpadmin/plc_python_image.tar.gz --use_local_copy
```

- Add a container entry to the PL/Container configuration file. This example adds configuration information for a PL/R runtime, and specifies a shared volume and settings for memory and logging.

```
plcontainer runtime-add -r runtime2 -i test_image2:0.1 -l r \
-v /host_dir2/shared2:/container_dir2/shared2:ro \
-s memory_mb=512 -s use_container_logging=yes
```

The utility displays progress information on the command line as it adds the runtime configuration to the configuration file and distributes the updated configuration to all instances.

- Show specific runtime with given runtime id in configuration file

```
plcontainer runtime-show -r plc_python_shared
```

The utility displays the configuration information similar to this output.

```

PL/Container Runtime Configuration:
-----
Runtime ID: plc_python_shared
Linked Docker Image: test1:latest
Runtime Setting(s):
Shared Directory:
---- Shared Directory From HOST '/usr/local/greenplum-db/bin/plcontainer_clients' to Container '/clientdir', access mode is 'ro'
---- Shared Directory From HOST '/home/gpadmin/share/' to Container '/opt/share', access mode is 'rw'
-----

```

- Edit the configuration in an interactive editor of your choice. This example edits the configuration file with the vim editor.

```
plcontainer runtime-edit -e vim
```

When you save the file, the utility displays progress information on the command line as it distributes the file to the Greenplum Database hosts.

- Save the current PL/Container configuration to a file. This example saves the file to the local file `/home/gpadmin/saved_plc_config.xml`

```
plcontainer runtime-backup -f /home/gpadmin/saved_plc_config.xml
```

- Overwrite PL/Container configuration file with an XML file. This example replaces the information in the configuration file with the information from the file in the `/home/gpadmin` directory.

```
plcontainer runtime-restore -f /home/gpadmin/new_plcontainer_configuration.xml
```

The utility displays progress information on the command line as it distributes the updated file to the Greenplum Database instances.

## plcontainer Configuration File

The Greenplum Database utility `plcontainer` manages the PL/Container configuration files in a Greenplum Database system. The utility ensures that the configuration files are consistent across the Greenplum Database master and segment instances.

**Warning:** Modifying the configuration files on the segment instances without using the utility might create different, incompatible configurations on different Greenplum Database segments that could cause unexpected behavior.

## PL/Container Configuration File

PL/Container maintains a configuration file `plcontainer_configuration.xml` in the data directory of all Greenplum Database segments. This query lists the Greenplum Database system data directories:

```
SELECT hostname, datadir FROM gp_segment_configuration;
```

A sample PL/Container configuration file is in `$GPHOME/share/postgresql/plcontainer`.

In an XML file, names, such as element and attribute names, and values are case sensitive.

In this XML file, the root element `configuration` contains one or more `runtime` elements. You specify the `id` of the `runtime` element in the `# container:` line of a PL/Container function definition.

This is an example file. Note that all XML elements, names, and attributes are case sensitive.

```
<?xml version="1.0" ?>
<configuration>
  <runtime>
    <id>plc_python_example1</id>
    <image>pivotaldata/plcontainer_python_with_clients:0.1</image>
    <command>./pyclient</command>
  </runtime>
  <runtime>
    <id>plc_python_example2</id>
    <image>pivotaldata/plcontainer_python_without_clients:0.1</image>
    <command>/clientdir/pyclient.sh</command>
    <shared_directory access="ro" container="/clientdir" host="/usr/local/greenplu
m-db/bin/plcontainer_clients"/>
    <setting memory_mb="512"/>
    <setting use_container_logging="yes"/>
    <setting cpu_share="1024"/>
    <setting resource_group_id="16391"/>
  </runtime>
  <runtime>
    <id>plc_r_example</id>
    <image>pivotaldata/plcontainer_r_without_clients:0.2</image>
    <command>/clientdir/rclient.sh</command>
    <shared_directory access="ro" container="/clientdir" host="/usr/local/greenplu
m-db/bin/plcontainer_clients"/>
    <setting use_container_logging="yes"/>
    <setting roles="gpadm, user1"/>
  </runtime>
  <runtime>
</configuration>
```

These are the XML elements and attributes in a PL/Container configuration file.

#### configuration

Root element for the XML file.

#### runtime

One element for each specific container available in the system. These are child elements of the `configuration` element.

#### id

Required. The value is used to reference a Docker container from a PL/Container user-defined function. The `id` value must be unique in the configuration. The `id` must start with a character or digit (a-z, A-Z, or 0-9) and can contain characters, digits, or the characters `_` (underscore), `.` (period), or `-` (dash). Maximum length is 63 Bytes.

The `id` specifies which Docker image to use when PL/Container creates a Docker container to run a user-defined function.

#### image

Required. The value is the full Docker image name, including image tag. The same way you specify them for starting this container in Docker. Configuration allows to have many container objects referencing the same image name, this way in Docker they would be represented by identical containers.

For example, you might have two `runtime` elements, with different `id` elements, `plc_python_128` and `plc_python_256`, both referencing the Docker image `pivotaldata/plcontainer_python:1.0.0`. The first `runtime` specifies a 128MB RAM limit and the second one specifies a 256MB limit that is specified by the `memory_mb` attribute of a `setting` element.

#### command

Required. The value is the command to be run inside of container to start the client process inside in the container. When creating a `runtime` element, the `plcontainer` utility adds a `command` element based on the language (the `-l` option).

`command` element for the Python 2 language.

```
<command>/clientdir/pyclient.sh</command>
```

`command` element for the Python 3 language.

```
<command>/clientdir/pyclient3.sh</command>
```

`command` element for the R language.

```
<command>/clientdir/rclient.sh</command>
```

You should modify the value only if you build a custom container and want to implement some additional initialization logic before the container starts.

**Note:** This element cannot be set with the `plcontainer` utility. You can update the configuration file with the `plcontainer runtime-edit` command.

#### shared\_directory

Optional. This element specifies a shared Docker shared volume for a container with access information. Multiple `shared_directory` elements are allowed. Each `shared_directory` element specifies a single shared volume. XML attributes for the `shared_directory` element:

- `host` - a directory location on the host system.
- `container` - a directory location inside of container.
- `access` - access level to the host directory, which can be either `ro` (read-only) or `rw` (read-write).

When creating a `runtime` element, the `plcontainer` utility adds a `shared_directory` element.

```
<shared_directory access="ro" container="/clientdir" host="/usr/local/greenplum-d
b/bin/plcontainer_clients"/>
```

For each `runtime` element, the `container` attribute of the `shared_directory` elements must be unique. For example, a `runtime` element cannot have two `shared_directory` elements with attribute `container="/clientdir"`.

**Warning:** Allowing read-write access to a host directory requires special consideration.

- When specifying read-write access to host directory, ensure that the specified host directory has the correct permissions.
- When running PL/Container user-defined functions, multiple concurrent Docker containers that are running on a host could change data in the host directory. Ensure that the functions support multiple concurrent access to the data in the host directory.

## settings

Optional. This element specifies Docker container configuration information. Each `setting` element contains one attribute. The element attribute specifies logging, memory, or networking information. For example, this element enables logging.

```
<setting use_container_logging="yes"/>
```

These are the valid attributes.

### cpu\_share

Optional. Specify the CPU usage for each PL/Container container in the runtime. The value of the element is a positive integer. The default value is 1024. The value is a relative weighting of CPU usage compared to other containers.

For example, a container with a `cpu_share` of 2048 is allocated double the CPU slice time compared with container with the default value of 1024.

### memory\_mb="size"

Optional. The value specifies the amount of memory, in MB, that each container is allowed to use. Each container starts with this amount of RAM and twice the amount of swap space. The container memory consumption is limited by the host system `cgroups` configuration, which means in case of memory overcommit, the container is terminated by the system.

### resource\_group\_id="rg\_groupid"

Optional. The value specifies the `groupid` of the resource group to assign to the PL/Container runtime. The resource group limits the total CPU and memory resource usage for all running containers that share this runtime configuration. You must specify the `groupid` of the resource group. If you do not assign a resource group to a PL/Container runtime configuration, its container instances are limited only by system resources. For information about managing PL/Container resources, see [About PL/Container Resource Management](#).

### roles="list\_of\_roles"

Optional. The value is a Greenplum Database role name or a comma-separated list of roles. PL/Container runs a container that uses the PL/Container runtime configuration only for the listed roles. If the attribute is not specified, any Greenplum Database role can run an instance of this container runtime configuration. For example, you create a UDF that specifies the `plcontainer` language and identifies a `# container:` runtime configuration that has the `roles` attribute set. When a role (user) runs the UDF, PL/Container checks the list of roles and runs the container only if the role is on the list.

```
use_container_logging="{yes | no}"
```

Optional. Activates or deactivates Docker logging for the container. The attribute value `yes` enables logging. The attribute value `no` deactivates logging (the default).

The Greenplum Database server configuration parameter `log_min_messages` controls the PL/Container log level. The default log level is `warning`. For information about PL/Container log information, see [Notes](#).

By default, the PL/Container log information is sent to a system service. On Red Hat 7 or CentOS 7 systems, the log information is sent to the `journald` service. On Red Hat 6 or CentOS 6 systems, the log is sent to the `syslogd` service.

## Update the PL/Container Configuration

You can add a `runtime` element to the PL/Container configuration file with the `plcontainer runtime-add` command. The command options specify information such as the runtime ID, Docker image, and language. You can use the `plcontainer runtime-replace` command to update an existing `runtime` element. The utility updates the configuration file on the master and all segment instances.

The PL/Container configuration file can contain multiple `runtime` elements that reference the same Docker image specified by the XML element `image`. In the example configuration file, the `runtime` elements contain `id` elements named `plc_python_128` and `plc_python_256`, both referencing the Docker container `pivotaldata/plcontainer_python:1.0.0`. The first `runtime` element is defined with a 128MB RAM limit and the second one with a 256MB RAM limit.

```
<configuration>
  <runtime>
    <id>plc_python_128</id>
    <image>pivotaldata/plcontainer_python:1.0.0</image>
    <command>./client</command>
    <shared_directory access="ro" container="/clientdir" host="/usr/local/gpdb/bin/plc
ontainer_clients"/>
    <setting memory_mb="128"/>
  </runtime>
  <runtime>
    <id>plc_python_256</id>
    <image>pivotaldata/plcontainer_python:1.0.0</image>
    <command>./client</command>
    <shared_directory access="ro" container="/clientdir" host="/usr/local/gpdb/bin/plc
ontainer_clients"/>
    <setting memory_mb="256"/>
    <setting resource_group_id="16391"/>
  </runtime>
</configuration>
```

Configuration changes that are made with the utility are applied to the XML files on all Greenplum Database segments. However, PL/Container configurations of currently running sessions use the configuration that existed during session start up. To update the PL/Container configuration in a running session, run this command in the session.

```
SELECT * FROM plcontainer_refresh_config;
```

The command runs a PL/Container function that updates the session configuration on the master and segment instances.

## psql

Interactive command-line interface for Greenplum Database

### Synopsis

```
psql [<option> ...] [<dbname> [<username>]]
```

### Description

`psql` is a terminal-based front-end to Greenplum Database. It enables you to type in queries interactively, issue them to Greenplum Database, and see the query results. Alternatively, input can be from a file. In addition, it provides a number of meta-commands and various shell-like features to facilitate writing scripts and automating a wide variety of tasks.

### Options

`-a` | `--echo-all`

Print all nonempty input lines to standard output as they are read. (This does not apply to lines read interactively.) This is equivalent to setting the variable `ECHO` to `all`.

`-A` | `--no-align`

Switches to unaligned output mode. (The default output mode is aligned.)

`-c 'command'` | `--command='command'`

Specifies that `psql` is to run the specified command string, and then exit. This is useful in shell scripts. `command` must be either a command string that is completely parseable by the server, or a single backslash command. Thus you cannot mix SQL and `psql` meta-commands with this option. To achieve that, you could pipe the string into `psql`, like this:

```
echo '\x \ SELECT * FROM foo;' | psql
```

(`\` is the separator meta-command.)

If the command string contains multiple SQL commands, they are processed in a single transaction, unless there are explicit `BEGIN/COMMIT` commands included in the string to divide it into multiple transactions. This is different from the behavior when the same string is fed to `psql`'s standard input. Also, only the result of the last SQL command is returned.

`-d dbname` | `--dbname=dbname`

Specifies the name of the database to connect to. This is equivalent to specifying `dbname` as the first non-option argument on the command line.

If this parameter contains an `=` sign or starts with a valid URI prefix (`postgresql://` or `postgres://`), it is treated as a `conninfo` string. See [Connection Strings](#) in the PostgreSQL documentation for more information.

`-e` | `--echo-queries`

Copy all SQL commands sent to the server to standard output as well.

**-E | --echo-hidden**

Echo the actual queries generated by `\d` and other backslash commands. You can use this to study `psql`'s internal operations. This is equivalent to setting the variable `ECHO_HIDDEN` to `on`.

**-f filename | --file=filename**

Use the file `filename` as the source of commands instead of reading commands interactively. After the file is processed, `psql` terminates. This is in many ways equivalent to the meta-command `\i`.

If `filename` is `-` (hyphen), then standard input is read until an EOF indication or `\q` meta-command. Note however that `Readline` is not used in this case (much as if `-n` had been specified).

Using this option is subtly different from writing `psql < <filename>`. In general, both will do what you expect, but using `-f` enables some nice features such as error messages with line numbers. There is also a slight chance that using this option will reduce the start-up overhead. On the other hand, the variant using the shell's input redirection is (in theory) guaranteed to yield exactly the same output you would have received had you entered everything by hand.

**-F separator | --field-separator=separator**

Use the specified separator as the field separator for unaligned output.

**-H | --html**

Turn on HTML tabular output.

**-l | --list**

List all available databases, then exit. Other non-connection options are ignored.

**-L filename | --log-file=filename**

Write all query output into the specified log file, in addition to the normal output destination.

**-n | --no-readline**

Do not use `Readline` for line editing and do not use the command history. This can be useful to turn off tab expansion when cutting and pasting.

**-o filename | --output=filename**

Put all query output into the specified file.

**-P assignment | --pset=assignment**

Allows you to specify printing options in the style of `\pset` on the command line. Note that here you have to separate name and value with an equal sign instead of a space. Thus to set the output format to `LaTeX`, you could write `-P format=latex`.

**-q | --quiet**

Specifies that `psql` should do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this happens. This is useful with the `-c` option. This is equivalent to setting the variable `QUIET` to `on`.

**-R separator | --record-separator=separator**

Use `separator` as the record separator for unaligned output.

**-s | --single-step**

Run in single-step mode. That means the user is prompted before each command is sent to the server, with the option to cancel execution as well. Use this to debug scripts.

**-S | --single-line**

Runs in single-line mode where a new line terminates an SQL command, as a semicolon does.

`-t | --tuples-only`

Turn off printing of column names and result row count footers, etc. This command is equivalent to `\pset tuples_only` and is provided for convenience.

`-T table_options | --table-attr= table_options`

Allows you to specify options to be placed within the HTML table tag. See `\pset` for details.

`-v assignment | --set=assignment | --variable= assignment`

Perform a variable assignment, like the `\set` meta command. Note that you must separate name and value, if any, by an equal sign on the command line. To unset a variable, leave off the equal sign. To set a variable with an empty value, use the equal sign but leave off the value. These assignments are done during a very early stage of start-up, so variables reserved for internal purposes might get overwritten later.

`-V | --version`

Print the `psql` version and exit.

`-x | --expanded`

Turn on the expanded table formatting mode.

`-X | --no-psqlrc`

Do not read the start-up file (neither the system-wide `psqlrc` file nor the user's `~/.psqlrc` file).

`-z | --field-separator-zero`

Set the field separator for unaligned output to a zero byte.

`-0 | --record-separator-zero`

Set the record separator for unaligned output to a zero byte. This is useful for interfacing, for example, with `xargs -0`.

`-1 | --single-transaction`

When `psql` runs a script, adding this option wraps `BEGIN/COMMIT` around the script to run it as a single transaction. This ensures that either all the commands complete successfully, or no changes are applied.

If the script itself uses `BEGIN`, `COMMIT`, or `ROLLBACK`, this option will not have the desired effects. Also, if the script contains any command that cannot be run inside a transaction block, specifying this option will cause that command (and hence the whole transaction) to fail.

`-? | --help`

Show help about `psql` command line arguments, and exit.

## Connection Options

`-h host | --host=host`

The host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to `localhost`.

When starting `psql` on the master host, if the host value begins with a slash, it is used as the directory for the UNIX-domain socket.

`-p port | --port=port`

The TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

`-U username | --username=username`

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system role name.

`-W | --password`

Force a password prompt. `psql` should automatically prompt for a password whenever the server requests password authentication. However, currently password request detection is not totally reliable, hence this option to force a prompt. If no password prompt is issued and the server requires password authentication, the connection attempt will fail.

`-w --no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

**Note:** This option remains set for the entire session, and so it affects uses of the meta-command `\connect` as well as the initial connection attempt.

## Exit Status

`psql` returns 0 to the shell if it finished normally, 1 if a fatal error of its own (out of memory, file not found) occurs, 2 if the connection to the server went bad and the session was not interactive, and 3 if an error occurred in a script and the variable `ON_ERROR_STOP` was set.

## Usage

### Connecting to a Database

`psql` is a client application for Greenplum Database. In order to connect to a database you need to know the name of your target database, the host name and port number of the Greenplum master server and what database user name you want to connect as. `psql` can be told about those parameters via command line options, namely `-d`, `-h`, `-p`, and `-U` respectively. If an argument is found that does not belong to any option it will be interpreted as the database name (or the user name, if the database name is already given). Not all of these options are required; there are useful defaults. If you omit the host name, `psql` will connect via a UNIX-domain socket to a master server on the local host, or via TCP/IP to `localhost` on machines that do not have UNIX-domain sockets. The default master port number is 5432. If you use a different port for the master, you must specify the port. The default database user name is your operating-system user name, as is the default database name. Note that you cannot just connect to any database under any user name. Your database administrator should have informed you about your access rights.

When the defaults are not right, you can save yourself some typing by setting any or all of the environment variables `PGAPPNAME`, `PGDATABASE`, `PGHOST`, `PGPORT`, and `PGUSER` to appropriate values.

It is also convenient to have a `~/.pgpass` file to avoid regularly having to type in passwords. This file should reside in your home directory and contain lines of the following format:

```
<hostname>:<port>:<database>:<username>:<password>
```

The permissions on `.pgpass` must disallow any access to world or group (for example: `chmod 0600 ~/.pgpass`). If the permissions are less strict than this, the file will be ignored. (The file permissions

are not currently checked on Microsoft Windows clients, however.)

An alternative way to specify connection parameters is in a `conninfo` string or a URI, which is used instead of a database name. This mechanism gives you very wide control over the connection. For example:

```
$ psql "service=myservice sslmode=require"
$ psql postgresql://gpmaster:5433/mydb?sslmode=require
```

This way you can also use LDAP for connection parameter lookup as described in [LDAP Lookup of Connection Parameters](#) in the PostgreSQL documentation. See [Parameter Keywords](#) in the PostgreSQL documentation for more information on all the available connection options.

If the connection could not be made for any reason (insufficient privileges, server is not running, etc.), `psql` will return an error and terminate.

If at least one of standard input or standard output are a terminal, then `psql` sets the client encoding to `auto`, which will detect the appropriate client encoding from the locale settings (`LC_CTYPE` environment variable on Unix systems). If this doesn't work out as expected, the client encoding can be overridden using the environment variable `PGCLIENTENCODING`.

## Entering SQL Commands

In normal operation, `psql` provides a prompt with the name of the database to which `psql` is currently connected, followed by the string `=>` for a regular user or `=#` for a superuser. For example:

```
testdb=>
testdb=#
```

At the prompt, the user may type in SQL commands. Ordinarily, input lines are sent to the server when a command-terminating semicolon is reached. An end of line does not terminate a command. Thus commands can be spread over several lines for clarity. If the command was sent and run without error, the results of the command are displayed on the screen.

If untrusted users have access to a database that has not adopted a [secure schema usage pattern](#), begin your session by removing publicly-writable schemas from `search_path`. You can add `options=-csearch_path=` to the connection string or issue `SELECT pg_catalog.set_config('search_path', '', false)` before other SQL commands. This consideration is not specific to `psql`; it applies to every interface for running arbitrary SQL commands.

## Meta-Commands

Anything you enter in `psql` that begins with an unquoted backslash is a `psql` meta-command that is processed by `psql` itself. These commands help make `psql` more useful for administration or scripting. Meta-commands are more commonly called slash or backslash commands.

The format of a `psql` command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace into an argument you may quote it with single quotes. To include a single quote into such an argument, write two single quotes within single-quoted text. Anything contained in single quotes is furthermore subject to C-like substitutions for `\n` (new line), `\t` (tab), `\b` (backspace), `\r` (carriage return), `\f` (form feed), `\digits` (octal), and `\xdigits` (hexadecimal). A backslash preceding any other character within single-quoted text quotes that single character, whatever it is.

Within an argument, text that is enclosed in backquotes (````) is taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) replaces the backquoted text.

If an unquoted colon (`:`) followed by a `psql` variable name appears within an argument, it is replaced by the variable's value, as described in [SQL Interpolation](#).

Some commands take an SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes (`"`) protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, `FOO"BAR"BAZ` is interpreted as `fooBARbaz`, and `"A weird" name"` becomes `A weird" name`.

Parsing for arguments stops when another unquoted backslash occurs. This is taken as the beginning of a new meta-command. The special sequence `\\` (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and `psql` commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

The following meta-commands are defined:

`\a`

If the current table output format is unaligned, it is switched to aligned. If it is not unaligned, it is set to unaligned. This command is kept for backwards compatibility. See `\pset` for a more general solution.

`\c | \connect [dbname [username] [host] [port]] | conninfo`

Establishes a new Greenplum Database connection. The connection parameters to use can be specified either using a positional syntax, or using `conninfo` connection strings as detailed in [libpq Connection Strings](#).

Where the command omits database name, user, host, or port, the new connection can reuse values from the previous connection. By default, values from the previous connection are reused except when processing a `conninfo` string. Passing a first argument of `-reuse-previous=on` or `-reuse-previous=off` overrides that default. When the command neither specifies nor reuses a particular parameter, the `libpq` default is used. Specifying any of `dbname`, `username`, `host` or `port` as `-` is equivalent to omitting that parameter.

If the new connection is successfully made, the previous connection is closed. If the connection attempt failed, the previous connection will only be kept if `psql` is in interactive mode. When running a non-interactive script, processing will immediately stop with an error. This distinction was chosen as a user convenience against typos, and a safety mechanism that scripts are not accidentally acting on the wrong database.

Examples:

```
=> \c mydb myuser host.dom 6432
=> \c service=foo
=> \c "host=localhost port=5432 dbname=mydb connect_timeout=10 sslmode=disable"
=> \c postgresql://tom@localhost/mydb?application_name=myapp
```

### \C [title]

Sets the title of any tables being printed as the result of a query or unset any such title. This command is equivalent to `\pset title`.

### \cd [directory]

Changes the current working directory. Without argument, changes to the current user's home directory. To print your current working directory, use `\!pwd`.

### \conninfo

Displays information about the current connection including the database name, the user name, the type of connection (UNIX domain socket, [TCP/IP](#), etc.), the host, and the port.

### \copy {table [(column\_list)] | (query)} {from | to} {'filename' | program 'command' | stdin | stdout | pstdin | pstdout} [with] (option [, ...]) ]

Performs a frontend (client) copy. This is an operation that runs an SQL [\[COPY\]](#) ([../ref\\_guide/sql\\_commands/COPY.html](#)) command, but instead of the server reading or writing the specified file, `psql` reads or writes the file and routes the data between the server and the local file system. This means that file accessibility and privileges are those of the local user, not the server, and no SQL superuser privileges are required.

When `program` is specified, `command` is run by `psql` and the data from or to `command` is routed between the server and the client. This means that the execution privileges are those of the local user, not the server, and no SQL superuser privileges are required.

`\copy ... from stdin | to stdout` reads/writes based on the command input and output respectively. All rows are read from the same source that issued the command, continuing until `\.` is read or the stream reaches `EOF`. Output is sent to the same place as `command` output. To read/write from `psql`'s standard input or output, use `pstdin` or `pstdout`. This option is useful for populating tables in-line within a SQL script file.

The syntax of the command is similar to that of the SQL [COPY](#) command, and option must indicate one of the options of the SQL [COPY](#) command. Note that, because of this, special parsing rules apply to the `\copy` command. In particular, the variable substitution rules and backslash escapes do not apply.

This operation is not as efficient as the SQL [COPY](#) command because all data must pass through the client/server connection.

### \copyright

Shows the copyright and distribution terms of PostgreSQL on which Greenplum Database is based.

### \d [relation\_pattern] | \d+ [relation\_pattern] | \ds [relation\_pattern]

For each relation (table, external table, view, materialized view, index, sequence, or foreign table) or composite type matching the relation pattern, show all columns, their types, the tablespace (if not the default) and any special attributes such as `NOT NULL` or defaults. Associated indexes, constraints, rules, and triggers are also shown. For foreign tables, the associated foreign server is shown as well.

- For some types of relation, `\d` shows additional information for each column: column values for sequences, indexed expressions for indexes, and foreign data wrapper options for foreign tables.
- The command form `\d+` is identical, except that more information is displayed: any comments associated with the columns of the table are shown, as is the presence of OIDs in the table, the view definition if the relation is a view.

For partitioned tables, the command `\d` or `\d+` specified with the root partition table or child partition table displays information about the table including partition keys on the current level of the partition table. The command `\d+` also displays the immediate child partitions of the table and whether the child partition is an external table or regular table.

For append-optimized tables and column-oriented tables, `\d+` displays the storage options for a table. For append-optimized tables, the options are displayed for the table. For column-oriented tables, storage options are displayed for each column.

- By default, only user-created objects are shown; supply a pattern or the `s` modifier to include system objects.

**Note:** If `\d` is used without a pattern argument, it is equivalent to `\dtvmsE` which will show a list of all visible tables, views, materialized views, sequences, and foreign tables.

`\da[S] [aggregate_pattern]`

Lists aggregate functions, together with the data types they operate on. If a pattern is specified, only aggregates whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the `s` modifier to include system objects.

`\db[+] [tablespace_pattern]`

Lists all available tablespaces and their corresponding paths. If pattern is specified, only tablespaces whose names match the pattern are shown. If `+` is appended to the command name, each object is listed with its associated permissions.

`\dc[S+] [conversion_pattern]`

Lists conversions between character-set encodings. If a pattern is specified, only conversions whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the `s` modifier to include system objects. If `+` is appended to the command name, each object is listed with its associated description.

`\dC[+] [pattern]`

Lists type casts. If a pattern is specified, only casts whose source or target types match the pattern are listed. If `+` is appended to the command name, each object is listed with its associated description.

`\dd[S] [pattern]`

Shows the descriptions of objects of type `constraint`, `operator class`, `operator family`, `rule`, and `trigger`. All other comments may be viewed by the respective backslash commands for those object types.

`\dd` displays descriptions for objects matching the pattern, or of visible objects of the appropriate type if no argument is given. But in either case, only objects that have a

description are listed. By default, only user-created objects are shown; supply a pattern or the `s` modifier to include system objects.

Descriptions for objects can be created with the `COMMENT` SQL command.

#### `\ddp [pattern]`

Lists default access privilege settings. An entry is shown for each role (and schema, if applicable) for which the default privilege settings have been changed from the built-in defaults. If pattern is specified, only entries whose role name or schema name matches the pattern are listed.

The `ALTER DEFAULT PRIVILEGES` command is used to set default access privileges. The meaning of the privilege display is explained under `GRANT`.

#### `\dD[S+] [domain_pattern]`

Lists domains. If a pattern is specified, only domains whose names match the pattern are shown. By default, only user-created objects are shown; supply a pattern or the `s` modifier to include system objects. If `+` is appended to the command name, each object is listed with its associated permissions and description.

#### `\dEimstPv[S+] [external_table | index | materialized_view | sequence | table | parent table | view]`

This is not the actual command name: the letters `E`, `i`, `m`, `s`, `t`, `P`, and `v` stand for external table, index, materialized view, sequence, table, parent table, and view, respectively. You can specify any or all of these letters, in any order, to obtain a listing of objects of these types. For example, `\dit` lists indexes and tables. If `+` is appended to the command name, each object is listed with its physical size on disk and its associated description, if any. If a pattern is specified, only objects whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the `s` modifier to include system objects.

#### `\des[+] [foreign_server_pattern]`

Lists foreign servers. If a pattern is specified, only those servers whose name matches the pattern are listed. If the form `\des+` is used, a full description of each server is shown, including the server's ACL, type, version, options, and description.

#### `\det[+] [foreign_table_pattern]`

Lists all foreign tables. If a pattern is specified, only entries whose table name or schema name matches the pattern are listed. If the form `\det+` is used, generic options and the foreign table description are also displayed.

#### `\deu[+] [user_mapping_pattern]`

Lists user mappings. If a pattern is specified, only those mappings whose user names match the pattern are listed. If the form `\deu+` is used, additional information about each mapping is shown.

**Warning:** `\deu+` might also display the user name and password of the remote user, so care should be taken not to disclose them.

#### `\dew[+] [foreign_data_wrapper_pattern]`

Lists foreign-data wrappers. If a pattern is specified, only those foreign-data wrappers whose name matches the pattern are listed. If the form `\dew+` is used, the ACL, options, and description of the foreign-data wrapper are also shown.

#### `\df[antwS+] [function_pattern]`

Lists functions, together with their arguments, return types, and function types, which are classified as "agg" (aggregate), "normal", "trigger", or "window". To display only functions of a specific type(s), add the corresponding letters `a`, `n`, `t`, or `w`, to the command. If a pattern is

specified, only functions whose names match the pattern are shown. If the form `\df+` is used, additional information about each function, including security, volatility, language, source code, and description, is shown. By default, only user-created objects are shown; supply a pattern or the `s` modifier to include system objects.

#### `\dF[+]` [pattern]

Lists text search configurations. If a pattern is specified, only configurations whose names match the pattern are shown. If the form `\dF+` is used, a full description of each configuration is shown, including the underlying text search parser and the dictionary list for each parser token type.

#### `\dFd[+]` [pattern]

Lists text search dictionaries. If a pattern is specified, only dictionaries whose names match the pattern are shown. If the form `\dFd+` is used, additional information is shown about each selected dictionary, including the underlying text search template and the option values.

#### `\dFp[+]` [pattern]

Lists text search parsers. If a pattern is specified, only parsers whose names match the pattern are shown. If the form `\dFp+` is used, a full description of each parser is shown, including the underlying functions and the list of recognized token types.

#### `\dFt[+]` [pattern]

Lists text search templates. If a pattern is specified, only templates whose names match the pattern are shown. If the form `\dFt+` is used, additional information is shown about each template, including the underlying function names.

#### `\dg[+]` [role\_pattern]

Lists database roles. (Since the concepts of "users" and "groups" have been unified into "roles", this command is now equivalent to `\du`.) If a pattern is specified, only those roles whose names match the pattern are listed. If the form `\dg+` is used, additional information is shown about each role; currently this adds the comment for each role.

#### `\dl`

This is an alias for `\lo_list`, which shows a list of large objects.

**Note:** Greenplum Database does not support the PostgreSQL [large object facility](#) for streaming user data that is stored in large-object structures.

#### `\dL[S+]` [pattern]

Lists procedural languages. If a pattern is specified, only languages whose names match the pattern are listed. By default, only user-created languages are shown; supply the `s` modifier to include system objects. If `+` is appended to the command name, each language is listed with its call handler, validator, access privileges, and whether it is a system object.

#### `\dn[S+]` [schema\_pattern]

Lists all available schemas (namespaces). If a pattern is specified, only schemas whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the `s` modifier to include system objects. If `+` is appended to the command name, each object is listed with its associated permissions and description, if any.

#### `\do[S]` [operator\_pattern]

Lists available operators with their operand and return types. If a pattern is specified, only operators whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the `s` modifier to include system objects.

#### `\dO[S+]` [pattern]

Lists collations. If a pattern is specified, only collations whose names match the pattern are listed. By default, only user-created objects are shown; supply a pattern or the `s` modifier to include system objects. If `+` is appended to the command name, each collation is listed with its associated description, if any. Note that only collations usable with the current database's encoding are shown, so the results may vary in different databases of the same installation.

`\dp [relation_pattern_to_show_privileges]`

Lists tables, views, and sequences with their associated access privileges. If a pattern is specified, only tables, views, and sequences whose names match the pattern are listed. The `GRANT` and `REVOKE` commands are used to set access privileges. The meaning of the privilege display is explained under `GRANT`.

`\drds [role-pattern [database-pattern]]`

Lists defined configuration settings. These settings can be role-specific, database-specific, or both. `role-pattern` and `database-pattern` are used to select specific roles and database to list, respectively. If omitted, or if `*` is specified, all settings are listed, including those not role-specific or database-specific, respectively.

The `ALTER ROLE` and `ALTER DATABASE` commands are used to define per-role and per-database role configuration settings.

`\dT[S+] [datatype_pattern]`

Lists data types. If a pattern is specified, only types whose names match the pattern are listed. If `+` is appended to the command name, each type is listed with its internal name and size, its allowed values if it is an `enum` type, and its associated permissions. By default, only user-created objects are shown; supply a pattern or the `s` modifier to include system objects.

`\du[+] [role_pattern]`

Lists database roles. (Since the concepts of "users" and "groups" have been unified into "roles", this command is now equivalent to `\dg`.) If a pattern is specified, only those roles whose names match the pattern are listed. If the form `\du+` is used, additional information is shown about each role; currently this adds the comment for each role.

`\dx[+] [extension_pattern]`

Lists installed extensions. If a pattern is specified, only those extensions whose names match the pattern are listed. If the form `\dx+` is used, all of the objects belonging to each matching extension are listed.

`\dy[+] [pattern]`

Lists event triggers. If a pattern is specified, only those triggers whose names match the pattern are listed. If `+` is appended to the command name, each object is listed with its associated description.

`\dy[+] [pattern]`

Lists event triggers. If a pattern is specified, only those triggers whose names match the pattern are listed. If `+` is appended to the command name, each object is listed with its associated description.

**Note:** Greenplum Database does not support user-defined triggers.

`\e | \edit [filename] [line_number]`

If `filename` is specified, the file is edited; after the editor exits, its content is copied back to the query buffer. If no `filename` is given, the current query buffer is copied to a temporary file which is then edited in the same fashion.

The new query buffer is then re-parsed according to the normal rules of `psql`, where the whole buffer is treated as a single line. (Thus you cannot make scripts this way. Use `\i` for that.) This means also that if the query ends with (or rather contains) a semicolon, it is immediately run. In other cases it will merely wait in the query buffer; type semicolon or `\g` to send it, or `\r` to cancel.

If a line number is specified, `psql` will position the cursor on the specified line of the file or query buffer. Note that if a single all-digits argument is given, `psql` assumes it is a line number, not a file name.

See [Environment](#) for information about configuring and customizing your editor.

`\echo text [ ... ]`

Prints the arguments to the standard output, separated by one space and followed by a newline. This can be useful to intersperse information in the output of scripts. If the first argument is an unquoted `-n`, the trailing newline is not written.

**Note:** If you use the `\o` command to redirect your query output you might wish to use `\qecho` instead of this command.

`\ef [function_description [line_number]]`

This command fetches and edits the definition of the named function, in the form of a `CREATE OR REPLACE FUNCTION` command. Editing is done in the same way as for `\edit`. After the editor exits, the updated command waits in the query buffer; type semicolon or `\g` to send it, or `\r` to cancel.

The target function can be specified by name alone, or by name and arguments, for example `foo(integer, text)`. The argument types must be given if there is more than one function with the same name.

If no function is specified, a blank `CREATE FUNCTION` template is presented for editing.

If a line number is specified, `psql` will position the cursor on the specified line of the function body. (Note that the function body typically does not begin on the first line of the file.)

See [Environment](#) for information about configuring and customizing your editor.

`\encoding [encoding]`

Sets the client character set encoding. Without an argument, this command shows the current encoding.

`\f [field_separator_string]`

Sets the field separator for unaligned query output. The default is the vertical bar (`|`). See also `\pset` for a generic way of setting output options.

`\g [filename]`

`\g [ | command ]`

Sends the current query input buffer to the server, and optionally stores the query's output in filename or pipes the output to the shell command command. The file or command is written to only if the query successfully returns zero or more tuples, not if the query fails or is a non-data-returning SQL command.

A bare `\g` is essentially equivalent to a semi-colon. A `\g` with argument is a one-shot alternative to the `\o` command.

`\gset [prefix]`

Sends the current query input buffer to the server and stores the query's output into `psql` variables. The query to be run must return exactly one row. Each column of the row is stored into a separate variable, named the same as the column. For example:

```
=> SELECT 'hello' AS var1, 10 AS var2;
-> \gset
=> \echo :var1 :var2
hello 10
```

If you specify a prefix, that string is prepended to the query's column names to create the variable names to use:

```
=> SELECT 'hello' AS var1, 10 AS var2;
-> \gset result_
=> \echo :result_var1 :result_var2
hello 10
```

If a column result is NULL, the corresponding variable is unset rather than being set.

If the query fails or does not return one row, no variables are changed.

#### `\h` | `\help` [sql\_command]

Gives syntax help on the specified SQL command. If a command is not specified, then `psql` will list all the commands for which syntax help is available. If command is an asterisk (\*) then syntax help on all SQL commands is shown. To simplify typing, commands that consist of several words do not have to be quoted.

#### `\H` | `\html`

Turns on HTML query output format. If the HTML format is already on, it is switched back to the default aligned text format. This command is for compatibility and convenience, but see `\pset` about setting other output options.

#### `\i` | `\include` filename

Reads input from the file filename and runs it as though it had been typed on the keyboard.

If filename is - (hyphen), then standard input is read until an EOF indication or `\q` meta-command. This can be used to intersperse interactive input with input from files. Note that Readline behavior will be used only if it is active at the outermost level.

If you want to see the lines on the screen as they are read you must set the variable `ECHO` to `all`.

#### `\ir` | `\include_relative` filename

The `\ir` command is similar to `\i`, but resolves relative file names differently. When running in interactive mode, the two commands behave identically. However, when invoked from a script, `\ir` interprets file names relative to the directory in which the script is located, rather than the current working directory.

#### `\l[+]` | `\list[+]` [pattern]

List the databases in the server and show their names, owners, character set encodings, and access privileges. If a pattern is specified, only databases whose names match the pattern are listed. If + is appended to the command name, database sizes, default tablespaces, and descriptions are also displayed. (Size information is only available for databases that the current user can connect to.)

#### `\lo_export` loid filename

Reads the large object with OID `loid` from the database and writes it to filename. Note that this is subtly different from the server function `lo_export`, which acts with the permissions of the user that the database server runs as and on the server's file system. Use `\lo_list` to find out the large object's OID.

**Note:** Greenplum Database does not support the PostgreSQL [large object facility](#) for streaming user data that is stored in large-object structures.

`\lo_import large_object_filename [comment]`

Stores the file into a large object. Optionally, it associates the given comment with the object. Example:

```
mydb=> \lo_import '/home/gpadmin/pictures/photo.xcf' 'a
picture of me'
lo_import 152801
```

The response indicates that the large object received object ID 152801 which one ought to remember if one wants to access the object ever again. For that reason it is recommended to always associate a human-readable comment with every object. Those can then be seen with the `\lo_list` command. Note that this command is subtly different from the server-side `lo_import` because it acts as the local user on the local file system, rather than the server's user and file system.

**Note:** Greenplum Database does not support the PostgreSQL [large object facility](#) for streaming user data that is stored in large-object structures.

`\lo_list`

Shows a list of all large objects currently stored in the database, along with any comments provided for them.

**Note:** Greenplum Database does not support the PostgreSQL [large object facility](#) for streaming user data that is stored in large-object structures.

`\lo_unlink largeobject_oid`

Deletes the large object of the specified OID from the database. Use `\lo_list` to find out the large object's OID.

**Note:** Greenplum Database does not support the PostgreSQL [large object facility](#) for streaming user data that is stored in large-object structures.

`\o | \out [ filename ]`

`\o | \out [ | command ]`

Saves future query results to the file filename or pipes future results to the shell command command. If no argument is specified, the query output is reset to the standard output.

Query results include all tables, command responses, and notices obtained from the database server, as well as output of various backslash commands that query the database (such as `\d`), but not error messages. To intersperse text output in between query results, use `\qecho`.

`\p`

Print the current query buffer to the standard output.

`\password [username]`

Changes the password of the specified user (by default, the current user). This command prompts for the new password, encrypts it, and sends it to the server as an `ALTER ROLE`

command. This makes sure that the new password does not appear in cleartext in the command history, the server log, or elsewhere.

`\prompt [ text ] name`

Prompts the user to supply text, which is assigned to the variable name. An optional prompt string, `text`, can be specified. (For multiword prompts, surround the text with single quotes.)

By default, `\prompt` uses the terminal for input and output. However, if the `-f` command line switch was used, `\prompt` uses standard input and standard output.

`\pset [print_option [value]]`

This command sets options affecting the output of query result tables. `print_option` describes which option is to be set. The semantics of `value` vary depending on the selected option. For some options, omitting `value` causes the option to be toggled or unset, as described under the particular option. If no such behavior is mentioned, then omitting `value` just results in the current setting being displayed.

`\pset` without any arguments displays the current status of all printing options.

Adjustable printing options are:

- `border` – The value must be a number. In general, the higher the number the more borders and lines the tables will have, but this depends on the particular format. In HTML format, this will translate directly into the `border=...` attribute; in the other formats only values `0` (no border), `1` (internal dividing lines), and `2` (table frame) make sense. `latex` and `latex-longtable` also support a `border` value of `3` which adds a dividing line between each row.
- `columns` – Sets the target width for the `wrapped` format, and also the width limit for determining whether output is wide enough to require the pager or switch to the vertical display in expanded auto mode. The default is zero. Zero causes the target width to be controlled by the environment variable `COLUMNS`, or the detected screen width if `COLUMNS` is not set. In addition, if `columns` is zero then the wrapped format affects screen output only. If `columns` is nonzero then file and pipe output is wrapped to that width as well.

After setting the target width, use the command `\pset format wrapped` to enable the wrapped format.

- `expanded | x` – If value is specified it must be either `on` or `off`, which will activate or deactivate expanded mode, or `auto`. If value is omitted the command toggles between the `on` and `off` settings. When expanded mode is enabled, query results are displayed in two columns, with the column name on the left and the data on the right. This mode is useful if the data wouldn't fit on the screen in the normal "horizontal" mode. In the `auto` setting, the expanded mode is used whenever the query output is wider than the screen, otherwise the regular mode is used. The `auto` setting is only effective in the aligned and wrapped formats. In other formats, it always behaves as if the expanded mode is `off`.
- `fieldsep` – Specifies the field separator to be used in unaligned output mode. That way one can create, for example, tab- or comma-separated output, which other programs might prefer. To set a tab as field separator, type `\pset fieldsep '\t'`. The default field separator is `'|'` (a vertical bar).

- `fieldsep_zero` - Sets the field separator to use in unaligned output format to a zero byte.
- `footer` – If value is specified it must be either `on` or `off` which will activate or deactivate display of the table footer (the (n rows) count). If value is omitted the command toggles footer display on or off.
- `format` – Sets the output format to one of `unaligned`, `aligned`, `html`, `latex` (uses `tabular`), `latex-longtable`, `troff-ms`, or `wrapped`. Unique abbreviations are allowed. `unaligned` format writes all columns of a row on one line, separated by the currently active field separator. This is useful for creating output that might be intended to be read in by other programs (for example, tab-separated or comma-separated format).

`aligned` format is the standard, human-readable, nicely formatted text output; this is the default.

The `html`, `latex`, `latex-longtable`, and `troff-ms` formats put out tables that are intended to be included in documents using the respective mark-up language. They are not complete documents! (This might not be so dramatic in HTML, but in LaTeX you must have a complete document wrapper. `latex-longtable` also requires the LaTeX `longtable` and `booktabs` packages.)

The `wrapped` format is like `aligned`, but wraps wide data values across lines to make the output fit in the target column width. The target width is determined as described under the `columns` option. Note that `psql` does not attempt to wrap column header titles; the `wrapped` format behaves the same as `aligned` if the total width needed for column headers exceeds the target.

- `linestyle` [`unicode` | `ascii` | `old-ascii`] – Sets the border line drawing style to one of `unicode`, `ascii`, or `old-ascii`. Unique abbreviations, including one letter, are allowed for the three styles. The default setting is `ascii`. This option only affects the `aligned` and `wrapped` output formats.

`ascii` – uses plain ASCII characters. Newlines in data are shown using a `+` symbol in the right-hand margin. When the wrapped format wraps data from one line to the next without a newline character, a dot (`.`) is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

`old-ascii` – style uses plain ASCII characters, using the formatting style used in PostgreSQL 8.4 and earlier. Newlines in data are shown using a `:` symbol in place of the left-hand column separator. When the data is wrapped from one line to the next without a newline character, a `;` symbol is used in place of the left-hand column separator.

`unicode` – style uses Unicode box-drawing characters. Newlines in data are shown using a carriage return symbol in the right-hand margin. When the data is wrapped from one line to the next without a newline character, an ellipsis symbol is shown in the right-hand margin of the first line, and again in the left-hand margin of the following line.

When the `border` setting is greater than zero, this option also determines the characters with which the border lines are drawn. Plain ASCII characters work everywhere, but Unicode characters look nicer on displays that recognize them.

- `null 'string'` – The second argument is a string to print whenever a column is null. The default is to print nothing, which can easily be mistaken for an empty string. For example, one might prefer `\pset null '(null)'`.
- `numericlocale` – If value is specified it must be either `on` or `off` which will activate or deactivate display of a locale-specific character to separate groups of digits to the left of the decimal marker. If value is omitted the command toggles between regular and locale-specific numeric output.
- `pager` – Controls the use of a pager for query and `psql` help output. If the environment variable `PAGER` is set, the output is piped to the specified program. Otherwise a platform-dependent default (such as `more`) is used. When `off`, the pager program is not used. When `on`, the pager is used only when appropriate, i.e. when the output is to a terminal and will not fit on the screen. Pager can also be set to `always`, which causes the pager to be used for all terminal output regardless of whether it fits on the screen. `\pset pager` without a value toggles pager use on and off.
- `recordsep` – Specifies the record (line) separator to use in unaligned output mode. The default is a newline character.
- `recordsep_zero` - Sets the record separator to use in unaligned output format to a zero byte.
- `tableattr | T [text]` – In HTML format, this specifies attributes to be placed inside the HTML `table` tag. This could for example be `cellpadding` or `bgcolor`. Note that you probably don't want to specify `border` here, as that is already taken care of by `\pset border`. If no value is given, the table attributes are unset.

In `latex-longtable` format, this controls the proportional width of each column containing a left-aligned data type. It is specified as a whitespace-separated list of values, e.g. `'0.2 0.2 0.6'`. Unspecified output columns use the last specified value.

- `title [text]` – Sets the table title for any subsequently printed tables. This can be used to give your output descriptive tags. If no value is given, the title is unset.
- `tuples_only | t [novalue | on | off]` – If value is specified, it must be either `on` or `off` which will activate or deactivate tuples-only mode. If value is omitted the command toggles between regular and tuples-only output. Regular output includes extra information such as column headers, titles, and various footers. In tuples-only mode, only actual table data is shown. The `\t` command is equivalent to `\pset `tuples_only` and is provided for convenience.

### Tip:

There are various shortcut commands for `\pset`. See `\a`, `\C`, `\f`, `\H`, `\t`, `\T`, and `\x`.

`\q | \quit`

Quits the `psql` program. In a script file, only execution of that script is terminated.

`\qecho text [ ... ]`

This command is identical to `\echo` except that the output will be written to the query output channel, as set by `\o`.

`\r` | `\reset`

Resets (clears) the query buffer.

`\s` [filename]

Print `psql`'s command line history to `filename`. If `filename` is omitted, the history is written to the standard output (using the pager if appropriate). This command is not available if `psql` was built without `Readline` support.

`\set` [name [value [ ... ]]]

Sets the `psql` variable name to value, or if more than one value is given, to the concatenation of all of them. If only one argument is given, the variable is just set with an empty value. To unset a variable, use the `\unset` command.

`\set` without any arguments displays the names and values of all currently-set `psql` variables.

Valid variable names can contain characters, digits, and underscores. See "Variables" in [Advanced Features](#). Variable names are case-sensitive.

Although you are welcome to set any variable to anything you want, `psql` treats several variables as special. They are documented in the topic about variables.

This command is unrelated to the SQL command `SET`.

`\setenv` name [ value ]

Sets the environment variable name to value, or if the value is not supplied, unsets the environment variable. Example:

```
testdb=> \setenv PAGER less
testdb=> \setenv LESS -imx4F
```

`\sf`[+] function\_description

This command fetches and shows the definition of the named function, in the form of a `CREATE OR REPLACE FUNCTION` command. The definition is printed to the current query output channel, as set by `\o`.

The target function can be specified by name alone, or by name and arguments, for example `foo(integer, text)`. The argument types must be given if there is more than one function of the same name.

If `+` is appended to the command name, then the output lines are numbered, with the first line of the function body being line 1.

`\t` [novalue | on | off]

The `\t` command by itself toggles a display of output column name headings and row count footer. The values `on` and `off` set the tuples display, regardless of the current setting. This command is equivalent to `\pset tuples_only` and is provided for convenience.

`\T` table\_options

Specifies attributes to be placed within the `table` tag in HTML output format. This command is equivalent to `\pset tableattr table_options`

`\timing` [novalue | on | off]

Without a parameter, toggles a display of how long each SQL statement takes, in milliseconds. The values `on` and `off` set the time display, regardless of the current setting.

`\unset name`

Unsets (deletes) the `psql` variable name.

`\w | \write filename`

`\w | \write | command`

Outputs the current query buffer to the file `filename` or pipes it to the shell command `command`.

`\watch [seconds]`

Repeatedly runs the current query buffer (like `\g`) until interrupted or the query fails. Wait the specified number of seconds (default 2) between executions.

`\x [ on | off | auto ]`

Sets or toggles expanded table formatting mode. As such it is equivalent to `\pset expanded`.

`\z [pattern]`

Lists tables, views, and sequences with their associated access privileges. If a pattern is specified, only tables, views and sequences whose names match the pattern are listed. This is an alias for `\dp`.

`\! [command]`

Escapes to a separate shell or runs the shell command `command`. The arguments are not further interpreted; the shell will see them as-is. In particular, the variable substitution rules and backslash escapes do not apply.

`\?`

Shows help information about the `psql` backslash commands.

## Patterns

The various `\d` commands accept a pattern parameter to specify the object name(s) to be displayed. In the simplest case, a pattern is just the exact name of the object. The characters within a pattern are normally folded to lower case, just as in SQL names; for example, `\dt FOO` will display the table named `foo`. As in SQL names, placing double quotes around a pattern stops folding to lower case. Should you need to include an actual double quote character in a pattern, write it as a pair of double quotes within a double-quote sequence; again this is in accord with the rules for SQL quoted identifiers. For example, `\dt "FOO"BAR` will display the table named `FOO"BAR` (not `foo"bar`). Unlike the normal rules for SQL names, you can put double quotes around just part of a pattern, for instance `\dt FOO"FOO"BAR` will display the table named `fooFOObar`.

Within a pattern, `*` matches any sequence of characters (including no characters) and `?` matches any single character. (This notation is comparable to UNIX shell file name patterns.) For example, `\dt int*` displays all tables whose names begin with `int`. But within double quotes, `*` and `?` lose these special meanings and are just matched literally.

A pattern that contains a dot (`.`) is interpreted as a schema name pattern followed by an object name pattern. For example, `\dt foo*.bar*` displays all tables whose table name starts with `bar` that are in schemas whose schema name starts with `foo`. When no dot appears, then the pattern matches only objects that are visible in the current schema search path. Again, a dot within double quotes loses its special meaning and is matched literally.

Advanced users can use regular-expression notations. All regular expression special characters work as specified in the [PostgreSQL documentation on regular expressions](#), except for `.` which is taken as a separator as mentioned above, `*` which is translated to the regular-expression notation `.*`, and `?` which is translated to `.`. You can emulate these pattern characters at need by writing `?`

for `.`, ``(R+|)` for `R*`, or `(R|)` for `R?`. Remember that the pattern must match the whole name, unlike the usual interpretation of regular expressions; write `*` at the beginning and/or end if you don't wish the pattern to be anchored. Note that within double quotes, all regular expression special characters lose their special meanings and are matched literally. Also, the regular expression special characters are matched literally in operator name patterns (such as the argument of `\do`).

Whenever the pattern parameter is omitted completely, the `\d` commands display all objects that are visible in the current schema search path – this is equivalent to using the pattern `*`. To see all objects in the database, use the pattern `*,*`.

## Advanced Features

### Variables

`psql` provides variable substitution features similar to common UNIX command shells. Variables are simply name/value pairs, where the value can be any string of any length. The name must consist of letters (including non-Latin letters), digits, and underscores.

To set a variable, use the `psql` meta-command `\set`. For example,

```
testdb=> \set foo bar
```

sets the variable `foo` to the value `bar`. To retrieve the content of the variable, precede the name with a colon, for example:

```
testdb=> \echo :foo
bar
```

This works in both regular SQL commands and meta-commands; there is more detail in [SQL Interpolation](#).

If you call `\set` without a second argument, the variable is set, with an empty string as value. To unset (i.e., delete) a variable, use the command `\unset`. To show the values of all variables, call `\set` without any argument.

**Note:** The arguments of `\set` are subject to the same substitution rules as with other commands. Thus you can construct interesting references such as `\set :foo 'something'` and get 'soft links' or 'variable variables' of Perl or PHP fame, respectively. Unfortunately, there is no way to do anything useful with these constructs. On the other hand, `\set bar :foo` is a perfectly valid way to copy a variable.

A number of these variables are treated specially by `psql`. They represent certain option settings that can be changed at run time by altering the value of the variable, or in some cases represent changeable state of `psql`. Although you can use these variables for other purposes, this is not recommended, as the program behavior might grow really strange really quickly. By convention, all specially treated variables' names consist of all upper-case ASCII letters (and possibly digits and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes. A list of all specially treated variables follows.

### AUTOCOMMIT

When on (the default), each SQL command is automatically committed upon successful completion. To postpone commit in this mode, you must enter a `BEGIN` or `START TRANSACTION`

SQL command. When off or unset, SQL commands are not committed until you explicitly issue `COMMIT` or `END`. The autocommit-on mode works by issuing an implicit `BEGIN` for you, just before any command that is not already in a transaction block and is not itself a `BEGIN` or other transaction-control command, nor a command that cannot be run inside a transaction block (such as `VACUUM`).

In autocommit-off mode, you must explicitly abandon any failed transaction by entering `ABORT` or `ROLLBACK`. Also keep in mind that if you exit the session without committing, your work will be lost.

The autocommit-on mode is PostgreSQL's traditional behavior, but autocommit-off is closer to the SQL spec. If you prefer autocommit-off, you may wish to set it in your `~/.psqlrc` file.

#### COMP\_KEYWORD\_CASE

Determines which letter case to use when completing an SQL key word. If set to `lower` or `upper`, the completed word will be in lower or upper case, respectively. If set to `preserve-lower` or `preserve-upper` (the default), the completed word will be in the case of the word already entered, but words being completed without anything entered will be in lower or upper case, respectively.

#### DBNAME

The name of the database you are currently connected to. This is set every time you connect to a database (including program start-up), but can be unset.

#### ECHO

If set to `all`, all nonempty input lines are printed to standard output as they are read. (This does not apply to lines read interactively.) To select this behavior on program start-up, use the switch `-a`. If set to `queries`, `psql` prints each query to standard output as it is sent to the server. The switch for this is `-e`.

#### ECHO\_HIDDEN

When this variable is set to `on` and a backslash command queries the database, the query is first shown. This feature helps you to study Greenplum Database internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch `-E`.) If you set the variable to the value `noexec`, the queries are just shown but are not actually sent to the server and run.

#### ENCODING

The current client character set encoding.

#### FETCH\_COUNT

If this variable is set to an integer value  $> 0$ , the results of `SELECT` queries are fetched and displayed in groups of that many rows, rather than the default behavior of collecting the entire result set before display. Therefore only a limited amount of memory is used, regardless of the size of the result set. Settings of 100 to 1000 are commonly used when enabling this feature. Keep in mind that when using this feature, a query may fail after having already displayed some rows.

Although you can use any output format with this feature, the default aligned format tends to look bad because each group of `FETCH_COUNT` rows will be formatted separately, leading to varying column widths across the row groups. The other output formats work better.

#### HISTCONTROL

If this variable is set to `ignoreSpace`, lines which begin with a space are not entered into the history list. If set to a value of `ignoreDups`, lines matching the previous history line are not

entered. A value of `ignoreboth` combines the two options. If unset, or if set to any other value than those above, all lines read in interactive mode are saved on the history list.

## HISTFILE

The file name that will be used to store the history list. The default value is `~/.psql_history`. For example, putting

```
\set HISTFILE ~/.psql_history- :DBNAME
```

in `~/.psqlrc` will cause `psql` to maintain a separate history for each database.

## HISTSIZE

The number of commands to store in the command history. The default value is 500.

## HOST

The database server host you are currently connected to. This is set every time you connect to a database (including program start-up), but can be unset.

## IGNOREEOF

If unset, sending an `EOF` character (usually `CTRL+D`) to an interactive session of `psql` will terminate the application. If set to a numeric value, that many `EOF` characters are ignored before the application terminates. If the variable is set but has no numeric value, the default is 10.

## LASTOID

The value of the last affected OID, as returned from an `INSERT` or `lo_import` command. This variable is only guaranteed to be valid until after the result of the next SQL command has been displayed.

## ON\_ERROR\_ROLLBACK

When set to `on`, if a statement in a transaction block generates an error, the error is ignored and the transaction continues. When set to `interactive`, such errors are only ignored in interactive sessions, and not when reading script files. When unset or set to `off`, a statement in a transaction block that generates an error cancels the entire transaction. The error rollback mode works by issuing an implicit `SAVEPOINT` for you, just before each command that is in a transaction block, and rolls back to the savepoint on error.

## ON\_ERROR\_STOP

By default, command processing continues after an error. When this variable is set to `on`, processing will instead stop immediately. In interactive mode, `psql` will return to the command prompt; otherwise, `psql` will exit, returning error code 3 to distinguish this case from fatal error conditions, which are reported using error code 1. In either case, any currently running scripts (the top-level script, if any, and any other scripts which it may have invoked) will be terminated immediately. If the top-level command string contained multiple SQL commands, processing will stop with the current command.

## PORT

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be unset.

## PROMPT1

## PROMPT2

## PROMPT3

These specify what the prompts `psql` issues should look like. See "Prompting".

## QUIET

Setting this variable to `on` is equivalent to the command line option `-q`. It is not very useful in interactive mode.

#### SINGLELINE

This variable is equivalent to the command line option `-s`.

#### SINGLESTEP

Setting this variable to `on` is equivalent to the command line option `-s`.

#### USER

The database user you are currently connected as. This is set every time you connect to a database (including program start-up), but can be unset.

#### VERBOSITY

This variable can be set to the values `default`, `verbose`, or `terse` to control the verbosity of error reports.

### SQL Interpolation

A key feature of `psql` variables is that you can substitute ("interpolate") them into regular SQL statements, as well as the arguments of meta-commands. Furthermore, `psql` provides facilities for ensuring that variable values used as SQL literals and identifiers are properly quoted. The syntax for interpolating a value without any quoting is to prepend the variable name with a colon (:). For example,

```
testdb=> \set foo 'my_table'
testdb=> SELECT * FROM :foo;
```

would query the table `my_table`. Note that this may be unsafe: the value of the variable is copied literally, so it can contain unbalanced quotes, or even backslash commands. You must make sure that it makes sense where you put it.

When a value is to be used as an SQL literal or identifier, it is safest to arrange for it to be quoted. To quote the value of a variable as an SQL literal, write a colon followed by the variable name in single quotes. To quote the value as an SQL identifier, write a colon followed by the variable name in double quotes. These constructs deal correctly with quotes and other special characters embedded within the variable value. The previous example would be more safely written this way:

```
testdb=> \set foo 'my_table'
testdb=> SELECT * FROM :'foo';
```

Variable interpolation will not be performed within quoted SQL literals and identifiers. Therefore, a construction such as `:'foo'` doesn't work to produce a quoted literal from a variable's value (and it would be unsafe if it did work, since it wouldn't correctly handle quotes embedded in the value).

One example use of this mechanism is to copy the contents of a file into a table column. First load the file into a variable and then interpolate the variable's value as a quoted string:

```
testdb=> \set content `cat my_file.txt`
testdb=> INSERT INTO my_table VALUES (: 'content');
```

(Note that this still won't work if `my_file.txt` contains `NUL` bytes. `psql` does not support embedded `NUL` bytes in variable values.)

Since colons can legally appear in SQL commands, an apparent attempt at interpolation (that is, `:name`, `:'name'`, or `:"name"`) is not replaced unless the named variable is currently set. In any case,

you can escape a colon with a backslash to protect it from substitution.

The colon syntax for variables is standard SQL for embedded query languages, such as ECPG. The colon syntaxes for array slices and type casts are Greenplum Database extensions, which can sometimes conflict with the standard usage. The colon-quote syntax for escaping a variable's value as an SQL literal or identifier is a `psql` extension.

## Prompting

The prompts `psql` issues can be customized to your preference. The three variables `PROMPT1`, `PROMPT2`, and `PROMPT3` contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when `psql` requests a new command. Prompt 2 is issued when more input is expected during command entry, for example because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you are running an SQL `COPY FROM STDIN` command and you need to type in a row value on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

`%M`

The full host name (with domain name) of the database server, or `[local]` if the connection is over a UNIX domain socket, or `[local:/dir/name]`, if the UNIX domain socket is not at the compiled in default location.

`%m`

The host name of the database server, truncated at the first dot, or `[local]` if the connection is over a UNIX domain socket.

`%>`

The port number at which the database server is listening.

`%n`

The database session user name. (The expansion of this value might change during a database session as the result of the command `SET SESSION AUTHORIZATION`.)

`%/`

The name of the current database.

`%~`

Like `%/`, but the output is `~` (tilde) if the database is your default database.

`%#`

If the session user is a database superuser, then a `#`, otherwise a `>`. (The expansion of this value might change during a database session as the result of the command `SET SESSION AUTHORIZATION`.)

`%R`

In prompt 1 normally `=`, but `^` if in single-line mode, or `!` if the session is disconnected from the database (which can happen if `\connect` fails). In prompt 2 `%R` is replaced by a character that depends on why `psql` expects more input: `-` if the command simply wasn't terminated yet, but `*` if there is an unfinished `/* ... */` comment, a single quote if there is an unfinished quoted string, a double quote if there is an unfinished quoted identifier, a dollar sign if there is an unfinished dollar-quoted string, or `(` if there is an unmatched left parenthesis. In prompt 3 `%R` doesn't produce anything.

`%X`

Transaction status: an empty string when not in a transaction block, or \* when in a transaction block, or ! when in a failed transaction block, or ? when the transaction state is indeterminate (for example, because there is no connection).

`%digits`

The character with the indicated octal code is substituted.

`:%:name:`

The value of the `psql` variable name. See "Variables" in [Advanced Features](#) for details.

`%`command``

The output of command, similar to ordinary back-tick substitution.

`%[ ... %]`

Prompts may contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for line editing to work properly, these non-printing control characters must be designated as invisible by surrounding them with `%[` and `%]`. Multiple pairs of these may occur within the prompt. For example,

```
testdb=> \set PROMPT1 '%[%033[1;33;40m%]n@%/%R%[%033[0m%]##'
```

results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals. To insert a percent sign into your prompt, write `%%`. The default prompts are `'%/%R%# '` for prompts 1 and 2, and `'>> '` for prompt 3.

## Command-Line Editing

`psql` uses the `readline` library for convenient line editing and retrieval. The command history is automatically saved when `psql` exits and is reloaded when `psql` starts up. Tab-completion is also supported, although the completion logic makes no claim to be an SQL parser. The queries generated by tab-completion can also interfere with other SQL commands, e.g. `SET TRANSACTION ISOLATION LEVEL`. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named `.inputrc` in your home directory:

```
$if psql
set disable-completion on
$endif
```

## Environment

### COLUMNS

If `\pset columns` is zero, controls the width for the wrapped format and width for determining if wide output requires the pager or should be switched to the vertical format in expanded auto mode.

### PAGER

If the query results do not fit on the screen, they are piped through this command. Typical values are `more` or `less`. The default is platform-dependent. The use of the pager can be deactivated by setting `PAGER` to empty, or by using pager-related options of the `\pset` command.

### PGDATABASE

### PGHOST

PGPORT

PGUSER

Default connection parameters.

PSQL\_EDITOR

EDITOR

VISUAL

Editor used by the `\e` and `\ef` commands. The variables are examined in the order listed; the first that is set is used.

The built-in default editors are `vi` on Unix systems and `notepad.exe` on Windows systems.

PSQL\_EDITOR\_LINENUMBER\_ARG

When `\e` or `\ef` is used with a line number argument, this variable specifies the command-line argument used to pass the starting line number to the user's editor. For editors such as Emacs or `vi`, this is a plus sign. Include a trailing space in the value of the variable if there needs to be space between the option name and the line number. Examples:

```
PSQL_EDITOR_LINENUMBER_ARG='+'
PSQL_EDITOR_LINENUMBER_ARG='--line '
```

The default is `+` on Unix systems (corresponding to the default editor `vi`, and useful for many other common editors); but there is no default on Windows systems.

PSQL\_HISTORY

Alternative location for the command history file. Tilde (`~`) expansion is performed.

PSQLRC

Alternative location of the user's `.psqlrc` file. Tilde (`~`) expansion is performed.

SHELL

Command run by the `\!` command.

TMPDIR

Directory for storing temporary files. The default is `/tmp`.

## Files

`psqlrc` and `~/.psqlrc`

Unless it is passed an `-x` or `-c` option, `psql` attempts to read and run commands from the system-wide startup file (`psqlrc`) and then the user's personal startup file (`~/.psqlrc`), after connecting to the database but before accepting normal commands. These files can be used to set up the client and/or the server to taste, typically with `\set` and `SET` commands.

The system-wide startup file is named `psqlrc` and is sought in the installation's "system configuration" directory, which is most reliably identified by running `pg_config --sysconfdir`. By default this directory will be `./etc/` relative to the directory containing the Greenplum Database executables. The name of this directory can be set explicitly via the `PGSYSCONFDIR` environment variable.

The user's personal startup file is named `.psqlrc` and is sought in the invoking user's home directory. On Windows, which lacks such a concept, the personal startup file is named `%APPDATA%\postgresql\psqlrc.conf`. The location of the user's startup file can be set explicitly via the `PSQLRC` environment variable.

Both the system-wide startup file and the user's personal startup file can be made `psql`-version-specific by appending a dash and the underlying PostgreSQL major or minor release number to the file name, for example `~/.psqlrc-9.4`. The most specific version-matching file will be read in preference to a non-version-specific file.

`.psql_history`

The command-line history is stored in the file `~/.psql_history`, or `%APPDATA%\postgresql\psql_history` on Windows.

The location of the history file can be set explicitly via the `PSQL_HISTORY` environment variable.

## Notes

`psql` works best with servers of the same or an older major version. Backslash commands are particularly likely to fail if the server is of a newer version than `psql` itself. However, backslash commands of the `\d` family should work with older server versions, though not necessarily with servers newer than `psql` itself. The general functionality of running SQL commands and displaying query results should also work with servers of a newer major version, but this cannot be guaranteed in all cases.

If you want to use `psql` to connect to several servers of different major versions, it is recommended that you use the newest version of `psql`. Alternatively, you can keep a copy of `psql` from each major version around and be sure to use the version that matches the respective server. But in practice, this additional complication should not be necessary.

## Notes for Windows Users

`psql` is built as a console application. Since the Windows console windows use a different encoding than the rest of the system, you must take special care when using 8-bit characters within `psql`. If `psql` detects a problematic console code page, it will warn you at startup. To change the console code page, two things are necessary:

Set the code page by entering:

```
cmd.exe /c chcp 1252
```

`1252` is a character encoding of the Latin alphabet, used by Microsoft Windows for English and some other Western languages. If you are using Cygwin, you can put this command in `/etc/profile`.

Set the console font to Lucida Console, because the raster font does not work with the ANSI code page.

## Examples

Start `psql` in interactive mode:

```
psql -p 54321 -U sally mydatabase
```

In `psql` interactive mode, spread a command over several lines of input. Notice the changing prompt:

```
testdb=> CREATE TABLE my_table (
testdb(> first integer not null default 0,
testdb(> second text)
testdb-> ;
CREATE TABLE
```

Look at the table definition:

```
testdb=> \d my_table
          Table "public.my_table"
  Column      | Type      | Modifiers
-----+-----+-----
 first       | integer   | not null default 0
 second      | text      |
Distributed by: (first)
```

Run `psql` in non-interactive mode by passing in a file containing SQL commands:

```
psql -f /home/gpadmin/test/myscript.sql
```

## reindexdb

Rebuilds indexes in a database.

## Synopsis

```
reindexdb [<connection-option> ...] [--table | -t <table> ]
          [--index | -i <index> ] [<dbname>]

reindexdb [<connection-option> ...] --all | -a

reindexdb [<connection-option> ...] --system | -s [<dbname>]

reindexdb -? | --help

reindexdb -V | --version
```

## Description

`reindexdb` is a utility for rebuilding indexes in Greenplum Database.

`reindexdb` is a wrapper around the SQL command `REINDEX`. There is no effective difference between reindexing databases via this utility and via other methods for accessing the server.

## Options

`-a` | `--all`  
Reindex all databases.

`[-d] dbname | [--dbname=]dbname`

Specifies the name of the database to be reindexed. If this is not specified and `-all` is not used, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

`-e | --echo`

Echo the commands that `reindexdb` generates and sends to the server.

`-i index | --index=index`

Recreate index only.

`-q | --quiet`

Do not display a response.

`-s | --system`

Reindex system catalogs.

`-t table | --table=table`

Reindex table only. Multiple tables can be reindexed by writing multiple `-t` switches.

`-V | --version`

Print the `reindexdb` version and exit.

`-? | --help`

Show help about `reindexdb` command line arguments, and exit.

## Connection Options

`-h host | --host=host`

Specifies the host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to `localhost`.

`-p port | --port=port`

Specifies the TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

`-U username | --username=username`

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system user name.

`-w | --no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W | --password`

Force a password prompt.

`--maintenance-db=dbname`

Specifies the name of the database to connect to discover what other databases should be reindexed. If not specified, the `postgres` database will be used, and if that does not exist, `template1` will be used.

## Notes

`reindexdb` causes locking of system catalog tables, which could affect currently running queries. To avoid disrupting ongoing business operations, schedule the `reindexdb` operation during a period of low activity.

`reindexdb` might need to connect several times to the master server, asking for a password each time. It is convenient to have a `~/ .pgpass` file in such cases.

## Examples

To reindex the database `mydb`:

```
reindexdb mydb
```

To reindex the table `foo` and the index `bar` in a database named `abcd`:

```
reindexdb --table foo --index bar abcd
```

## See Also

[REINDEX](#)

## vacuumdb

Garbage-collects and analyzes a database.

## Synopsis

```
vacuumdb [<connection-option>...] [--full | -f] [--freeze | -F] [--verbose | -v]
  [--analyze | -z] [--analyze-only | -Z] [--table | -t <table> [( <column> [,...] )]
] [<dbname>]

vacuumdb [<connection-option>...] [--all | -a] [--full | -f] [-F]
  [--verbose | -v] [--analyze | -z]
  [--analyze-only | -Z]

vacuumdb -? | --help

vacuumdb -V | --version
```

## Description

`vacuumdb` is a utility for cleaning a Greenplum Database database. `vacuumdb` will also generate internal statistics used by the Greenplum Database query optimizer.

`vacuumdb` is a wrapper around the SQL command `VACUUM`. There is no effective difference between vacuuming databases via this utility and via other methods for accessing the server.

## Options

`-a` | `--all`

Vacuums all databases.

`[-d] dbname` |  `[--dbname=]dbname`

The name of the database to vacuum. If this is not specified and `-a` (or `--all`) is not used, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

`-e` | `--echo`

Echo the commands that `reindexdb` generates and sends to the server.

`-f` | `--full`

Selects a full vacuum, which may reclaim more space, but takes much longer and exclusively locks the table.

**Warning:** A `VACUUM FULL` is not recommended in Greenplum Database.

`-F` | `--freeze`

Freeze row transaction information.

`-q` | `--quiet`

Do not display a response.

`-t` table [(column)] | `--table=` table [(column)]

Clean or analyze this table only. Column names may be specified only in conjunction with the `--analyze` or `--analyze-all` options. Multiple tables can be vacuumed by writing multiple `-t` switches. If you specify columns, you probably have to escape the parentheses from the shell.

`-v` | `--verbose`

Print detailed information during processing.

`-z` | `--analyze`

Collect statistics for use by the query planner.

`-Z` | `--analyze-only`

Only calculate statistics for use by the query planner (no vacuum).

`-V` | `--version`

Print the `vacuumdb` version and exit.

`-?` | `--help`

Show help about `vacuumdb` command line arguments, and exit.

## Connection Options

`-h` host | `--host=`host

Specifies the host name of the machine on which the Greenplum master database server is running. If not specified, reads from the environment variable `PGHOST` or defaults to localhost.

`-p` port | `--port=`port

Specifies the TCP port on which the Greenplum master database server is listening for connections. If not specified, reads from the environment variable `PGPORT` or defaults to 5432.

`-U` username | `--username=`username

The database role name to connect as. If not specified, reads from the environment variable `PGUSER` or defaults to the current system user name.

`-w` | `--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W` | `--password`

Force a password prompt.

`--maintenance-db=dbname`

Specifies the name of the database to connect to discover what other databases should be vacuumed. If not specified, the `postgres` database will be used, and if that does not exist, `template1` will be used.

## Notes

`vacuumdb` might need to connect several times to the master server, asking for a password each time. It is convenient to have a `~/.pgpass` file in such cases.

## Examples

To clean the database `test`:

```
vacuumdb test
```

To clean and analyze a database named `bigdb`:

```
vacuumdb --analyze bigdb
```

To clean a single table `foo` in a database named `mydb`, and analyze a single column `bar` of the table. Note the quotes around the table and column names to escape the parentheses from the shell:

```
vacuumdb --analyze --verbose --table 'foo(bar)' mydb
```

## Additional Supplied Programs

Additional programs available in the Greenplum Database installation.

The following PostgreSQL `contrib` server utility programs are installed:

- `pg_upgrade` - Server program to upgrade a Postgres Database server instance.  
**Note:** `pg_upgrade` is not intended for direct use with Greenplum 6, but will be used by Greenplum upgrade utilities in a future release.
- `pg_upgrade_support` - supporting library for `pg_upgrade`.
- `pg_xlogdump` - Server utility program to display a human-readable rendering of the write-ahead log of a Greenplum Database cluster.

**Parent topic:** [Greenplum Database Utility Guide](#)

## System Catalogs

This reference describes the Greenplum Database system catalog tables and views. System tables prefixed with `gp_` relate to the parallel features of Greenplum Database. Tables prefixed with `pg_`

are either standard PostgreSQL system catalog tables supported in Greenplum Database, or are related to features Greenplum that provides to enhance PostgreSQL for data warehousing workloads. Note that the global system catalog for Greenplum Database resides on the master instance.

**Warning:** Changes to Greenplum Database system catalog tables or views are not supported. If a catalog table or view is changed by the customer, the Tanzu Greenplum cluster is not supported. The cluster must be reinitialized and restored by the customer.

## foreign\_data\_wrapper\_options

The `foreign_data_wrapper_options` view contains all of the options defined for foreign-data wrappers in the current database. Greenplum Database displays only those foreign-data wrappers to which the current user has access (by way of being the owner or having some privilege).

| column                                    | type           | references | description  |
|---|----------------|------------|--|
| <code>foreign_data_wrapper_catalog</code> | sql_identifier |            | Name of the database in which the foreign-data wrapper is defined (always the current database). |
| <code>foreign_data_wrapper_name</code>    | sql_identifier |            | Name of the foreign-data wrapper.  |
| <code>option_name</code>                  | sql_identifier |            | Name of an option.   |
| <code>option_value</code>                 | character_data |            | Value of the option.   |

Parent topic: [System Catalogs Definitions](#)

## foreign\_data\_wrappers

The `foreign_data_wrappers` view contains all foreign-data wrappers defined in the current database. Greenplum Database displays only those foreign-data wrappers to which the current user has access (by way of being the owner or having some privilege).

| column                                     | type           | references | description  |
|--|----------------|------------|--|
| <code>foreign_data_wrapper_catalog</code>  | sql_identifier |            | Name of the database in which the foreign-data wrapper is defined (always the current database). |
| <code>foreign_data_wrapper_name</code>     | sql_identifier |            | Name of the foreign-data wrapper.  |
| <code>authorization_identifier</code>      | sql_identifier |            | Name of the owner of the foreign server.   |
| <code>library_name</code>                  | character_data |            | File name of the library that implements this foreign-data wrapper.                              |
| <code>foreign_data_wrapper_language</code> | character_data |            | Language used to implement the foreign-data wrapper.   |

Parent topic: [System Catalogs Definitions](#)

## foreign\_server\_options

The `foreign_server_options` view contains all of the options defined for foreign servers in the current database. Greenplum Database displays only those foreign servers to which the current user has access (by way of being the owner or having some privilege).

| column                              | type           | references | description  |
|-------------------------------------|----------------|------------|--|
| <code>foreign_server_catalog</code> | sql_identifier |            | Name of the database in which the foreign server is defined (always the current database). |
| <code>foreign_server_name</code>    | sql_identifier |            | Name of the foreign server.  |
| <code>option_name</code>            | sql_identifier |            | Name of an option.   |
| <code>option_value</code>           | character_data |            | Value of the option.   |

Parent topic: [System Catalogs Definitions](#)

## foreign\_servers

The `foreign_servers` view contains all foreign servers defined in the current database. Greenplum Database displays only those foreign servers to which the current user has access (by way of being the owner or having some privilege).

| column                              | type           | references | description  |
|-------------------------------------|----------------|------------|--|
| <code>foreign_server_catalog</code> | sql_identifier |            | Name of the database in which the foreign server is defined (always the current database). |

| column                                    | type           | references | description   |
|---|----------------|------------|---|
| <code>foreign_server_name</code>          | sql_identifier |            | Name of the foreign server.   |
| <code>foreign_data_wrapper_catalog</code> | sql_identifier |            | Name of the database in which the foreign-data wrapper used by the foreign server is defined (always the current database). |
| <code>foreign_data_wrapper_name</code>    | sql_identifier |            | Name of the foreign-data wrapper used by the foreign server.  |
| <code>foreign_server_type</code>          | character_data |            | Foreign server type information, if specified upon creation.  |
| <code>foreign_server_version</code>       | character_data |            | Foreign server version information, if specified upon creation.   |
| <code>authorization_identifier</code>     | sql_identifier |            | Name of the owner of the foreign server.  |

Parent topic: [System Catalogs Definitions](#)

## foreign\_table\_options

The `foreign_table_options` view contains all of the options defined for foreign tables in the current database. Greenplum Database displays only those foreign tables to which the current user has access (by way of being the owner or having some privilege).

| column                             | type           | references | description   |
|------------------------------------|----------------|------------|---|
| <code>foreign_table_catalog</code> | sql_identifier |            | Name of the database in which the foreign table is defined (always the current database). |
| <code>foreign_table_schema</code>  | sql_identifier |            | Name of the schema that contains the foreign table.                                       |
| <code>foreign_table_name</code>    | sql_identifier |            | Name of the foreign table.  |
| <code>option_name</code>           | sql_identifier |            | Name of an option.  |
| <code>option_value</code>          | character_data |            | Value of the option.  |

Parent topic: [System Catalogs Definitions](#)

## foreign\_tables

The `foreign_tables` view contains all foreign tables defined in the current database. Greenplum Database displays only those foreign tables to which the current user has access (by way of being the owner or having some privilege).

| column                             | type           | references | description   |
|------------------------------------|----------------|------------|---|
| <code>foreign_table_catalog</code> | sql_identifier |            | Name of the database in which the foreign table is defined (always the current database). |

| column                              | type           | references | description  |
|-------------------------------------|----------------|------------|--|
| <code>foreign_table_schema</code>   | sql_identifier |            | Name of the schema that contains the foreign table.  |
| <code>foreign_table_name</code>     | sql_identifier |            | Name of the foreign table.   |
| <code>foreign_server_catalog</code> | sql_identifier |            | Name of the database in which the foreign server is defined (always the current database). |
| <code>foreign_server_name</code>    | sql_identifier |            | Name of the foreign server.  |

Parent topic: [System Catalogs Definitions](#)

## gp\_configuration\_history

The `gp_configuration_history` table contains information about system changes related to fault detection and recovery operations. The `fts_probe` process logs data to this table, as do certain related management utilities such as `gprecoverseg` and `gpinitssystem`. For example, when you add a new segment and mirror segment to the system, records for these events are logged to `gp_configuration_history`.

The event descriptions stored in this table may be helpful for troubleshooting serious system issues in collaboration with VMware Support technicians.

This table is populated only on the master. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

| column            | type                     | references                                 | description  |
|-------------------|--------------------------|--|--|
| <code>time</code> | timestamp with time zone |  | Timestamp for the event recorded.  |
| <code>dbid</code> | smallint                 | <code>gp_segment_configuration.dbid</code> | System-assigned ID. The unique identifier of a segment (or master) instance. |
| <code>desc</code> | text                     |  | Text description of the event.   |

For information about `gprecoverseg` and `gpinitssystem`, see the Greenplum Database Utility Guide.

Parent topic: [System Catalogs Definitions](#)

## gp\_distributed\_log

The `gp_distributed_log` view contains status information about distributed transactions and their associated local transactions. A distributed transaction is a transaction that involves modifying data on the segment instances. Greenplum's distributed transaction manager ensures that the segments stay in synch. This view allows you to see the status of distributed transactions.

| column                  | type     | references                                    | description  |
|-------------------------|----------|---|--|
| <code>segment_id</code> | smallint | <code>gp_segment_configuration.content</code> | The content id of the segment. The master is always -1 (no content). |

| column                         | type     | references                                 | description   |
|--------------------------------|----------|--|---|
| <code>dbid</code>              | smallint | <code>gp_segment_configuration.dbid</code> | The unique id of the segment instance.                            |
| <code>distributed_xid</code>   | xid      |  | The global transaction id.  |
| <code>distributed_id</code>    | text     |  | A system assigned ID for a distributed transaction.               |
| <code>status</code>            | text     |  | The status of the distributed transaction (Committed or Aborted). |
| <code>local_transaction</code> | xid      |  | The local transaction ID.   |

Parent topic: [System Catalogs Definitions](#)

## gp\_distributed\_xacts

The `gp_distributed_xacts` view contains information about Greenplum Database distributed transactions. A distributed transaction is a transaction that involves modifying data on the segment instances. Greenplum's distributed transaction manager ensures that the segments stay in synch. This view allows you to see the currently active sessions and their associated distributed transactions.

| column                                 | type | references | description  |
|--|------|------------|--|
| <code>distributed_xid</code>           | xid  |            | The transaction ID used by the distributed transaction across the Greenplum Database array.  |
| <code>distributed_id</code>            | text |            | The distributed transaction identifier. It has 2 parts — a unique timestamp and the distributed transaction number.  |
| <code>state</code>                     | text |            | The current state of this session with regards to distributed transactions.  |
| <code>gp_session_id</code>             | int  |            | The ID number of the Greenplum Database session associated with this transaction.  |
| <code>xmin_distributed_snapshot</code> | xid  |            | The minimum distributed transaction number found among all open transactions when this transaction was started. It is used for MVCC distributed snapshot purposes. |

Parent topic: [System Catalogs Definitions](#)

## gp\_distribution\_policy

The `gp_distribution_policy` table contains information about Greenplum Database tables and their policy for distributing table data across the segments. This table is populated only on the master. This table is not globally shared, meaning each database has its own copy of this table.

| column                | type | references                | description                        |
|-----------------------|------|---------------------------|------------------------------------|
| <code>localoid</code> | oid  | <code>pg_class.oid</code> | The table object identifier (OID). |

| column                   | type       | references             | description   |
|--------------------------|------------|------------------------|---|
| <code>policytype</code>  | char       |                        | The table distribution policy:<br><br><code>p</code> - Partitioned policy. Table data is distributed among segment instances.<br><br><code>r</code> - Replicated policy. Table data is replicated on each segment instance. |
| <code>numsegments</code> | integer    |                        | The number of segment instances on which the table data is distributed.   |
| <code>distkey</code>     | int2vector | pg_attribute.attribute | The column number(s) of the distribution column(s).   |
| <code>distclass</code>   | oidvector  | pg_opclass.oid         | The operator class identifier(s) of the distribution column(s).   |

Parent topic: [System Catalogs Definitions](#)

## gpexpand.expansion\_progress

The `gpexpand.expansion_progress` view contains information about the status of a system expansion operation. The view provides calculations of the estimated rate of table redistribution and estimated time to completion.

Status for specific tables involved in the expansion is stored in [gpexpand.status\\_detail](#).

| column             | type | references | description   |
|--------------------|------|------------|---|
| <code>name</code>  | text |            | Name for the data field provided. Includes:<br><br>Bytes Left<br><br>Bytes Done<br><br>Estimated Expansion Rate<br><br>Estimated Time to Completion<br><br>Tables Expanded<br><br>Tables Left |
| <code>value</code> | text |            | The value for the progress data. For example: <code>Estimated Expansion Rate - 9.75667095996092 MB/s</code>   |

Parent topic: [System Catalogs Definitions](#)

## gp\_endpoints

The `gp_endpoints` view lists the endpoints created for all active parallel retrieve cursors declared by the current session user in the current database. When the Greenplum Database superuser accesses this view, it returns a list of all endpoints created for all parallel retrieve cursors declared by all users in the current database.

Endpoints exist only for the duration of the transaction that defines the parallel retrieve cursor, or until the cursor is closed.

| name          | type        | references | description  |
|---------------|-------------|------------|--|
| gp_segment_id | integer     |            | The QE's endpoint <code>gp_segment_id</code> .   |
| auth_token    | text        |            | The authentication token for a retrieve session.   |
| cursorname    | text        |            | The name of the parallel retrieve cursor.  |
| sessionid     | integer     |            | The identifier of the session in which the parallel retrieve cursor was created.   |
| hostname      | varchar(64) |            | The name of the host from which to retrieve the data for the endpoint.   |
| port          | integer     |            | The port number from which to retrieve the data for the endpoint.  |
| username      | text        |            | The name of the session user (not the current user); <i>you must initiate the retrieve session as this user</i> .  |
| state         | text        |            | The state of the endpoint; the valid states are:<br><br>READY: The endpoint is ready to be retrieved.<br><br>ATTACHED: The endpoint is attached to a retrieve connection.<br><br>RETRIEVING: A retrieve session is retrieving data from the endpoint at this moment.<br><br>FINISHED: The endpoint has been fully retrieved.<br><br>RELEASED: Due to an error, the endpoint has been released and the connection closed. |
| endpointname  | text        |            | The endpoint identifier; you provide this identifier to the <code>RETRIEVE</code> command.   |

Parent topic: [System Catalogs Definitions](#)

## gpexpand.status

The `gpexpand.status` table contains information about the status of a system expansion operation. Status for specific tables involved in the expansion is stored in `gpexpand.status_detail`.

In a normal expansion operation it is not necessary to modify the data stored in this table.

| column               | type                        | references | description   |
|----------------------|-----------------------------|------------|---|
| <code>status</code>  | text                        |            | Tracks the status of an expansion operation. Valid values are:<br><br><code>SETUP</code><br><br><code>SETUP DONE</code><br><br><code>EXPANSION STARTED</code><br><br><code>EXPANSION STOPPED</code><br><br><code>COMPLETED</code> |
| <code>updated</code> | timestamp without time zone |            | Timestamp of the last change in status.   |

Parent topic: [System Catalogs Definitions](#)

## gpexpand.status\_detail

The `gpexpand.status_detail` table contains information about the status of tables involved in a system expansion operation. You can query this table to determine the status of tables being expanded, or to view the start and end time for completed tables.

This table also stores related information about the table such as the oid and disk size. Overall status information for the expansion is stored in [gpexpand.status](#).

In a normal expansion operation it is not necessary to modify the data stored in this table.

| column                          | type    | references | description  |
|---------------------------------|---------|------------|--|
| <code>dbname</code>             | text    |            | Name of the database to which the table belongs.   |
| <code>fq_name</code>            | text    |            | Fully qualified name of the table.   |
| <code>table_oid</code>          | oid     |            | OID of the table.  |
| <code>root_partition_oid</code> | oid     |            | For a partitioned table, the OID of the root partition. Otherwise, <code>None</code> .   |
| <code>rank</code>               | int     |            | Rank determines the order in which tables are expanded. The expansion utility will sort on rank and expand the lowest-ranking tables first.  |
| <code>external_writable</code>  | boolean |            | Identifies whether or not the table is an external writable table. (External writable tables require a different syntax to expand).  |
| <code>status</code>             | text    |            | Status of expansion for this table. Valid values are:<br><br><code>NOT STARTED</code><br><br><code>IN PROGRESS</code><br><br><code>COMPLETED</code><br><br><code>NO LONGER EXISTS</code> |

| column                        | type                        | references | description  |
|-------------------------------|-----------------------------|------------|--|
| <code>expansion_start</code>  | timestamp without time zone |            | Timestamp for the start of the expansion of this table. This field is only populated after a table is successfully expanded.   |
| <code>expansion_finish</code> | timestamp without time zone |            | Timestamp for the completion of expansion of this table.   |
| <code>source_bytes</code>     |                             |            | The size of disk space associated with the source table. Due to table bloat in heap tables and differing numbers of segments after expansion, it is not expected that the final number of bytes will equal the source number. This information is tracked to help provide progress measurement to aid in duration estimation for the end-to-end expansion operation. |

Parent topic: [System Catalogs Definitions](#)

## gp\_fastsequence

The `gp_fastsequence` table contains information about append-optimized and column-oriented tables. The `last_sequence` value indicates maximum row number currently used by the table.

| column                     | type   | references                | description  |
|----------------------------|--------|---------------------------|--|
| <code>objid</code>         | oid    | <code>pg_class.oid</code> | Object id of the <code>pg_aoseg.pg_aocssseg_*</code> table used to track append-optimized file segments. |
| <code>objmod</code>        | bigint |                           | Object modifier.   |
| <code>last_sequence</code> | bigint |                           | The last sequence number used by the object.   |

Parent topic: [System Catalogs Definitions](#)

## gp\_id

The `gp_id` system catalog table identifies the Greenplum Database system name and number of segments for the system. It also has `local` values for the particular database instance (segment or master) on which the table resides. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

| column                   | type    | references | description   |
|--------------------------|---------|------------|---|
| <code>gpname</code>      | name    |            | The name of this Greenplum Database system.                 |
| <code>numsegments</code> | integer |            | The number of segments in the Greenplum Database system.    |
| <code>dbid</code>        | integer |            | The unique identifier of this segment (or master) instance. |

| column               | type    | references | description   |
|----------------------|---------|------------|---|
| <code>content</code> | integer |            | The ID for the portion of data on this segment instance. A primary and its mirror will have the same content ID.<br><br>For a segment the value is from 0- <i>N</i> -1, where <i>N</i> is the number of segments in Greenplum Database.<br><br>For the master, the value is -1. |

Parent topic: [System Catalogs Definitions](#)

## gp\_pgdatabase

The `gp_pgdatabase` view shows status information about the Greenplum segment instances and whether they are acting as the mirror or the primary. This view is used internally by the Greenplum fault detection and recovery utilities to determine failed segments.

| column                      | type     | references   | description  |
|-----------------------------|----------|--|--|
| <code>dbid</code>           | smallint | <code>gp_segment_configuration.dbid</code>           | System-assigned ID. The unique identifier of a segment (or master) instance.   |
| <code>isprimary</code>      | boolean  | <code>gp_segment_configuration.role</code>           | Whether or not this instance is active. Is it currently acting as the primary segment (as opposed to the mirror).  |
| <code>content</code>        | smallint | <code>gp_segment_configuration.content</code>        | The ID for the portion of data on an instance. A primary segment instance and its mirror will have the same content ID.<br><br>For a segment the value is from 0- <i>N</i> -1, where <i>N</i> is the number of segments in Greenplum Database.<br><br>For the master, the value is -1. |
| <code>valid</code>          | boolean  | <code>gp_segment_configuration.mode</code>           | Whether or not this instance is up and the mode is either <i>s</i> (synchronized) or <i>n</i> (not in sync).   |
| <code>definedprimary</code> | boolean  | <code>gp_segment_configuration.preferred_role</code> | Whether or not this instance was defined as the primary (as opposed to the mirror) at the time the system was initialized.   |

Parent topic: [System Catalogs Definitions](#)

## gp\_resgroup\_config

The `gp_toolkit.gp_resgroup_config` view allows administrators to see the current CPU, memory, and concurrency limits for a resource group.

**Note:** The `gp_resgroup_config` view is valid only when resource group-based resource management is active.

| column                 | type | references                       | description                     |
|------------------------|------|----------------------------------|---------------------------------|
| <code>groupid</code>   | oid  | <code>pg_resgroup.oid</code>     | The ID of the resource group.   |
| <code>groupname</code> | name | <code>pg_resgroup.rsgname</code> | The name of the resource group. |

| column                            | type | references  | description  |
|-----------------------------------|------|---|--|
| <code>concurrency</code>          | text | <code>pg_resgroupcapability.value</code> for<br><code>pg_resgroupcapability.reslimittype = 1</code> | The concurrency ( <code>CONCURRENCY</code> ) value specified for the resource group.                 |
| <code>cpu_rate_limit</code>       | text | <code>pg_resgroupcapability.value</code> for<br><code>pg_resgroupcapability.reslimittype = 2</code> | The CPU limit ( <code>CPU_RATE_LIMIT</code> ) value specified for the resource group, or -1.         |
| <code>memory_limit</code>         | text | <code>pg_resgroupcapability.value</code> for<br><code>pg_resgroupcapability.reslimittype = 3</code> | The memory limit ( <code>MEMORY_LIMIT</code> ) value specified for the resource group.               |
| <code>memory_share_d_quota</code> | text | <code>pg_resgroupcapability.value</code> for<br><code>pg_resgroupcapability.reslimittype = 4</code> | The shared memory quota ( <code>MEMORY_SHARED_QUOTA</code> ) value specified for the resource group. |
| <code>memory_spill_ratio</code>   | text | <code>pg_resgroupcapability.value</code> for<br><code>pg_resgroupcapability.reslimittype = 5</code> | The memory spill ratio ( <code>MEMORY_SPILL_RATIO</code> ) value specified for the resource group.   |
| <code>memory_auditor</code>       | text | <code>pg_resgroupcapability.value</code> for<br><code>pg_resgroupcapability.reslimittype = 6</code> | The memory auditor in use for the resource group.  |
| <code>cpuset</code>               | text | <code>pg_resgroupcapability.value</code> for<br><code>pg_resgroupcapability.reslimittype = 7</code> | The CPU cores reserved for the resource group, or -1.  |

Parent topic: [System Catalogs Definitions](#)

## gp\_resgroup\_status

The `gp_toolkit.gp_resgroup_status` view allows administrators to see status and activity for a resource group. It shows how many queries are waiting to run and how many queries are currently active in the system for each resource group. The view also displays current memory and CPU usage for the resource group.

**Note:** The `gp_resgroup_status` view is valid only when resource group-based resource management is active.

| column                            | type     | references  | description   |
|-----------------------------------|----------|---|---|
| <code>rsgname</code>              | name     | <code>pg_resgroup</code><br><code>.rsgname</code> | The name of the resource group.   |
| <code>groupid</code>              | oid      | <code>pg_resgroup</code><br><code>.oid</code>     | The ID of the resource group.   |
| <code>num_running</code>          | integer  |   | The number of transactions currently running in the resource group.   |
| <code>num_queueing</code>         | integer  |   | The number of currently queued transactions for the resource group.   |
| <code>num_queued</code>           | integer  |   | The total number of queued transactions for the resource group since the Greenplum Database cluster was last started, excluding the <code>num_queueing</code> . |
| <code>num_executed</code>         | integer  |   | The total number of transactions run in the resource group since the Greenplum Database cluster was last started, excluding the <code>num_running</code> .      |
| <code>total_queue_duration</code> | interval |   | The total time any transaction was queued since the Greenplum Database cluster was last started.  |

| column                    | type | references | description   |
|---------------------------|------|------------|---|
| <code>cpu_usage</code>    | json |            | A set of key-value pairs. For each segment instance (the key), the value is the real-time, per-segment instance CPU core usage by a resource group. The value is the sum of the percentages (as a decimal value) of CPU cores that are used by the resource group for the segment instance. |
| <code>memory_usage</code> | json |            | The real-time memory usage of the resource group on each Greenplum Database segment's host.   |

The `cpu_usage` field is a JSON-formatted, key:value string that identifies, for each resource group, the per-segment instance CPU core usage. The key is the segment id. The value is the sum of the percentages (as a decimal value) of the CPU cores used by the segment instance's resource group on the segment host; the maximum value is 1.00. The total CPU usage of all segment instances running on a host should not exceed the `gp_resource_group_cpu_limit`. Example `cpu_usage` column output:

```
{"-1":0.01, "0":0.31, "1":0.31}
```

In the example, segment 0 and segment 1 are running on the same host; their CPU usage is the same.

The `memory_usage` field is also a JSON-formatted, key:value string. The string contents differ depending upon the type of resource group. For each resource group that you assign to a role (default memory auditor `vmtracker`), this string identifies the used and available fixed and shared memory quota allocations on each segment. The key is segment id. The values are memory values displayed in MB units. The following example shows `memory_usage` column output for a single segment for a resource group that you assign to a role:

```
"0":{"used":0, "available":76, "quota_used":-1, "quota_available":60, "shared_used":0, "shared_available":16}
```

For each resource group that you assign to an external component, the `memory_usage` JSON-formatted string identifies the memory used and the memory limit on each segment. The following example shows `memory_usage` column output for an external component resource group for a single segment:

```
"1":{"used":11, "limit_granted":15}
```

**Parent topic:** [System Catalogs Definitions](#)

## gp\_resgroup\_status\_per\_host

The `gp_toolkit.gp_resgroup_status_per_host` view allows administrators to see current memory and CPU usage and allocation for each resource group on a per-host basis.

Memory amounts are specified in MBs.

**Note:** The `gp_resgroup_status_per_host` view is valid only when resource group-based resource management is active.

| column                               | type    | references                                     | description  |
|--------------------------------------|---------|--|--|
| <code>rsgname</code>                 | name    | <code>pg_resgroup.rsgname</code>               | The name of the resource group.  |
| <code>groupid</code>                 | oid     | <code>pg_resgroup.oid</code>                   | The ID of the resource group.  |
| <code>hostname</code>                | text    | <code>gp_segment_configuration.hostname</code> | The hostname of the segment host.  |
| <code>cpu</code>                     | numeric |  | The real-time CPU core usage by the resource group on a host. The value is the sum of the percentages (as a decimal value) of the CPU cores that are used by the resource group on the host. |
| <code>memory_used</code>             | integer |  | The real-time memory usage of the resource group on the host. This total includes resource group fixed and shared memory. It also includes global shared memory used by the resource group.  |
| <code>memory_available</code>        | integer |  | The unused fixed and shared memory for the resource group that is available on the host. This total does not include available resource group global shared memory.                          |
| <code>memory_quota_used</code>       | integer |  | The real-time fixed memory usage for the resource group on the host.   |
| <code>memory_quota_available</code>  | integer |  | The fixed memory available to the resource group on the host.  |
| <code>memory_shared_used</code>      | integer |  | The group shared memory used by the resource group on the host. If any global shared memory is used by the resource group, this amount is included in the total as well.                     |
| <code>memory_shared_available</code> | integer |  | The amount of group shared memory available to the resource group on the host. Resource group global shared memory is not included in this total.  |

Parent topic: [System Catalogs Definitions](#)

## gp\_resgroup\_status\_per\_segment

The `gp_toolkit.gp_resgroup_status_per_segment` view allows administrators to see current memory and CPU usage and allocation for each resource group on a per-host and per-segment basis.

Memory amounts are specified in MBs.

**Note:** The `gp_resgroup_status_per_segment` view is valid only when resource group-based resource management is active.

| column                | type | references                                     | description                       |
|-----------------------|------|--|-----------------------------------|
| <code>rsgname</code>  | name | <code>pg_resgroup.rsgname</code>               | The name of the resource group.   |
| <code>groupid</code>  | oid  | <code>pg_resgroup.oid</code>                   | The ID of the resource group.     |
| <code>hostname</code> | text | <code>gp_segment_configuration.hostname</code> | The hostname of the segment host. |

| column                               | type      | references                                    | description   |
|--------------------------------------|-----------|---|---|
| <code>segment_id</code>              | small int | <code>gp_segment_configuration.content</code> | The content ID for a segment instance on the segment host.  |
| <code>cpu</code>                     | numeric   |   | The real-time, per-segment instance CPU core usage by the resource group on the host. The value is the sum of the percentages (as a decimal value) of the CPU cores that are used by the resource group for the segment instance. |
| <code>memory_used</code>             | integer   |   | The real-time memory usage of the resource group for the segment instance on the host. This total includes resource group fixed and shared memory. It also includes global shared memory used by the resource group.              |
| <code>memory_available</code>        | integer   |   | The unused fixed and shared memory for the resource group for the segment instance on the host.   |
| <code>memory_quota_used</code>       | integer   |   | The real-time fixed memory usage for the resource group for the segment instance on the host.   |
| <code>memory_quota_available</code>  | integer   |   | The fixed memory available to the resource group for the segment instance on the host.  |
| <code>memory_shared_used</code>      | integer   |   | The group shared memory used by the resource group for the segment instance on the host.  |
| <code>memory_shared_available</code> | integer   |   | The amount of group shared memory available for the segment instance on the host. Resource group global shared memory is not included in this total.  |

Parent topic: [System Catalogs Definitions](#)

## gp\_resqueue\_status

The `gp_toolkit.gp_resqueue_status` view allows administrators to see status and activity for a resource queue. It shows how many queries are waiting to run and how many queries are currently active in the system from a particular resource queue.

**Note:** The `gp_resqueue_status` view is valid only when resource queue-based resource management is active.

| column                     | type | references  | description   |
|----------------------------|------|---|---|
| <code>queueid</code>       | oid  | <code>gp_toolkit.gp_resqueue_queueid</code>       | The ID of the resource queue.   |
| <code>rsqname</code>       | name | <code>gp_toolkit.gp_resqueue_rsqname</code>       | The name of the resource queue.   |
| <code>rsqcountlimit</code> | real | <code>gp_toolkit.gp_resqueue_rsqcountlimit</code> | The active query threshold of the resource queue. A value of -1 means no limit. |
| <code>rsqcountvalue</code> | real | <code>gp_toolkit.gp_resqueue_rsqcountvalue</code> | The number of active query slots currently being used in the resource queue.    |
| <code>rsqcostlimit</code>  | real | <code>gp_toolkit.gp_resqueue_rsqcostlimit</code>  | The query cost threshold of the resource queue. A value of -1 means no limit.   |

| column                      | type    | references   | description  |
|-----------------------------|---------|--|--|
| <code>rsqcostvalue</code>   | real    | <code>gp_toolkit.gp_resqueue_rsqcostvalue</code>   | The total cost of all statements currently in the resource queue.                  |
| <code>rsqmemorylimit</code> | real    | <code>gp_toolkit.gp_resqueue_rsqmemorylimit</code> | The memory limit for the resource queue.   |
| <code>rsqmemoryvalue</code> | real    | <code>gp_toolkit.gp_resqueue_rsqmemoryvalue</code> | The total memory used by all statements currently in the resource queue.           |
| <code>rsqwaiters</code>     | integer | <code>gp_toolkit.gp_resqueue_rsqwaiter</code>      | The number of statements currently waiting in the resource queue.                  |
| <code>rsqholders</code>     | integer | <code>gp_toolkit.gp_resqueue_rsqholders</code>     | The number of statements currently running on the system from this resource queue. |

Parent topic: [System Catalogs Definitions](#)

## gp\_segment\_configuration

The `gp_segment_configuration` table contains information about mirroring and segment instance configuration.

| column                      | type     | references | description  |
|-----------------------------|----------|------------|--|
| <code>dbid</code>           | smallint |            | Unique identifier of a segment (or master) instance.   |
| <code>content</code>        | smallint |            | The content identifier for a segment instance. A primary segment instance and its corresponding mirror will always have the same content identifier.<br><br>For a segment the value is from 0 to $N-1$ , where $N$ is the number of primary segments in the system.<br><br>For the master, the value is always -1.   |
| <code>role</code>           | char     |            | The role that a segment is currently running as. Values are <code>p</code> (primary) or <code>m</code> (mirror).   |
| <code>preferred_role</code> | char     |            | The role that a segment was originally assigned at initialization time. Values are <code>p</code> (primary) or <code>m</code> (mirror).  |
| <code>mode</code>           | char     |            | The synchronization status of a segment instance with its mirror copy. Values are <code>s</code> (Synchronized) or <code>n</code> (Not In Sync).<br><br><b>Note:</b> This column always shows <code>n</code> for the master segment and <code>s</code> for the standby master segment, but these values do not describe the synchronization state for the master segment. Use <code>gp_stat_replication</code> to determine the synchronization state between the master and standby master. |
| <code>status</code>         | char     |            | The fault status of a segment instance. Values are <code>u</code> (up) or <code>d</code> (down).   |
| <code>port</code>           | integer  |            | The TCP port the database server listener process is using.  |
| <code>hostname</code>       | text     |            | The hostname of a segment host.  |
| <code>address</code>        | text     |            | The hostname used to access a particular segment instance on a segment host. This value may be the same as <code>hostname</code> on systems that do not have per-interface hostnames configured.   |

| column               | type | references | description                      |
|----------------------|------|------------|----------------------------------|
| <code>datadir</code> | text |            | Segment instance data directory. |

Parent topic: [System Catalogs Definitions](#)

## gp\_segment\_endpoints

The `gp_segment_endpoints` view lists the endpoints created in the QE for all active parallel retrieve cursors declared by the current session user. When the Greenplum Database superuser accesses this view, it returns a list of all endpoints on the QE created for all parallel retrieve cursors declared by all users.

Endpoints exist only for the duration of the transaction that defines the parallel retrieve cursor, or until the cursor is closed.

| name                       | type    | references | description  |
|----------------------------|---------|------------|--|
| <code>auth_token</code>    | text    |            | The authentication token for the retrieve session.   |
| <code>databaseid</code>    | oid     |            | The identifier of the database in which the parallel retrieve cursor was created.  |
| <code>senderpid</code>     | integer |            | The identifier of the process sending the query results.   |
| <code>receiverpid</code>   | integer |            | The process identifier of the retrieve session that is receiving the query results.  |
| <code>state</code>         | text    |            | The state of the endpoint; the valid states are:<br><br>READY: The endpoint is ready to be retrieved.<br><br>ATTACHED: The endpoint is attached to a retrieve connection.<br><br>RETRIEVING: A retrieve session is retrieving data from the endpoint at this moment.<br><br>FINISHED: The endpoint has been fully retrieved.<br><br>RELEASED: Due to an error, the endpoint has been released and the connection closed. |
| <code>gp_segment_id</code> | integer |            | The QE's endpoint <code>gp_segment_id</code> .   |
| <code>sessionid</code>     | integer |            | The identifier of the session in which the parallel retrieve cursor was created.   |
| <code>username</code>      | text    |            | The name of the session user (not the current user); <i>you must initiate the retrieve session as this user</i> .  |
| <code>endpointname</code>  | text    |            | The endpoint identifier; you provide this identifier to the <code>RETRIEVE</code> command.   |
| <code>cursorname</code>    | text    |            | The name of the parallel retrieve cursor.  |

Parent topic: [System Catalogs Definitions](#)

## gp\_session\_endpoints

The `gp_session_endpoints` view lists the endpoints created for all active parallel retrieve cursors declared by the current session user in the current session.

Endpoints exist only for the duration of the transaction that defines the parallel retrieve cursor, or until the cursor is closed.

| name                       | type        | references | description  |
|----------------------------|-------------|------------|--|
| <code>gp_segment_id</code> | integer     |            | The QE's endpoint <code>gp_segment_id</code> .   |
| <code>auth_token</code>    | text        |            | The authentication token for a retrieve session.   |
| <code>cursorname</code>    | text        |            | The name of the parallel retrieve cursor.  |
| <code>sessionid</code>     | integer     |            | The identifier of the session in which the parallel retrieve cursor was created.   |
| <code>hostname</code>      | varchar(64) |            | The name of the host from which to retrieve the data for the endpoint.   |
| <code>port</code>          | integer     |            | The port number from which to retrieve the data for the endpoint.  |
| <code>username</code>      | text        |            | The name of the session user (not the current user); <i>you must initiate the retrieve session as this user</i> .  |
| <code>state</code>         | text        |            | The state of the endpoint; the valid states are:<br><br>READY: The endpoint is ready to be retrieved.<br><br>ATTACHED: The endpoint is attached to a retrieve connection.<br><br>RETRIEVING: A retrieve session is retrieving data from the endpoint at this moment.<br><br>FINISHED: The endpoint has been fully retrieved.<br><br>RELEASED: Due to an error, the endpoint has been released and the connection closed. |
| <code>endpointname</code>  | text        |            | The endpoint identifier; you provide this identifier to the <code>RETRIEVE</code> command.   |

## gp\_stat\_replication

The `gp_stat_replication` view contains replication statistics of the `walsender` process that is used for Greenplum Database Write-Ahead Logging (WAL) replication when master or segment mirroring is enabled.

| column                     | type    | references | description  |
|----------------------------|---------|------------|--|
| <code>gp_segment_id</code> | integer |            | Unique identifier of a segment (or master) instance.                 |
| <code>pid</code>           | integer |            | Process ID of the <code>walsender</code> backend process.            |
| <code>usesysid</code>      | oid     |            | User system ID that runs the <code>walsender</code> backend process. |

| column                        | type      | references | description  |
|-------------------------------|-----------|------------|--|
| <code>username</code>         | name      |            | User name that runs the <code>walsender</code> backend process.  |
| <code>application_name</code> | text      |            | Client application name.   |
| <code>client_addr</code>      | inet      |            | Client IP address.   |
| <code>client_hostname</code>  | text      |            | Client host name.  |
| <code>client_port</code>      | integer   |            | Client port number.  |
| <code>backend_start</code>    | timestamp |            | Operation start timestamp.   |
| <code>backend_xmin</code>     | xid       |            | The current backend's <code>xmin</code> horizon.   |
| <code>state</code>            | text      |            | <code>walsender</code> state. The value can be:<br><br><code>startup</code><br><br><code>backup</code><br><br><code>catchup</code><br><br><code>streaming</code> |
| <code>sent_location</code>    | text      |            | <code>walsender</code> xlog record sent location.  |
| <code>write_location</code>   | text      |            | <code>walreceiver</code> xlog record write location.   |
| <code>flush_location</code>   | text      |            | <code>walreceiver</code> xlog record flush location.   |
| <code>replay_location</code>  | text      |            | Master standby or segment mirror xlog record replay location.  |
| <code>sync_priority</code>    | integer   |            | Priority. The value is 1.  |
| <code>sync_state</code>       | text      |            | <code>walsender</code> synchronization state. The value is <code>sync</code> .   |
| <code>sync_error</code>       | text      |            | <code>walsender</code> synchronization error. <code>none</code> if no error.   |

## gp\_transaction\_log

The `gp_transaction_log` view contains status information about transactions local to a particular segment. This view allows you to see the status of local transactions.

| column                   | type     | references                                    | description  |
|--------------------------|----------|---|--|
| <code>segment_id</code>  | smallint | <code>gp_segment_configuration.content</code> | The content id of the segment. The master is always -1 (no content). |
| <code>dbid</code>        | smallint | <code>gp_segment_configuration.dbid</code>    | The unique id of the segment instance.                               |
| <code>transaction</code> | xid      |   | The local transaction ID.  |
| <code>status</code>      | text     |   | The status of the local transaction (Committed or Aborted).          |

Parent topic: [System Catalogs Definitions](#)

## gp\_version\_at\_initdb

The `gp_version_at_initdb` table is populated on the master and each segment in the Greenplum Database system. It identifies the version of Greenplum Database used when the system was first initialized. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

| column                      | type    | references | description             |
|-----------------------------|---------|------------|-------------------------|
| <code>schemaversion</code>  | integer |            | Schema version number.  |
| <code>productversion</code> | text    |            | Product version number. |

Parent topic: [System Catalogs Definitions](#)

## pg\_aggregate

The `pg_aggregate` table stores information about aggregate functions. An aggregate function is a function that operates on a set of values (typically one column from each row that matches a query condition) and returns a single value computed from all these values. Typical aggregate functions are `sum`, `count`, and `max`. Each entry in `pg_aggregate` is an extension of an entry in `pg_proc`. The `pg_proc` entry carries the aggregate's name, input and output data types, and other information that is similar to ordinary functions.

| column                        | type    | references               | description  |
|-------------------------------|---------|--------------------------|--|
| <code>aggfnoid</code>         | regproc | <code>pg_proc.oid</code> | OID of the aggregate function  |
| <code>aggkind</code>          | char    |                          | Aggregate kind: <code>n</code> for <i>normal</i> aggregates, <code>o</code> for <i>ordered-set</i> aggregates, or <code>h</code> for <i>hypothetical-set</i> aggregates  |
| <code>aggnumdirectargs</code> | int2    |                          | Number of direct (non-aggregated) arguments of an ordered-set or hypothetical-set aggregate, counting a variadic array as one argument. If equal to <code>pronargs</code> , the aggregate must be variadic and the variadic array describes the aggregated arguments as well as the final direct arguments. Always zero for normal aggregates. |
| <code>aggtransfn</code>       | regproc | <code>pg_proc.oid</code> | Transition function OID  |
| <code>aggfinalfn</code>       | regproc | <code>pg_proc.oid</code> | Final function OID (zero if none)  |
| <code>aggcombinefn</code>     | regproc | <code>pg_proc.oid</code> | Combine function OID (zero if none)  |
| <code>aggserialfn</code>      | regproc | <code>pg_proc.oid</code> | OID of the serialization function to convert transtype to <code>bytea</code> (zero if none)  |
| <code>aggdeserialfn</code>    | regproc | <code>pg_proc.oid</code> | OID of the deserialization function to convert <code>bytea</code> to transtype (zero if none)  |
| <code>aggmtransfn</code>      | regproc | <code>pg_proc.oid</code> | Forward transition function OID for moving-aggregate mode (zero if none)   |
| <code>aggminvtransfn</code>   | regproc | <code>pg_proc.oid</code> | Inverse transition function OID for moving-aggregate mode (zero if none)   |

| column                       | type    | references                   | description  |
|------------------------------|---------|------------------------------|--|
| <code>aggmfinalfn</code>     | regproc | <code>pg_proc.oid</code>     | Final function OID for moving-aggregate mode (zero if none)  |
| <code>aggfinalextra</code>   | bool    |                              | True to pass extra dummy arguments to <code>aggfinalfn</code>  |
| <code>aggmfinallextra</code> | bool    |                              | True to pass extra dummy arguments to <code>aggmfinalfn</code>   |
| <code>aggsortop</code>       | oid     | <code>pg_operator.oid</code> | Associated sort operator OID (zero if none)  |
| <code>aggtranstype</code>    | oid     | <code>pg_type.oid</code>     | Data type of the aggregate function's internal transition (state) data   |
| <code>aggtransspace</code>   | int4    |                              | Approximate average size (in bytes) of the transition state data, or zero to use a default estimate  |
| <code>aggmtranstype</code>   | oid     | <code>pg_type.oid</code>     | Data type of the aggregate function's internal transition (state) data for moving-aggregate mode (zero if none)  |
| <code>aggmtranospace</code>  | int4    |                              | Approximate average size (in bytes) of the transition state data for moving-aggregate mode, or zero to use a default estimate  |
| <code>agginitval</code>      | text    |                              | The initial value of the transition state. This is a text field containing the initial value in its external string representation. If this field is NULL, the transition state value starts out NULL.                           |
| <code>aggminival</code>      | text    |                              | The initial value of the transition state for moving-aggregate mode. This is a text field containing the initial value in its external string representation. If this field is NULL, the transition state value starts out NULL. |

## pg\_am

The `pg_am` table stores information about index access methods. There is one row for each index access method supported by the system.

| column                      | type    | references | description   |
|-----------------------------|---------|------------|---|
| <code>oid</code>            | oid     |            | Row identifier (hidden attribute; must be explicitly selected)  |
| <code>amname</code>         | name    |            | Name of the access method   |
| <code>amstrategies</code>   | int2    |            | Number of operator strategies for this access method, or zero if the access method does not have a fixed set of operator strategies |
| <code>amsupport</code>      | int2    |            | Number of support routines for this access method   |
| <code>amcanorder</code>     | boolean |            | Does the access method support ordered scans sorted by the indexed column's value?  |
| <code>amcanorderbyop</code> | boolean |            | Does the access method support ordered scans sorted by the result of an operator on the indexed column?                             |
| <code>amcanbackward</code>  | boolean |            | Does the access method support backward scanning?   |

| column                       | type    | references               | description  |
|------------------------------|---------|--------------------------|--|
| <code>amcanunique</code>     | boolean |                          | Does the access method support unique indexes?   |
| <code>amcanmulticol</code>   | boolean |                          | Does the access method support multicolumn indexes?                                      |
| <code>amoptionalkey</code>   | boolean |                          | Does the access method support a scan without any constraint for the first index column? |
| <code>amsearcharray</code>   | boolean |                          | Does the access method support <code>ScalarArrayOpExpr</code> searches?                  |
| <code>amsearchnulls</code>   | boolean |                          | Does the access method support <code>IS NULL/NOT NULL</code> searches?                   |
| <code>amstorage</code>       | boolean |                          | Can index storage data type differ from column data type?                                |
| <code>amclusterable</code>   | boolean |                          | Can an index of this type be clustered on?   |
| <code>ampredlocks</code>     | boolean |                          | Does an index of this type manage fine-grained predicate locks?                          |
| <code>amkeytype</code>       | oid     | <code>pg_type.oid</code> | Type of data stored in index, or zero if not a fixed type                                |
| <code>amininsert</code>      | regproc | <code>pg_proc.oid</code> | "Insert this tuple" function   |
| <code>ambeginscan</code>     | regproc | <code>pg_proc.oid</code> | "Prepare for index scan" function  |
| <code>amgettupletuple</code> | regproc | <code>pg_proc.oid</code> | "Next valid tuple" function, or zero if none   |
| <code>amgetbitmap</code>     | regproc | <code>pg_proc.oid</code> | "Fetch all tuples" function, or zero if none   |
| <code>amrescan</code>        | regproc | <code>pg_proc.oid</code> | "(Re)start index scan" function  |
| <code>amendscan</code>       | regproc | <code>pg_proc.oid</code> | "Clean up after index scan" function   |
| <code>ammarkpos</code>       | regproc | <code>pg_proc.oid</code> | "Mark current scan position" function  |
| <code>amrestrpos</code>      | regproc | <code>pg_proc.oid</code> | "Restore marked scan position" function  |
| <code>ambuild</code>         | regproc | <code>pg_proc.oid</code> | "Build new index" function   |
| <code>ambuildempty</code>    | regproc | <code>pg_proc.oid</code> | "Build empty index" function   |
| <code>ambulkdelete</code>    | regproc | <code>pg_proc.oid</code> | Bulk-delete function   |

| column                       | type    | references  | description  |
|------------------------------|---------|-------------|--|
| <code>amvacuumcleanup</code> | regproc | pg_proc.oid | Post- <code>VACUUM</code> cleanup function                                 |
| <code>amcanreturn</code>     | regproc | pg_proc.oid | Function to check whether index supports index-only scans, or zero if none |
| <code>amcostestimate</code>  | regproc | pg_proc.oid | Function to estimate cost of an index scan                                 |
| <code>amoptions</code>       | regproc | pg_proc.oid | Function to parse and validate <code>reloptions</code> for an index        |

Parent topic: [System Catalogs Definitions](#)

## pg\_amop

The `pg_amop` table stores information about operators associated with index access method operator classes. There is one row for each operator that is a member of an operator class.

An entry's `amopmethod` must match the `opfmethod` of its containing operator family (including `amopmethod` here is an intentional denormalization of the catalog structure for performance reasons). Also, `amoplefttype` and `amoprightrightype` must match the `oprleft` and `oprright` fields of the referenced `pg_operator` entry.

| column                         | type | references      | description   |
|--------------------------------|------|-----------------|---|
| <code>oid</code>               | oid  |                 | Row identifier (hidden attribute; must be explicitly selected)  |
| <code>amopfamily</code>        | oid  | pg_opfamily.oid | The operator family that this entry is for  |
| <code>amoplefttype</code>      | oid  | pg_type.oid     | Left-hand input data type of operator   |
| <code>amoprightrightype</code> | oid  | pg_type.oid     | Right-hand input data type of operator  |
| <code>amopstrategy</code>      | int2 |                 | Operator strategy number  |
| <code>amoppurpose</code>       | char |                 | Operator purpose, either <code>s</code> for search or <code>o</code> for ordering                                 |
| <code>amopopr</code>           | oid  | pg_operator.oid | OID of the operator   |
| <code>amopmethod</code>        | oid  | pg_am.oid       | Index access method for the operator family   |
| <code>amopsortfamily</code>    | oid  | pg_opfamily.oid | If an ordering operator, the B-tree operator family that this entry sorts according to; zero if a search operator |

Parent topic: [System Catalogs Definitions](#)

## pg\_amproc

The `pg_amproc` table stores information about support procedures associated with index access method operator classes. There is one row for each support procedure belonging to an operator

class.

| column                       | type    | references                   | description  |
|------------------------------|---------|------------------------------|--|
| <code>oid</code>             | oid     |                              | Row identifier (hidden attribute; must be explicitly selected) |
| <code>amprocfamily</code>    | oid     | <code>pg_opfamily.oid</code> | The operator family this entry is for                          |
| <code>amproclefttype</code>  | oid     | <code>pg_type.oid</code>     | Left-hand input data type of associated operator               |
| <code>amprocrighttype</code> | oid     | <code>pg_type.oid</code>     | Right-hand input data type of associated operator              |
| <code>amprocnum</code>       | int2    |                              | Support procedure number                                       |
| <code>amproc</code>          | regproc | <code>pg_proc.oid</code>     | OID of the procedure   |

Parent topic: [System Catalogs Definitions](#)

## pg\_appendonly

The `pg_appendonly` table contains information about the storage options and other characteristics of append-optimized tables.

| column                        | type     | references | description  |
|-------------------------------|----------|------------|--|
| <code>relid</code>            | oid      |            | The table object identifier (OID) of the compressed table.   |
| <code>blocksize</code>        | integer  |            | Block size used for compression of append-optimized tables. Valid values are 8K - 2M. Default is 32K.  |
| <code>safefswritesize</code>  | integer  |            | Minimum size for safe write operations to append-optimized tables in a non-mature file system. Commonly set to a multiple of the extent size of the file system; for example, Linux ext3 is 4096 bytes, so a value of 32768 is commonly used.  |
| <code>compressionlevel</code> | smallint |            | The compression level, with compression ratio increasing from 1 to 19. When <code>quicklz<sup>1</sup></code> is specified for <code>compresstype</code> , valid values are 1 or 3. With <code>zlib</code> specified, valid values are 1-9. When <code>zstd</code> is specified, valid values are 1-19.   |
| <code>majorversion</code>     | smallint |            | The major version number of the <code>pg_appendonly</code> table.  |
| <code>minorversion</code>     | smallint |            | The minor version number of the <code>pg_appendonly</code> table.  |
| <code>checksum</code>         | boolean  |            | A checksum value that is stored to compare the state of a block of data at compression time and at scan time to ensure data integrity.   |
| <code>compresstype</code>     | text     |            | Type of compression used to compress append-optimized tables. Valid values are: <ul style="list-style-type: none"> <li>- <code>none</code> (no compression)</li> <li>- <code>rle_type</code> (run-length encoding compression)</li> <li>- <code>zlib</code> (gzip compression)</li> <li>- <code>zstd</code> (Zstandard compression)</li> <li>- <code>quicklz<sup>1</sup></code></li> </ul> |

| column                    | type    | references | description  |
|---------------------------|---------|------------|--|
| <code>columnstore</code>  | boolean |            | 1 for column-oriented storage, 0 for row-oriented storage. |
| <code>segrelid</code>     | oid     |            | Table on-disk segment file id.                             |
| <code>segidxid</code>     | oid     |            | Index on-disk segment file id.                             |
| <code>blkdirrelid</code>  | oid     |            | Block used for on-disk column-oriented table file.         |
| <code>blkdiridxid</code>  | oid     |            | Block used for on-disk column-oriented index file.         |
| <code>visimaprelid</code> | oid     |            | Visibility map for the table.                              |
| <code>visimapidxid</code> | oid     |            | B-tree index on the visibility map.                        |

**Note:**<sup>1</sup>QuickLZ compression is available only in the commercial release of Tanzu Greenplum.

**Parent topic:** [System Catalogs Definitions](#)

## pg\_attrdef

The `pg_attrdef` table stores column default values. The main information about columns is stored in `pg_attribute`. Only columns that explicitly specify a default value (when the table is created or the column is added) will have an entry here.

| column               | type | references                       | description   |
|----------------------|------|----------------------------------|---|
| <code>adrelid</code> | oid  | <code>pg_class.oid</code>        | The table this column belongs to  |
| <code>adnum</code>   | int2 | <code>pg_attribute.attnum</code> | The number of the column  |
| <code>adbin</code>   | text |                                  | The internal representation of the column default value   |
| <code>adsrc</code>   | text |                                  | A human-readable representation of the default value. This field is historical, and is best not used. |

**Parent topic:** [System Catalogs Definitions](#)

## pg\_attribute

The `pg_attribute` table stores information about table columns. There will be exactly one `pg_attribute` row for every column in every table in the database. (There will also be attribute entries for indexes, and all objects that have `pg_class` entries.) The term attribute is equivalent to column.

| column                | type | references                | description                       |
|-----------------------|------|---------------------------|-----------------------------------|
| <code>attrelid</code> | oid  | <code>pg_class.oid</code> | The table this column belongs to. |

| column                     | type      | references                    | description  |
|----------------------------|-----------|-------------------------------|--|
| <code>attname</code>       | name      |                               | The column name.   |
| <code>atttypid</code>      | oid       | <code>pg_type.oid</code>      | The data type of this column.  |
| <code>attstattarget</code> | int4      |                               | Controls the level of detail of statistics accumulated for this column by <code>ANALYZE</code> . A zero value indicates that no statistics should be collected. A negative value says to use the system default statistics target. The exact meaning of positive values is data type-dependent. For scalar data types, it is both the target number of "most common values" to collect, and the target number of histogram bins to create. |
| <code>attlen</code>        | int2      |                               | A copy of <code>pg_type.typelen</code> of this column's type.  |
| <code>attnum</code>        | int2      |                               | The number of the column. Ordinary columns are numbered from 1 up. System columns, such as <code>oid</code> , have (arbitrary) negative numbers.   |
| <code>attndims</code>      | int4      |                               | Number of dimensions, if the column is an array type; otherwise 0. (Presently, the number of dimensions of an array is not enforced, so any nonzero value effectively means it is an array.)   |
| <code>attcacheoff</code>   | int4      |                               | Always -1 in storage, but when loaded into a row descriptor in memory this may be updated to cache the offset of the attribute within the row.   |
| <code>atttypmod</code>     | int4      |                               | Records type-specific data supplied at table creation time (for example, the maximum length of a <code>varchar</code> column). It is passed to type-specific input functions and length coercion functions. The value will generally be -1 for types that do not need it.  |
| <code>attbyval</code>      | boolean   |                               | A copy of <code>pg_type.typbyval</code> of this column's type.   |
| <code>attstorage</code>    | char      |                               | Normally a copy of <code>pg_type.typstorage</code> of this column's type. For TOAST-able data types, this can be altered after column creation to control storage policy.  |
| <code>attalign</code>      | char      |                               | A copy of <code>pg_type.typalign</code> of this column's type.   |
| <code>attnotnull</code>    | boolean   |                               | This represents a not-null constraint. It is possible to change this column to activate or deactivate the constraint.  |
| <code>atthasdef</code>     | boolean   |                               | This column has a default value, in which case there will be a corresponding entry in the <code>pg_attrdef</code> catalog that actually defines the value.   |
| <code>attisdropped</code>  | boolean   |                               | This column has been dropped and is no longer valid. A dropped column is still physically present in the table, but is ignored by the parser and so cannot be accessed via SQL.  |
| <code>attislocal</code>    | boolean   |                               | This column is defined locally in the relation. Note that a column may be locally defined and inherited simultaneously.  |
| <code>attinhcount</code>   | int4      |                               | The number of direct ancestors this column has. A column with a nonzero number of ancestors cannot be dropped nor renamed.   |
| <code>attcollation</code>  | oid       | <code>pg_collation.oid</code> | The defined collation of the column, or zero if the is not of a collatable data type.  |
| <code>attacl</code>        | aclitem[] |                               | Column-level access privileges, if any have been granted specifically on this column.  |

| column                    | type   | references | description   |
|---------------------------|--------|------------|---|
| <code>attpoptions</code>  | text[] |            | Attribute-level options, as "keyword=value" strings.                      |
| <code>attdwoptions</code> | text[] |            | Attribute-level foreign data wrapper options, as "keyword=value" strings. |

Parent topic: [System Catalogs Definitions](#)

## pg\_attribute\_encoding

The `pg_attribute_encoding` system catalog table contains column storage information.

| column                   | type     | modifiers | storage  | description                                       |
|--------------------------|----------|-----------|----------|---|
| <code>attrelid</code>    | oid      | not null  | plain    | Foreign key to <code>pg_attribute.attrelid</code> |
| <code>attnum</code>      | smallint | not null  | plain    | Foreign key to <code>pg_attribute.attnum</code>   |
| <code>attpoptions</code> | text [ ] |           | extended | The options                                       |

Parent topic: [System Catalogs Definitions](#)

## pg\_auth\_members

The `pg_auth_members` system catalog table shows the membership relations between roles. Any non-circular set of relationships is allowed. Because roles are system-wide, `pg_auth_members` is shared across all databases of a Greenplum Database system.

| column                    | type    | references                 | description  |
|---------------------------|---------|----------------------------|--|
| <code>roleid</code>       | oid     | <code>pg_authid.oid</code> | ID of the parent-level (group) role                |
| <code>member</code>       | oid     | <code>pg_authid.oid</code> | ID of a member role                                |
| <code>grantor</code>      | oid     | <code>pg_authid.oid</code> | ID of the role that granted this membership        |
| <code>admin_option</code> | boolean |                            | True if role member may grant membership to others |

Parent topic: [System Catalogs Definitions](#)

## pg\_authid

The `pg_authid` table contains information about database authorization identifiers (roles). A role subsumes the concepts of users and groups. A user is a role with the `rolcanlogin` flag set. Any role (with or without `rolcanlogin`) may have other roles as members. See [pg\\_auth\\_members](#).

Since this catalog contains passwords, it must not be publicly readable. [pg\\_roles](#) is a publicly readable view on `pg_authid` that blanks out the password field.

Because user identities are system-wide, `pg_authid` is shared across all databases in a Greenplum Database system: there is only one copy of `pg_authid` per system, not one per database.

| column                                  | type       | references | description   |
|---|------------|------------|---|
| <code>oid</code>                        | oid        |            | Row identifier (hidden attribute; must be explicitly selected)  |
| <code>rolname</code>                    | name       |            | Role name   |
| <code>rolsuper</code>                   | boolean    |            | Role has superuser privileges   |
| <code>rolinherit</code>                 | boolean    |            | Role automatically inherits privileges of roles it is a member of   |
| <code>rolcreaterole</code>              | boolean    |            | Role may create more roles  |
| <code>rolcreatedb</code>                | boolean    |            | Role may create databases   |
| <code>rolcatupdate</code>               | boolean    |            | Role may update system catalogs directly. (Even a superuser may not do this unless this column is true)   |
| <code>rolcanlogin</code>                | boolean    |            | Role may log in. That is, this role can be given as the initial session authorization identifier  |
| <code>rolreplication</code>             | boolean    |            | Role is a replication role. That is, this role can initiate streaming replication and set/unset the system backup mode using <code>pg_start_backup</code> and <code>pg_stop_backup</code> . |
| <code>rolconnlimit</code>               | int4       |            | For roles that can log in, this sets maximum number of concurrent connections this role can make. <code>-1</code> means no limit  |
| <code>rolpassword</code>                | text       |            | Password (possibly encrypted); NULL if none. The format depends on the form of encryption used. <sup>1</sup>  |
| <code>rolvaliduntil</code>              | timestampz |            | Password expiry time (only used for password authentication); NULL if no expiration   |
| <code>rolresqueue</code>                | oid        |            | Object ID of the associated resource queue ID in <code>pg_resqueue</code>   |
| <code>rolcreateexternalgpfd</code>      | boolean    |            | Privilege to create read external tables with the <code>gpfdist</code> or <code>gpfdists</code> protocol  |
| <code>rolcreateexternalhttp</code>      | boolean    |            | Privilege to create read external tables with the <code>http</code> protocol  |
| <code>rolcreateexternalgpfdwrite</code> | boolean    |            | Privilege to create write external tables with the <code>gpfdist</code> or <code>gpfdists</code> protocol   |
| <code>rolresgroup</code>                | oid        |            | Object ID of the associated resource group ID in <code>pg_resgroup</code>   |

Notes<sup>1</sup>:

- For an MD5-encrypted password, `rolpassword` column will begin with the string `md5` followed by a 32-character hexadecimal MD5 hash. The MD5 hash will be of the user's password concatenated to their user name. For example, if user `joe` has password `xyzyz` Greenplum Database will store the md5 hash of `xyzyzjoe`.
- If the password is encrypted with SCRAM-SHA-256, the `rolpassword` column has the format:

```
SCRAM-SHA-256${iteration count}:<salt>${StoredKey}:<ServerKey>
```

where `<salt>`, `<StoredKey>` and `<ServerKey>` are in Base64-encoded format. This format is the same as that specified by RFC 5803.

- If the password is encrypted with SHA-256, the `rolpassword` column is a 64-byte hexadecimal string prefixed with the characters `sha256`.

A password that does not follow any of these formats is assumed to be unencrypted.

Parent topic: [System Catalogs Definitions](#)

## pg\_available\_extension\_versions

The `pg_available_extension_versions` view lists the specific extension versions that are available for installation. The `pg_extension` system catalog table shows the extensions currently installed.

The view is read only.

| column                   | type    | description   |
|--------------------------|---------|---|
| <code>name</code>        | name    | Extension name.   |
| <code>version</code>     | text    | Version name.   |
| <code>installed</code>   | boolean | <code>True</code> if this version of this extension is currently installed, <code>False</code> otherwise.             |
| <code>superuser</code>   | boolean | <code>True</code> if only superusers are allowed to install the extension, <code>False</code> otherwise.              |
| <code>relocatable</code> | boolean | <code>True</code> if extension can be relocated to another schema, <code>False</code> otherwise.                      |
| <code>schema</code>      | name    | Name of the schema that the extension must be installed into, or <code>NULL</code> if partially or fully relocatable. |
| <code>requires</code>    | name[]  | Names of prerequisite extensions, or <code>NULL</code> if none  |
| <code>comment</code>     | text    | Comment string from the extension control file.   |

Parent topic: [System Catalogs Definitions](#)

## pg\_available\_extensions

The `pg_available_extensions` view lists the extensions that are available for installation. The `pg_extension` system catalog table shows the extensions currently installed.

The view is read only.

| column                         | type | description  |
|--------------------------------|------|--|
| <code>name</code>              | name | Extension name.  |
| <code>default_version</code>   | text | Name of default version, or <code>NULL</code> if none is specified.                  |
| <code>installed_version</code> | text | Currently installed version of the extension, or <code>NULL</code> if not installed. |

| column               | type | description                                     |
|----------------------|------|---|
| <code>comment</code> | text | Comment string from the extension control file. |

Parent topic: [System Catalogs Definitions](#)

## pg\_cast

The `pg_cast` table stores data type conversion paths, both built-in paths and those defined with `CREATE CAST`.

Note that `pg_cast` does not represent every type conversion known to the system, only those that cannot be deduced from some generic rule. For example, casting between a domain and its base type is not explicitly represented in `pg_cast`. Another important exception is that "automatic I/O conversion casts", those performed using a data type's own I/O functions to convert to or from `text` or other string types, are not explicitly represented in `pg_cast`.

The cast functions listed in `pg_cast` must always take the cast source type as their first argument type, and return the cast destination type as their result type. A cast function can have up to three arguments. The second argument, if present, must be type `integer`; it receives the type modifier associated with the destination type, or `-1` if there is none. The third argument, if present, must be type `boolean`; it receives `true` if the cast is an explicit cast, `false` otherwise.

It is legitimate to create a `pg_cast` entry in which the source and target types are the same, if the associated function takes more than one argument. Such entries represent 'length coercion functions' that coerce values of the type to be legal for a particular type modifier value.

When a `pg_cast` entry has different source and target types and a function that takes more than one argument, the entry converts from one type to another and applies a length coercion in a single step. When no such entry is available, coercion to a type that uses a type modifier involves two steps, one to convert between data types and a second to apply the modifier.

| column                        | type | references      | description   |
|-------------------------------|------|-----------------|---|
| <code>castsour<br/>ce</code>  | oid  | pg_type.o<br>id | OID of the source data type.  |
| <code>casttarg<br/>et</code>  | oid  | pg_type.o<br>id | OID of the target data type.  |
| <code>castfunc</code>         | oid  | pg_proc.o<br>id | The OID of the function to use to perform this cast. Zero is stored if the cast method does not require a function.   |
| <code>castcont<br/>ext</code> | char |                 | Indicates what contexts the cast may be invoked in. <code>e</code> means only as an explicit cast (using <code>CAST</code> or <code>::</code> syntax). <code>a</code> means implicitly in assignment to a target column, as well as explicitly. <code>i</code> means implicitly in expressions, as well as the other cases*.* |
| <code>castmeth<br/>od</code>  | char |                 | Indicates how the cast is performed:<br><br><code>f</code> - The function identified in the <code>castfunc</code> field is used.<br><br><code>i</code> - The input/output functions are used.<br><br><code>b</code> - The types are binary-coercible, and no conversion is required.  |

Parent topic: [System Catalogs Definitions](#)

## pg\_class

The system catalog table `pg_class` catalogs tables and most everything else that has columns or is otherwise similar to a table (also known as *relations*). This includes indexes (see also `pg_index`), sequences, views, composite types, and TOAST tables. Not all columns are meaningful for all relation types.

| column                      | type    | references                     | description  |
|-----------------------------|---------|--------------------------------|--|
| <code>relname</code>        | name    |                                | Name of the table, index, view, etc.   |
| <code>relnamespace</code>   | oid     | <code>pg_namespace.oid</code>  | The OID of the namespace (schema) that contains this relation  |
| <code>reltype</code>        | oid     | <code>pg_type.oid</code>       | The OID of the data type that corresponds to this table's row type, if any (zero for indexes, which have no <code>pg_type</code> entry)  |
| <code>reltoastrelid</code>  | oid     | <code>pg_type.oid</code>       | The OID of an entry in <code>pg_type</code> for an underlying composite type.  |
| <code>relowner</code>       | oid     | <code>pg_authid.oid</code>     | Owner of the relation  |
| <code>relam</code>          | oid     | <code>pg_am.oid</code>         | If this is an index, the access method used (B-tree, Bitmap, hash, etc.)   |
| <code>relfilenode</code>    | oid     |                                | Name of the on-disk file of this relation; 0 if none.  |
| <code>reltablespace</code>  | oid     | <code>pg_tablespace.oid</code> | The tablespace in which this relation is stored. If zero, the database's default tablespace is implied. (Not meaningful if the relation has no on-disk file.)  |
| <code>relpages</code>       | int4    |                                | Size of the on-disk representation of this table in pages (of 32K each). This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands.   |
| <code>reltuples</code>      | float4  |                                | Number of rows in the table. This is only an estimate used by the planner. It is updated by <code>VACUUM</code> , <code>ANALYZE</code> , and a few DDL commands.   |
| <code>relallvisible</code>  | int32   |                                | Number of all-visible blocks (this value may not be up-to-date).   |
| <code>reltoastrelid</code>  | oid     | <code>pg_class.oid</code>      | OID of the TOAST table associated with this table, 0 if none. The TOAST table stores large attributes "out of line" in a secondary table.  |
| <code>relhasindex</code>    | boolean |                                | True if this is a table and it has (or recently had) any indexes. This is set by <code>CREATE INDEX</code> , but not cleared immediately by <code>DROP INDEX</code> . <code>VACUUM</code> will clear if it finds the table has no indexes.   |
| <code>relisshared</code>    | boolean |                                | True if this table is shared across all databases in the system. Only certain system catalog tables are shared.  |
| <code>relpersistence</code> | char    |                                | The type of object persistence: <code>p</code> = heap or append-optimized table, <code>u</code> = unlogged temporary table, <code>t</code> = temporary table.  |
| <code>relkind</code>        | char    |                                | The type of object<br><br><code>r</code> = heap or append-optimized table, <code>i</code> = index, <code>s</code> = sequence, <code>t</code> = TOAST value, <code>v</code> = view, <code>c</code> = composite type, <code>f</code> = foreign table, <code>u</code> = uncatalogued temporary heap table, <code>o</code> = internal append-optimized segment files and EOFs, <code>b</code> = append-only block directory, <code>M</code> = append-only visibility map |

| column                       | type      | references | description   |
|------------------------------|-----------|------------|---|
| <code>relstorage</code>      | char      |            | The storage mode of a table<br><br>a= append-optimized, c= column-oriented, h = heap, v = virtual, x= external table.   |
| <code>relnatts</code>        | int2      |            | Number of user columns in the relation (system columns not counted). There must be this many corresponding entries in <code>pg_attribute</code> .   |
| <code>relchecks</code>       | int2      |            | Number of check constraints on the table.   |
| <code>relhasoids</code>      | boolean   |            | True if an OID is generated for each row of the relation.   |
| <code>relhasprimary</code>   | boolean   |            | True if the table has (or once had) a primary key.  |
| <code>relhasrules</code>     | boolean   |            | True if table has rules.  |
| <code>relhastriggers</code>  | boolean   |            | True if table has (or once had) triggers.   |
| <code>relhassubclass</code>  | boolean   |            | True if table has (or once had) any inheritance children.   |
| <code>relispopulated</code>  | boolean   |            | True if relation is populated (this is true for all relations other than some materialized views).  |
| <code>relreplicaident</code> | char      |            | Columns used to form "replica identity" for rows: d = default (primary key, if any), n = nothing, f = all columns i = index with <code>indisreplident</code> set, or default  |
| <code>relfrozenxid</code>    | xid       |            | All transaction IDs before this one have been replaced with a permanent (frozen) transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent transaction ID wraparound or to allow <code>pg_xact</code> to be shrunk.<br><br>The value is 0 ( <code>InvalidTransactionId</code> ) if the relation is not a table or if the table does not require vacuuming to prevent transaction ID wraparound. The table still might require vacuuming to reclaim disk space. |
| <code>relminmxid</code>      | xid       |            | All multixact IDs before this one have been replaced by a transaction ID in this table. This is used to track whether the table needs to be vacuumed in order to prevent multixact ID wraparound or to allow <code>pg_multixact</code> to be shrunk. Zero ( <code>InvalidMultiXactId</code> ) if the relation is not a table.   |
| <code>relacl</code>          | aclitem[] |            | Access privileges assigned by <code>GRANT</code> and <code>REVOKE</code> .  |
| <code>reloptions</code>      | text[]    |            | Access-method-specific options, as "keyword=value" strings.   |

## pg\_compression

The `pg_compression` system catalog table describes the compression methods available.

| column                        | type    | modifiers | storage | description                       |
|-------------------------------|---------|-----------|---------|-----------------------------------|
| <code>compname</code>         | name    | not null  | plain   | Name of the compression           |
| <code>compconstructor</code>  | regproc | not null  | plain   | Name of compression constructor   |
| <code>compdestructor</code>   | regproc | not null  | plain   | Name of compression destructor    |
| <code>compcompressor</code>   | regproc | not null  | plain   | Name of the compressor            |
| <code>compdecompressor</code> | regproc | not null  | plain   | Name of the decompressor          |
| <code>compvalidator</code>    | regproc | not null  | plain   | Name of the compression validator |
| <code>compowner</code>        | oid     | not null  | plain   | oid from <code>pg_authid</code>   |

Parent topic: [System Catalogs Definitions](#)

## pg\_constraint

The `pg_constraint` system catalog table stores check, primary key, unique, and foreign key constraints on tables. Column constraints are not treated specially. Every column constraint is equivalent to some table constraint. Not-null constraints are represented in the `pg_attribute` catalog table. Check constraints on domains are stored here, too.

| column                    | type    | references                    | description  |
|---------------------------|---------|-------------------------------|--|
| <code>conname</code>      | name    |                               | Constraint name (not necessarily unique!)  |
| <code>connamespace</code> | oid     | <code>pg_namespace.oid</code> | The OID of the namespace (schema) that contains this constraint.   |
| <code>contype</code>      | char    |                               | <code>c</code> = check constraint, <code>f</code> = foreign key constraint, <code>p</code> = primary key constraint, <code>u</code> = unique constraint. |
| <code>condeferable</code> | boolean |                               | Is the constraint deferrable?  |
| <code>condeferred</code>  | boolean |                               | Is the constraint deferred by default?   |
| <code>convalidated</code> | boolean |                               | Has the constraint been validated? Currently, can only be false for foreign keys   |
| <code>conrelid</code>     | oid     | <code>pg_class.oid</code>     | The table this constraint is on; 0 if not a table constraint.  |
| <code>contypid</code>     | oid     | <code>pg_type.oid</code>      | The domain this constraint is on; 0 if not a domain constraint.  |
| <code>conindid</code>     | oid     | <code>pg_class.oid</code>     | The index supporting this constraint, if it's a unique, primary key, foreign key, or exclusion constraint; else 0  |
| <code>confrelid</code>    | oid     | <code>pg_class.oid</code>     | If a foreign key, the referenced table; else 0.  |
| <code>confupdtype</code>  | char    |                               | Foreign key update action code.  |
| <code>confdeltype</code>  | char    |                               | Foreign key deletion action code.  |

| column                          | type    | references                            | description  |
|---------------------------------|---------|---------------------------------------|--|
| <code>confmatc<br/>htype</code> | char    |                                       | Foreign key match type.  |
| <code>conisloc<br/>al</code>    | boolean |                                       | This constraint is defined locally for the relation. Note that a constraint can be locally defined and inherited simultaneously.   |
| <code>coninhco<br/>unt</code>   | int4    |                                       | The number of direct inheritance ancestors this constraint has. A constraint with a nonzero number of ancestors cannot be dropped nor renamed.   |
| <code>conkey</code>             | int2[]  | <code>pg_attribute<br/>.attnum</code> | If a table constraint, list of columns which the constraint constrains.  |
| <code>confkey</code>            | int2[]  | <code>pg_attribute<br/>.attnum</code> | If a foreign key, list of the referenced columns.  |
| <code>confeqo<br/>p</code>      | oid[]   | <code>pg_operator<br/>.oid</code>     | If a foreign key, list of the equality operators for PK = FK comparisons.  |
| <code>confpeqo<br/>p</code>     | oid[]   | <code>pg_operator<br/>.oid</code>     | If a foreign key, list of the equality operators for PK = PK comparisons.  |
| <code>conffeqo<br/>p</code>     | oid[]   | <code>pg_operator<br/>.oid</code>     | If a foreign key, list of the equality operators for PK = PK comparisons.  |
| <code>conexclo<br/>p</code>     | oid[]   | <code>pg_operator<br/>.oid</code>     | If an exclusion constraint, list of the per-column exclusion operators.  |
| <code>conbin</code>             | text    |                                       | If a check constraint, an internal representation of the expression.   |
| <code>consrc</code>             | text    |                                       | If a check constraint, a human-readable representation of the expression. This is not updated when referenced objects change; for example, it won't track renaming of columns. Rather than relying on this field, it is best to use <code>pg_get_constraintdef()</code> to extract the definition of a check constraint. |

## pg\_conversion

The `pg_conversion` system catalog table describes the available encoding conversion procedures as defined by `CREATE CONVERSION`.

| column                      | type    | references                    | description  |
|-----------------------------|---------|-------------------------------|--|
| <code>conname</code>        | name    |                               | Conversion name (unique within a namespace).                     |
| <code>connamespace</code>   | oid     | <code>pg_namespace.oid</code> | The OID of the namespace (schema) that contains this conversion. |
| <code>conowner</code>       | oid     | <code>pg_authid.oid</code>    | Owner of the conversion.   |
| <code>conforencoding</code> | int4    |                               | Source encoding ID.  |
| <code>contoencoding</code>  | int4    |                               | Destination encoding ID.   |
| <code>conproc</code>        | regproc | <code>pg_proc.oid</code>      | Conversion procedure.  |
| <code>condefault</code>     | boolean |                               | True if this is the default conversion.                          |

Parent topic: [System Catalogs Definitions](#)

## pg\_cursors

The `pg_cursors` view lists the currently available cursors. Cursors can be defined in one of the following ways:

- via the DECLARE SQL statement
- via the Bind message in the frontend/backend protocol
- via the Server Programming Interface (SPI)

**Note:** Greenplum Database does not support the definition, or access of, parallel retrieve cursors via SPI.

Cursors exist only for the duration of the transaction that defines them, unless they have been declared `WITH HOLD`. Non-holdable cursors are only present in the view until the end of their creating transaction.

**Note:** Greenplum Database does not support holdable parallel retrieve cursors.

| name                       | type      | references | description   |
|----------------------------|-----------|------------|---|
| <code>name</code>          | text      |            | The name of the cursor.   |
| <code>statement</code>     | text      |            | The verbatim query string submitted to declare this cursor.   |
| <code>is_holdable</code>   | boolean   |            | <code>true</code> if the cursor is holdable (that is, it can be accessed after the transaction that declared the cursor has committed); <code>false</code> otherwise.<br><br><b>Note:</b> Greenplum Database does not support holdable parallel retrieve cursors, this value is always <code>false</code> for such cursors. |
| <code>is_binary</code>     | boolean   |            | <code>true</code> if the cursor was declared <code>BINARY</code> ; <code>false</code> otherwise.  |
| <code>is_scrollable</code> | boolean   |            | <code>true</code> if the cursor is scrollable (that is, it allows rows to be retrieved in a nonsequential manner); <code>false</code> otherwise.<br><br><b>Note:</b> Greenplum Database does not support scrollable cursors, this value is always <code>false</code> .  |
| <code>creation_time</code> | timestamp |            | The time at which the cursor was declared.  |
| <code>is_parallel</code>   | boolean   |            | <code>true</code> if the cursor was declared <code>PARALLEL RETRIEVE</code> ; <code>false</code> otherwise.   |

Parent topic: [System Catalogs Definitions](#)

## pg\_database

The `pg_database` system catalog table stores information about the available databases. Databases are created with the `CREATE DATABASE` SQL command. Unlike most system catalogs, `pg_database` is shared across all databases in the system. There is only one copy of `pg_database` per system, not one per database.

| column                     | type      | references                     | description   |
|----------------------------|-----------|--------------------------------|---|
| <code>datname</code>       | name      |                                | Database name.  |
| <code>datdba</code>        | oid       | <code>pg_authid.oid</code>     | Owner of the database, usually the user who created it.   |
| <code>encoding</code>      | int4      |                                | Character encoding for this database. <code>pg_encoding_to_char()</code> can translate this number to the encoding name.  |
| <code>datcollate</code>    | name      |                                | <code>LC_COLLATE</code> for this database.  |
| <code>datctype</code>      | name      |                                | <code>LC_CTYPE</code> for this database.  |
| <code>datistemplate</code> | boolean   |                                | If true then this database can be used in the <code>TEMPLATE</code> clause of <code>CREATE DATABASE</code> to create a new database as a clone of this one.   |
| <code>dataallowconn</code> | boolean   |                                | If false then no one can connect to this database. This is used to protect the <code>template0</code> database from being altered.  |
| <code>datconnlimit</code>  | int4      |                                | Sets the maximum number of concurrent connections that can be made to this database. <code>-1</code> means no limit.  |
| <code>datlastsysoid</code> | oid       |                                | Last system OID in the database.  |
| <code>datfrozenxid</code>  | xid       |                                | All transaction IDs (XIDs) before this one have been replaced with a permanent (frozen) transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent transaction ID wraparound or to allow <code>pg_clog</code> to be shrunk. It is the minimum of the per-table <code>pg_class.relfrozensid</code> values.   |
| <code>datminmxid</code>    | xid       |                                | A <i>Multixact ID</i> is used to support row locking by multiple transactions. All multixact IDs before this one have been replaced with a transaction ID in this database. This is used to track whether the database needs to be vacuumed in order to prevent multixact ID wraparound or to allow <code>pg_multixact</code> to be shrunk. It is the minimum of the per-table <code>pg_class.relminmxid</code> values. |
| <code>dattablespace</code> | oid       | <code>pg_tablespace.oid</code> | The default tablespace for the database. Within this database, all tables for which <code>pg_class.reltablespace</code> is zero will be stored in this tablespace. All non-shared system catalogs will also be there.   |
| <code>dataacl</code>       | aclitem[] |                                | Database access privileges as given by <code>GRANT</code> and <code>REVOKE</code> .   |

Parent topic: [System Catalogs Definitions](#)

## pg\_db\_role\_setting

The `pg_db_role_setting` system catalog table records the default values of server configuration settings for each role and database combination.

There is a single copy of `pg_db_role_settings` per Greenplum Database cluster. This system catalog table is shared across all databases.

You can view the server configuration settings for your Greenplum Database cluster with `psql's \drds` meta-command.

| column                   | type    | references      | description   |
|--------------------------|---------|-----------------|---|
| <code>setdatabase</code> | oid     | pg_database.oid | The database to which the setting is applicable, or zero if the setting is not database-specific. |
| <code>setrole</code>     | oid     | pg_authid.oid   | The role to which the setting is applicable, or zero if the setting is not role-specific.         |
| <code>setconfig</code>   | text[ ] |                 | Per-database- and per-role-specific defaults for user-settable server configuration parameters.   |

Parent topic: [System Catalogs Definitions](#)

## pg\_depend

The `pg_depend` system catalog table records the dependency relationships between database objects. This information allows `DROP` commands to find which other objects must be dropped by `DROP CASCADE` or prevent dropping in the `DROP RESTRICT` case. See also `pg_shdepend`, which performs a similar function for dependencies involving objects that are shared across a Greenplum system.

In all cases, a `pg_depend` entry indicates that the referenced object may not be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

- **DEPENDENCY\_NORMAL (n)** — A normal relationship between separately-created objects. The dependent object may be dropped without affecting the referenced object. The referenced object may only be dropped by specifying `CASCADE`, in which case the dependent object is dropped, too. Example: a table column has a normal dependency on its data type.
- **DEPENDENCY\_AUTO (a)** — The dependent object can be dropped separately from the referenced object, and should be automatically dropped (regardless of `RESTRICT` or `CASCADE` mode) if the referenced object is dropped. Example: a named constraint on a table is made autodependent on the table, so that it will go away if the table is dropped.
- **DEPENDENCY\_INTERNAL (i)** — The dependent object was created as part of creation of the referenced object, and is really just a part of its internal implementation. A `DROP` of the dependent object will be disallowed outright (we'll tell the user to issue a `DROP` against the referenced object, instead). A `DROP` of the referenced object will be propagated through to drop the dependent object whether `CASCADE` is specified or not.
- **DEPENDENCY\_PIN (p)** — There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by system initialization. The columns for the dependent object contain zeroes.

| column                | type | references     | description   |
|-----------------------|------|----------------|---|
| <code>classid</code>  | oid  | pg_class.oid   | The OID of the system catalog the dependent object is in.                                       |
| <code>objid</code>    | oid  | any OID column | The OID of the specific dependent object.   |
| <code>objsubid</code> | int4 |                | For a table column, this is the column number. For all other object types, this column is zero. |

| column                   | type | references     | description  |
|--------------------------|------|----------------|--|
| <code>refclassid</code>  | oid  | pg_class.oid   | The OID of the system catalog the referenced object is in.   |
| <code>refobjid</code>    | oid  | any OID column | The OID of the specific referenced object.   |
| <code>refobjsubid</code> | int4 |                | For a table column, this is the referenced column number. For all other object types, this column is zero. |
| <code>deptype</code>     | char |                | A code defining the specific semantics of this dependency relationship.                                    |

Parent topic: [System Catalogs Definitions](#)

## pg\_description

The `pg_description` system catalog table stores optional descriptions (comments) for each database object. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` meta-commands. Descriptions of many built-in system objects are provided in the initial contents of `pg_description`. See also [pg\\_shdescription](#), which performs a similar function for descriptions involving objects that are shared across a Greenplum system.

| column                   | type | references     | description  |
|--------------------------|------|----------------|--|
| <code>objoid</code>      | oid  | any OID column | The OID of the object this description pertains to.  |
| <code>classoid</code>    | oid  | pg_class.oid   | The OID of the system catalog this object appears in   |
| <code>objsubid</code>    | int4 |                | For a comment on a table column, this is the column number. For all other object types, this column is zero. |
| <code>description</code> | text |                | Arbitrary text that serves as the description of this object.  |

Parent topic: [System Catalogs Definitions](#)

## pg\_enum

The `pg_enum` table contains entries matching enum types to their associated values and labels. The internal representation of a given enum value is actually the OID of its associated row in `pg_enum`. The OIDs for a particular enum type are guaranteed to be ordered in the way the type should sort, but there is no guarantee about the ordering of OIDs of unrelated enum types.

| Column                     | Type   | References  | Description  |
|----------------------------|--------|-------------|--|
| <code>enumtypeid</code>    | oid    | pg_type.oid | The OID of the <code>pg_type</code> entry owning this enum value |
| <code>enumsortorder</code> | float4 |             | The sort position of this enum value within its enum type        |
| <code>enumlabel</code>     | name   |             | The textual label for this enum value                            |

Parent topic: [System Catalogs Definitions](#)

## pg\_extension

The system catalog table `pg_extension` stores information about installed extensions.

| column                      | type    | references                    | description   |
|-----------------------------|---------|-------------------------------|---|
| <code>extname</code>        | name    |                               | Name of the extension.  |
| <code>extowner</code>       | oid     | <code>pg_authid.oid</code>    | Owner of the extension  |
| <code>extnamespace</code>   | oid     | <code>pg_namespace.oid</code> | Schema containing the extension exported objects.   |
| <code>extrelocatable</code> | boolean |                               | True if the extension can be relocated to another schema.   |
| <code>extversion</code>     | text    |                               | Version name for the extension.   |
| <code>extconfig</code>      | oid[]   | <code>pg_class.oid</code>     | Array of <code>regclass</code> OIDs for the extension configuration tables, or <code>NULL</code> if none.                   |
| <code>extcondition</code>   | text[]  |                               | Array of <code>WHERE</code> -clause filter conditions for the extension configuration tables, or <code>NULL</code> if none. |

Unlike most catalogs with a namespace column, `extnamespace` does not imply that the extension belongs to that schema. Extension names are never schema-qualified. The `extnamespace` schema indicates the schema that contains most or all of the extension objects. If `extrelocatable` is `true`, then this schema must contain all schema-qualifiable objects that belong to the extension.

Parent topic: [System Catalogs Definitions](#)

## pg\_exttable

The `pg_exttable` system catalog table is used to track external tables and web tables created by the `CREATE EXTERNAL TABLE` command.

| column                       | type    | references                | description  |
|------------------------------|---------|---------------------------|--|
| <code>reloid</code>          | oid     | <code>pg_class.oid</code> | The OID of this external table.  |
| <code>urilocation</code>     | text[]  |                           | The URI location(s) of the external table files.   |
| <code>execlocation</code>    | text[]  |                           | The ON segment locations defined for the external table.   |
| <code>fmttype</code>         | char    |                           | Format of the external table files: <code>t</code> for text, or <code>c</code> for csv.                          |
| <code>fmtopts</code>         | text    |                           | Formatting options of the external table files, such as the field delimiter, null string, escape character, etc. |
| <code>options</code>         | text[]  |                           | The options defined for the external table.  |
| <code>command</code>         | text    |                           | The OS command to run when the external table is accessed.   |
| <code>rejectlimit</code>     | integer |                           | The per segment reject limit for rows with errors, after which the load will fail.                               |
| <code>rejectlimittype</code> | char    |                           | Type of reject limit threshold: <code>r</code> for number of rows.   |
| <code>logerrors</code>       | bool    |                           | <code>1</code> to log errors, <code>0</code> to not.   |
| <code>encoding</code>        | text    |                           | The client encoding.   |

| column                | type    | references | description   |
|-----------------------|---------|------------|---|
| <code>writable</code> | boolean |            | 0 for readable external tables, 1 for writable external tables. |

Parent topic: [System Catalogs Definitions](#)

## pg\_foreign\_data\_wrapper

The system catalog table `pg_foreign_data_wrapper` stores foreign-data wrapper definitions. A foreign-data wrapper is a mechanism by which you access external data residing on foreign servers.

| column                    | type      | references                 | description  |
|---------------------------|-----------|----------------------------|--|
| <code>fdwname</code>      | name      |                            | Name of the foreign-data wrapper.  |
| <code>fdwowner</code>     | oid       | <code>pg_authid.oid</code> | Owner of the foreign-data wrapper.   |
| <code>fdwhandler</code>   | oid       | <code>pg_proc.oid</code>   | A reference to a handler function that is responsible for supplying execution routines for the foreign-data wrapper. Zero if no handler is provided.   |
| <code>fdwvalidator</code> | oid       | <code>pg_proc.oid</code>   | A reference to a validator function that is responsible for checking the validity of the options provided to the foreign-data wrapper. This function also checks the options for foreign servers and user mappings using the foreign-data wrapper. Zero if no validator is provided. |
| <code>fdwaccl</code>      | aclitem[] |                            | Access privileges; see <a href="#">GRANT</a> and <a href="#">REVOKE</a> for details.   |
| <code>fdwoptions</code>   | text[]    |                            | Foreign-data wrapper-specific options, as "keyword=value" strings.   |

Parent topic: [System Catalogs Definitions](#)

## pg\_foreign\_server

The system catalog table `pg_foreign_server` stores foreign server definitions. A foreign server describes a source of external data, such as a remote server. You access a foreign server via a foreign-data wrapper.

| column                  | type      | references                               | description  |
|-------------------------|-----------|--|--|
| <code>srvname</code>    | name      |  | Name of the foreign server.  |
| <code>srvowner</code>   | oid       | <code>pg_authid.oid</code>               | Owner of the foreign server.   |
| <code>srvfdw</code>     | oid       | <code>pg_foreign_data_wrapper.oid</code> | OID of the foreign-data wrapper of this foreign server.                              |
| <code>srvtype</code>    | text      |  | Type of server (optional).   |
| <code>srvversion</code> | text      |  | Version of the server (optional).  |
| <code>srvaccl</code>    | aclitem[] |  | Access privileges; see <a href="#">GRANT</a> and <a href="#">REVOKE</a> for details. |

| column                  | type   | references | description  |
|-------------------------|--------|------------|--|
| <code>srvoptions</code> | text[] |            | Foreign server-specific options, as "keyword=value" strings. |

Parent topic: [System Catalogs Definitions](#)

## pg\_foreign\_table

The system catalog table `pg_foreign_table` contains auxiliary information about foreign tables. A foreign table is primarily represented by a `pg_class` entry, just like a regular table. Its `pg_foreign_table` entry contains the information that is pertinent only to foreign tables and not any other kind of relation.

| column                 | type   | references                         | description  |
|------------------------|--------|------------------------------------|--|
| <code>ftrelid</code>   | oid    | <code>pg_class.oid</code>          | OID of the <code>pg_class</code> entry for this foreign table. |
| <code>ftserver</code>  | oid    | <code>pg_foreign_server.oid</code> | OID of the foreign server for this foreign table.              |
| <code>ftoptions</code> | text[] |                                    | Foreign table options, as "keyword=value" strings.             |

Parent topic: [System Catalogs Definitions](#)

## pg\_index

The `pg_index` system catalog table contains part of the information about indexes. The rest is mostly in `pg_class`.

| column                      | type    | references                | description  |
|-----------------------------|---------|---------------------------|--|
| <code>indexrelid</code>     | oid     | <code>pg_class.oid</code> | The OID of the <code>pg_class</code> entry for this index.   |
| <code>indrelid</code>       | oid     | <code>pg_class.oid</code> | The OID of the <code>pg_class</code> entry for the table this index is for.  |
| <code>indnatts</code>       | int2    |                           | The number of columns in the index (duplicates <code>pg_class.relnatts</code> ).   |
| <code>indisunique</code>    | boolean |                           | If true, this is a unique index.   |
| <code>indisprimary</code>   | boolean |                           | If true, this index represents the primary key of the table. (indisunique should always be true when this is true.)  |
| <code>indisexclusion</code> | boolean |                           | If true, this index supports an exclusion constraint   |
| <code>indimmediate</code>   | boolean |                           | If true, the uniqueness check is enforced immediately on insertion (irrelevant if <code>indisunique</code> is not true)  |
| <code>indisclustered</code> | boolean |                           | If true, the table was last clustered on this index via the <code>CLUSTER</code> command.  |
| <code>indisvalid</code>     | boolean |                           | If true, the index is currently valid for queries. False means the index is possibly incomplete: it must still be modified by <code>INSERT/UPDATE</code> operations, but it cannot safely be used for queries. |

| column                       | type       | references                       | description  |
|------------------------------|------------|----------------------------------|--|
| <code>indcheckxmin</code>    | boolean    |                                  | If true, queries must not use the index until the <code>xmin</code> of this <code>pg_index</code> row is below their <code>TransactionXmin</code> event horizon, because the table may contain broken HOT chains with incompatible rows that they can see  |
| <code>indisready</code>      | boolean    |                                  | If true, the index is currently ready for inserts. False means the index must be ignored by <code>INSERT/UPDATE</code> operations  |
| <code>indislive</code>       | boolean    |                                  | If false, the index is in process of being dropped, and should be ignored for all purposes   |
| <code>indisreplicated</code> | boolean    |                                  | If true this index has been chosen as "replica identity" using <code>ALTER TABLE ... REPLICA IDENTITY USING INDEX ...</code>   |
| <code>indkey</code>          | int2vector | <code>pg_attribute.attnum</code> | This is an array of <code>indnatts</code> values that indicate which table columns this index indexes. For example a value of 1 3 would mean that the first and the third table columns make up the index key. A zero in this array indicates that the corresponding index attribute is an expression over the table columns, rather than a simple column reference. |
| <code>indcollation</code>    | oidvector  |                                  | For each column in the index key, this contains the OID of the collation to use for the index.   |
| <code>indclass</code>        | oidvector  | <code>pg_opclass.oid</code>      | For each column in the index key this contains the OID of the operator class to use.   |
| <code>indoption</code>       | int2vector |                                  | This is an array of <code>indnatts</code> values that store per-column flag bits. The meaning of the bits is defined by the index's access method.   |
| <code>indexprs</code>        | text       |                                  | Expression trees (in <code>nodeToString()</code> representation) for index attributes that are not simple column references. This is a list with one element for each zero entry in <code>indkey</code> . NULL if all index attributes are simple references.  |
| <code>indpred</code>         | text       |                                  | Expression tree (in <code>nodeToString()</code> representation) for partial index predicate. NULL if not a partial index.  |

Parent topic: [System Catalogs Definitions](#)

## pg\_inherits

The `pg_inherits` system catalog table records information about table inheritance hierarchies. There is one entry for each direct child table in the database. (Indirect inheritance can be determined by following chains of entries.) In Greenplum Database, inheritance relationships are created by both the `INHERITS` clause (standalone inheritance) and the `PARTITION BY` clause (partitioned child table inheritance) of `CREATE TABLE`.

| column                 | type | references                | description   |
|------------------------|------|---------------------------|---|
| <code>inhrelid</code>  | oid  | <code>pg_class.oid</code> | The OID of the child table.   |
| <code>inhparent</code> | oid  | <code>pg_class.oid</code> | The OID of the parent table.  |
| <code>inhseqno</code>  | int4 |                           | If there is more than one direct parent for a child table (multiple inheritance), this number tells the order in which the inherited columns are to be arranged. The count starts at 1. |

Parent topic: [System Catalogs Definitions](#)

## pg\_language

The `pg_language` system catalog table registers languages in which you can write functions or stored procedures. It is populated by `CREATE LANGUAGE`.

| column                     | type      | references                 | description  |
|----------------------------|-----------|----------------------------|--|
| <code>lanname</code>       | name      |                            | Name of the language.  |
| <code>lanowner</code>      | oid       | <code>pg_authid.oid</code> | Owner of the language.   |
| <code>lanispl</code>       | boolean   |                            | This is false for internal languages (such as SQL) and true for user-defined languages. Currently, <code>pg_dump</code> still uses this to determine which languages need to be dumped, but this may be replaced by a different mechanism in the future. |
| <code>lanpltrusted</code>  | boolean   |                            | True if this is a trusted language, which means that it is believed not to grant access to anything outside the normal SQL execution environment. Only superusers may create functions in untrusted languages.   |
| <code>lanplcallfoid</code> | oid       | <code>pg_proc.oid</code>   | For noninternal languages this references the language handler, which is a special function that is responsible for running all functions that are written in the particular language.   |
| <code>laninline</code>     | oid       | <code>pg_proc.oid</code>   | This references a function that is responsible for running inline anonymous code blocks (see the <code>DO</code> command). Zero if anonymous blocks are not supported.   |
| <code>lanvalidator</code>  | oid       | <code>pg_proc.oid</code>   | This references a language validator function that is responsible for checking the syntax and validity of new functions when they are created. Zero if no validator is provided.   |
| <code>lanacl</code>        | aclitem[] |                            | Access privileges for the language.  |

Parent topic: [System Catalogs Definitions](#)

## pg\_largeobject

**Note:** Greenplum Database does not support the PostgreSQL [large object facility](#) for streaming user data that is stored in large-object structures.

The `pg_largeobject` system catalog table holds the data making up 'large objects'. A large object is identified by an OID assigned when it is created. Each large object is broken into segments or 'pages' small enough to be conveniently stored as rows in `pg_largeobject`. The amount of data per page is defined to be `LOBLKSIZE` (which is currently `BLCKSZ/4`, or typically 8K).

Each row of `pg_largeobject` holds data for one page of a large object, beginning at byte offset (`pageno* LOBLKSIZE`) within the object. The implementation allows sparse storage: pages may be missing, and may be shorter than `LOBLKSIZE` bytes even if they are not the last page of the object. Missing regions within a large object read as zeroes.

| column            | type | references | description   |
|-------------------|------|------------|---|
| <code>loid</code> | oid  |            | Identifier of the large object that includes this page. |

| column              | type      | references | description  |
|---------------------|-----------|------------|--|
| <code>pageno</code> | int4      |            | Page number of this page within its large object (counting from zero).   |
| <code>data</code>   | byte<br>a |            | Actual data stored in the large object. This will never be more than <code>LOBLKSIZE</code> bytes and may be less. |

Parent topic: [System Catalogs Definitions](#)

## pg\_locks

The `pg_locks` view provides access to information about the locks held by open transactions within Greenplum Database.

`pg_locks` contains one row per active lockable object, requested lock mode, and relevant transaction. Thus, the same lockable object may appear many times if multiple transactions are holding or waiting for locks on it. An object with no current locks on it will not appear in the view at all.

There are several distinct types of lockable objects: whole relations (such as tables), individual pages of relations, individual tuples of relations, transaction IDs (both virtual and permanent IDs), and general database objects. Also, the right to extend a relation is represented as a separate lockable object.

| column                          | type     | references                   | description   |
|---------------------------------|----------|------------------------------|---|
| <code>locktype</code>           | text     |                              | Type of the lockable object: <code>relation</code> , <code>extend</code> , <code>page</code> , <code>tuple</code> , <code>transactionid</code> , <code>object</code> , <code>userlock</code> , <code>resource queue</code> , or <code>advisory</code> |
| <code>database</code>           | oid      | <code>pg_database.oid</code> | OID of the database in which the object exists, zero if the object is a shared object, or NULL if the object is a transaction ID  |
| <code>relation</code>           | oid      | <code>pg_class.oid</code>    | OID of the relation, or NULL if the object is not a relation or part of a relation  |
| <code>page</code>               | integer  |                              | Page number within the relation, or NULL if the object is not a tuple or relation page  |
| <code>tuple</code>              | smallint |                              | Tuple number within the page, or NULL if the object is not a tuple  |
| <code>virtualxid</code>         | text     |                              | Virtual ID of a transaction, or NULL if the object is not a virtual transaction ID  |
| <code>transactionid</code>      | xid      |                              | ID of a transaction, or NULL if the object is not a transaction ID  |
| <code>classid</code>            | oid      | <code>pg_class.oid</code>    | OID of the system catalog containing the object, or NULL if the object is not a general database object   |
| <code>objid</code>              | oid      | any OID column               | OID of the object within its system catalog, or NULL if the object is not a general database object   |
| <code>objsubid</code>           | smallint |                              | For a table column, this is the column number (the <code>classid</code> and <code>objid</code> refer to the table itself). For all other object types, this column is zero. NULL if the object is not a general database object                       |
| <code>virtualtransaction</code> | text     |                              | Virtual ID of the transaction that is holding or awaiting this lock   |

| column                     | type    | references | description  |
|----------------------------|---------|------------|--|
| <code>pid</code>           | integer |            | Process ID of the server process holding or awaiting this lock. NULL if the lock is held by a prepared transaction |
| <code>mode</code>          | text    |            | Name of the lock mode held or desired by this process  |
| <code>granted</code>       | boolean |            | True if lock is held, false if lock is awaited.  |
| <code>fastpath</code>      | boolean |            | True if lock was taken via fastpath, false if lock is taken via main lock table.                                   |
| <code>mppsessionid</code>  | integer |            | The id of the client session associated with this lock.  |
| <code>mppiswriter</code>   | boolean |            | Specifies whether the lock is held by a writer process.  |
| <code>gp_segment_id</code> | integer |            | The Greenplum segment id ( <code>dbid</code> ) where the lock is held.   |

Parent topic: [System Catalogs Definitions](#)

## pg\_matviews

The view `pg_matviews` provides access to useful information about each materialized view in the database.

| column                    | type    | references                         | description  |
|---------------------------|---------|------------------------------------|--|
| <code>schemaname</code>   | name    | <code>pg_namespace.nspname</code>  | Name of the schema containing the materialized view  |
| <code>matviewname</code>  | name    | <code>pg_class.relname</code>      | Name of the materialized view  |
| <code>matviewowner</code> | name    | <code>pg_authid.rolname</code>     | Name of the materialized view's owner  |
| <code>tablespace</code>   | name    | <code>pg_tablespace.spcname</code> | Name of the tablespace containing the materialized view (NULL if default for the database) |
| <code>hasindexes</code>   | boolean |                                    | True if the materialized view has (or recently had) any indexes                            |
| <code>ispopulated</code>  | boolean |                                    | True if the materialized view is currently populated                                       |
| <code>definition</code>   | text    |                                    | Materialized view definition (a reconstructed <code>SELECT</code> command)                 |

Parent topic: [System Catalogs Definitions](#)

## pg\_max\_external\_files

The `pg_max_external_files` view shows the maximum number of external table files allowed per segment host when using the external table `file` protocol.

| column                | type   | references | description   |
|-----------------------|--------|------------|---|
| <code>hostname</code> | name   |            | The host name used to access a particular segment instance on a segment host. |
| <code>maxfiles</code> | bigint |            | Number of primary segment instances on the host.                              |

Parent topic: [System Catalogs Definitions](#)

## pg\_namespace

The `pg_namespace` system catalog table stores namespaces. A namespace is the structure underlying SQL schemas: each namespace can have a separate collection of relations, types, etc. without name conflicts.

| column                | type      | references                 | description  |
|-----------------------|-----------|----------------------------|--|
| <code>oid</code>      | oid       |                            | Row identifier (hidden attribute; must be explicitly selected)           |
| <code>nspname</code>  | name      |                            | Name of the namespace  |
| <code>nspowner</code> | oid       | <code>pg_authid.oid</code> | Owner of the namespace   |
| <code>nspacl</code>   | aclitem[] |                            | Access privileges as given by <code>GRANT</code> and <code>REVOKE</code> |

Parent topic: [System Catalogs Definitions](#)

## pg\_opclass

The `pg_opclass` system catalog table defines index access method operator classes. Each operator class defines semantics for index columns of a particular data type and a particular index access method. An operator class essentially specifies that a particular operator family is applicable to a particular indexable column data type. The set of operators from the family that are actually usable with the indexed column are those that accept the column's data type as their left-hand input.

An operator class's `opcmethod` must match the `opfmethod` of its containing operator family. Also, there must be no more than one `pg_opclass` row having `opcdefault` true for any given combination of `opcmethod` and `opcintype`.

| column                    | type    | references                    | description   |
|---------------------------|---------|-------------------------------|---|
| <code>oid</code>          | oid     |                               | Row identifier (hidden attribute; must be explicitly selected)                      |
| <code>opcmethod</code>    | oid     | <code>pg_am.oid</code>        | Index access method operator class is for   |
| <code>opcname</code>      | name    |                               | Name of this operator class   |
| <code>opcnamespace</code> | oid     | <code>pg_namespace.oid</code> | Namespace of this operator class  |
| <code>opcowner</code>     | oid     | <code>pg_authid.oid</code>    | Owner of the operator class   |
| <code>opcfamily</code>    | oid     | <code>pg_opfamily.oid</code>  | Operator family containing the operator class                                       |
| <code>opcintype</code>    | oid     | <code>pg_type.oid</code>      | Data type that the operator class indexes   |
| <code>opcdefault</code>   | boolean |                               | True if this operator class is the default for the data type <code>opcintype</code> |
| <code>opckeytype</code>   | oid     | <code>pg_type.oid</code>      | Type of data stored in index, or zero if same as <code>opcintype</code>             |

Parent topic: [System Catalogs Definitions](#)

## pg\_operator

The `pg_operator` system catalog table stores information about operators, both built-in and those defined by `CREATE OPERATOR`. Unused columns contain zeroes. For example, `oprleft` is zero for a prefix operator.

| column                    | type    | references                    | description   |
|---------------------------|---------|-------------------------------|---|
| <code>oid</code>          | oid     |                               | Row identifier (hidden attribute, must be explicitly selected)                                  |
| <code>oprname</code>      | name    |                               | Name of the operator  |
| <code>oprnamespace</code> | oid     | <code>pg_namespace.oid</code> | The OID of the namespace that contains this operator  |
| <code>oprowner</code>     | oid     | <code>pg_authid.oid</code>    | Owner of the operator   |
| <code>oprkind</code>      | char    |                               | <code>b</code> = infix (both), <code>l</code> = prefix (left), <code>r</code> = postfix (right) |
| <code>oprcanmerge</code>  | boolean |                               | This operator supports merge joins  |
| <code>oprcanhash</code>   | boolean |                               | This operator supports hash joins   |
| <code>oprleft</code>      | oid     | <code>pg_type.oid</code>      | Type of the left operand  |
| <code>oprright</code>     | oid     | <code>pg_type.oid</code>      | Type of the right operand   |
| <code>oprresult</code>    | oid     | <code>pg_type.oid</code>      | Type of the result  |
| <code>oprcom</code>       | oid     | <code>pg_operator.oid</code>  | Commutator of this operator, if any   |
| <code>oprnegate</code>    | oid     | <code>pg_operator.oid</code>  | Negator of this operator, if any  |
| <code>oprcode</code>      | regproc | <code>pg_proc.oid</code>      | Function that implements this operator  |
| <code>oprrest</code>      | regproc | <code>pg_proc.oid</code>      | Restriction selectivity estimation function for this operator                                   |
| <code>oprjoin</code>      | regproc | <code>pg_proc.oid</code>      | Join selectivity estimation function for this operator  |

## pg\_opfamily

The catalog `pg_opfamily` defines operator families. Each operator family is a collection of operators and associated support routines that implement the semantics specified for a particular index access method. Furthermore, the operators in a family are all compatible in a way that is specified by the access method. The operator family concept allows cross-data-type operators to be used with indexes and to be reasoned about using knowledge of access method semantics.

The majority of the information defining an operator family is not in its `pg_opfamily` row, but in the associated rows in `pg_amop`, `pg_amproc`, and `pg_opclass`.

| Name                   | Type | References             | Description  |
|------------------------|------|------------------------|--|
| <code>oid</code>       | oid  |                        | Row identifier (hidden attribute; must be explicitly selected) |
| <code>opfmethod</code> | oid  | <code>pg_am.oid</code> | Index access method operator for this family                   |

| Name                      | Type | References                    | Description                       |
|---------------------------|------|-------------------------------|-----------------------------------|
| <code>opfname</code>      | name |                               | Name of this operator family      |
| <code>opfnamespace</code> | oid  | <code>pg_namespace.oid</code> | Namespace of this operator family |
| <code>opfowner</code>     | oid  | <code>pg_authid.oid</code>    | Owner of the operator family      |

Parent topic: [System Catalogs Definitions](#)

## pg\_partition

The `pg_partition` system catalog table is used to track partitioned tables and their inheritance level relationships. Each row of `pg_partition` represents either the level of a partitioned table in the partition hierarchy, or a subpartition template description. The value of the attribute `paristemplate` determines what a particular row represents.

| column                     | type       | references                  | description   |
|----------------------------|------------|-----------------------------|---|
| <code>parrelid</code>      | oid        | <code>pg_class.oid</code>   | The object identifier of the table.   |
| <code>parkind</code>       | char       |                             | The partition type - <code>R</code> for range or <code>L</code> for list.   |
| <code>parlevel</code>      | smallint   |                             | The partition level of this row: 0 for the top-level parent table, 1 for the first level under the parent table, 2 for the second level, and so on. |
| <code>paristemplate</code> | boolean    |                             | Whether or not this row represents a subpartition template definition (true) or an actual partitioning level (false).                               |
| <code>parnatts</code>      | smallint   |                             | The number of attributes that define this level.  |
| <code>paratts</code>       | smallint() |                             | An array of the attribute numbers (as in <code>pg_attribute.attnum</code> ) of the attributes that participate in defining this level.              |
| <code>parclass</code>      | oidvector  | <code>pg_opclass.oid</code> | The operator class identifier(s) of the partition columns.  |

## pg\_partition\_columns

The `pg_partition_columns` system view is used to show the partition key columns of a partitioned table.

| column                                 | type     | references | description  |
|--|----------|------------|--|
| <code>schemaname</code>                | name     |            | The name of the schema the partitioned table is in.  |
| <code>tablename</code>                 | name     |            | The table name of the top-level parent table.  |
| <code>columnname</code>                | name     |            | The name of the partition key column.  |
| <code>partitionlevel</code>            | smallint |            | The level of this subpartition in the hierarchy.   |
| <code>position_in_partition_key</code> | integer  |            | For list partitions you can have a composite (multi-column) partition key. This shows the position of the column in a composite key. |

## pg\_partition\_encoding

The `pg_partition_encoding` system catalog table describes the available column compression options for a partition template.

| column                        | type     | modifiers | storage  | description |
|-------------------------------|----------|-----------|----------|-------------|
| <code>parencoid</code>        | oid      | not null  | plain    |             |
| <code>parencattnum</code>     | smallint | not null  | plain    |             |
| <code>parencattoptions</code> | text [ ] |           | extended |             |

Parent topic: [System Catalogs Definitions](#)

## pg\_partition\_rule

The `pg_partition_rule` system catalog table is used to track partitioned tables, their check constraints, and data containment rules. Each row of `pg_partition_rule` represents either a leaf partition (the bottom level partitions that contain data), or a branch partition (a top or mid-level partition that is used to define the partition hierarchy, but does not contain any data).

| column                          | type     | references                            | description   |
|---------------------------------|----------|---------------------------------------|---|
| <code>paroid</code>             | oid      | <code>pg_partition.oid</code>         | Row identifier of the partitioning level (from <code>pg_partition</code> ) to which this partition belongs. In the case of a branch partition, the corresponding table (identified by <code>pg_partition_rule</code> ) is an empty container table. In case of a leaf partition, the table contains the rows for that partition containment rule. |
| <code>parchildrelid</code>      | oid      | <code>pg_class.oid</code>             | The table identifier of the partition (child table).  |
| <code>parparentrule</code>      | oid      | <code>pg_partition_rule.paroid</code> | The row identifier of the rule associated with the parent table of this partition.  |
| <code>parname</code>            | name     |                                       | The given name of this partition.   |
| <code>parisdefault</code>       | boolean  |                                       | Whether or not this partition is a default partition.   |
| <code>parruleord</code>         | smallint |                                       | For range partitioned tables, the rank of this partition on this level of the partition hierarchy.  |
| <code>parrangesstartincl</code> | boolean  |                                       | For range partitioned tables, whether or not the starting value is inclusive.   |
| <code>parrangeendincl</code>    | boolean  |                                       | For range partitioned tables, whether or not the ending value is inclusive.   |
| <code>parrangesstart</code>     | text     |                                       | For range partitioned tables, the starting value of the range.  |
| <code>parrangeend</code>        | text     |                                       | For range partitioned tables, the ending value of the range.  |

| column                     | type | references | description  |
|----------------------------|------|------------|--|
| <code>parrangeevery</code> | text |            | For range partitioned tables, the interval value of the <code>EVERY</code> clause. |
| <code>parlistvalues</code> | text |            | For list partitioned tables, the list of values assigned to this partition.        |
| <code>parreloptions</code> | text |            | An array describing the storage characteristics of the particular partition.       |

Parent topic: [System Catalogs Definitions](#)

## pg\_partition\_templates

The `pg_partition_templates` system view is used to show the subpartitions that were created using a subpartition template.

| column                                      | type     | references | description   |
|---|----------|------------|---|
| <code>schemaname</code>                     | name     |            | The name of the schema the partitioned table is in.   |
| <code>tablename</code>                      | name     |            | The table name of the top-level parent table.   |
| <code>partitionname</code>                  | name     |            | The name of the subpartition (this is the name to use if referring to the partition in an <code>ALTER TABLE</code> command). <code>NULL</code> if the partition was not given a name at create time or generated by an <code>EVERY</code> clause. |
| <code>partitiontype</code>                  | text     |            | The type of subpartition (range or list).   |
| <code>partitionlevel</code>                 | smallint |            | The level of this subpartition in the hierarchy.  |
| <code>partitionrank</code>                  | bigint   |            | For range partitions, the rank of the partition compared to other partitions of the same level.   |
| <code>partitionposition</code>              | smallint |            | The rule order position of this subpartition.   |
| <code>partitionlistvalues</code>            | text     |            | For list partitions, the list value(s) associated with this subpartition.   |
| <code>partitionrange_start</code>           | text     |            | For range partitions, the start value of this subpartition.   |
| <code>partitionrange_start_inclusive</code> | boolean  |            | <code>T</code> if the start value is included in this subpartition. <code>F</code> if it is excluded.   |
| <code>partitionrange_end</code>             | text     |            | For range partitions, the end value of this subpartition.   |
| <code>partitionrange_end_inclusive</code>   | boolean  |            | <code>T</code> if the end value is included in this subpartition. <code>F</code> if it is excluded.   |
| <code>partitionevery_clause</code>          | text     |            | The <code>EVERY</code> clause (interval) of this subpartition.  |
| <code>partitionis_default</code>            | boolean  |            | <code>T</code> if this is a default subpartition, otherwise <code>F</code> .  |

| column                         | type | references | description   |
|--------------------------------|------|------------|---|
| <code>partitionboundary</code> | text |            | The entire partition specification for this subpartition. |

Parent topic: [System Catalogs Definitions](#)

## pg\_partitions

The `pg_partitions` system view is used to show the structure of a partitioned table.

| column                                      | type     | references | description  |
|---|----------|------------|--|
| <code>schemaname</code>                     | name     |            | The name of the schema the partitioned table is in.  |
| <code>tablename</code>                      | name     |            | The name of the top-level parent table.  |
| <code>partitionsschemaname</code>           | name     |            | The namespace of the partition table.  |
| <code>partitiontablename</code>             | name     |            | The relation name of the partitioned table (this is the table name to use if accessing the partition directly).  |
| <code>partitionname</code>                  | name     |            | The name of the partition (this is the name to use if referring to the partition in an <code>ALTER TABLE</code> command). <code>NULL</code> if the partition was not given a name at create time or generated by an <code>EVERY</code> clause. |
| <code>parentpartitiontablename</code>       | name     |            | The relation name of the parent table one level up from this partition.  |
| <code>parentpartitionname</code>            | name     |            | The given name of the parent table one level up from this partition.   |
| <code>partitiontype</code>                  | text     |            | The type of partition (range or list).   |
| <code>partitionlevel</code>                 | smallint |            | The level of this partition in the hierarchy.  |
| <code>partitionrank</code>                  | bigint   |            | For range partitions, the rank of the partition compared to other partitions of the same level.  |
| <code>partitionposition</code>              | smallint |            | The rule order position of this partition.   |
| <code>partitionlistvalues</code>            | text     |            | For list partitions, the list value(s) associated with this partition.   |
| <code>partitionrange_start</code>           | text     |            | For range partitions, the start value of this partition.   |
| <code>partitionrange_start_inclusive</code> | boolean  |            | <code>T</code> if the start value is included in this partition. <code>F</code> if it is excluded.   |
| <code>partitionrange_end</code>             | text     |            | For range partitions, the end value of this partition.   |
| <code>partitionrange_end_inclusive</code>   | boolean  |            | <code>T</code> if the end value is included in this partition. <code>F</code> if it is excluded.   |
| <code>partitioneveryclause</code>           | text     |            | The <code>EVERY</code> clause (interval) of this partition.  |

| column                           | type    | references | description   |
|----------------------------------|---------|------------|---|
| <code>partitionisdefault</code>  | boolean |            | <code>T</code> if this is a default partition, otherwise <code>F</code> . |
| <code>partitionboundary</code>   | text    |            | The entire partition specification for this partition.                    |
| <code>parenttablespace</code>    | text    |            | The tablespace of the parent table one level up from this partition.      |
| <code>partitiontablespace</code> | text    |            | The tablespace of this partition.   |

Parent topic: [System Catalogs Definitions](#)

## pg\_pltemplate

The `pg_pltemplate` system catalog table stores template information for procedural languages. A template for a language allows the language to be created in a particular database by a simple `CREATE LANGUAGE` command, with no need to specify implementation details. Unlike most system catalogs, `pg_pltemplate` is shared across all databases of Greenplum system: there is only one copy of `pg_pltemplate` per system, not one per database. This allows the information to be accessible in each database as it is needed.

There are not currently any commands that manipulate procedural language templates; to change the built-in information, a superuser must modify the table using ordinary `INSERT`, `DELETE`, or `UPDATE` commands.

| column                    | type      | references | description   |
|---------------------------|-----------|------------|---|
| <code>tplname</code>      | name      |            | Name of the language this template is for                 |
| <code>tpltrusted</code>   | boolean   |            | True if language is considered trusted                    |
| <code>tpldbcreate</code>  | boolean   |            | True if language may be created by a database owner       |
| <code>tplhandler</code>   | text      |            | Name of call handler function                             |
| <code>tplinline</code>    | text      |            | Name of anonymous-block handler function, or null if none |
| <code>tplvalidator</code> | text      |            | Name of validator function, or NULL if none               |
| <code>tpllibrary</code>   | text      |            | Path of shared library that implements language           |
| <code>tplacl</code>       | aclitem[] |            | Access privileges for template (not yet implemented).     |

Parent topic: [System Catalogs Definitions](#)

## pg\_proc

The `pg_proc` system catalog table stores information about functions (or procedures), both built-in functions and those defined by `CREATE FUNCTION`. The table contains data for aggregate and window functions as well as plain functions. If `proisagg` is true, there should be a matching row in `pg_aggregate`.

For compiled functions, both built-in and dynamically loaded, `prosrc` contains the function's C-language name (link symbol). For all other currently-known language types, `prosrc` contains the function's source text. `probin` is unused except for dynamically-loaded C functions, for which it gives the name of the shared library file containing the function.

| column                        | type    | references                    | description  |
|-------------------------------|---------|-------------------------------|--|
| <code>oid</code>              | oid     |                               | Row identifier (hidden attribute; ust be explicitly selected)  |
| <code>proname</code>          | name    |                               | Name of the function   |
| <code>pronamespace</code>     | oid     | <code>pg_namespace.oid</code> | The OID of the namespace that contains this function   |
| <code>proowner</code>         | oid     | <code>pg_authid.oid</code>    | Owner of the function  |
| <code>prolang</code>          | oid     | <code>pg_language.oid</code>  | Implementation language or call interface of this function   |
| <code>procost</code>          | float4  |                               | Estimated execution cost (in <code>cpu_operator_cost</code> units); if <code>proretset</code> is <code>true</code> , identifies the cost per row returned  |
| <code>prorows</code>          | float4  |                               | Estimated number of result rows (zero if not <code>proretset</code> )  |
| <code>provariadic</code>      | oid     | <code>pg_type.oid</code>      | Data type of the variadic array parameter's elements, or zero if the function does not have a variadic parameter   |
| <code>protransform</code>     | regproc | <code>pg_proc.oid</code>      | Calls to this function can be simplified by this other function  |
| <code>proisagg</code>         | boolean |                               | Function is an aggregate function  |
| <code>proiswindow</code>      | boolean |                               | Function is a window function  |
| <code>prosecdef</code>        | boolean |                               | Function is a security definer (for example, a 'setuid' function)  |
| <code>proleakproof</code>     | boolean |                               | The function has no side effects. No information about the arguments is conveyed except via the return value. Any function that might throw an error depending on the values of its arguments is not leak-proof.   |
| <code>proisstrict</code>      | boolean |                               | Function returns NULL if any call argument is NULL. In that case the function will not actually be called at all. Functions that are not strict must be prepared to handle NULL inputs.  |
| <code>proretset</code>        | boolean |                               | Function returns a set (multiple values of the specified data type)  |
| <code>provolatile</code>      | char    |                               | Tells whether the function's result depends only on its input arguments, or is affected by outside factors. <code>i</code> = <i>immutable</i> (always delivers the same result for the same inputs), <code>s</code> = <i>stable</i> (results (for fixed inputs) do not change within a scan), or <code>v</code> = <i>volatile</i> (results may change at any time or functions with side-effects). |
| <code>pronargs</code>         | int2    |                               | Number of arguments  |
| <code>pronargsdefaults</code> | int2    |                               | Number of arguments that have default values   |

| column                      | type         | references  | description   |
|-----------------------------|--------------|-------------|---|
| <code>prorettype</code>     | oid          | pg_type oid | Data type of the return value   |
| <code>proargtypes</code>    | oidvector    | pg_type oid | An array with the data types of the function arguments. This includes only input arguments (including <code>INOUT</code> and <code>VARIADIC</code> arguments), and thus represents the call signature of the function.  |
| <code>proallargtypes</code> | oid[]        | pg_type oid | An array with the data types of the function arguments. This includes all arguments (including <code>OUT</code> and <code>INOUT</code> arguments); however, if all of the arguments are <code>IN</code> arguments, this field will be null. Note that subscripting is 1-based, whereas for historical reasons <code>proargtypes</code> is subscripted from 0. |
| <code>proargmodes</code>    | char[]       |             | An array with the modes of the function arguments: <code>i = IN</code> , <code>o = OUT</code> , <code>b = INOUT</code> , <code>v = VARIADIC</code> . If all the arguments are <code>IN</code> arguments, this field will be null. Note that subscripts correspond to positions of <code>proallargtypes</code> , not <code>proargtypes</code> .                |
| <code>proargnames</code>    | text[]       |             | An array with the names of the function arguments. Arguments without a name are set to empty strings in the array. If none of the arguments have a name, this field will be null. Note that subscripts correspond to positions of <code>proallargtypes</code> not <code>proargtypes</code> .  |
| <code>proargdefaults</code> | pg_node_tree |             | Expression trees (in <code>nodeToString()</code> representation) for default argument values. This is a list with <code>pronargdefaults</code> elements, corresponding to the last N input arguments (i.e., the last N <code>proargtypes</code> positions). If none of the arguments have defaults, this field will be null.                                  |
| <code>prosrc</code>         | text         |             | This tells the function handler how to invoke the function. It might be the actual source code of the function for interpreted languages, a link symbol, a file name, or just about anything else, depending on the implementation language/call convention.  |
| <code>probin</code>         | text         |             | Additional information about how to invoke the function. Again, the interpretation is language-specific.  |
| <code>proconfig</code>      | text[]       |             | Function's local settings for run-time configuration variables.   |
| <code>proacl</code>         | aclitem[]    |             | Access privileges for the function as given by <code>GRANT/REVOKE</code>  |
| <code>prodataaccess</code>  | char         |             | Provides a hint regarding the type SQL statements that are included in the function: <code>n</code> - does not contain SQL, <code>c</code> - contains SQL, <code>r</code> - contains SQL that reads data, <code>m</code> - contains SQL that modifies data  |
| <code>proexecution</code>   | char         |             | Where the function runs when it is invoked: <code>m</code> - master only, <code>a</code> - any segment instance, <code>s</code> - all segment instances, <code>i</code> - initplan.   |

## pg\_resgroup

**Note:** The `pg_resgroup` system catalog table is valid only when resource group-based resource management is active.

The `pg_resgroup` system catalog table contains information about Greenplum Database resource groups, which are used for managing concurrent statements, CPU, and memory resources. This table, defined in the `pg_global` tablespace, is globally shared across all databases in the system.

| column               | type | references | description                      |
|----------------------|------|------------|----------------------------------|
| <code>rsgname</code> | name |            | The name of the resource group.  |
| <code>parent</code>  | oid  |            | Unused; reserved for future use. |

Parent topic: [System Catalogs Definitions](#)

## pg\_resgroupcapability

**Note:** The `pg_resgroupcapability` system catalog table is valid only when resource group-based resource management is active.

The `pg_resgroupcapability` system catalog table contains information about the capabilities and limits of defined Greenplum Database resource groups. You can join this table to the `pg_resgroup` table by resource group object ID.

The `pg_resgroupcapability` table, defined in the `pg_global` tablespace, is globally shared across all databases in the system.

| column                     | type        | references                    | description   |
|----------------------------|-------------|-------------------------------|---|
| <code>resgroup id</code>   | oid         | <code>pg_resgroup .oid</code> | The object ID of the associated resource group.   |
| <code>reslimit type</code> | smallint    | ``                            | The resource group limit type:<br><br>0 - Unknown<br><br>1 - Concurrency<br><br>2 - CPU<br><br>3 - Memory<br><br>4 - Memory shared quota<br><br>5 - Memory spill ratio<br><br>6 - Memory auditor<br><br>7 - CPU set |
| <code>value</code>         | opaque type |                               | The specific value set for the resource limit referenced in this record. This value has the fixed type <code>text</code> , and will be converted to a different data type depending upon the limit referenced.      |

Parent topic: [System Catalogs Definitions](#)

## pg\_resourcetype

The `pg_resourcetype` system catalog table contains information about the extended attributes that can be assigned to Greenplum Database resource queues. Each row details an attribute and inherent qualities such as its default setting, whether it is required, and the value to deactivate it (when allowed).

This table is populated only on the master. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

| column                          | type     | references | description   |
|---------------------------------|----------|------------|---|
| <code>restypid</code>           | smallint |            | The resource type ID.   |
| <code>resname</code>            | name     |            | The name of the resource type.  |
| <code>resrequired</code>        | boolean  |            | Whether the resource type is required for a valid resource queue.   |
| <code>reshasdefault</code>      | boolean  |            | Whether the resource type has a default value. When true, the default value is specified in <code>reshasdefaultsetting</code> . |
| <code>rescandisable</code>      | boolean  |            | Whether the type can be removed or deactivated. When true, the default value is specified in <code>resdisabledsetting</code> .  |
| <code>resdefaultsetting</code>  | text     |            | Default setting for the resource type, when applicable.   |
| <code>resdisabledsetting</code> | text     |            | The value that deactivates this resource type (when allowed).   |

Parent topic: [System Catalogs Definitions](#)

## pg\_resqueue

**Note:** The `pg_resqueue` system catalog table is valid only when resource queue-based resource management is active.

The `pg_resqueue` system catalog table contains information about Greenplum Database resource queues, which are used for the resource management feature. This table is populated only on the master. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

| column                          | type    | references | description  |
|---------------------------------|---------|------------|--|
| <code>rsqname</code>            | name    |            | The name of the resource queue.  |
| <code>rsqcountlimit</code>      | real    |            | The active query threshold of the resource queue.  |
| <code>rsqcostlimit</code>       | real    |            | The query cost threshold of the resource queue.  |
| <code>rsqovercommit</code>      | boolean |            | Allows queries that exceed the cost threshold to run when the system is idle.  |
| <code>rsqignorecostlimit</code> | real    |            | The query cost limit of what is considered a 'small query'. Queries with a cost under this limit will not be queued and run immediately. |

Parent topic: [System Catalogs Definitions](#)

## pg\_resqueue\_attributes

**Note:** The `pg_resqueue_attributes` view is valid only when resource queue-based resource management is active.

The `pg_resqueue_attributes` view allows administrators to see the attributes set for a resource queue, such as its active statement limit, query cost limits, and priority.

| column                 | type    | references                       | description                                      |
|------------------------|---------|----------------------------------|--|
| <code>rsqname</code>   | name    | <code>pg_resqueue.rsqname</code> | The name of the resource queue.                  |
| <code>resname</code>   | text    |                                  | The name of the resource queue attribute.        |
| <code>resetting</code> | text    |                                  | The current value of a resource queue attribute. |
| <code>restypid</code>  | integer |                                  | System assigned resource type id.                |

Parent topic: [System Catalogs Definitions](#)

## pg\_resqueuecapability

**Note:** The `pg_resqueuecapability` system catalog table is valid only when resource queue-based resource management is active.

The `pg_resqueuecapability` system catalog table contains information about the extended attributes, or capabilities, of existing Greenplum Database resource queues. Only resource queues that have been assigned an extended capability, such as a priority setting, are recorded in this table. This table is joined to the `pg_resqueue` table by resource queue object ID, and to the `pg_resourcetype` table by resource type ID (`restypid`).

This table is populated only on the master. This table is defined in the `pg_global` tablespace, meaning it is globally shared across all databases in the system.

| column                 | type        | references                            | description   |
|------------------------|-------------|---------------------------------------|---|
| <code>rsqueueid</code> | oid         | <code>pg_resqueue.oid</code>          | The object ID of the associated resource queue.   |
| <code>restypid</code>  | smallint    | <code>pg_resourcetype.restypid</code> | The resource type, derived from the <code>pg_resqueuecapability</code> system table.  |
| <code>resetting</code> | opaque type |                                       | The specific value set for the capability referenced in this record. Depending on the actual resource type, this value may have different data types. |

Parent topic: [System Catalogs Definitions](#)

## pg\_rewrite

The `pg_rewrite` system catalog table stores rewrite rules for tables and views. `pg_class.relhasrules` must be true if a table has any rules in this catalog.

| column                | type | references                | description   |
|-----------------------|------|---------------------------|---|
| <code>rulename</code> | name |                           | Rule name.  |
| <code>ev_class</code> | oid  | <code>pg_class.oid</code> | The table this rule is for.   |
| <code>ev_type</code>  | char |                           | Event type that the rule is for: 1 = SELECT, 2 = UPDATE, 3 = INSERT, 4 = DELETE |

| column         | type             | references | description   |
|----------------|------------------|------------|---|
| ev_enable<br>d | char             |            | Controls in which session replication role mode the rule fires. Always O, rule fires in origin mode.              |
| is_instead     | bool             |            | True if the rule is an <code>INSTEAD</code> rule  |
| ev_qual        | pg_node_t<br>ree |            | Expression tree (in the form of a <code>nodeToString()</code> representation) for the rule's qualifying condition |
| ev_action      | pg_node_t<br>ree |            | Query tree (in the form of a <code>nodeToString()</code> representation) for the rule's action                    |

Parent topic: [System Catalogs Definitions](#)

## pg\_roles

The view `pg_roles` provides access to information about database roles. This is simply a publicly readable view of `pg_authid` that blanks out the password field. This view explicitly exposes the OID column of the underlying table, since that is needed to do joins to other catalogs.

| column             | type            | references          | description   |
|--------------------|-----------------|---------------------|---|
| rolname            | name            |                     | Role name   |
| rolsuper           | bool            |                     | Role has superuser privileges   |
| rolinherit         | bool            |                     | Role automatically inherits privileges of roles it is a member of   |
| rolcreaterole      | bool            |                     | Role may create more roles  |
| rolcreatedb        | bool            |                     | Role may create databases   |
| rolcatupdate       | bool            |                     | Role may update system catalogs directly. (Even a superuser may not do this unless this column is true.)            |
| rolcanlogin        | bool            |                     | Role may log in. That is, this role can be given as the initial session authorization identifier                    |
| rolconnlimit       | int4            |                     | For roles that can log in, this sets maximum number of concurrent connections this role can make. -1 means no limit |
| rolpassword        | text            |                     | Not the password (always reads as <code>*****</code> )  |
| rolvaliduntil      | timesta<br>mptz |                     | Password expiry time (only used for password authentication); NULL if no expiration                                 |
| rolconfig          | text[]          |                     | Role-specific defaults for run-time configuration variables   |
| rolresqueue        | oid             | pg_resqueue.<br>oid | Object ID of the resource queue this role is assigned to.   |
| oid                | oid             | pg_authid.oid       | Object ID of role   |
| rolcreaterextgpfid | bool            |                     | Role may create readable external tables that use the gpfdist protocol.   |
| rolcreaterexthttp  | bool            |                     | Role may create readable external tables that use the http protocol.  |

| column  | type | references                       | description   |
|---|------|----------------------------------|---|
| <code>rolcreatewex</code><br><code>tgdfd</code> | bool |                                  | Role may create writable external tables that use the gpfdist protocol. |
| <code>rolresgroup</code>                        | oid  | <code>pg_resgroup.</code><br>oid | Object ID of the resource group to which this role is assigned.         |

Parent topic: [System Catalogs Definitions](#)

## pg\_rules

The view `pg_rules` provides access to useful information about query rewrite rules.

The `pg_rules` view excludes the `ON SELECT` rules of views and materialized views; those can be seen in `pg_views` and `pg_matviews`.

| column                  | type | references                        | description  |
|-------------------------|------|-----------------------------------|--|
| <code>schemaname</code> | name | <code>pg_namespace.nspname</code> | Name of schema containing table                    |
| <code>tablename</code>  | name | <code>pg_class.relname</code>     | Name of table the rule is for                      |
| <code>rulename</code>   | name | <code>pg_rewrite.rulename</code>  | Name of rule                                       |
| <code>definition</code> | text |                                   | Rule definition (a reconstructed creation command) |

Parent topic: [System Catalogs Definitions](#)

## pg\_shdepend

The `pg_shdepend` system catalog table records the dependency relationships between database objects and shared objects, such as roles. This information allows Greenplum Database to ensure that those objects are unreferenced before attempting to delete them. See also `pg_depend`, which performs a similar function for dependencies involving objects within a single database. Unlike most system catalogs, `pg_shdepend` is shared across all databases of Greenplum system: there is only one copy of `pg_shdepend` per system, not one per database.

In all cases, a `pg_shdepend` entry indicates that the referenced object may not be dropped without also dropping the dependent object. However, there are several subflavors identified by `deptype`:

- **SHARED\_DEPENDENCY\_OWNER (o)** — The referenced object (which must be a role) is the owner of the dependent object.
- **SHARED\_DEPENDENCY\_ACL (a)** — The referenced object (which must be a role) is mentioned in the ACL (access control list) of the dependent object.
- **SHARED\_DEPENDENCY\_PIN (p)** — There is no dependent object; this type of entry is a signal that the system itself depends on the referenced object, and so that object must never be deleted. Entries of this type are created only by system initialization. The columns for the dependent object contain zeroes.

| column            | type | references                       | description  |
|-------------------|------|----------------------------------|--|
| <code>dbid</code> | oid  | <code>pg_database.</code><br>oid | The OID of the database the dependent object is in, or zero for a shared object. |

| column                   | type | references     | description  |
|--------------------------|------|----------------|--|
| <code>classid</code>     | oid  | pg_class.oid   | The OID of the system catalog the dependent object is in.  |
| <code>objid</code>       | oid  | any OID column | The OID of the specific dependent object.  |
| <code>objsubid</code>    | int4 |                | For a table column, this is the column number. For all other object types, this column is zero.            |
| <code>refclassid</code>  | oid  | pg_class.oid   | The OID of the system catalog the referenced object is in (must be a shared catalog).                      |
| <code>refobjid</code>    | oid  | any OID column | The OID of the specific referenced object.   |
| <code>refobjsubid</code> | int4 |                | For a table column, this is the referenced column number. For all other object types, this column is zero. |
| <code>deptype</code>     | char |                | A code defining the specific semantics of this dependency relationship.                                    |

Parent topic: [System Catalogs Definitions](#)

## pg\_shdescription

The `pg_shdescription` system catalog table stores optional descriptions (comments) for shared database objects. Descriptions can be manipulated with the `COMMENT` command and viewed with `psql`'s `\d` meta-commands. See also [pg\\_description](#), which performs a similar function for descriptions involving objects within a single database. Unlike most system catalogs, `pg_shdescription` is shared across all databases of a Greenplum system: there is only one copy of `pg_shdescription` per system, not one per database.

| column                   | type | references     | description   |
|--------------------------|------|----------------|---|
| <code>objoid</code>      | oid  | any OID column | The OID of the object this description pertains to.           |
| <code>classoid</code>    | oid  | pg_class.oid   | The OID of the system catalog this object appears in          |
| <code>description</code> | text |                | Arbitrary text that serves as the description of this object. |

Parent topic: [System Catalogs Definitions](#)

## pg\_stat\_activity

The view `pg_stat_activity` shows one row per server process with details about the associated user session and query. The columns that report data on the current query are available unless the parameter `stats_command_string` has been turned off. Furthermore, these columns are only visible if the user examining the view is a superuser or the same as the user owning the process being reported on.

The maximum length of the query text string stored in the column `query` can be controlled with the server configuration parameter `track_activity_query_size`.

| column                        | type        | references      | description   |
|-------------------------------|-------------|-----------------|---|
| <code>datid</code>            | oid         | pg_database.oid | Database OID  |
| <code>datname</code>          | name        |                 | Database name   |
| <code>pid</code>              | integer     |                 | Process ID of this backend  |
| <code>sess_id</code>          | integer     |                 | Session ID  |
| <code>usesysid</code>         | oid         | pg_authid.oid   | OID of the user logged into this backend  |
| <code>username</code>         | name        |                 | Name of the user logged into this backend   |
| <code>application_name</code> | text        |                 | Name of the application that is connected to this backend   |
| <code>client_addr</code>      | inet        |                 | IP address of the client connected to this backend. If this field is null, it indicates either that the client is connected via a Unix socket on the server machine or that this is an internal process such as autovacuum. |
| <code>client_hostname</code>  | text        |                 | Host name of the connected client, as reported by a reverse DNS lookup of <code>client_addr</code> . This field will only be non-null for IP connections, and only when <code>log_hostname</code> is enabled.               |
| <code>client_port</code>      | integer     |                 | TCP port number that the client is using for communication with this backend, or -1 if a Unix socket is used  |
| <code>backend_start</code>    | timestamptz |                 | Time backend process was started  |
| <code>xact_start</code>       | timestamptz |                 | Transaction start time  |
| <code>query_start</code>      | timestamptz |                 | Time query began execution  |
| <code>state_change</code>     | timestamptz |                 | Time when the <code>state</code> was last changed   |
| <code>wait_event_type</code>  | text        |                 | Type of event for which the backend is waiting  |
| <code>wait_event</code>       | text        |                 | Wait event name if backend is currently waiting   |

| column               | type | references                       | description   |
|----------------------|------|----------------------------------|---|
| <code>state</code>   | text |                                  | <p>Current overall state of this backend. Possible values are:</p> <ul style="list-style-type: none"> <li>- <code>active</code>: The backend is running a query.</li> <li>- <code>idle</code>: The backend is waiting for a new client command.</li> <li>- <code>idle in transaction</code>: The backend is in a transaction, but is not currently running a query.</li> <li>- <code>idle in transaction (aborted)</code>: This state is similar to idle in transaction, except one of the statements in the transaction caused an error.</li> <li>- <code>fastpath function call</code>: The backend is running a fast-path function.</li> <li>- <code>disabled</code>: This state is reported if <code>track_activities</code> is deactivated in this backend.</li> </ul> |
| <code>query</code>   | text |                                  | Text of this backend's most recent query. If <code>state</code> is active this field shows the currently running query. In all other states, it shows the last query that was run.  |
| <code>rsgid</code>   | oid  | <code>pg_resgroup.oid</code>     | Resource group OID or 0.<br><br>See <a href="#">Note</a> .  |
| <code>rsgname</code> | text | <code>pg_resgroup.rsgname</code> | Resource group name or <code>unknown</code> .<br><br>See <a href="#">Note</a> .   |

## pg\_stat\_all\_indexes

The `pg_stat_all_indexes` view shows one row for each index in the current database that displays statistics about accesses to that specific index.

The `pg_stat_user_indexes` and `pg_stat_sys_indexes` views contain the same information, but filtered to only show user and system indexes respectively.

In Greenplum Database 6, the `pg_stat_*_indexes` views display access statistics for indexes only from the master instance. Access statistics from segment instances are ignored. You can create views that display usage statistics that combine statistics from the master and the segment instances, see [Index Access Statistics from the Master and Segment Instances](#).

| Column                    | Type   | Description  |
|---------------------------|--------|--|
| <code>relid</code>        | oid    | OID of the table for this index  |
| <code>indexrelid</code>   | oid    | OID of this index  |
| <code>schemaname</code>   | name   | Name of the schema this index is in  |
| <code>relname</code>      | name   | Name of the table for this index   |
| <code>indexrelname</code> | name   | Name of this index   |
| <code>idx_scan</code>     | bigint | Total number of index scans initiated on this index from all segment instances |

| Column                     | Type   | Description  |
|----------------------------|--------|--|
| <code>idx_tup_read</code>  | bigint | Number of index entries returned by scans on this index                  |
| <code>idx_tup_fetch</code> | bigint | Number of live table rows fetched by simple index scans using this index |

## Index Access Statistics from the Master and Segment Instances

To display index access statistics that combine statistics from the master and the segment instances you can create these views. A user requires `SELECT` privilege on the views to use them.

```
-- Create these index access statistics views
-- pg_stat_all_indexes_gpdb6
-- pg_stat_sys_indexes_gpdb6
-- pg_stat_user_indexes_gpdb6

CREATE VIEW pg_stat_all_indexes_gpdb6 AS
SELECT
    s.relid,
    s.indexrelid,
    s.schemaname,
    s.relname,
    s.indexrelname,
    m.idx_scan,
    m.idx_tup_read,
    m.idx_tup_fetch
FROM
    (SELECT
        relid,
        indexrelid,
        schemaname,
        relname,
        indexrelname,
        sum(idx_scan) as idx_scan,
        sum(idx_tup_read) as idx_tup_read,
        sum(idx_tup_fetch) as idx_tup_fetch
    FROM gp_dist_random('pg_stat_all_indexes')
    WHERE relid >= 16384
    GROUP BY relid, indexrelid, schemaname, relname, indexrelname
    UNION ALL
    SELECT *
    FROM pg_stat_all_indexes
    WHERE relid < 16384) m, pg_stat_all_indexes s
WHERE m.relid = s.relid;

CREATE VIEW pg_stat_sys_indexes_gpdb6 AS
SELECT * FROM pg_stat_all_indexes_gpdb6
WHERE schemaname IN ('pg_catalog', 'information_schema') OR
    schemaname ~ '^pg_toast';

CREATE VIEW pg_stat_user_indexes_gpdb6 AS
SELECT * FROM pg_stat_all_indexes_gpdb6
WHERE schemaname NOT IN ('pg_catalog', 'information_schema') AND
```

```
schemaname !~ '^pg_toast';
```

Parent topic: [System Catalogs Definitions](#)

## pg\_stat\_all\_tables

The `pg_stat_all_tables` view shows one row for each table in the current database (including TOAST tables) to display statistics about accesses to that specific table.

The `pg_stat_user_tables` and `pg_stat_sys_table` views contain the same information, but filtered to only show user and system tables respectively.

| Column                           | Type                     | Description  |
|----------------------------------|--------------------------|--|
| <code>relid</code>               | oid                      | OID of a table   |
| <code>schemaname</code>          | name                     | Name of the schema that this table is in   |
| <code>relname</code>             | name                     | Name of this table   |
| <code>seq_scan</code>            | bigint                   | Total number of sequential scans initiated on this table from all segment instances            |
| <code>seq_tup_read</code>        | bigint                   | Number of live rows fetched by sequential scans  |
| <code>idx_scan</code>            | bigint                   | Total number of index scans initiated on this table from all segment instances                 |
| <code>idx_tup_fetch</code>       | bigint                   | Number of live rows fetched by index scans   |
| <code>n_tup_ins</code>           | bigint                   | Number of rows inserted  |
| <code>n_tup_upd</code>           | bigint                   | Number of rows updated (includes HOT updated rows)   |
| <code>n_tup_del</code>           | bigint                   | Number of rows deleted   |
| <code>n_tup_hot_upd</code>       | bigint                   | Number of rows HOT updated (i.e., with no separate index update required)                      |
| <code>n_live_tup</code>          | bigint                   | Estimated number of live rows  |
| <code>n_dead_tup</code>          | bigint                   | Estimated number of dead rows  |
| <code>n_mod_since_analyze</code> | bigint                   | Estimated number of rows modified since this table was last analyzed                           |
| <code>last_vacuum</code>         | timestamp with time zone | Last time this table was manually vacuumed (not counting <code>VACUUM FULL</code> )            |
| <code>last_autovacuum</code>     | timestamp with time zone | Last time this table was vacuumed by the autovacuum daemon <sup>1</sup>                        |
| <code>last_analyze</code>        | timestamp with time zone | Last time this table was manually analyzed   |
| <code>last_autoanalyze</code>    | timestamp with time zone | Last time this table was analyzed by the autovacuum daemon <sup>1</sup>                        |
| <code>vacuum_count</code>        | bigint                   | Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code> ) |

| Column                         | Type   | Description  |
|--------------------------------|--------|--|
| <code>autovacuum_count</code>  | bigint | Number of times this table has been vacuumed by the autovacuum daemon <sup>1</sup> |
| <code>analyze_count</code>     | bigint | Number of times this table has been manually analyzed                              |
| <code>autoanalyze_count</code> | bigint | Number of times this table has been analyzed by the autovacuum daemon <sup>1</sup> |

**Note:** <sup>1</sup>In Greenplum Database, the autovacuum daemon is deactivated and not supported for user defined databases.

## pg\_stat\_last\_operation

The `pg_stat_last_operation` table contains metadata tracking information about database objects (tables, views, etc.).

| column                     | type                    | references                 | description  |
|----------------------------|-------------------------|----------------------------|--|
| <code>classid</code>       | oid                     | <code>pg_class.oid</code>  | OID of the system catalog containing the object.   |
| <code>objid</code>         | oid                     | any OID column             | OID of the object within its system catalog.   |
| <code>staactionname</code> | name                    |                            | The action that was taken on the object.   |
| <code>stasysid</code>      | oid                     | <code>pg_authid.oid</code> | A foreign key to <code>pg_authid.oid</code> .  |
| <code>stausename</code>    | name                    |                            | The name of the role that performed the operation on this object.  |
| <code>stasubtype</code>    | text                    |                            | The type of object operated on or the subclass of operation performed.   |
| <code>statime</code>       | timestamp with timezone |                            | The timestamp of the operation. This is the same timestamp that is written to the Greenplum Database server log files in case you need to look up more detailed information about the operation in the logs. |

The `pg_stat_last_operation` table contains metadata tracking information about operations on database objects. This information includes the object id, DDL action, user, type of object, and operation timestamp. Greenplum Database updates this table when a database object is created, altered, truncated, vacuumed, analyzed, or partitioned, and when privileges are granted to an object.

If you want to track the operations performed on a specific object, use the `objid` value. Because the `stasubtype` value can identify either the type of object operated on or the subclass of operation performed, it is not a suitable parameter when querying the `pg_stat_last_operation` table.

The following example creates and replaces a view, and then shows how to use `objid` as a query parameter on the `pg_stat_last_operation` table.

```
testdb=# CREATE VIEW trial AS SELECT * FROM gp_segment_configuration;
CREATE VIEW
testdb=# CREATE OR REPLACE VIEW trial AS SELECT * FROM gp_segment_configuration;
CREATE VIEW
testdb=# SELECT * FROM pg_stat_last_operation WHERE objid='trial'::regclass::oid;
 classid | objid | staactionname | stasysid | stausename | stasubtype | sta
time
-----+-----+-----+-----+-----+-----+-----
1259 | 24735 | CREATE | 10 | gpadmin | VIEW | 2020-04-07 16:
44:28.808811+00
1259 | 24735 | ALTER | 10 | gpadmin | SET | 2020-04-07 16:
44:38.110615+00
(2 rows)
```

Notice that the `pg_stat_last_operation` table entry for the view `REPLACE` operation specifies the `ALTER` action (`staactionname`) and the `SET` subtype (`stasubtype`).

Parent topic: [System Catalogs Definitions](#)

## pg\_stat\_last\_shoperation

The `pg_stat_last_shoperation` table contains metadata tracking information about global objects (roles, tablespaces, etc.).

| column                     | type                    | references                | description  |
|----------------------------|-------------------------|---------------------------|--|
| <code>classid</code>       | oid                     | <code>pg_class.oid</code> | OID of the system catalog containing the object.   |
| <code>objid</code>         | oid                     | any OID column            | OID of the object within its system catalog.   |
| <code>staactionname</code> | name                    |                           | The action that was taken on the object.   |
| <code>stasysid</code>      | oid                     |                           |  |
| <code>stausename</code>    | name                    |                           | The name of the role that performed the operation on this object.  |
| <code>stasubtype</code>    | text                    |                           | The type of object operated on or the subclass of operation performed.   |
| <code>statime</code>       | timestamp with timezone |                           | The timestamp of the operation. This is the same timestamp that is written to the Greenplum Database server log files in case you need to look up more detailed information about the operation in the logs. |

Parent topic: [System Catalogs Definitions](#)

## pg\_stat\_operations

The view `pg_stat_operations` shows details about the last operation performed on a database object (such as a table, index, view or database) or a global object (such as a role).

| column                  | type            | references | description  |
|-------------------------|-----------------|------------|--|
| <code>classname</code>  | text            |            | The name of the system table in the <code>pg_catalog</code> schema where the record about this object is stored ( <code>pg_class</code> =relations, <code>pg_database</code> =databases, <code>pg_namespace</code> =schemas, <code>pg_authid</code> =roles)  |
| <code>objname</code>    | name            |            | The name of the object.  |
| <code>objid</code>      | oid             |            | The OID of the object.   |
| <code>schemaname</code> | name            |            | The name of the schema where the object resides.   |
| <code>usestatus</code>  | text            |            | The status of the role who performed the last operation on the object ( <code>CURRENT</code> =a currently active role in the system, <code>DROPPED</code> =a role that no longer exists in the system, <code>CHANGED</code> =a role name that exists in the system, but has changed since the last operation was performed). |
| <code>username</code>   | name            |            | The name of the role that performed the operation on this object.  |
| <code>actionname</code> | name            |            | The action that was taken on the object.   |
| <code>subtype</code>    | text            |            | The type of object operated on or the subclass of operation performed.   |
| <code>statime</code>    | timest<br>amptz |            | The timestamp of the operation. This is the same timestamp that is written to the Greenplum Database server log files in case you need to look up more detailed information about the operation in the logs.   |

Parent topic: [System Catalogs Definitions](#)

## pg\_stat\_partition\_operations

The `pg_stat_partition_operations` view shows details about the last operation performed on a partitioned table.

| column                  | type | references | description   |
|-------------------------|------|------------|---|
| <code>classname</code>  | text |            | The name of the system table in the <code>pg_catalog</code> schema where the record about this object is stored (always <code>pg_class</code> for tables and partitions).   |
| <code>objname</code>    | name |            | The name of the object.   |
| <code>objid</code>      | oid  |            | The OID of the object.  |
| <code>schemaname</code> | name |            | The name of the schema where the object resides.  |
| <code>usestatus</code>  | text |            | The status of the role who performed the last operation on the object ( <code>CURRENT</code> =a currently active role in the system, <code>DROPPED</code> =a role that no longer exists in the system, <code>CHANGED</code> =a role name that exists in the system, but its definition has changed since the last operation was performed). |
| <code>username</code>   | name |            | The name of the role that performed the operation on this object.   |
| <code>actionname</code> | name |            | The action that was taken on the object.  |
| <code>subtype</code>    | text |            | The type of object operated on or the subclass of operation performed.  |

| column                            | type               | references | description  |
|-----------------------------------|--------------------|------------|--|
| <code>statime</code>              | timestamp<br>amptz |            | The timestamp of the operation. This is the same timestamp that is written to the Greenplum Database server log files in case you need to look up more detailed information about the operation in the logs. |
| <code>partition<br/>level</code>  | smallint           |            | The level of this partition in the hierarchy.  |
| <code>parenttab<br/>lename</code> | name               |            | The relation name of the parent table one level up from this partition.  |
| <code>parentsch<br/>ename</code>  | name               |            | The name of the schema where the parent table resides.   |
| <code>parent_re<br/>lid</code>    | oid                |            | The OID of the parent table one level up from this partition.  |

Parent topic: [System Catalogs Definitions](#)

## pg\_stat\_replication

The `pg_stat_replication` view contains metadata of the `walsender` process that is used for Greenplum Database master mirroring.

The `gp_stat_replication` view contains `walsender` replication information for master and segment mirroring.

| column                        | type      | references | description   |
|-------------------------------|-----------|------------|---|
| <code>pid</code>              | integer   |            | Process ID of WAL sender backend process.   |
| <code>usesysid</code>         | integer   |            | User system ID that runs the WAL sender backend process   |
| <code>username</code>         | name      |            | User name that runs WAL sender backend process.   |
| <code>application_name</code> | oid       |            | Client application name.  |
| <code>client_addr</code>      | name      |            | Client IP address.  |
| <code>client_hostname</code>  | text      |            | The host name of the client machine.  |
| <code>client_port</code>      | integer   |            | Client port number.   |
| <code>backend_start</code>    | timestamp |            | Operation start timestamp.  |
| <code>backend_xmin</code>     | xid       |            | The current backend's <code>xmin</code> horizon.  |
| <code>state</code>            | text      |            | WAL sender state. The value can be: <ul style="list-style-type: none"> <li><code>startup</code></li> <li><code>backup</code></li> <li><code>catchup</code></li> <li><code>streaming</code></li> </ul> |
| <code>sent_location</code>    | text      |            | WAL sender xlog record sent location.   |

| column                       | type | references | description  |
|------------------------------|------|------------|--|
| <code>write_location</code>  | text |            | WAL receiver xlog record write location.                           |
| <code>flush_location</code>  | text |            | WAL receiver xlog record flush location.                           |
| <code>replay_location</code> | text |            | Standby xlog record replay location.                               |
| <code>sync_priority</code>   | text |            | Priority. the value is 1.  |
| <code>sync_state</code>      | text |            | WAL sender synchronization state. The value is <code>sync</code> . |

Parent topic: [System Catalogs Definitions](#)

## pg\_statistic

The `pg_statistic` system catalog table stores statistical data about the contents of the database. Entries are created by `ANALYZE` and subsequently used by the query optimizer. There is one entry for each table column that has been analyzed. Note that all the statistical data is inherently approximate, even assuming that it is up-to-date.

`pg_statistic` also stores statistical data about the values of index expressions. These are described as if they were actual data columns; in particular, `starelid` references the index. No entry is made for an ordinary non-expression index column, however, since it would be redundant with the entry for the underlying table column. Currently, entries for index expressions always have `stainherit = false`.

When `stainherit = false`, there is normally one entry for each table column that has been analyzed. If the table has inheritance children, Greenplum Database creates a second entry with `stainherit = true`. This row represents the column's statistics over the inheritance tree, for example, statistics for the data you would see with `SELECT column FROM table*`, whereas the `stainherit = false` row represents the results of `SELECT column FROM ONLY table`.

Since different kinds of statistics may be appropriate for different kinds of data, `pg_statistic` is designed not to assume very much about what sort of statistics it stores. Only extremely general statistics (such as nullness) are given dedicated columns in `pg_statistic`. Everything else is stored in slots, which are groups of associated columns whose content is identified by a code number in one of the slot's columns.

Statistical information about a table's contents should be considered sensitive (for example: minimum and maximum values of a salary column). `pg_stats` is a publicly readable view on `pg_statistic` that only exposes information about those tables that are readable by the current user.

**Warning:** Diagnostic tools such as `gpsd` and `minirepro` collect sensitive information from `pg_statistic`, such as histogram boundaries, in a clear, readable form. Always review the output files of these utilities to ensure that the contents are acceptable for transport outside of the database in your organization.

| column                | type | references                | description  |
|-----------------------|------|---------------------------|--|
| <code>starelid</code> | oid  | <code>pg_class.oid</code> | The table or index that the described column belongs to. |

| column                     | type     | references                       | description   |
|----------------------------|----------|----------------------------------|---|
| <code>staattnum</code>     | int2     | <code>pg_attribute.attnum</code> | The number of the described column.   |
| <code>stainherit</code>    | bool     |                                  | If true, the statistics include inheritance child columns, not just the values in the specified relations.  |
| <code>stanullfrac</code>   | float4   |                                  | The fraction of the column's entries that are null.   |
| <code>stawidthh</code>     | int4     |                                  | The average stored width, in bytes, of nonnull entries.   |
| <code>stadistinct</code>   | float4   |                                  | The number of distinct nonnull data values in the column. A value greater than zero is the actual number of distinct values. A value less than zero is the negative of a fraction of the number of rows in the table (for example, a column in which values appear about twice on the average could be represented by <code>stadistinct = -0.5</code> ). A zero value means the number of distinct values is unknown. |
| <code>stakind*N*</code>    | int2     |                                  | A code number indicating the kind of statistics stored in the <code>n</code> th slot of the <code>pg_statistic</code> row.  |
| <code>staop*N*</code>      | oid      | <code>pg_operator.oid</code>     | An operator used to derive the statistics stored in the <code>n</code> th slot. For example, a histogram slot would show the <code>&lt;</code> operator that defines the sort order of the data.  |
| <code>stanumbers*N*</code> | float4[] |                                  | Numerical statistics of the appropriate kind for the <code>n</code> th slot, or NULL if the slot kind does not involve numerical values.  |
| <code>stavalues*N*</code>  | anyarray |                                  | Column data values of the appropriate kind for the <code>n</code> th slot, or NULL if the slot kind does not store any data values. Each array's element values are actually of the specific column's data type, so there is no way to define these columns' type more specifically than <code>anyarray</code> .  |

## pg\_stat\_resqueues

**Note:** The `pg_stat_resqueues` view is valid only when resource queue-based resource management is active.

The `pg_stat_resqueues` view allows administrators to view metrics about a resource queue's workload over time. To allow statistics to be collected for this view, you must enable the `stats_queue_level` server configuration parameter on the Greenplum Database master instance. Enabling the collection of these metrics does incur a small performance penalty, as each statement submitted through a resource queue must be logged in the system catalog tables.

| column                      | type   | references | description  |
|-----------------------------|--------|------------|--|
| <code>queueid</code>        | oid    |            | The OID of the resource queue.   |
| <code>queuename</code>      | name   |            | The name of the resource queue.  |
| <code>n_queries_exec</code> | bigint |            | Number of queries submitted for execution from this resource queue.                        |
| <code>n_queries_wait</code> | bigint |            | Number of queries submitted to this resource queue that had to wait before they could run. |

| column                    | type   | references | description  |
|---------------------------|--------|------------|--|
| <code>elapsed_exec</code> | bigint |            | Total elapsed execution time for statements submitted through this resource queue.                         |
| <code>elapsed_wait</code> | bigint |            | Total elapsed time that statements submitted through this resource queue had to wait before they were run. |

## pg\_tablespace

The `pg_tablespace` system catalog table stores information about the available tablespaces. Tables can be placed in particular tablespaces to aid administration of disk layout. Unlike most system catalogs, `pg_tablespace` is shared across all databases of a Greenplum system: there is only one copy of `pg_tablespace` per system, not one per database.

| column                  | type      | references                 | description   |
|-------------------------|-----------|----------------------------|---|
| <code>spcname</code>    | name      |                            | Tablespace name.  |
| <code>spcowner</code>   | oid       | <code>pg_authid.oid</code> | Owner of the tablespace, usually the user who created it. |
| <code>spcacl</code>     | aclitem[] |                            | Tablespace access privileges.                             |
| <code>spcoptions</code> | text[]    |                            | Tablespace contentID locations.                           |

Parent topic: [System Catalogs Definitions](#)

## pg\_trigger

The `pg_trigger` system catalog table stores triggers on tables.

**Note:** Greenplum Database does not support triggers.

| column                    | type    | references                | description  |
|---------------------------|---------|---------------------------|--|
| <code>tgrelid</code>      | oid     | <code>pg_class.oid</code> | The table this trigger is on.<br><br>Note that Greenplum Database does not enforce referential integrity.              |
| <code>tgname</code>       | name    |                           | Trigger name (must be unique among triggers of same table).  |
| <code>tgfoid</code>       | oid     | <code>pg_proc.oid</code>  | The function to be called.<br><br>Note that Greenplum Database does not enforce referential integrity.                 |
| <code>tgtype</code>       | int2    |                           | Bit mask identifying trigger conditions.   |
| <code>tgenabled</code>    | boolean |                           | True if trigger is enabled.  |
| <code>tgisinternal</code> | boolean |                           | True if trigger is internally generated (usually, to enforce the constraint identified by <code>tgconstraint</code> ). |

| column                      | type                      | references  | description   |
|-----------------------------|---------------------------|---|---|
| <code>tgconstrrelid</code>  | oid                       | <code>pg_class.oid</code><br><br>Note that Greenplum Database does not enforce referential integrity. | The table referenced by an referential integrity constraint.  |
| <code>tgconstrindid</code>  | oid                       | <code>pg_class.oid</code>   | The index supporting a unique, primary key, or referential integrity constraint.  |
| <code>tgconstraint</code>   | oid                       | <code>pg_constraint.oid</code>  | The <code>pg_constraint</code> entry associated with the trigger, if any.   |
| <code>tgdeferrable</code>   | boolean                   |   | True if deferrable.   |
| <code>tginitdeferred</code> | boolean                   |   | True if initially deferred.   |
| <code>tgargs</code>         | int2                      |   | Number of argument strings passed to trigger function.  |
| <code>tgattr</code>         | int2vector                |   | Currently not used.   |
| <code>tgargs</code>         | bytea                     |   | Argument strings to pass to trigger, each NULL-terminated.  |
| <code>tgqual</code>         | <code>pg_node_tree</code> |   | Expression tree (in <code>nodeToString()</code> representation) for the trigger's <code>WHEN</code> condition, or null if none. |

Parent topic: [System Catalogs Definitions](#)

## pg\_type

The `pg_type` system catalog table stores information about data types. Base types (scalar types) are created with `CREATE TYPE`, and domains with `CREATE DOMAIN`. A composite type is automatically created for each table in the database, to represent the row structure of the table. It is also possible to create composite types with `CREATE TYPE AS`.

| column                    | type | references                    | description   |
|---------------------------|------|-------------------------------|---|
| <code>oid</code>          | oid  |                               | Row identifier (hidden attribute; must be explicitly selected)  |
| <code>typname</code>      | name |                               | Data type name  |
| <code>typnamespace</code> | oid  | <code>pg_namespace.oid</code> | The OID of the namespace that contains this type  |
| <code>typowner</code>     | oid  | <code>pg_authid.oid</code>    | Owner of the type   |
| <code>typelen</code>      | int2 |                               | For a fixed-size type, <code>typelen</code> is the number of bytes in the internal representation of the type. But for a variable-length type, <code>typelen</code> is negative. <code>-1</code> indicates a 'varlena' type (one that has a length word), <code>-2</code> indicates a null-terminated C string. |

| column                      | type    | references                | description  |
|-----------------------------|---------|---------------------------|--|
| <code>typbyval</code>       | boolean |                           | Determines whether internal routines pass a value of this type by value or by reference. <code>typbyval</code> had better be false if <code>typelen</code> is not 1, 2, or 4 (or 8 on machines where Datum is 8 bytes). Variable-length types are always passed by reference. Note that <code>typbyval</code> can be false even if the length would allow pass-by-value.   |
| <code>typtype</code>        | char    |                           | <code>b</code> for a base type, <code>c</code> for a composite type, <code>d</code> for a domain, <code>e</code> for an enum type, <code>p</code> for a pseudo-type, or <code>r</code> for a range type. See also <code>typrelid</code> and <code>typbasetype</code> .   |
| <code>typcategory</code>    | char    |                           | Arbitrary classification of data types that is used by the parser to determine which implicit casts should be preferred. See <a href="#">Category Codes</a> .  |
| <code>typispreferred</code> | boolean |                           | True if the type is a preferred cast target within its <code>typcategory</code>  |
| <code>typisdefined</code>   | boolean |                           | True if the type is defined, false if this is a placeholder entry for a not-yet-defined type. When false, nothing except the type name, namespace, and OID can be relied on.   |
| <code>typdelim</code>       | char    |                           | Character that separates two values of this type when parsing array input. Note that the delimiter is associated with the array element data type, not the array data type.  |
| <code>typrelid</code>       | oid     | <code>pg_class.oid</code> | If this is a composite type (see <code>typtype</code> ), then this column points to the <code>pg_class</code> entry that defines the corresponding table. (For a free-standing composite type, the <code>pg_class</code> entry does not really represent a table, but it is needed anyway for the type's <code>pg_attribute</code> entries to link to.) Zero for non-composite types.  |
| <code>typelem</code>        | oid     | <code>pg_type.oid</code>  | If not 0 then it identifies another row in <code>pg_type</code> . The current type can then be subscripted like an array yielding values of type <code>typelem</code> . A "true" array type is variable length ( <code>typelen = -1</code> ), but some fixed-length ( <code>typelen &gt; 0</code> ) types also have nonzero <code>typelem</code> , for example <code>name</code> and <code>point</code> . If a fixed-length type has a <code>typelem</code> then its internal representation must be some number of values of the <code>typelem</code> data type with no other data. Variable-length array types have a header defined by the array subroutines. |
| <code>typarray</code>       | oid     | <code>pg_type.oid</code>  | If not 0, identifies another row in <code>pg_type</code> , which is the "true" array type having this type as its element. Use <code>pg_type.typarray</code> to locate the array type associated with a specific type.   |
| <code>typinput</code>       | regproc | <code>pg_proc.oid</code>  | Input conversion function (text format)  |
| <code>typoutput</code>      | regproc | <code>pg_proc.oid</code>  | Output conversion function (text format)   |
| <code>typreceive</code>     | regproc | <code>pg_proc.oid</code>  | Input conversion function (binary format), or 0 if none  |
| <code>typsend</code>        | regproc | <code>pg_proc.oid</code>  | Output conversion function (binary format), or 0 if none   |
| <code>typmodin</code>       | regproc | <code>pg_proc.oid</code>  | Type modifier input function, or 0 if the type does not support modifiers  |
| <code>typmodout</code>      | regproc | <code>pg_proc.oid</code>  | Type modifier output function, or 0 to use the standard format   |
| <code>typanalyze</code>     | regproc | <code>pg_proc.oid</code>  | Custom <code>ANALYZE</code> function, or 0 to use the standard function  |

| column                     | type                      | references                    | description   |
|----------------------------|---------------------------|-------------------------------|---|
| <code>typalign</code>      | char                      |                               | <p>The alignment required when storing a value of this type. It applies to storage on disk as well as most representations of the value inside Greenplum Database. When multiple values are stored consecutively, such as in the representation of a complete row on disk, padding is inserted before a datum of this type so that it begins on the specified boundary. The alignment reference is the beginning of the first datum in the sequence. Possible values are:</p> <p><code>c</code> = char alignment (no alignment needed).</p> <p><code>s</code> = short alignment (2 bytes on most machines).</p> <p><code>i</code> = int alignment (4 bytes on most machines).</p> <p><code>d</code> = double alignment (8 bytes on many machines, but not all).</p> |
| <code>typstorage</code>    | char                      |                               | <p>For varlena types (those with <code>typplen = -1</code>) tells if the type is prepared for toasting and what the default strategy for attributes of this type should be. Possible values are:</p> <p><code>p</code>: Value must always be stored plain.</p> <p><code>e</code>: Value can be stored in a secondary relation (if relation has one, see <code>pg_class.reltoastrelid</code>).</p> <p><code>m</code>: Value can be stored compressed inline.</p> <p><code>x</code>: Value can be stored compressed inline or stored in secondary storage.</p> <p>Note that <code>m</code> columns can also be moved out to secondary storage, but only as a last resort (<code>e</code> and <code>x</code> columns are moved first).</p>                             |
| <code>typnotnull</code>    | boolean                   |                               | Represents a not-null constraint on a type. Used for domains only.  |
| <code>typbasetype</code>   | oid                       | <code>pg_type.oid</code>      | Identifies the type that a domain is based on. Zero if this type is not a domain.   |
| <code>typmod</code>        | int4                      |                               | Domains use <code>typmod</code> to record the <code>typmod</code> to be applied to their base type (-1 if base type does not use a <code>typmod</code> ). -1 if this type is not a domain.  |
| <code>typndims</code>      | int4                      |                               | The number of array dimensions for a domain over an array (if <code>typbasetype</code> is an array type). Zero for types other than domains over array types.   |
| <code>typcollation</code>  | oid                       | <code>pg_collation.oid</code> | Specifies the collation of the type. Zero if the type does not support collations. The value is <code>DEFAULT_COLLATION_OID</code> for a base type that supports collations. A domain over a collatable type can have some other collation OID if one was specified for the domain.   |
| <code>typdefaultbin</code> | <code>pg_node_tree</code> |                               | If not null, it is the <code>nodeToString()</code> representation of a default expression for the type. This is only used for domains.  |
| <code>typdefault</code>    | text                      |                               | Null if the type has no associated default value. If <code>typdefaultbin</code> is not null, <code>typdefault</code> must contain a human-readable version of the default expression represented by <code>typdefaultbin</code> . If <code>typdefaultbin</code> is null and <code>typdefault</code> is not, then <code>typdefault</code> is the external representation of the type's default value, which may be fed to the type's input converter to produce a constant.   |

| column              | type                   | references | description  |
|---------------------|------------------------|------------|--|
| <code>typacl</code> | <code>aclitem[]</code> |            | Access privileges; see <a href="#">GRANT</a> and <a href="#">REVOKE</a> for details. |

The following table lists the system-defined values of `typcategory`. Any future additions to this list will also be upper-case ASCII letters. All other ASCII characters are reserved for user-defined categories.

| Code | Category                  |
|------|---------------------------|
| A    | Array types               |
| B    | Boolean types             |
| C    | Composite types           |
| D    | Date/time types           |
| E    | Enum types                |
| G    | Geometric types           |
| I    | Network address types     |
| N    | Numeric types             |
| P    | Pseudo-types              |
| R    | Range types               |
| S    | String types              |
| T    | Timespan types            |
| U    | User-defined types        |
| V    | Bit-string types          |
| X    | <code>unknown</code> type |

Parent topic: [System Catalogs Definitions](#)

## pg\_type\_encoding

The `pg_type_encoding` system catalog table contains the column storage type information.

| column                | type                 | modifiers             | storage               | description                                 |
|-----------------------|----------------------|-----------------------|-----------------------|---|
| <code>typeid</code>   | <code>oid</code>     | <code>not null</code> | <code>plain</code>    | Foreign key to <a href="#">pg_attribute</a> |
| <code>typtions</code> | <code>text []</code> |                       | <code>extended</code> | The actual options                          |

Parent topic: [System Catalogs Definitions](#)

## pg\_user\_mapping

The system catalog table `pg_user_mapping` stores the mappings from local user to remote user. You must have administrator privileges to view this catalog. Access to this catalog is restricted from

normal users, use the `pg_user_mappings` view instead.

| column                 | type   | references                         | description  |
|------------------------|--------|------------------------------------|--|
| <code>umuser</code>    | oid    | <code>pg_authid.oid</code>         | OID of the local role being mapped, 0 if the user mapping is public. |
| <code>umserver</code>  | oid    | <code>pg_foreign_server.oid</code> | OID of the foreign server that contains this mapping.                |
| <code>umoptions</code> | text[] |                                    | User mapping-specific options, as "keyword=value" strings.           |

Parent topic: [System Catalogs Definitions](#)

## pg\_user\_mappings

The `pg_user_mappings` view provides access to information about user mappings. This view is essentially a public-readable view of the `pg_user_mapping` system catalog table that omits the options field if the user does not have access rights to view it.

| column                 | type   | references                             | description  |
|------------------------|--------|--|--|
| <code>umid</code>      | oid    | <code>pg_user_mapping.oid</code>       | OID of the user mapping.   |
| <code>srvid</code>     | oid    | <code>pg_foreign_server.oid</code>     | OID of the foreign server that contains this mapping.                |
| <code>srvname</code>   | text   | <code>pg_foreign_server.srvname</code> | Name of the foreign server.  |
| <code>umuser</code>    | oid    | <code>pg_authid.oid</code>             | OID of the local role being mapped, 0 if the user mapping is public. |
| <code>username</code>  | name   |  | Name of the local user to be mapped.                                 |
| <code>umoptions</code> | text[] |  | User mapping-specific options, as "keyword=value" strings.           |

To protect password information stored as a user mapping option, the `umoptions` column reads as null unless one of the following applies:

- The current user is the user being mapped, and owns the server or holds `USAGE` privilege on it.
- The current user is the server owner and the mapping is for `PUBLIC`.
- The current user is a superuser.

Parent topic: [System Catalogs Definitions](#)

## user\_mapping\_options

The `user_mapping_options` view contains all of the options defined for user mappings in the current database. Greenplum Database displays only those user mappings to which the current user has access (by way of being the owner or having some privilege).

| column                                | type           | references | description   |
|---------------------------------------|----------------|------------|---|
| <code>authorization_identifier</code> | sql_identifier |            | Name of the user being mapped, or <code>PUBLIC</code> if the mapping is public.                                 |
| <code>foreign_server_catalog</code>   | sql_identifier |            | Name of the database in which the foreign server used by this mapping is defined (always the current database). |

| column                           | type           | references | description   |
|----------------------------------|----------------|------------|---|
| <code>foreign_server_name</code> | sql_identifier |            | Name of the foreign server used by this mapping.  |
| <code>option_name</code>         | sql_identifier |            | Name of an option.  |
| <code>option_value</code>        | character_data |            | Value of the option. This column will display null unless: <ul style="list-style-type: none"> <li>- The current user is the user being mapped.</li> <li>- The mapping is for <code>PUBLIC</code> and the current user is the foreign server owner.</li> <li>- The current user is a superuser.</li> </ul> <p>The intent is to protect password information stored as a user mapping option.</p> |

Parent topic: [System Catalogs Definitions](#)

## user\_mappings

The `user_mappings` view contains all of the user mappings defined in the current database. Greenplum Database displays only those user mappings to which the current user has access (by way of being the owner or having some privilege).

| column                                | type           | references | description   |
|---------------------------------------|----------------|------------|---|
| <code>authorization_identifier</code> | sql_identifier |            | Name of the user being mapped, or <code>PUBLIC</code> if the mapping is public.                                 |
| <code>foreign_server_catalog</code>   | sql_identifier |            | Name of the database in which the foreign server used by this mapping is defined (always the current database). |
| <code>foreign_server_name</code>      | sql_identifier |            | Name of the foreign server used by this mapping.  |

Parent topic: [System Catalogs Definitions](#)

## The gp\_toolkit Administrative Schema

Greenplum Database provides an administrative schema called `gp_toolkit` that you can use to query the system catalogs, log files, and operating environment for system status information. The `gp_toolkit` schema contains a number of views that you can access using SQL commands. The `gp_toolkit` schema is accessible to all database users, although some objects may require superuser permissions. For convenience, you may want to add the `gp_toolkit` schema to your schema search path. For example:

```
=> ALTER ROLE myrole SET search_path TO myschema, gp_toolkit;
```

This documentation describes the most useful views in `gp_toolkit`. You may notice other objects (views, functions, and external tables) within the `gp_toolkit` schema that are not described in this documentation (these are supporting objects to the views described in this section).

**Warning:** Do not change database objects in the `gp_toolkit` schema. Do not create database objects in the schema. Changes to objects in the schema might affect the accuracy of administrative information returned by schema objects. Any changes made in the `gp_toolkit` schema are lost when the database is backed up and then restored with the `gpbackup` and `gprestore` utilities.

These are the categories for views in the `gp_toolkit` schema.

- [Checking for Tables that Need Routine Maintenance](#)
- [Checking for Locks](#)
- [Checking Append-Optimized Tables](#)
- [Viewing Greenplum Database Server Log Files](#)
- [Checking Server Configuration Files](#)
- [Checking for Failed Segments](#)
- [Checking Resource Group Activity and Status](#)
- [Checking Resource Queue Activity and Status](#)
- [Checking Query Disk Spill Space Usage](#)
- [Viewing Users and Groups \(Roles\)](#)
- [Checking Database Object Sizes and Disk Space](#)
- [Checking for Uneven Data Distribution](#)

Parent topic: [Greenplum Database Reference Guide](#)

## Checking for Tables that Need Routine Maintenance

The following views can help identify tables that need routine table maintenance (`VACUUM` and/or `ANALYZE`).

- [gp\\_bloat\\_diag](#)
- [gp\\_stats\\_missing](#)

The `VACUUM` or `VACUUM FULL` command reclaims disk space occupied by deleted or obsolete rows. Because of the MVCC transaction concurrency model used in Greenplum Database, data rows that are deleted or updated still occupy physical space on disk even though they are not visible to any new transactions. Expired rows increase table size on disk and eventually slow down scans of the table.

The `ANALYZE` command collects column-level statistics needed by the query optimizer. Greenplum Database uses a cost-based query optimizer that relies on database statistics. Accurate statistics allow the query optimizer to better estimate selectivity and the number of rows retrieved by a query operation in order to choose the most efficient query plan.

Parent topic: [The gp\\_toolkit Administrative Schema](#)

### gp\_bloat\_diag

This view shows regular heap-storage tables that have bloat (the actual number of pages on disk exceeds the expected number of pages given the table statistics). Tables that are bloated require a `VACUUM` or a `VACUUM FULL` in order to reclaim disk space occupied by deleted or obsolete rows. This view is accessible to all users, however non-superusers will only be able to see the tables that they have permission to access.

**Note:** For diagnostic functions that return append-optimized table information, see [Checking Append-Optimized Tables](#).

| Column                   | Description                                    |
|--------------------------|--|
| <code>bdirelid</code>    | Table object id.                               |
| <code>bdinspname</code>  | Schema name.                                   |
| <code>bdirelname</code>  | Table name.                                    |
| <code>bdirelpages</code> | Actual number of pages on disk.                |
| <code>bdiexppages</code> | Expected number of pages given the table data. |
| <code>bdidiag</code>     | Bloat diagnostic message.                      |

## gp\_stats\_missing

This view shows tables that do not have statistics and therefore may require an `ANALYZE` be run on the table.

**Note:** By default, `gp_stats_missing` does not display data for materialized views. Refer to [Including Data for Materialized Views](#) for instructions on adding this data to the `gp_stats_missing*` view output.

| Column                                  | Description  |
|---|--|
| <code>smische</code><br><code>ma</code> | Schema name.   |
| <code>smitable</code>                   | Table name.  |
| <code>smisize</code>                    | Does this table have statistics? False if the table does not have row count and row sizing statistics recorded in the system catalog, which may indicate that the table needs to be analyzed. This will also be false if the table does not contain any rows. For example, the parent tables of partitioned tables are always empty and will always return a false result. |
| <code>smicols</code>                    | Number of columns in the table.  |
| <code>smirecs</code>                    | The total number of columns in the table that have statistics recorded.  |

## Checking for Locks

When a transaction accesses a relation (such as a table), it acquires a lock. Depending on the type of lock acquired, subsequent transactions may have to wait before they can access the same relation. For more information on the types of locks, see "Managing Data" in the *Greenplum Database Administrator Guide*. Greenplum Database resource queues (used for resource management) also use locks to control the admission of queries into the system.

The `gp_locks_*` family of views can help diagnose queries and sessions that are waiting to access an object due to a lock.

- [gp\\_locks\\_on\\_relation](#)
- [gp\\_locks\\_on\\_resqueue](#)

**Parent topic:** [The gp\\_toolkit Administrative Schema](#)

## gp\_locks\_on\_relation

This view shows any locks currently being held on a relation, and the associated session information about the query associated with the lock. For more information on the types of locks, see "Managing Data" in the *Greenplum Database Administrator Guide*. This view is accessible to all users, however non-superusers will only be able to see the locks for relations that they have permission to access.

| Column          | Description   |
|-----------------|---|
| lorlocktype     | Type of the lockable object: <code>relation</code> , <code>extend</code> , <code>page</code> , <code>tuple</code> , <code>transactionid</code> , <code>object</code> , <code>userlock</code> , <code>resource queue</code> , or <code>advisory</code> |
| lordatabase     | Object ID of the database in which the object exists, zero if the object is a shared object.  |
| lorrelname      | The name of the relation.   |
| lorrelation     | The object ID of the relation.  |
| lortransaction  | The transaction ID that is affected by the lock.  |
| lorpid          | Process ID of the server process holding or awaiting this lock. NULL if the lock is held by a prepared transaction.   |
| lormode         | Name of the lock mode held or desired by this process.  |
| lorgranted      | Displays whether the lock is granted (true) or not granted (false).   |
| lorcurrentquery | The current query in the session.   |

## gp\_locks\_on\_resqueue

**Note:** The `gp_locks_on_resqueue` view is valid only when resource queue-based resource management is active.

This view shows any locks currently being held on a resource queue, and the associated session information about the query associated with the lock. This view is accessible to all users, however non-superusers will only be able to see the locks associated with their own sessions.

| Column      | Description  |
|-------------|--|
| lorusername | Name of the user running the session.                    |
| lorsrqname  | The resource queue name.                                 |
| lorlocktype | Type of the lockable object: <code>resource queue</code> |
| lorobjid    | The ID of the locked transaction.                        |

| Column         | Description   |
|----------------|---|
| lortransaction | The ID of the transaction that is affected by the lock.             |
| lorpid         | The process ID of the transaction that is affected by the lock.     |
| lormode        | The name of the lock mode held or desired by this process.          |
| lorgranted     | Displays whether the lock is granted (true) or not granted (false). |
| lorwaiting     | Displays whether or not the session is waiting.                     |

## Checking Append-Optimized Tables

The `gp_toolkit` schema includes a set of diagnostic functions you can use to investigate the state of append-optimized tables.

When an append-optimized table (or column-oriented append-optimized table) is created, another table is implicitly created, containing metadata about the current state of the table. The metadata includes information such as the number of records in each of the table's segments.

Append-optimized tables may have non-visible rows—rows that have been updated or deleted, but remain in storage until the table is compacted using `VACUUM`. The hidden rows are tracked using an auxiliary visibility map table, or visimap.

The following functions let you access the metadata for append-optimized and column-oriented tables and view non-visible rows.

For most of the functions, the input argument is `regclass`, either the table `name` or the `oid` of a table.

**Parent topic:** [The gp\\_toolkit Administrative Schema](#)

### \_\_gp\_aovisimap\_compaction\_info(oid)

This function displays compaction information for an append-optimized table. The information is for the on-disk data files on Greenplum Database segments that store the table data. You can use the information to determine the data files that will be compacted by a `VACUUM` operation on an append-optimized table.

**Note:** Until a `VACUUM` operation deletes the row from the data file, deleted or updated data rows occupy physical space on disk even though they are hidden to new transactions. The configuration parameter `gp_appendonly_compaction` controls the functionality of the `VACUUM` command.

This table describes the `__gp_aovisimap_compaction_info` function output table.

| Column              | Description  |
|---------------------|--|
| content             | Greenplum Database segment ID.   |
| datafile            | ID of the data file on the segment.  |
| compaction_possible | The value is either <code>t</code> or <code>f</code> . The value <code>t</code> indicates that the data in data file be compacted when a <code>VACUUM</code> operation is performed.<br><br>The server configuration parameter <code>gp_appendonly_compaction_threshold</code> affects this value. |

| Column          | Description  |
|-----------------|--|
| hidden_tupcount | In the data file, the number of hidden (deleted or updated) rows.                                |
| total_tupcount  | In the data file, the total number of rows.  |
| percent_hidden  | In the data file, the ratio (as a percentage) of hidden (deleted or updated) rows to total rows. |

## \_\_gp\_aoseg(regclass)

This function returns metadata information contained in the append-optimized table's on-disk segment file.

The input argument is the name or the oid of an append-optimized table.

| Column           | Description  |
|------------------|--|
| segno            | The file segment number.   |
| eof              | The effective end of file for this file segment.   |
| tupcount         | The total number of tuples in the segment, including invisible tuples.                                     |
| varblockcount    | The total number of varblocks in the file segment.   |
| eof_uncompressed | The end of file if the file segment were uncompressed.   |
| modcount         | The number of data modification operations.  |
| state            | The state of the file segment. Indicates if the segment is active or ready to be dropped after compaction. |

## \_\_gp\_aoseg\_history(regclass)

This function returns metadata information contained in the append-optimized table's on-disk segment file. It displays all different versions (heap tuples) of the aoseg meta information. The data is complex, but users with a deep understanding of the system may find it useful for debugging.

The input argument is the name or the oid of an append-optimized table.

| Column          | Description  |
|-----------------|--|
| gp_tid          | The id of the tuple.                                   |
| gp_xmin         | The id of the earliest transaction.                    |
| gp_xmin_status  | Status of the gp_xmin transaction.                     |
| gp_xmin_commit_ | The commit distribution id of the gp_xmin transaction. |
| gp_xmax         | The id of the latest transaction.                      |
| gp_xmax_status  | The status of the latest transaction.                  |
| gp_xmax_commit_ | The commit distribution id of the gp_xmax transaction. |
| gp_command_id   | The id of the query command.                           |
| gp_infomask     | A bitmap containing state information.                 |

| Column           | Description  |
|------------------|--|
| gp_update_tid    | The ID of the newer tuple if the row is updated.           |
| gp_visibility    | The tuple visibility status.                               |
| segno            | The number of the segment in the segment file.             |
| tupcount         | The number of tuples, including hidden tuples.             |
| eof              | The effective end of file for the segment.                 |
| eof_uncompressed | The end of file for the segment if data were uncompressed. |
| modcount         | A count of data modifications.                             |
| state            | The status of the segment.                                 |

## \_\_gp\_aocsseg(regclass)

This function returns metadata information contained in a column-oriented append-optimized table's on-disk segment file, excluding non-visible rows. Each row describes a segment for a column in the table.

The input argument is the name or the oid of a column-oriented append-optimized table.

| Column           | Description  |
|------------------|--|
| gp_tid           | The table id.  |
| segno            | The segment number.  |
| column_num       | The column number.   |
| physical_segno   | The number of the segment in the segment file.                 |
| tupcount         | The number of rows in the segment, excluding hidden tuples.    |
| eof              | The effective end of file for the segment.                     |
| eof_uncompressed | The end of file for the segment if the data were uncompressed. |
| modcount         | A count of data modification operations for the segment.       |
| state            | The status of the segment.                                     |

## \_\_gp\_aocsseg\_history(regclass)

This function returns metadata information contained in a column-oriented append-optimized table's on-disk segment file. Each row describes a segment for a column in the table. The data is complex, but users with a deep understanding of the system may find it useful for debugging.

The input argument is the name or the oid of a column-oriented append-optimized table.

| Column  | Description               |
|---------|---------------------------|
| gp_tid  | The oid of the tuple.     |
| gp_xmin | The earliest transaction. |

| Column           | Description  |
|------------------|--|
| gp_xmin_status   | The status of the gp_xmin transaction.                         |
| gp_xmin_         | Text representation of gp_xmin.                                |
| gp_xmax          | The latest transaction.  |
| gp_xmax_status   | The status of the gp_xmax transaction.                         |
| gp_xmax_         | Text representation of gp_max.                                 |
| gp_command_id    | ID of the command operating on the tuple.                      |
| gp_infomask      | A bitmap containing state information.                         |
| gp_update_tid    | The ID of the newer tuple if the row is updated.               |
| gp_visibility    | The tuple visibility status.                                   |
| segno            | The segment number in the segment file.                        |
| column_num       | The column number.   |
| physical_segno   | The segment containing data for the column.                    |
| tupcount         | The total number of tuples in the segment.                     |
| eof              | The effective end of file for the segment.                     |
| eof_uncompressed | The end of file for the segment if the data were uncompressed. |
| modcount         | A count of the data modification operations.                   |
| state            | The state of the segment.                                      |

## `__gp_aovisimap(regclass)`

This function returns the tuple ID, the segment file, and the row number of each non-visible tuple according to the visibility map.

The input argument is the name or the oid of an append-optimized table.

| Column  | Description   |
|---------|---|
| tid     | The tuple id.   |
| segno   | The number of the segment file.                           |
| row_num | The row number of a row that has been deleted or updated. |

## `__gp_aovisimap_hidden_info(regclass)`

This function returns the numbers of hidden and visible tuples in the segment files for an append-optimized table.

The input argument is the name or the oid of an append-optimized table.

| Column | Description                     |
|--------|---------------------------------|
| segno  | The number of the segment file. |

| Column          | Description                                      |
|-----------------|--|
| hidden_tupcount | The number of hidden tuples in the segment file. |
| total_tupcount  | The total number of tuples in the segment file.  |

## \_\_gp\_aovisimap\_entry(regclass)

This function returns information about each visibility map entry for the table.

The input argument is the name or the oid of an append-optimized table.

| Column          | Description                                     |
|-----------------|---|
| segno           | Segment number of the visibility map entry.     |
| first_row_num   | The first row number of the entry.              |
| hidden_tupcount | The number of hidden tuples in the entry.       |
| bitmap          | A text representation of the visibility bitmap. |

## Viewing Greenplum Database Server Log Files

Each component of a Greenplum Database system (master, standby master, primary segments, and mirror segments) keeps its own server log files. The `gp_log_*` family of views allows you to issue SQL queries against the server log files to find particular entries of interest. The use of these views require superuser permissions.

- [gp\\_log\\_command\\_timings](#)
- [gp\\_log\\_database](#)
- [gp\\_log\\_master\\_concise](#)
- [gp\\_log\\_system](#)

**Parent topic:** [The gp\\_toolkit Administrative Schema](#)

### gp\_log\_command\_timings

This view uses an external table to read the log files on the master and report the run time of SQL commands in a database session. The use of this view requires superuser permissions.

| Column      | Description  |
|-------------|--|
| logsession  | The session identifier (prefixed with "con").              |
| logcmdcount | The command number within a session (prefixed with "cmd"). |
| logdatabase | The name of the database.                                  |
| loguser     | The name of the database user.                             |
| logpid      | The process id (prefixed with "p").                        |
| logtimemin  | The time of the first log message for this command.        |
| logtimemax  | The time of the last log message for this command.         |

| Column      | Description                                |
|-------------|--|
| logduration | Statement duration from start to end time. |

## gp\_log\_database

This view uses an external table to read the server log files of the entire Greenplum system (master, segments, and mirrors) and lists log entries associated with the current database. Associated log entries can be identified by the session id (logsession) and command id (logcmdcount). The use of this view requires superuser permissions.

| Column         | Description   |
|----------------|---|
| logtime        | The timestamp of the log message.   |
| loguser        | The name of the database user.  |
| logdatabase    | The name of the database.   |
| logpid         | The associated process id (prefixed with "p").  |
| logthread      | The associated thread count (prefixed with "th").   |
| loghost        | The segment or master host name.  |
| logport        | The segment or master port.   |
| logsessiontime | Time session connection was opened.   |
| logtransaction | Global transaction id.  |
| logsession     | The session identifier (prefixed with "con").   |
| logcmdcount    | The command number within a session (prefixed with "cmd").  |
| logsegment     | The segment content identifier (prefixed with "seg" for primary or "mir" for mirror. The master always has a content id of -1). |
| logslice       | The slice id (portion of the query plan being run).   |
| logdistxact    | Distributed transaction id.   |
| loglocalxact   | Local transaction id.   |
| logsubxact     | Subtransaction id.  |
| logseverity    | LOG, ERROR, FATAL, PANIC, DEBUG1 or DEBUG2.   |
| logstate       | SQL state code associated with the log message.   |
| logmessage     | Log or error message text.  |
| logdetail      | Detail message text associated with an error message.   |
| loghint        | Hint message text associated with an error message.   |
| logquery       | The internally-generated query text.  |
| logquerypos    | The cursor index into the internally-generated query text.  |

| Column       | Description  |
|--------------|--|
| logcontext   | The context in which this message gets generated.            |
| logdebug     | Query string with full detail for debugging.                 |
| logcursorpos | The cursor index into the query string.                      |
| logfunction  | The function in which this message is generated.             |
| logfile      | The log file in which this message is generated.             |
| logline      | The line in the log file in which this message is generated. |
| logstack     | Full text of the stack trace associated with this message.   |

## gp\_log\_master\_concise

This view uses an external table to read a subset of the log fields from the master log file. The use of this view requires superuser permissions.

| Column      | Description  |
|-------------|--|
| logtime     | The timestamp of the log message.                          |
| logdatabase | The name of the database.                                  |
| logsession  | The session identifier (prefixed with "con").              |
| logcmdcount | The command number within a session (prefixed with "cmd"). |
| logseverity | The log severity level.                                    |
| logmessage  | Log or error message text.                                 |

## gp\_log\_system

This view uses an external table to read the server log files of the entire Greenplum system (master, segments, and mirrors) and lists all log entries. Associated log entries can be identified by the session id (logsession) and command id (logcmdcount). The use of this view requires superuser permissions.

| Column         | Description                                       |
|----------------|---|
| logtime        | The timestamp of the log message.                 |
| loguser        | The name of the database user.                    |
| logdatabase    | The name of the database.                         |
| logpid         | The associated process id (prefixed with "p").    |
| logthread      | The associated thread count (prefixed with "th"). |
| loghost        | The segment or master host name.                  |
| logport        | The segment or master port.                       |
| logsessiontime | Time session connection was opened.               |

| Column         | Description   |
|----------------|---|
| logtransaction | Global transaction id.  |
| logsession     | The session identifier (prefixed with "con").   |
| logcmdcount    | The command number within a session (prefixed with "cmd").  |
| logsegment     | The segment content identifier (prefixed with "seg" for primary or "mir" for mirror. The master always has a content id of -1). |
| logslice       | The slice id (portion of the query plan being run).   |
| logdistxact    | Distributed transaction id.   |
| loglocalxact   | Local transaction id.   |
| logsubxact     | Subtransaction id.  |
| logseverity    | LOG, ERROR, FATAL, PANIC, DEBUG1 or DEBUG2.   |
| logstate       | SQL state code associated with the log message.   |
| logmessage     | Log or error message text.  |
| logdetail      | Detail message text associated with an error message.   |
| loghint        | Hint message text associated with an error message.   |
| logquery       | The internally-generated query text.  |
| logquerypos    | The cursor index into the internally-generated query text.  |
| logcontext     | The context in which this message gets generated.   |
| logdebug       | Query string with full detail for debugging.  |
| logcursorpos   | The cursor index into the query string.   |
| logfunction    | The function in which this message is generated.  |
| logfile        | The log file in which this message is generated.  |
| logline        | The line in the log file in which this message is generated.  |
| logstack       | Full text of the stack trace associated with this message.  |

## Checking Server Configuration Files

Each component of a Greenplum Database system (master, standby master, primary segments, and mirror segments) has its own server configuration file (`postgresql.conf`). The following `gp_toolkit` objects can be used to check parameter settings across all primary `postgresql.conf` files in the system:

- `gp_param_setting('parameter_name')`
- `gp_param_settings_seg_value_diffs`

**Parent topic:** [The gp\\_toolkit Administrative Schema](#)

## gp\_param\_setting('parameter\_name')

This function takes the name of a server configuration parameter and returns the `postgresql.conf` value for the master and each active segment. This function is accessible to all users.

| Column       | Description  |
|--------------|--|
| paramsegment | The segment content id (only active segments are shown). The master content id is always -1. |
| paramname    | The name of the parameter.   |
| paramvalue   | The value of the parameter.  |

### Example:

```
SELECT * FROM gp_param_setting('max_connections');
```

## gp\_param\_settings\_seg\_value\_diffs

Server configuration parameters that are classified as *local* parameters (meaning each segment gets the parameter value from its own `postgresql.conf` file), should be set identically on all segments. This view shows local parameter settings that are inconsistent. Parameters that are supposed to have different values (such as `port`) are not included. This view is accessible to all users.

| Column   | Description                                  |
|----------|--|
| psdname  | The name of the parameter.                   |
| psdvalue | The value of the parameter.                  |
| psdcount | The number of segments that have this value. |

## Checking for Failed Segments

The `gp_pgdatabase_invalid` view can be used to check for down segments.

**Parent topic:** [The gp\\_toolkit Administrative Schema](#)

## gp\_pgdatabase\_invalid

This view shows information about segments that are marked as down in the system catalog. This view is accessible to all users.

| Column              | Description   |
|---------------------|---|
| pgdbidbid           | The segment dbid. Every segment has a unique dbid.                                    |
| pgdbiisprimary      | Is the segment currently acting as the primary (active) segment? (t or f)             |
| pgdbicontent        | The content id of this segment. A primary and mirror will have the same content id.   |
| pgdbivalid          | Is this segment up and valid? (t or f)  |
| pgdbidefinedprimary | Was this segment assigned the role of primary at system initialization time? (t or f) |

## Checking Resource Group Activity and Status

**Note:** The resource group activity and status views described in this section are valid only when resource group-based resource management is active.

Resource groups manage transactions to avoid exhausting system CPU and memory resources. Every database user is assigned a resource group. Greenplum Database evaluates every transaction submitted by a user against the limits configured for the user's resource group before running the transaction.

You can use the `gp_resgroup_config` view to check the configuration of each resource group. You can use the `gp_resgroup_status*` views to display the current transaction status and resource usage of each resource group.

- `gp_resgroup_config`
- `gp_resgroup_status`
- `gp_resgroup_status_per_host`
- `gp_resgroup_status_per_segment`

**Parent topic:** [The gp\\_toolkit Administrative Schema](#)

### gp\_resgroup\_config

The `gp_resgroup_config` view allows administrators to see the current CPU, memory, and concurrency limits for a resource group.

This view is accessible to all users.

| Column              | Description  |
|---------------------|--|
| groupid             | The ID of the resource group.  |
| groupname           | The name of the resource group.  |
| concurrency         | The concurrency ( <code>CONCURRENCY</code> ) value specified for the resource group.                 |
| cpu_rate_limit      | The CPU limit ( <code>CPU_RATE_LIMIT</code> ) value specified for the resource group, or -1.         |
| memory_limit        | The memory limit ( <code>MEMORY_LIMIT</code> ) value specified for the resource group.               |
| memory_shared_quota | The shared memory quota ( <code>MEMORY_SHARED_QUOTA</code> ) value specified for the resource group. |
| memory_spill_ratio  | The memory spill ratio ( <code>MEMORY_SPILL_RATIO</code> ) value specified for the resource group.   |
| memory_auditor      | The memory auditor for the resource group.   |
| cpuset              | The CPU cores reserved for the resource group, or -1.  |

### gp\_resgroup\_status

The `gp_resgroup_status` view allows administrators to see status and activity for a resource group. It shows how many queries are waiting to run and how many queries are currently active in the system for each resource group. The view also displays current memory and CPU usage for the resource group.

**Note:** Resource groups use the Linux control groups (cgroups) configured on the host systems. The cgroups are used to manage host system resources. When resource groups use cgroups that are as part of a nested set of cgroups, resource group limits are relative to the parent cgroup allotment. For information about nested cgroups and Greenplum Database resource group limits, see [Using Resource Groups](#).

This view is accessible to all users.

| Column               | Description   |
|----------------------|---|
| rsgname              | The name of the resource group.   |
| groupid              | The ID of the resource group.   |
| num_running          | The number of transactions currently running in the resource group.   |
| num_queueing         | The number of currently queued transactions for the resource group.   |
| num_queued           | The total number of queued transactions for the resource group since the Greenplum Database cluster was last started, excluding the num_queueing.   |
| num_executed         | The total number of transactions run in the resource group since the Greenplum Database cluster was last started, excluding the num_running.  |
| total_queue_duration | The total time any transaction was queued since the Greenplum Database cluster was last started.  |
| cpu_usage            | A set of key-value pairs. For each segment instance (the key), the value is the real-time, per-segment instance CPU core usage by a resource group. The value is the sum of the percentages (as a decimal value) of CPU cores that are used by the resource group for the segment instance. |
| memory_usage         | The real-time memory usage of the resource group on each Greenplum Database segment's host.   |

The `cpu_usage` field is a JSON-formatted, key:value string that identifies, for each resource group, the per-segment instance CPU core usage. The key is the segment id. The value is the sum of the percentages (as a decimal value) of the CPU cores used by the segment instance's resource group on the segment host; the maximum value is 1.00. The total CPU usage of all segment instances running on a host should not exceed the `gp_resource_group_cpu_limit`. Example `cpu_usage` column output:

```
{ "-1":0.01, "0":0.31, "1":0.31 }
```

In the example, segment 0 and segment 1 are running on the same host; their CPU usage is the same.

The `memory_usage` field is also a JSON-formatted, key:value string. The string contents differ depending upon the type of resource group. For each resource group that you assign to a role (default memory auditor `vmtracker`), this string identifies the used and available fixed and shared memory quota allocations on each segment. The key is segment id. The values are memory values displayed in MB units. The following example shows `memory_usage` column output for a single segment for a resource group that you assign to a role:

```
"0":{"used":0, "available":76, "quota_used":-1, "quota_available":60, "shared_used":0, "shared_available":16}
```

For each resource group that you assign to an external component, the `memory_usage` JSON-formatted string identifies the memory used and the memory limit on each segment. The following example shows `memory_usage` column output for an external component resource group for a single segment:

```
"1":{"used":11, "limit_granted":15}
```

**Note:** See the `gp_resgroup_status_per_host` and `gp_resgroup_status_per_segment` views, described below, for more user-friendly display of CPU and memory usage.

## gp\_resgroup\_status\_per\_host

The `gp_resgroup_status_per_host` view displays the real-time CPU and memory usage (MBs) for each resource group on a per-host basis. The view also displays available and granted group fixed and shared memory for each resource group on a host.

| Column                               | Description  |
|--------------------------------------|--|
| <code>rsgname</code>                 | The name of the resource group.  |
| <code>groupid</code>                 | The ID of the resource group.  |
| <code>hostname</code>                | The hostname of the segment host.  |
| <code>cpu</code>                     | The real-time CPU core usage by the resource group on a host. The value is the sum of the percentages (as a decimal value) of the CPU cores that are used by the resource group on the host. |
| <code>memory_used</code>             | The real-time memory usage of the resource group on the host. This total includes resource group fixed and shared memory. It also includes global shared memory used by the resource group.  |
| <code>memory_available</code>        | The unused fixed and shared memory for the resource group that is available on the host. This total does not include available resource group global shared memory.                          |
| <code>memory_quota_used</code>       | The real-time fixed memory usage for the resource group on the host.   |
| <code>memory_quota_available</code>  | The fixed memory available to the resource group on the host.  |
| <code>memory_shared_used</code>      | The group shared memory used by the resource group on the host. If any global shared memory is used by the resource group, this amount is included in the total as well.                     |
| <code>memory_shared_available</code> | The amount of group shared memory available to the resource group on the host. Resource group global shared memory is not included in this total.  |

Sample output for the `gp_resgroup_status_per_host` view:

```

rsgname      | groupid | hostname  | cpu  | memory_used | memory_available | memory
_quota_used | memory_quota_available | memory_shared_used | memory_shared_available
-----+-----+-----+-----+-----+-----+-----
admin_group  | 6438    | my-desktop | 0.84 | 1           | 271              | 68
| 68                | 0           |          | 136

```

```

default_group | 6437      | my-desktop | 0.00 | 0          | 816          | 0
| 400          | 0          |         |         |         |         |
(2 rows)

```

## gp\_resgroup\_status\_per\_segment

The `gp_resgroup_status_per_segment` view displays the real-time CPU and memory usage (MBs) for each resource group on a per-segment-instance and per-host basis. The view also displays available and granted group fixed and shared memory for each resource group and segment instance combination on the host.

| Column                               | Description   |
|--------------------------------------|---|
| <code>rsgname</code>                 | The name of the resource group.   |
| <code>groupid</code>                 | The ID of the resource group.   |
| <code>hostname</code>                | The hostname of the segment host.   |
| <code>segment_id</code>              | The content ID for a segment instance on the segment host.  |
| <code>cpu</code>                     | The real-time, per-segment instance CPU core usage by the resource group on the host. The value is the sum of the percentages (as a decimal value) of the CPU cores that are used by the resource group for the segment instance. |
| <code>memory_used</code>             | The real-time memory usage of the resource group for the segment instance on the host. This total includes resource group fixed and shared memory. It also includes global shared memory used by the resource group.              |
| <code>memory_available</code>        | The unused fixed and shared memory for the resource group for the segment instance on the host.   |
| <code>memory_quota_used</code>       | The real-time fixed memory usage for the resource group for the segment instance on the host.   |
| <code>memory_quota_available</code>  | The fixed memory available to the resource group for the segment instance on the host.  |
| <code>memory_shared_used</code>      | The group shared memory used by the resource group for the segment instance on the host.  |
| <code>memory_shared_available</code> | The amount of group shared memory available for the segment instance on the host. Resource group global shared memory is not included in this total.  |

Query output for this view is similar to that of the `gp_resgroup_status_per_host` view, and breaks out the CPU and memory (used and available) for each segment instance on each host.

## Checking Resource Queue Activity and Status

**Note:** The resource queue activity and status views described in this section are valid only when resource queue-based resource management is active.

The purpose of resource queues is to limit the number of active queries in the system at any given time in order to avoid exhausting system resources such as memory, CPU, and disk I/O. All database users are assigned to a resource queue, and every statement submitted by a user is first evaluated against the resource queue limits before it can run. The `gp_resq_*` family of views can be

used to check the status of statements currently submitted to the system through their respective resource queue. Note that statements issued by superusers are exempt from resource queuing.

- [gp\\_resq\\_activity](#)
- [gp\\_resq\\_activity\\_by\\_queue](#)
- [gp\\_resq\\_priority\\_statement](#)
- [gp\\_resq\\_role](#)
- [gp\\_resqueue\\_status](#)

**Parent topic:** [The gp\\_toolkit Administrative Schema](#)

## gp\_resq\_activity

For the resource queues that have active workload, this view shows one row for each active statement submitted through a resource queue. This view is accessible to all users.

| Column      | Description  |
|-------------|--|
| resqprocpid | Process ID assigned to this statement (on the master). |
| resqrole    | User name.   |
| resqoid     | Resource queue object id.                              |
| resqname    | Resource queue name.                                   |
| resqstart   | Time statement was issued to the system.               |
| resqstatus  | Status of statement: running, waiting or cancelled.    |

## gp\_resq\_activity\_by\_queue

For the resource queues that have active workload, this view shows a summary of queue activity. This view is accessible to all users.

| Column     | Description  |
|------------|--|
| resqoid    | Resource queue object id.                                |
| resqname   | Resource queue name.                                     |
| resqlast   | Time of the last statement issued to the queue.          |
| resqstatus | Status of last statement: running, waiting or cancelled. |
| resqtotal  | Total statements in this queue.                          |

## gp\_resq\_priority\_statement

This view shows the resource queue priority, session ID, and other information for all statements currently running in the Greenplum Database system. This view is accessible to all users.

| Column   | Description   |
|----------|---|
| rqpdname | The database name that the session is connected to. |

| Column      | Description  |
|-------------|--|
| rqpusername | The user who issued the statement.   |
| rqpsession  | The session ID.  |
| rqpcommand  | The number of the statement within this session (the command id and session id uniquely identify a statement). |
| rqppriority | The resource queue priority for this statement (MAX, HIGH, MEDIUM, LOW).                                       |
| rqpweight   | An integer value associated with the priority of this statement.   |
| rqpquery    | The query text of the statement.   |

## gp\_resq\_role

This view shows the resource queues associated with a role. This view is accessible to all users.

| Column    | Description  |
|-----------|--|
| rrrolname | Role (user) name.  |
| rrrsqname | The resource queue name assigned to this role. If a role has not been explicitly assigned to a resource queue, it will be in the default resource queue ( <i>pg_default</i> ). |

## gp\_resqueue\_status

This view allows administrators to see status and activity for a resource queue. It shows how many queries are waiting to run and how many queries are currently active in the system from a particular resource queue.

| Column         | Description  |
|----------------|--|
| queueid        | The ID of the resource queue.  |
| rsqname        | The name of the resource queue.  |
| rsqcountlimit  | The active query threshold of the resource queue. A value of -1 means no limit.    |
| rsqcountvalue  | The number of active query slots currently being used in the resource queue.       |
| rsqcostlimit   | The query cost threshold of the resource queue. A value of -1 means no limit.      |
| rsqcostvalue   | The total cost of all statements currently in the resource queue.                  |
| rsqmemorylimit | The memory limit for the resource queue.   |
| rsqmemoryvalue | The total memory used by all statements currently in the resource queue.           |
| rsqwaiters     | The number of statements currently waiting in the resource queue.                  |
| rsqholders     | The number of statements currently running on the system from this resource queue. |

## Checking Query Disk Spill Space Usage

The `gp_workfile_*` views show information about all the queries that are currently using disk spill space. Greenplum Database creates work files on disk if it does not have sufficient memory to run the query in memory. This information can be used for troubleshooting and tuning queries. The information in the views can also be used to specify the values for the Greenplum Database configuration parameters `gp_workfile_limit_per_query` and `gp_workfile_limit_per_segment`.

- [gp\\_workfile\\_entries](#)
- [gp\\_workfile\\_usage\\_per\\_query](#)
- [gp\\_workfile\\_usage\\_per\\_segment](#)

**Parent topic:** [The gp\\_toolkit Administrative Schema](#)

## gp\_workfile\_entries

This view contains one row for each operator using disk space for workfiles on a segment at the current time. The view is accessible to all users, however non-superusers only to see information for the databases that they have permission to access.

| Column                   | Type    | References | Description  |
|--------------------------|---------|------------|--|
| <code>datname</code>     | name    |            | Greenplum database name.   |
| <code>pid</code>         | integer |            | Process ID of the server process.                                      |
| <code>sess_id</code>     | integer |            | Session ID.  |
| <code>command_cnt</code> | integer |            | Command ID of the query.   |
| <code>username</code>    | name    |            | Role name.   |
| <code>query</code>       | text    |            | Current query that the process is running.                             |
| <code>segid</code>       | integer |            | Segment ID.  |
| <code>slice</code>       | integer |            | The query plan slice. The portion of the query plan that is being run. |
| <code>optype</code>      | text    |            | The query operator type that created the work file.                    |
| <code>size</code>        | bigint  |            | The size of the work file in bytes.                                    |
| <code>numfiles</code>    | integer |            | The number of files created.   |
| <code>prefix</code>      | text    |            | Prefix used when naming a related set of workfiles.                    |

## gp\_workfile\_usage\_per\_query

This view contains one row for each query using disk space for workfiles on a segment at the current time. The view is accessible to all users, however non-superusers only to see information for the databases that they have permission to access.

| Column               | Type    | References | Description                       |
|----------------------|---------|------------|-----------------------------------|
| <code>datname</code> | name    |            | Greenplum database name.          |
| <code>pid</code>     | integer |            | Process ID of the server process. |
| <code>sess_id</code> | integer |            | Session ID.                       |

| Column                   | Type    | References | Description                                |
|--------------------------|---------|------------|--|
| <code>command_cnt</code> | integer |            | Command ID of the query.                   |
| <code>username</code>    | name    |            | Role name.                                 |
| <code>query</code>       | text    |            | Current query that the process is running. |
| <code>segid</code>       | integer |            | Segment ID.                                |
| <code>size</code>        | numeric |            | The size of the work file in bytes.        |
| <code>numfiles</code>    | bigint  |            | The number of files created.               |

## gp\_workfile\_usage\_per\_segment

This view contains one row for each segment. Each row displays the total amount of disk space used for workfiles on the segment at the current time. The view is accessible to all users, however non-superusers only to see information for the databases that they have permission to access.

| Column                | Type     | References | Description                                    |
|-----------------------|----------|------------|--|
| <code>segid</code>    | smallint |            | Segment ID.                                    |
| <code>size</code>     | numeric  |            | The total size of the work files on a segment. |
| <code>numfiles</code> | bigint   |            | The number of files created.                   |

## Viewing Users and Groups (Roles)

It is frequently convenient to group users (roles) together to ease management of object privileges: that way, privileges can be granted to, or revoked from, a group as a whole. In Greenplum Database this is done by creating a role that represents the group, and then granting membership in the group role to individual user roles.

The `gp_roles_assigned` view can be used to see all of the roles in the system, and their assigned members (if the role is also a group role).

**Parent topic:** [The gp\\_toolkit Administrative Schema](#)

### gp\_roles\_assigned

This view shows all of the roles in the system, and their assigned members (if the role is also a group role). This view is accessible to all users.

| Column                    | Description   |
|---------------------------|---|
| <code>raroleid</code>     | The role object ID. If this role has members (users), it is considered a <i>group</i> role. |
| <code>rarolename</code>   | The role (user or group) name.  |
| <code>ramemberid</code>   | The role object ID of the role that is a member of this role.                               |
| <code>ramembername</code> | Name of the role that is a member of this role.   |

## Checking Database Object Sizes and Disk Space

The `gp_size_*` family of views can be used to determine the disk space usage for a distributed Greenplum Database, schema, table, or index. The following views calculate the total size of an object across all primary segments (mirrors are not included in the size calculations).

**Note:** By default, the `gp_size_*` views do not display data for materialized views. Refer to [Including Data for Materialized Views](#) for instructions on adding this data to `gp_size_*` view output.

- `gp_size_of_all_table_indexes`
- `gp_size_of_database`
- `gp_size_of_index`
- `gp_size_of_partition_and_indexes_disk`
- `gp_size_of_schema_disk`
- `gp_size_of_table_and_indexes_disk`
- `gp_size_of_table_and_indexes_licensing`
- `gp_size_of_table_disk`
- `gp_size_of_table_uncompressed`
- `gp_disk_free`

The table and index sizing views list the relation by object ID (not by name). To check the size of a table or index by name, you must look up the relation name (`relname`) in the `pg_class` table. For example:

```
SELECT relname as name, sotdsize as size, sotdtoastsize as
toast, sotdadditionalsize as other
FROM gp_size_of_table_disk as sotd, pg_class
WHERE sotd.sotdoid=pg_class.oid ORDER BY relname;
```

**Parent topic:** [The gp\\_toolkit Administrative Schema](#)

## gp\_size\_of\_all\_table\_indexes

This view shows the total size of all indexes for a table. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

| Column          | Description                                  |
|-----------------|--|
| soatoid         | The object ID of the table                   |
| soatize         | The total size of all table indexes in bytes |
| soatischemaname | The schema name                              |
| soatitablename  | The table name                               |

## gp\_size\_of\_database

This view shows the total size of a database. This view is accessible to all users, however non-superusers will only be able to see databases that they have permission to access.

| Column      | Description                       |
|-------------|-----------------------------------|
| sodddatname | The name of the database          |
| sodddatsize | The size of the database in bytes |

## gp\_size\_of\_index

This view shows the total size of an index. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

| Column         | Description   |
|----------------|---|
| soioid         | The object ID of the index                            |
| soitableoid    | The object ID of the table to which the index belongs |
| soisize        | The size of the index in bytes                        |
| soiindexschema | The name of the index schema                          |
| soiindexname   | The name of the index                                 |
| soitableschema | The name of the table schema                          |
| soitable       | The name of the table                                 |

## gp\_size\_of\_partition\_and\_indexes\_disk

This view shows the size on disk of partitioned child tables and their indexes. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

| Column                     | Description                                     |
|----------------------------|---|
| sopaidparentoid            | The object ID of the parent table               |
| sopaidpartitionoid         | The object ID of the partition table            |
| sopaidpartitiontablesize   | The partition table size in bytes               |
| sopaidpartitionindexessize | The total size of all indexes on this partition |
| Sopaidparentschemaname     | The name of the parent schema                   |
| Sopaidparenttablename      | The name of the parent table                    |
| Sopaidpartitionschemaname  | The name of the partition schema                |
| sopaidpartitiontablename   | The name of the partition table                 |

## gp\_size\_of\_schema\_disk

This view shows schema sizes for the public schema and the user-created schemas in the current database. This view is accessible to all users, however non-superusers will be able to see only the schemas that they have permission to access.

| Column              | Description                                      |
|---------------------|--|
| sosdnsp             | The name of the schema                           |
| sosdschematablesize | The total size of tables in the schema in bytes  |
| sosdschemaidxsize   | The total size of indexes in the schema in bytes |

## gp\_size\_of\_table\_and\_indexes\_disk

This view shows the size on disk of tables and their indexes. This view is accessible to all users, however non-superusers will only be able to see relations that they have permission to access.

| Column          | Description                                |
|-----------------|--|
| sotaidoid       | The object ID of the parent table          |
| sotaidtablesiz  | The disk size of the table                 |
| sotaididxsize   | The total size of all indexes on the table |
| sotaidtablename | The name of the schema                     |
| sotaidtablename | The name of the table                      |

## gp\_size\_of\_table\_and\_indexes\_licensing

This view shows the total size of tables and their indexes for licensing purposes. The use of this view requires superuser permissions.

| Column              | Description  |
|---------------------|--|
| sotailoid           | The object ID of the table   |
| sotailtablesizedisk | The total disk size of the table   |
| sotailtablesiz      | If the table is a compressed append-optimized table, shows the uncompressed table size in bytes. |
| sotailindexessize   | The total size of all indexes in the table   |
| sotailschemaname    | The schema name  |
| sotailtablename     | The table name   |

## gp\_size\_of\_table\_disk

This view shows the size of a table on disk. This view is accessible to all users, however non-superusers will only be able to see tables that they have permission to access

| Column        | Description  |
|---------------|--|
| sotdoid       | The object ID of the table   |
| sotdsize      | The size of the table in bytes. The size is only the main table size. The size does not include auxiliary objects such as oversized (toast) attributes, or additional storage objects for AO tables. |
| sotdtoastsize | The size of the TOAST table (oversized attribute storage), if there is one.  |

| Column             | Description  |
|--------------------|--|
| sotdadditionalsize | Reflects the segment and block directory table sizes for append-optimized (AO) tables. |
| sotdschemaname     | The schema name  |
| sotdtablename      | The table name   |

## gp\_size\_of\_table\_uncompressed

This view shows the uncompressed table size for append-optimized (AO) tables. Otherwise, the table size on disk is shown. The use of this view requires superuser permissions.

| Column         | Description  |
|----------------|--|
| sotuid         | The object ID of the table   |
| sotusize       | The uncompressed size of the table in bytes if it is a compressed AO table. Otherwise, the table size on disk. |
| sotuschemaname | The schema name  |
| sotutablename  | The table name   |

## gp\_disk\_free

This external table runs the `df` (disk free) command on the active segment hosts and reports back the results. Inactive mirrors are not included in the calculation. The use of this external table requires superuser permissions.

| Column     | Description  |
|------------|--|
| dfsegment  | The content id of the segment (only active segments are shown) |
| dfhostname | The hostname of the segment host                               |
| dfdevice   | The device name  |
| dfspace    | Free disk space in the segment file system in kilobytes        |

## Checking for Uneven Data Distribution

All tables in Greenplum Database are distributed, meaning their data is divided across all of the segments in the system. If the data is not distributed evenly, then query processing performance may decrease. The following views can help diagnose if a table has uneven data distribution:

- [gp\\_skew\\_coefficients](#)
- [gp\\_skew\\_idle\\_fractions](#)

**Note:** By default, the `gp_skew_*` views do not display data for materialized views. Refer to [Including Data for Materialized Views](#) for instructions on adding this data to `gp_skew_*` view output.

Parent topic: [The gp\\_toolkit Administrative Schema](#)

## gp\_skew\_coefficients

This view shows data distribution skew by calculating the coefficient of variation (CV) for the data stored on each segment. This view is accessible to all users, however non-superusers will only be able to see tables that they have permission to access

| Column           | Description  |
|------------------|--|
| skcoid           | The object id of the table.  |
| skcnames<br>pace | The namespace where the table is defined.  |
| skcrelname       | The table name.  |
| skccoeff         | The coefficient of variation (CV) is calculated as the standard deviation divided by the average. It takes into account both the average and variability around the average of a data series. The lower the value, the better. Higher values indicate greater data skew. |

## gp\_skew\_idle\_fractions

This view shows data distribution skew by calculating the percentage of the system that is idle during a table scan, which is an indicator of processing data skew. This view is accessible to all users, however non-superusers will only be able to see tables that they have permission to access

| Column           | Description   |
|------------------|---|
| sifoid           | The object id of the table.   |
| sifnames<br>pace | The namespace where the table is defined.   |
| sifrelname       | The table name.   |
| siffraction      | The percentage of the system that is idle during a table scan, which is an indicator of uneven data distribution or query processing skew. For example, a value of 0.1 indicates 10% skew, a value of 0.5 indicates 50% skew, and so on. Tables that have more than 10% skew should have their distribution policies evaluated. |

## Including Data for Materialized Views

You must update a `gp_toolkit` internal view if you want data about materialized views to be included in the output of relevant `gp_toolkit` views.

Run the following SQL commands as the Greenplum Database administrator to update the internal view:

```
CREATE or REPLACE VIEW gp_toolkit.__gp_user_tables
AS
SELECT
    fn.fnnspace as autnspace,
    fn.fnrelname as autrelname,
```

```

    relkind as autrelkind,
    reltuples as autreltuples,
    relpages as autrelpages,
    relacl as autrelacl,
    pgc.oid as autoid,
    pgc.reltoastrelid as auttoastoid,
    pgc.relstorage as autrelstorage
FROM
    pg_catalog.pg_class pgc,
    gp_toolkit.__gp_fullname fn
WHERE pgc.relnamespace IN
    (
        SELECT aunoid
        FROM gp_toolkit.__gp_user_namespaces
    )
AND (pgc.relkind = 'r' OR pgc.relkind = 'm')
AND pgc.relispopulated = 't'
AND pgc.oid = fn.fnoid;

GRANT SELECT ON TABLE gp_toolkit.__gp_user_tables TO public;

```

## The gpperfmon Database

The `gpperfmon` database is a dedicated database where data collection agents on Greenplum segment hosts save query and system statistics.

The `gpperfmon` database is created using the `gpperfmon_install` command-line utility. The utility creates the database and the `gpmon` database role and enables the data collection agents on the master and segment hosts. See the `gpperfmon_install` reference in the *Greenplum Database Utility Guide* for information about using the utility and configuring the data collection agents.

The `gpperfmon` database consists of three sets of tables that capture query and system status information at different stages.

- `_now` tables store current system metrics such as active queries.
- `_tail` tables are used to stage data before it is saved to the `_history` tables. The `_tail` tables are for internal use only and not to be queried by users.
- `_history` tables store historical metrics.

The data for `_now` and `_tail` tables are stored as text files on the master host file system, and are accessed in the `gpperfmon` database via external tables. The `history` tables are regular heap database tables in the `gpperfmon` database. History is saved only for queries that run for a minimum number of seconds, 20 by default. You can set this threshold to another value by setting the `min_query_time` parameter in the `$MASTER_DATA_DIRECTORY/gpperfmon/conf/gpperfmon.conf` configuration file. Setting the value to 0 saves history for all queries.

**Note:** `gpperfmon` does not support SQL `ALTER` commands. `ALTER` queries are not recorded in the `gpperfmon` query history tables.

The `history` tables are partitioned by month. See [History Table Partition Retention](#) for information about removing old partitions.

The database contains the following categories of tables:

- The `database_*` tables store query workload information for a Greenplum Database instance.
- The `diskspace_*` tables store diskspace metrics.
- The `log_alert_*` tables store error and warning messages from `pg_log`.
- The `queries_*` tables store high-level query status information.
- The `segment_*` tables store memory allocation statistics for the Greenplum Database segment instances.
- The `socket_stats_*` tables store statistical metrics about socket usage for a Greenplum Database instance. Note: These tables are in place for future use and are not currently populated.
- The `system_*` tables store system utilization metrics.

The `gpperfmon` database also contains the following views:

- The `dynamic_memory_info` view shows an aggregate of all the segments per host and the amount of dynamic memory used per host.
- The `memory_info` view shows per-host memory information from the `system_history` and `segment_history` tables.

## History Table Partition Retention

The `history` tables in the `gpperfmon` database are partitioned by month. Partitions are automatically added in two month increments as needed.

The `partition_age` parameter in the `$MASTER_DATA_DIRECTORY/gpperfmon/conf/gpperfmon.conf` file can be set to the maximum number of monthly partitions to keep. Partitions older than the specified value are removed automatically when new partitions are added.

The default value for `partition_age` is 0, which means that administrators must manually remove unneeded partitions.

## Alert Log Processing and Log Rotation

When the `gp_enable_gpperfmon` server configuration parameter is set to true, the Greenplum Database sysloger writes alert messages to a `.csv` file in the `$MASTER_DATA_DIRECTORY/gpperfmon/logs` directory.

The level of messages written to the log can be set to `none`, `warning`, `error`, `fatal`, or `panic` by setting the `gpperfmon_log_alert_level` server configuration parameter in `postgresql.conf`. The default message level is `warning`.

The directory where the log is written can be changed by setting the `log_location` configuration variable in the `$MASTER_DATA_DIRECTORY/gpperfmon/conf/gpperfmon.conf` configuration file.

The sysloger rotates the alert log every 24 hours or when the current log file reaches or exceeds 1MB.

A rotated log file can exceed 1MB if a single error message contains a large SQL statement or a large stack trace. Also, the sysloger processes error messages in chunks, with a separate chunk

for each logging process. The size of a chunk is OS-dependent; on Red Hat Enterprise Linux, for example, it is 4096 bytes. If many Greenplum Database sessions generate error messages at the same time, the log file can grow significantly before its size is checked and log rotation is triggered.

## gpperfmon Data Collection Process

When Greenplum Database starts up with gpperfmon support enabled, it forks a `gpmmmon` agent process. `gpmmmon` then starts a `gpsmon` agent process on the master host and every segment host in the Greenplum Database cluster. The Greenplum Database postmaster process monitors the `gpmmmon` process and restarts it if needed, and the `gpmmmon` process monitors and restarts `gpsmon` processes as needed.

The `gpmmmon` process runs in a loop and at configurable intervals retrieves data accumulated by the `gpsmon` processes, adds it to the data files for the `_now` and `_tail` external database tables, and then into the `_history` regular heap database tables.

**Note:** The `log_alert` tables in the `gpperfmon` database follow a different process, since alert messages are delivered by the Greenplum Database system logger instead of through `gpsmon`. See [Alert Log Processing and Log Rotation](#) for more information.

Two configuration parameters in the `$MASTER_DATA_DIRECTORY/gpperfmon/conf/gpperfmon.conf` configuration file control how often `gpmmmon` activities are triggered:

- The `quantum` parameter is how frequently, in seconds, `gpmmmon` requests data from the `gpsmon` agents on the segment hosts and adds retrieved data to the `_now` and `_tail` external table data files. Valid values for the `quantum` parameter are 10, 15, 20, 30, and 60. The default is 15.
- The `harvest_interval` parameter is how frequently, in seconds, data in the `_tail` tables is moved to the `_history` tables. The `harvest_interval` must be at least 30. The default is 120.

See the `gpperfmon_install` management utility reference in the *Greenplum Database Utility Guide* for the complete list of gpperfmon configuration parameters.

The following steps describe the flow of data from Greenplum Database into the `gpperfmon` database when gpperfmon support is enabled.

1. While executing queries, the Greenplum Database query dispatcher and query executor processes send out query status messages in UDP datagrams. The `gp_gpperfmon_send_interval` server configuration variable determines how frequently the database sends these messages. The default is every second.
2. The `gpsmon` process on each host receives the UDP packets, consolidates and summarizes the data they contain, and adds additional host metrics, such as CPU and memory usage.
3. The `gpsmon` processes continue to accumulate data until they receive a dump command from `gpmmmon`.
4. The `gpsmon` processes respond to a dump command by sending their accumulated status data and log alerts to a listening `gpmmmon` event handler thread.
5. The `gpmmmon` event handler saves the metrics to `.txt` files in the `$MASTER_DATA_DIRECTORY/gpperfmon/data` directory on the master host.

At each `quantum` interval (15 seconds by default), `gpmmmon` performs the following steps:

1. Sends a dump command to the `gpsmon` processes.
2. Gathers and converts the `.txt` files saved in the `$MASTER_DATA_DIRECTORY/gpperfmon/data` directory into `.dat` external data files for the `_now` and `_tail` external tables in the `gpperfmon` database.

For example, disk space metrics are added to the `diskspace_now.dat` and `_diskspace_tail.dat` delimited text files. These text files are accessed via the `diskspace_now` and `_diskspace_tail` tables in the `gpperfmon` database.

At each `harvest_interval` (120 seconds by default), `gpmmmon` performs the following steps for each `_tail` file:

1. Renames the `_tail` file to a `_stage` file.
2. Creates a new `_tail` file.
3. Appends data from the `_stage` file into the `_tail` file.
4. Runs a SQL command to insert the data from the `_tail` external table into the corresponding `_history` table.

For example, the contents of the `_database_tail` external table is inserted into the `database_history` regular (heap) table.

5. Deletes the `_tail` file after its contents have been loaded into the database table.
6. Gathers all of the `gpdb-alert-*.csv` files in the `$MASTER_DATA_DIRECTORY/gpperfmon/logs` directory (except the most recent, which the `syslogger` has open and is writing to) into a single file, `alert_log_stage`.
7. Loads the `alert_log_stage` file into the `log_alert_history` table in the `gpperfmon` database.
8. Truncates the `alert_log_stage` file.

The following topics describe the contents of the tables in the `gpperfmon` database.

- `database_*`
- `diskspace_*`
- `interface_stats_*`
- `log_alert_*`
- `queries_*`
- `segment_*`
- `socket_stats_*`
- `system_*`
- `dynamic_memory_info`
- `memory_info`

Parent topic: [Greenplum Database Reference Guide](#)

## database\_\*

The `database_*` tables store query workload information for a Greenplum Database instance. There are three database tables, all having the same columns:

- `database_now` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. Current query workload data is stored in `database_now` during the period between data collection from the data collection agents and automatic commitment to the `database_history` table.
- `database_tail` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. This is a transitional table for query workload data that has been cleared from `database_now` but has not yet been committed to `database_history`. It typically only contains a few minutes worth of data.
- `database_history` is a regular table that stores historical database-wide query workload data. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

| Column                       | Type      | Description  |
|------------------------------|-----------|--|
| <code>ctime</code>           | timestamp | Time this row was created.   |
| <code>queries_total</code>   | int       | The total number of queries in Greenplum Database at data collection time.   |
| <code>queries_running</code> | int       | The number of active queries running at data collection time.  |
| <code>queries_queued</code>  | int       | The number of queries waiting in a resource group or resource queue, depending upon which resource management scheme is active, at data collection time. |

Parent topic: [The gpperfmon Database](#)

## diskspace\_\*

The `diskspace_*` tables store diskspace metrics.

- `diskspace_now` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. Current diskspace metrics are stored in `database_now` during the period between data collection from the `gpperfmon` agents and automatic commitment to the `diskspace_history` table.
- `diskspace_tail` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. This is a transitional table for diskspace metrics that have been cleared from `diskspace_now` but has not yet been committed to `diskspace_history`. It typically only contains a few minutes worth of data.
- `diskspace_history` is a regular table that stores historical diskspace metrics. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

| Column                | Type                           | Description   |
|-----------------------|--------------------------------|---|
| <code>ctime</code>    | timestamp(0) without time zone | Time of diskspace measurement.                          |
| <code>hostname</code> | varchar(64)                    | The hostname associated with the diskspace measurement. |

| Column                       | Type   | Description  |
|------------------------------|--------|--|
| <code>Filesystem</code>      | text   | Name of the filesystem for the disk space measurement. |
| <code>total_bytes</code>     | bigint | Total bytes in the file system.                        |
| <code>bytes_used</code>      | bigint | Total bytes used in the file system.                   |
| <code>bytes_available</code> | bigint | Total bytes available in file system.                  |

Parent topic: [The gpperfmon Database](#)

## interface\_stats\_\*

The `interface_stats_*` tables store statistical metrics about communications over each active interface for a Greenplum Database instance.

These tables are in place for future use and are not currently populated.

There are three `interface_stats` tables, all having the same columns:

- `interface_stats_now` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`.
- `interface_stats_tail` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. This is a transitional table for statistical interface metrics that has been cleared from `interface_stats_now` but has not yet been committed to `interface_stats_history`. It typically only contains a few minutes worth of data.
- `interface_stats_history` is a regular table that stores statistical interface metrics. It is pre-partitioned into monthly partitions. Partitions are automatically added in one month increments as needed.

| Column                                  | Type   | Description  |
|---|--------|--|
| <code>interface_name</code>             | string | Name of the interface. For example: eth0, eth1, lo.  |
| <code>bytes_received</code>             | bigint | Amount of data received in bytes.  |
| <code>packets_received</code>           | bigint | Number of packets received.  |
| <code>receive_errors</code>             | bigint | Number of errors encountered while data was being received.                                      |
| <code>receive_drops</code>              | bigint | Number of times packets were dropped while data was being received.                              |
| <code>receive_fifo_errors</code>        | bigint | Number of times FIFO (first in first out) errors were encountered while data was being received. |
| <code>receive_frame_errors</code>       | bigint | Number of frame errors while data was being received.  |
| <code>receive_compressed_packets</code> | int    | Number of packets received in compressed format.   |

| Column                                   | Type   | Description   |
|--|--------|---|
| <code>receive_multicast_packets</code>   | int    | Number of multicast packets received.                                       |
| <code>bytes_transmitted</code>           | bigint | Amount of data transmitted in bytes.  |
| <code>packets_transmitted</code>         | bigint | Amount of data transmitted in bytes.  |
| <code>packets_transmitted</code>         | bigint | Number of packets transmitted.  |
| <code>transmit_errors</code>             | bigint | Number of errors encountered during data transmission.                      |
| <code>transmit_drops</code>              | bigint | Number of times packets were dropped during data transmission.              |
| <code>transmit_fifo_errors</code>        | bigint | Number of times fifo errors were encountered during data transmission.      |
| <code>transmit_collision_errors</code>   | bigint | Number of times collision errors were encountered during data transmission. |
| <code>transmit_carrier_errors</code>     | bigint | Number of times carrier errors were encountered during data transmission.   |
| <code>transmit_compressed_packets</code> | int    | Number of packets transmitted in compressed format.                         |

## log\_alert\_\*

The `log_alert_*` tables store `pg_log` errors and warnings.

See [Alert Log Processing and Log Rotation](#) for information about configuring the system logger for `gpperfmon`.

There are three `log_alert` tables, all having the same columns:

- `log_alert_now` is an external table whose data is stored in `.csv` files in the `$MASTER_DATA_DIRECTORY/gpperfmon/logs` directory. Current `pg_log` errors and warnings data are available in `log_alert_now` during the period between data collection from the `gpperfmon` agents and automatic commitment to the `log_alert_history` table.
- `log_alert_tail` is an external table with data stored in `$MASTER_DATA_DIRECTORY/gpperfmon/logs/alert_log_stage`. This is a transitional table for data that has been cleared from `log_alert_now` but has not yet been committed to `log_alert_history`. The table includes records from all alert logs except the most recent. It typically contains only a few minutes' worth of data.
- `log_alert_history` is a regular table that stores historical database-wide errors and warnings data. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

| Column                      | Type                     | Description             |
|-----------------------------|--------------------------|-------------------------|
| <code>logtime</code>        | timestamp with time zone | Timestamp for this log  |
| <code>loguser</code>        | text                     | User of the query       |
| <code>logdatabase</code>    | text                     | The accessed database   |
| <code>logpid</code>         | text                     | Process id              |
| <code>logthread</code>      | text                     | Thread number           |
| <code>loghost</code>        | text                     | Host name or ip address |
| <code>logport</code>        | text                     | Port number             |
| <code>logsessiontime</code> | timestamp with time zone | Session timestamp       |
| <code>logtransaction</code> | integer                  | Transaction id          |
| <code>logsession</code>     | text                     | Session id              |
| <code>logcmdcount</code>    | text                     | Command count           |
| <code>logsegment</code>     | text                     | Segment number          |
| <code>logslice</code>       | text                     | Slice number            |
| <code>logdistxact</code>    | text                     | Distributed transaction |
| <code>loglocalxact</code>   | text                     | Local transaction       |
| <code>logsubxact</code>     | text                     | Subtransaction          |
| <code>logseverity</code>    | text                     | Log severity            |
| <code>logstate</code>       | text                     | State                   |
| <code>logmessage</code>     | text                     | Log message             |
| <code>logdetail</code>      | text                     | Detailed message        |
| <code>loghint</code>        | text                     | Hint info               |
| <code>logquery</code>       | text                     | Executed query          |
| <code>logquerypos</code>    | text                     | Query position          |
| <code>logcontext</code>     | text                     | Context info            |
| <code>logdebug</code>       | text                     | Debug                   |
| <code>logcursorpos</code>   | text                     | Cursor position         |
| <code>logfunction</code>    | text                     | Function info           |
| <code>logfile</code>        | text                     | Source code file        |
| <code>logline</code>        | text                     | Source code line        |
| <code>logstack</code>       | text                     | Stack trace             |

**Parent topic:** [The gpperfmon Database](#)

## queries\_\*

The `queries_*` tables store high-level query status information.

The `tmid`, `ssid` and `ccnt` columns are the composite key that uniquely identifies a particular query.

There are three queries tables, all having the same columns:

- `queries_now` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. Current query status is stored in `queries_now` during the period between data collection from the `gpperfmon` agents and automatic commitment to the `queries_history` table.
- `queries_tail` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. This is a transitional table for query status data that has been cleared from `queries_now` but has not yet been committed to `queries_history`. It typically only contains a few minutes worth of data.
- `queries_history` is a regular table that stores historical query status data. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

| Column                | Type            | Description   |
|-----------------------|-----------------|---|
| <code>ctime</code>    | timest<br>amp   | Time this row was created.  |
| <code>tmid</code>     | int             | A time identifier for a particular query. All records associated with the query will have the same <code>tmid</code> .  |
| <code>ssid</code>     | int             | The session id as shown by <code>gp_session_id</code> . All records associated with the query will have the same <code>ssid</code> .                            |
| <code>ccnt</code>     | int             | The command number within this session as shown by <code>gp_command_count</code> . All records associated with the query will have the same <code>ccnt</code> . |
| <code>username</code> | varcha<br>r(64) | Greenplum role name that issued this query.   |
| <code>db</code>       | varcha<br>r(64) | Name of the database queried.   |
| <code>cost</code>     | int             | Not implemented in this release.  |
| <code>tsubmit</code>  | timest<br>amp   | Time the query was submitted.   |
| <code>tstart</code>   | timest<br>amp   | Time the query was started.   |
| <code>tfinish</code>  | timest<br>amp   | Time the query finished.  |
| <code>status</code>   | varcha<br>r(64) | Status of the query -- <code>start</code> , <code>done</code> , or <code>abort</code> .   |
| <code>rows_out</code> | bigint          | Rows out for the query.   |

| Column                        | Type        | Description  |
|-------------------------------|-------------|--|
| <code>cpu_elapsed</code>      | bigint      | CPU usage by all processes across all segments executing this query (in seconds). It is the sum of the CPU usage values taken from all active primary segments in the database system.<br><br>Note that the value is logged as 0 if the query runtime is shorter than the value for the quantum. This occurs even if the query runtime is greater than the value for <code>min_query_time</code> , and this value is lower than the value for the quantum. |
| <code>cpu_current</code>      | float       | Current CPU percent average for all processes executing this query. The percentages for all processes running on each segment are averaged, and then the average of all those values is calculated to render this metric.<br><br>Current CPU percent average is always zero in historical and tail data.   |
| <code>skew_cpu</code>         | float       | Displays the amount of processing skew in the system for this query. Processing/CPU skew occurs when one segment performs a disproportionate amount of processing for a query. This value is the coefficient of variation in the CPU% metric across all segments for this query, multiplied by 100. For example, a value of .95 is shown as 95.  |
| <code>skew_rows</code>        | float       | Displays the amount of row skew in the system. Row skew occurs when one segment produces a disproportionate number of rows for a query. This value is the coefficient of variation for the <code>rows_in</code> metric across all segments for this query, multiplied by 100. For example, a value of .95 is shown as 95.  |
| <code>query_hash</code>       | bigint      | Not implemented in this release.   |
| <code>query_text</code>       | text        | The SQL text of this query.  |
| <code>query_plan</code>       | text        | Text of the query plan. Not implemented in this release.   |
| <code>application_name</code> | varchar(64) | The name of the application.   |
| <code>rsqname</code>          | varchar(64) | If the resource queue-based resource management scheme is active, this column specifies the name of the resource queue.  |
| <code>rqppriority</code>      | varchar(64) | If the resource queue-based resource management scheme is active, this column specifies the priority of the query -- <code>max</code> , <code>high</code> , <code>med</code> , <code>low</code> , or <code>min</code> .  |

Parent topic: [The gpperfmon Database](#)

## segment\_\*

The `segment_*` tables contain memory allocation statistics for the Greenplum Database segment instances. This tracks the amount of memory consumed by all postgres processes of a particular segment instance, and the remaining amount of memory available to a segment as per the settings configured by the currently active resource management scheme (resource group-based or resource queue-based). See the *Greenplum Database Administrator Guide* for more information about resource management schemes.

There are three segment tables, all having the same columns:

- `segment_now` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. Current memory allocation data is stored in

`segment_now` during the period between data collection from the `gpperfmon` agents and automatic commitment to the `segment_history` table.

- `segment_tail` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. This is a transitional table for memory allocation data that has been cleared from `segment_now` but has not yet been committed to `segment_history`. It typically only contains a few minutes worth of data.
- `segment_history` is a regular table that stores historical memory allocation metrics. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

A particular segment instance is identified by its `hostname` and `dbid` (the unique segment identifier as per the `gp_segment_configuration` system catalog table).

| Column                                | Type                                    | Description  |
|---------------------------------------|---|--|
| <code>ctime</code>                    | timestamp(0)<br><br>(without time zone) | The time the row was created.  |
| <code>dbid</code>                     | int                                     | The segment ID ( <code>dbid</code> from <code>gp_segment_configuration</code> ).   |
| <code>hostname</code>                 | charvar(64)                             | The segment hostname.  |
| <code>dynamic_memory_used</code>      | bigint                                  | The amount of dynamic memory (in bytes) allocated to query processes running on this segment.  |
| <code>dynamic_memory_available</code> | bigint                                  | The amount of additional dynamic memory (in bytes) that the segment can request before reaching the limit set by the currently active resource management scheme (resource group-based or resource queue-based). |

See also the views `memory_info` and `dynamic_memory_info` for aggregated memory allocation and utilization by host.

Parent topic: [The gpperfmon Database](#)

## socket\_stats\_\*

The `socket_stats_*` tables store statistical metrics about socket usage for a Greenplum Database instance. There are three system tables, all having the same columns:

These tables are in place for future use and are not currently populated.

- `socket_stats_now` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`.
- `socket_stats_tail` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. This is a transitional table for socket statistical metrics that has been cleared from `socket_stats_now` but has not yet been committed to `socket_stats_history`. It typically only contains a few minutes worth of data.

- `socket_stats_history` is a regular table that stores historical socket statistical metrics. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

| Column                                     | Type | Description                                |
|--|------|--|
| <code>total_sockets_used</code>            | int  | Total sockets used in the system.          |
| <code>tcp_sockets_inuse</code>             | int  | Number of TCP sockets in use.              |
| <code>tcp_sockets_orphan</code>            | int  | Number of TCP sockets orphaned.            |
| <code>tcp_sockets_timewait</code>          | int  | Number of TCP sockets in Time-Wait.        |
| <code>tcp_sockets_alloc</code>             | int  | Number of TCP sockets allocated.           |
| <code>tcp_sockets_memusage_inbytes</code>  | int  | Amount of memory consumed by TCP sockets.  |
| <code>udp_sockets_inuse</code>             | int  | Number of UDP sockets in use.              |
| <code>udp_sockets_memusage_inbytes</code>  | int  | Amount of memory consumed by UDP sockets.  |
| <code>raw_sockets_inuse</code>             | int  | Number of RAW sockets in use.              |
| <code>frag_sockets_inuse</code>            | int  | Number of FRAG sockets in use.             |
| <code>frag_sockets_memusage_inbytes</code> | int  | Amount of memory consumed by FRAG sockets. |

Parent topic: [The gpperfmon Database](#)

## system\_\*

The `system_*` tables store system utilization metrics. There are three system tables, all having the same columns:

- `system_now` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. Current system utilization data is stored in `system_now` during the period between data collection from the `gpperfmon` agents and automatic commitment to the `system_history` table.
- `system_tail` is an external table whose data files are stored in `$MASTER_DATA_DIRECTORY/gpperfmon/data`. This is a transitional table for system utilization data that has been cleared from `system_now` but has not yet been committed to `system_history`. It typically only contains a few minutes worth of data.
- `system_history` is a regular table that stores historical system utilization metrics. It is pre-partitioned into monthly partitions. Partitions are automatically added in two month increments as needed.

| Column                 | Type        | Description  |
|------------------------|-------------|--|
| <code>ctime</code>     | timestamp   | Time this row was created.                                       |
| <code>hostname</code>  | varchar(64) | Segment or master hostname associated with these system metrics. |
| <code>mem_total</code> | bigint      | Total system memory in Bytes for this host.                      |

| Column                       | Type   | Description  |
|------------------------------|--------|--|
| <code>mem_used</code>        | bigint | Used system memory in Bytes for this host.   |
| <code>mem_actual_used</code> | bigint | Used actual memory in Bytes for this host (not including the memory reserved for cache and buffers). |
| <code>mem_actual_free</code> | bigint | Free actual memory in Bytes for this host (not including the memory reserved for cache and buffers). |
| <code>swap_total</code>      | bigint | Total swap space in Bytes for this host.   |
| <code>swap_used</code>       | bigint | Used swap space in Bytes for this host.  |
| <code>swap_page_in</code>    | bigint | Number of swap pages in.   |
| <code>swap_page_out</code>   | bigint | Number of swap pages out.  |
| <code>cpu_user</code>        | float  | CPU usage by the Greenplum system user.  |
| <code>cpu_sys</code>         | float  | CPU usage for this host.   |
| <code>cpu_idle</code>        | float  | Idle CPU capacity at metric collection time.   |
| <code>load0</code>           | float  | CPU load average for the prior one-minute period.  |
| <code>load1</code>           | float  | CPU load average for the prior five-minute period.   |
| <code>load2</code>           | float  | CPU load average for the prior fifteen-minute period.  |
| <code>quantum</code>         | int    | Interval between metric collection for this metric entry.  |
| <code>disk_ro_rate</code>    | bigint | Disk read operations per second.   |
| <code>disk_wo_rate</code>    | bigint | Disk write operations per second.  |
| <code>disk_rb_rate</code>    | bigint | Bytes per second for disk read operations.   |
| <code>disk_wb_rate</code>    | bigint | Bytes per second for disk write operations.  |
| <code>net_rp_rate</code>     | bigint | Packets per second on the system network for read operations.  |
| <code>net_wp_rate</code>     | bigint | Packets per second on the system network for write operations.                                       |
| <code>net_rb_rate</code>     | bigint | Bytes per second on the system network for read operations.  |
| <code>net_wb_rate</code>     | bigint | Bytes per second on the system network for write operations.   |

Parent topic: [The gpperfmon Database](#)

## dynamic\_memory\_info

The `dynamic_memory_info` view shows a sum of the used and available dynamic memory for all segment instances on a segment host. Dynamic memory refers to the maximum amount of memory that Greenplum Database instance will allow the query processes of a single segment instance to consume before it starts cancelling processes. This limit, determined by the currently active resource management scheme (resource group-based or resource queue-based), is evaluated on a per-segment basis.

| Column                                   | Type                           | Description  |
|--|--------------------------------|--|
| <code>ctime</code>                       | timestamp(0) without time zone | Time this row was created in the <code>segment_history</code> table.   |
| <code>hostname</code>                    | varchar(64)                    | Segment or master hostname associated with these system memory metrics.  |
| <code>dynamic_memory_used_mb</code>      | numeric                        | The amount of dynamic memory in MB allocated to query processes running on this segment.   |
| <code>dynamic_memory_available_mb</code> | numeric                        | The amount of additional dynamic memory (in MB) available to the query processes running on this segment host. Note that this value is a sum of the available memory for all segments on a host. Even though this value reports available memory, it is possible that one or more segments on the host have exceeded their memory limit. |

Parent topic: [The gpperfmon Database](#)

## memory\_info

The `memory_info` view shows per-host memory information from the `system_history` and `segment_history` tables. This allows administrators to compare the total memory available on a segment host, total memory used on a segment host, and dynamic memory used by query processes.

| Column                                   | Type                           | Description  |
|--|--------------------------------|--|
| <code>ctime</code>                       | timestamp(0) without time zone | Time this row was created in the <code>segment_history</code> table.   |
| <code>hostname</code>                    | varchar(64)                    | Segment or master hostname associated with these system memory metrics.  |
| <code>mem_total_mb</code>                | numeric                        | Total system memory in MB for this segment host.   |
| <code>mem_used_mb</code>                 | numeric                        | Total system memory used in MB for this segment host.  |
| <code>mem_actual_used_mb</code>          | numeric                        | Actual system memory used in MB for this segment host.   |
| <code>mem_actual_free_mb</code>          | numeric                        | Actual system memory free in MB for this segment host.   |
| <code>swap_total_mb</code>               | numeric                        | Total swap space in MB for this segment host.  |
| <code>swap_used_mb</code>                | numeric                        | Total swap space used in MB for this segment host.   |
| <code>dynamic_memory_used_mb</code>      | numeric                        | The amount of dynamic memory in MB allocated to query processes running on this segment.   |
| <code>dynamic_memory_available_mb</code> | numeric                        | The amount of additional dynamic memory (in MB) available to the query processes running on this segment host. Note that this value is a sum of the available memory for all segments on a host. Even though this value reports available memory, it is possible that one or more segments on the host have exceeded their memory limit. |

- [SQL 2008 Optional Feature Compliance](#)

**Parent topic:** [Greenplum Database Reference Guide](#)

## Summary of Greenplum Features

This section provides a high-level overview of the system requirements and feature set of Greenplum Database. It contains the following topics:

- [Greenplum SQL Standard Conformance](#)
- [Greenplum and PostgreSQL Compatibility](#)

## Greenplum SQL Standard Conformance

The SQL language was first formally standardized in 1986 by the American National Standards Institute (ANSI) as SQL 1986. Subsequent versions of the SQL standard have been released by ANSI and as International Organization for Standardization (ISO) standards: SQL 1989, SQL 1992, SQL 1999, SQL 2003, SQL 2006, and finally SQL 2008, which is the current SQL standard. The official name of the standard is ISO/IEC 9075-14:2008. In general, each new version adds more features, although occasionally features are deprecated or removed.

It is important to note that there are no commercial database systems that are fully compliant with the SQL standard. Greenplum Database is almost fully compliant with the SQL 1992 standard, with most of the features from SQL 1999. Several features from SQL 2003 have also been implemented (most notably the SQL OLAP features).

This section addresses the important conformance issues of Greenplum Database as they relate to the SQL standards. For a feature-by-feature list of Greenplum's support of the latest SQL standard, see [SQL 2008 Optional Feature Compliance](#).

## Core SQL Conformance

In the process of building a parallel, shared-nothing database system and query optimizer, certain common SQL constructs are not currently implemented in Greenplum Database. The following SQL constructs are not supported:

1. Some set returning subqueries in `EXISTS` or `NOT EXISTS` clauses that Greenplum's parallel optimizer cannot rewrite into joins.
2. Backwards scrolling cursors, including the use of `FETCH PRIOR`, `FETCH FIRST`, `FETCH ABSOLUTE`, and `FETCH RELATIVE`.
3. In `CREATE TABLE` statements (on hash-distributed tables): a `UNIQUE` or `PRIMARY KEY` clause must include all of (or a superset of) the distribution key columns. Because of this

restriction, only one `UNIQUE` clause or `PRIMARY KEY` clause is allowed in a `CREATE TABLE` statement. `UNIQUE` or `PRIMARY KEY` clauses are not allowed on randomly-distributed tables.

4. `CREATE UNIQUE INDEX` statements that do not contain all of (or a superset of) the distribution key columns. `CREATE UNIQUE INDEX` is not allowed on randomly-distributed tables.

Note that `UNIQUE INDEXES` (but not `UNIQUE CONSTRAINTS`) are enforced on a part basis within a partitioned table. They guarantee the uniqueness of the key within each part or sub-part.

5. `VOLATILE` or `STABLE` functions cannot run on the segments, and so are generally limited to being passed literal values as the arguments to their parameters.
6. Triggers are not generally supported because they typically rely on the use of `VOLATILE` functions. PostgreSQL [Event Triggers](#) are supported because they capture only DDL events.
7. Referential integrity constraints (foreign keys) are not enforced in Greenplum Database. Users can declare foreign keys and this information is kept in the system catalog, however.
8. Sequence manipulation functions `CURRVAL` and `LASTVAL`.

## SQL 1992 Conformance

The following features of SQL 1992 are not supported in Greenplum Database:

1. `NATIONAL CHARACTER (NCHAR)` and `NATIONAL CHARACTER VARYING (NVARCHAR)`. Users can declare the `NCHAR` and `NVARCHAR` types, however they are just synonyms for `CHAR` and `VARCHAR` in Greenplum Database.
2. `CREATE ASSERTION` statement.
3. `INTERVAL` literals are supported in Greenplum Database, but do not conform to the standard.
4. `GET DIAGNOSTICS` statement.
5. `GLOBAL TEMPORARY TABLES` and `LOCAL TEMPORARY TABLES`. Greenplum `TEMPORARY TABLES` do not conform to the SQL standard, but many commercial database systems have implemented temporary tables in the same way. Greenplum temporary tables are the same as `VOLATILE TABLES` in Teradata.
6. `UNIQUE` predicate.
7. `MATCH PARTIAL` for referential integrity checks (most likely will not be implemented in Greenplum Database).

## SQL 1999 Conformance

The following features of SQL 1999 are not supported in Greenplum Database:

1. Large Object data types: `BLOB`, `CLOB`, `NCLOB`. However, the `BYTEA` and `TEXT` columns can store very large amounts of data in Greenplum Database (hundreds of megabytes).
2. `MODULE` (SQL client modules).
3. `CREATE PROCEDURE (SQL/PSM)`. This can be worked around in Greenplum Database by creating a `FUNCTION` that returns `void`, and invoking the function as follows:

```
SELECT <myfunc>(<args>);
```

4. The PostgreSQL/Greenplum function definition language (PL/PGSQL) is a subset of Oracle's PL/SQL, rather than being compatible with the SQL/PSM function definition language. Greenplum Database also supports function definitions written in Python, Perl, Java, and R.
5. BIT and BIT VARYING data types (intentionally omitted). These were deprecated in SQL 2003, and replaced in SQL 2008.
6. Greenplum supports identifiers up to 63 characters long. The SQL standard requires support for identifiers up to 128 characters long.
7. Prepared transactions (PREPARE TRANSACTION, COMMIT PREPARED, ROLLBACK PREPARED). This also means Greenplum does not support XA Transactions (2 phase commit coordination of database transactions with external transactions).
8. CHARACTER SET option on the definition of CHAR() or VARCHAR() columns.
9. Specification of CHARACTERS or OCTETS (BYTES) on the length of a CHAR() or VARCHAR() column. For example, VARCHAR(15 CHARACTERS) or VARCHAR(15 OCTETS) or VARCHAR(15 BYTES).
10. CREATE DISTINCT TYPE statement. CREATE DOMAIN can be used as a workaround in Greenplum.
11. The *explicit table* construct.

## SQL 2003 Conformance

The following features of SQL 2003 are not supported in Greenplum Database:

1. MERGE statements.
2. IDENTITY columns and the associated GENERATED ALWAYS/GENERATED BY DEFAULT clause. The SERIAL or BIGSERIAL data types are very similar to INT or BIGINT GENERATED BY DEFAULT AS IDENTITY.
3. MULTISET modifiers on data types.
4. ROW data type.
5. Greenplum Database syntax for using sequences is non-standard. For example, nextval('seq') is used in Greenplum instead of the standard NEXT VALUE FOR seq.
6. GENERATED ALWAYS AS columns. Views can be used as a workaround.
7. The sample clause (TABLESAMPLE) on SELECT statements. The random() function can be used as a workaround to get random samples from tables.
8. The *partitioned join tables* construct (PARTITION BY in a join).
9. Greenplum array data types are almost SQL standard compliant with some exceptions. Generally customers should not encounter any problems using them.

## SQL 2008 Conformance

The following features of SQL 2008 are not supported in Greenplum Database:

1. `BINARY` and `VARBINARY` data types. `BYTEA` can be used in place of `VARBINARY` in Greenplum Database.
2. The `ORDER BY` clause is ignored in views and subqueries unless a `LIMIT` clause is also used. This is intentional, as the Greenplum optimizer cannot determine when it is safe to avoid the sort, causing an unexpected performance impact for such `ORDER BY` clauses. To work around, you can specify a really large `LIMIT`. For example:

```
SELECT * FROM mytable ORDER BY 1 LIMIT 9999999999
```

3. The *row subquery* construct is not supported.
4. `TRUNCATE TABLE` does not accept the `CONTINUE IDENTITY` and `RESTART IDENTITY` clauses.

## Greenplum and PostgreSQL Compatibility

Greenplum Database is based on PostgreSQL 9.4. To support the distributed nature and typical workload of a Greenplum Database system, some SQL commands have been added or modified, and there are a few PostgreSQL features that are not supported. Greenplum has also added features not found in PostgreSQL, such as physical data distribution, parallel query optimization, external tables, resource queues, and enhanced table partitioning. For full SQL syntax and references, see the [SQL Commands](#).

**Note:** Greenplum Database does not support the PostgreSQL [large object facility](#) for streaming user data that is stored in large-object structures.

**Note:** VMware does not support using `WITH OIDS` or `oids=TRUE` to assign an OID system column when creating or altering a table. This syntax is deprecated and will be removed in a future Greenplum release.

Table 1. SQL Support in Greenplum Database

| SQL Command                      | Supported in Greenplum | Modifications, Limitations, Exceptions  |
|----------------------------------|------------------------|---|
| <code>ALTER AGGREGATE</code>     | YES                    |   |
| <code>ALTER CONVERSION</code>    | YES                    |   |
| <code>ALTER DATABASE</code>      | YES                    |   |
| <code>ALTER DOMAIN</code>        | YES                    |   |
| <code>ALTER EVENT TRIGGER</code> | YES                    |   |
| <code>ALTER EXTENSION</code>     | YES                    | Changes the definition of a Greenplum Database extension - based on PostgreSQL 9.6. |
| <code>ALTER FUNCTION</code>      | YES                    |   |
| <code>ALTER GROUP</code>         | YES                    | An alias for <a href="#">ALTER ROLE</a>   |
| <code>ALTER INDEX</code>         | YES                    |   |
| <code>ALTER LANGUAGE</code>      | YES                    |   |
| <code>ALTER OPERATOR</code>      | YES                    |   |

| SQL Command           | Supported in Greenplum | Modifications, Limitations, Exceptions   |
|-----------------------|------------------------|--|
| ALTER OPERATOR CLASS  | YES                    |  |
| ALTER OPERATOR FAMILY | YES                    |  |
| ALTER PROTOCOL        | YES                    |  |
| ALTER RESOURCE QUEUE  | YES                    | Greenplum Database resource management feature - not in PostgreSQL.  |
| ALTER ROLE            | YES                    | <b>Greenplum Database Clauses:</b><br><code>RESOURCE QUEUE queue_name   none</code>  |
| ALTER SCHEMA          | YES                    |  |
| ALTER SEQUENCE        | YES                    |  |
| ALTER SYSTEM          | NO                     |  |
| ALTER TABLE           | YES                    | <b>Unsupported Clauses / Options:</b><br><code>CLUSTER ON</code><br><code>ENABLE/DISABLE TRIGGER</code><br><b>Greenplum Database Clauses:</b><br><code>ADD   DROP   RENAME   SPLIT   EXCHANGE PARTITION   SET SUBPARTITION TEMPLATE   SET WITH (REORGANIZE=true   false)   SET DISTRIBUTED BY</code> |
| ALTER TABLESPACE      | YES                    |  |
| ALTER TRIGGER         | NO                     |  |
| ALTER TYPE            | YES                    | <b>Greenplum Database Clauses:</b><br><code>SET DEFAULT ENCODING</code>  |
| ALTER USER            | YES                    | An alias for <a href="#">ALTER ROLE</a>  |
| ALTER VIEW            | YES                    |  |
| ANALYZE               | YES                    |  |
| BEGIN                 | YES                    |  |
| CHECKPOINT            | YES                    |  |
| CLOSE                 | YES                    |  |
| CLUSTER               | YES                    |  |
| COMMENT               | YES                    |  |
| COMMIT                | YES                    |  |
| COMMIT PREPARED       | NO                     |  |

| SQL Command               | Supported in Greenplum | Modifications, Limitations, Exceptions   |
|---------------------------|------------------------|--|
| COPY                      | YES                    | <p><b>Modified Clauses:</b></p> <p>ESCAPE [ AS ] 'escape'   'OFF'</p> <p><b>Greenplum Database Clauses:</b></p> <p>[LOG ERRORS] SEGMENT REJECT LIMIT count<br/>[ROWS PERCENT]</p>  |
| CREATE AGGREGATE          | YES                    | <p><b>Unsupported Clauses / Options:</b></p> <p>[ , SORTOP = sort_operator ]</p> <p><b>Greenplum Database Clauses:</b></p> <p>[ , COMBINEFUNC = combinefunc ]</p> <p><b>Limitations:</b></p> <p>The functions used to implement the aggregate must be IMMUTABLE functions.</p>   |
| CREATE CAST               | YES                    |  |
| CREATE CONSTRAINT TRIGGER | NO                     |  |
| CREATE CONVERSION         | YES                    |  |
| CREATE DATABASE           | YES                    |  |
| CREATE DOMAIN             | YES                    |  |
| CREATE EVENT TRIGGER      | YES                    |  |
| CREATE EXTENSION          | YES                    | Loads a new extension into Greenplum Database - based on PostgreSQL 9.6.   |
| CREATE EXTERNAL TABLE     | YES                    | Greenplum Database parallel ETL feature - not in PostgreSQL 9.4.   |
| CREATE FUNCTION           | YES                    | <p><b>Limitations:</b></p> <p>Functions defined as STABLE or VOLATILE can be run in Greenplum Database provided that they are run on the master only. STABLE and VOLATILE functions cannot be used in statements that run at the segment level.</p>  |
| CREATE GROUP              | YES                    | An alias for CREATE ROLE   |
| CREATE INDEX              | YES                    | <p><b>Greenplum Database Clauses:</b></p> <p>USING bitmap (bitmap indexes)</p> <p><b>Limitations:</b></p> <p>UNIQUE indexes are allowed only if they contain all of (or a superset of) the Greenplum distribution key columns. On partitioned tables, a unique index is only supported within an individual partition - not across all partitions.</p> <p>CONCURRENTLY keyword not supported in Greenplum.</p> |

| SQL Command              | Supported in Greenplum | Modifications, Limitations, Exceptions   |
|--------------------------|------------------------|--|
| CREATE LANGUAGE          | YES                    |  |
| CREATE MATERIALIZED VIEW | YES                    | Based on PostgreSQL 9.4.   |
| CREATE OPERATOR          | YES                    | <b>Limitations:</b><br>The function used to implement the operator must be an IMMUTABLE function.  |
| CREATE OPERATOR CLASS    | YES                    |  |
| CREATE OPERATOR FAMILY   | YES                    |  |
| CREATE PROTOCOL          | YES                    |  |
| CREATE RESOURCE QUEUE    | YES                    | Greenplum Database resource management feature - not in PostgreSQL 9.4.  |
| CREATE ROLE              | YES                    | <b>Greenplum Database Clauses:</b><br>RESOURCE QUEUE <i>queue_name</i>   none  |
| CREATE RULE              | YES                    |  |
| CREATE SCHEMA            | YES                    |  |
| CREATE SEQUENCE          | YES                    | <b>Limitations:</b><br>The lastval() and currval() functions are not supported.<br>The setval() function is only allowed in queries that do not operate on distributed data.   |
| CREATE TABLE             | YES                    | <b>Unsupported Clauses / Options:</b><br>[GLOBAL   LOCAL]<br>REFERENCES<br>FOREIGN KEY<br>[DEFERRABLE   NOT DEFERRABLE]<br><b>Limited Clauses:</b><br>UNIQUE or PRIMARY KEY constraints are only allowed on hash-distributed tables (DISTRIBUTED BY), and the constraint columns must be the same as or a superset of the distribution key columns of the table and must include all the distribution key columns of the partitioning key.<br><b>Greenplum Database Clauses:</b><br>DISTRIBUTED BY ( <i>column</i> , [ ... ] )  <br>DISTRIBUTED RANDOMLY<br>PARTITION BY <i>type</i> ( <i>column</i> [, ...]) ( <i>partition_specification</i> , [...] )<br>WITH (appendoptimized=true<br>[,compresslevel=value,blocksize=value] ) |

| SQL Command        | Supported in Greenplum | Modifications, Limitations, Exceptions   |
|--------------------|------------------------|--|
| CREATE TABLE AS    | YES                    | See <a href="#">CREATE TABLE</a>   |
| CREATE TABLESPACE  | YES                    | <p><b>Greenplum Database Clauses:</b></p> <p>Specify host file system locations for specific segment instances.</p> <pre>WITH (contentID_1='/path/to/dir1...)</pre>  |
| CREATE TRIGGER     | NO                     |  |
| CREATE TYPE        | YES                    | <p><b>Greenplum Database Clauses:</b></p> <pre>COMPRESSTYPE   COMPRESSLEVEL   BLOCKSIZE</pre> <p><b>Limitations:</b></p> <p>The functions used to implement a new base type must be IMMUTABLE functions.</p>   |
| CREATE USER        | YES                    | An alias for <a href="#">CREATE ROLE</a>   |
| CREATE VIEW        | YES                    |  |
| DEALLOCATE         | YES                    |  |
| DECLARE            | YES                    | <p><b>Unsupported Clauses / Options:</b></p> <pre>SCROLL</pre> <pre>FOR UPDATE [ OF column [, ...] ]</pre> <p><b>Limitations:</b></p> <p>Cursors cannot be backward-scrolled. Forward scrolling is supported.</p> <p>PL/pgSQL does not have support for updatable cursors.</p> |
| DELETE             | YES                    |  |
| DISCARD            | YES                    | <b>Limitation:</b> DISCARD ALL is not supported.   |
| DO                 | YES                    | PostgreSQL 9.0 feature   |
| DROP AGGREGATE     | YES                    |  |
| DROP CAST          | YES                    |  |
| DROP CONVERSION    | YES                    |  |
| DROP DATABASE      | YES                    |  |
| DROP DOMAIN        | YES                    |  |
| DROP EVENT TRIGGER | YES                    |  |
| DROP EXTENSION     | YES                    | Removes an extension from Greenplum Database – based on PostgreSQL 9.6.  |

| SQL Command                       | Supported in Greenplum | Modifications, Limitations, Exceptions                                  |
|-----------------------------------|------------------------|---|
| <code>DROP EXTERNAL TABLE</code>  | YES                    | Greenplum Database parallel ETL feature - not in PostgreSQL 9.4.        |
| <code>DROP FUNCTION</code>        | YES                    |   |
| <code>DROP GROUP</code>           | YES                    | An alias for <a href="#">DROP ROLE</a>                                  |
| <code>DROP INDEX</code>           | YES                    |   |
| <code>DROP LANGUAGE</code>        | YES                    |   |
| <code>DROP OPERATOR</code>        | YES                    |   |
| <code>DROP OPERATOR CLASS</code>  | YES                    |   |
| <code>DROP OPERATOR FAMILY</code> | YES                    |   |
| <code>DROP OWNED</code>           | <b>NO</b>              |   |
| <code>DROP PROTOCOL</code>        | YES                    |   |
| <code>DROP RESOURCE QUEUE</code>  | YES                    | Greenplum Database resource management feature - not in PostgreSQL 9.4. |
| <code>DROP ROLE</code>            | YES                    |   |
| <code>DROP RULE</code>            | YES                    |   |
| <code>DROP SCHEMA</code>          | YES                    |   |
| <code>DROP SEQUENCE</code>        | YES                    |   |
| <code>DROP TABLE</code>           | YES                    |   |
| <code>DROP TABLESPACE</code>      | YES                    |   |
| <code>DROP TRIGGER</code>         | <b>NO</b>              |   |
| <code>DROP TYPE</code>            | YES                    |   |
| <code>DROP USER</code>            | YES                    | An alias for <a href="#">DROP ROLE</a>                                  |
| <code>DROP VIEW</code>            | YES                    |   |
| <code>END</code>                  | YES                    |   |
| <code>EXECUTE</code>              | YES                    |   |
| <code>EXPLAIN</code>              | YES                    |   |

| SQL Command                            | Supported in Greenplum | Modifications, Limitations, Exceptions   |
|--|------------------------|--|
| <code>FETCH</code>                     | YES                    | <b>Unsupported Clauses / Options:</b><br><code>LAST</code><br><code>PRIOR</code><br><code>BACKWARD</code><br><code>BACKWARD ALL</code><br><b>Limitations:</b><br>Cannot fetch rows in a nonsequential fashion; backward scan is not supported. |
| <code>GRANT</code>                     | YES                    |  |
| <code>INSERT</code>                    | YES                    |  |
| <code>LATERAL</code> Join Type         | <b>NO</b>              |  |
| <code>LISTEN</code>                    | <b>YES</b>             |  |
| <code>LOAD</code>                      | YES                    |  |
| <code>LOCK</code>                      | YES                    |  |
| <code>MOVE</code>                      | YES                    | See <a href="#">FETCH</a>  |
| <code>NOTIFY</code>                    | <b>YES</b>             |  |
| <code>PREPARE</code>                   | YES                    |  |
| <code>PREPARE TRANSACTION</code>       | <b>NO</b>              |  |
| <code>REASSIGN OWNED</code>            | YES                    |  |

## Reserved Identifiers and SQL Key Words

This topic describes Greenplum Database reserved identifiers and object names, and SQL key words recognized by the Greenplum Database and PostgreSQL command parsers.

### Reserved Identifiers

In the Greenplum Database system, names beginning with `gp_` and `pg_` are reserved and should not be used as names for user-created objects, such as tables, views, and functions.

The resource group names `admin_group`, `default_group`, and `none` are reserved. The resource queue name `pg_default` is reserved.

The tablespace names `pg_default` and `pg_global` are reserved.

The role names `gpadmin` and `gpmon` are reserved. `gpadmin` is the default Greenplum Database superuser role. The `gpmon` role owns the `gpperfmon` database and is also used by Greenplum Command Center.

In data files, the characters that delimit fields (columns) and rows have a special meaning. If they appear within the data you must escape them so that Greenplum Database treats them as data and not as delimiters. The backslash character (`\`) is the default escape character. See [Escaping](#) for details.

See [SQL Syntax](#) in the PostgreSQL documentation for more information about SQL identifiers, constants, operators, and expressions.

## SQL Key Words

[Table 1](#) lists all tokens that are key words in Greenplum Database 6 and PostgreSQL 9.4.

ANSI SQL distinguishes between *reserved* and *unreserved* key words. According to the standard, reserved key words are the only real key words; they are never allowed as identifiers. Unreserved key words only have a special meaning in particular contexts and can be used as identifiers in other contexts. Most unreserved key words are actually the names of built-in tables and functions specified by SQL. The concept of unreserved key words essentially only exists to declare that some predefined meaning is attached to a word in some contexts.

In the Greenplum Database and PostgreSQL parsers there are several different classes of tokens ranging from those that can never be used as an identifier to those that have absolutely no special status in the parser as compared to an ordinary identifier. (The latter is usually the case for functions specified by SQL.) Even reserved key words are not completely reserved, but can be used as column labels (for example, `SELECT 55 AS CHECK`, even though `CHECK` is a reserved key word).

[Table 1](#) classifies as "unreserved" those key words that are explicitly known to the parser but are allowed as column or table names. Some key words that are otherwise unreserved cannot be used as function or data type names and are marked accordingly. (Most of these words represent built-in functions or data types with special syntax. The function or type is still available but it cannot be redefined by the user.) Key words labeled "reserved" are not allowed as column or table names. Some reserved key words are allowable as names for functions or data types; this is also shown in the table. If not so marked, a reserved key word is only allowed as an "AS" column label name.

If you get spurious parser errors for commands that contain any of the listed key words as an identifier you should try to quote the identifier to see if the problem goes away.

Before studying the table, note the fact that a key word is not reserved does not mean that the feature related to the word is not implemented. Conversely, the presence of a key word does not indicate the existence of a feature.

| Key Word      | Greenplum Database                           | PostgreSQL 9.4                               |
|---------------|--|--|
| ABORT         | unreserved                                   | unreserved                                   |
| ABSOLUTE      | unreserved                                   | unreserved                                   |
| ACCESS        | unreserved                                   | unreserved                                   |
| ACTION        | unreserved                                   | unreserved                                   |

## SQL 2008 Optional Feature Compliance

The following table lists the features described in the 2008 SQL standard. Features that are supported in Greenplum Database are marked as YES in the 'Supported' column, features that are not implemented are marked as NO.

For information about Greenplum features and SQL compliance, see the *Greenplum Database Administrator Guide*.

| ID   | Feature           | Supported | Comments   |
|------|-------------------|-----------|--|
| B011 | Embedded Ada      | NO        |  |
| B012 | Embedded C        | NO        | Due to issues with PostgreSQL <a href="#">ecpg</a> |
| B013 | Embedded COBOL    | NO        |  |
| B014 | Embedded Fortran  | NO        |  |
| B015 | Embedded MUMPS    | NO        |  |
| B016 | Embedded Pascal   | NO        |  |
| B017 | Embedded PL/I     | NO        |  |
| B021 | Direct SQL        | YES       |  |
| B031 | Basic dynamic SQL | NO        |  |

| ID          | Feature   | Supported | Comments |
|-------------|---|-----------|----------|
| B03<br>2    | Extended dynamic SQL  | NO        |          |
| B03<br>3    | Untyped SQL-invoked function arguments                          | NO        |          |
| B03<br>4    | Dynamic specification of cursor attributes                      | NO        |          |
| B03<br>5    | Non-extended descriptor names                                   | NO        |          |
| B041        | Extensions to embedded SQL exception declarations               | NO        |          |
| B051        | Enhanced execution rights                                       | NO        |          |
| B111        | Module language Ada   | NO        |          |
| B112        | Module language C   | NO        |          |
| B113        | Module language COBOL   | NO        |          |
| B114        | Module language Fortran   | NO        |          |
| B115        | Module language MUMPS   | NO        |          |

## Objects Deprecated in Greenplum 6

Greenplum Database 6 has deprecated several database objects. These changes can effect the successful upgrade from one major version to another. Review these objects when using Geenplum Upgrade, or Greenplum Backup and Restore. This topic highlight these changes.

- [Deprecated Relations](#)
- [Deprecated Columns](#)
- [Deprecated Functions and Procedures](#)
- [Deprecated Types, Domains, and Composite Types](#)
- [Deprecated Operators](#)

**Parent topic:** [Greenplum Database Reference Guide](#)

## Deprecated Relations

The following list includes the Greenplum Database 6 deprecated relations.

- gp\_toolkit.\_\_gp\_localid
- gp\_toolkit.\_\_gp\_masterid
- gp\_toolkit.\_\_gp\_masterid
- pg\_catalog.gp\_configuration
- pg\_catalog.gp\_configuration
- pg\_catalog.gp\_db\_interfaces
- pg\_catalog.gp\_fault\_strategy
- pg\_catalog.gp\_global\_sequence
- pg\_catalog.gp\_interfaces

- `pg_catalog.gp_persistent_database_node`
- `pg_catalog.gp_persistent_filespace_node`
- `pg_catalog.gp_persistent_relation_node`
- `pg_catalog.gp_persistent_tablespace_node`
- `pg_catalog.gp_relation_node`
- `pg_catalog.pg_autovacuum`
- `pg_catalog.pg_filespace`
- `pg_catalog.pg_filespace_entry`
- `pg_catalog.pg_listener`
- `pg_catalog.pg_window`

## Deprecated Columns

The following list includes the Greenplum Database 6 deprecated columns.

- `gp_toolkit.gp_resgroup_config.proposed_concurrency`
- `gp_toolkit.gp_resgroup_config.proposed_memory_limit`
- `gp_toolkit.gp_resgroup_config.proposed_memory_shared_quota`
- `gp_toolkit.gp_resgroup_config.proposed_memory_spill_ratio`
- `gp_toolkit.gp_workfile_entries.current_query`
- `gp_toolkit.gp_workfile_entries.directory`
- `gp_toolkit.gp_workfile_entries.procpid`
- `gp_toolkit.gp_workfile_entries.state`
- `gp_toolkit.gp_workfile_entries.workmem`
- `gp_toolkit.gp_workfile_usage_per_query.current_query`
- `gp_toolkit.gp_workfile_usage_per_query.procpid`
- `gp_toolkit.gp_workfile_usage_per_query.state`
- `information_schema.triggers.condition_reference_new_row`
- `information_schema.triggers.condition_reference_new_table`
- `information_schema.triggers.condition_reference_old_row`
- `information_schema.triggers.condition_reference_old_table`
- `information_schema.triggers.condition_timing`
- `pg_catalog.gp_distribution_policy.attrnums`
- `pg_catalog.gp_segment_configuration.replication_port`
- `pg_catalog.pg_aggregate.agginvprelimfn`
- `pg_catalog.pg_aggregate.agginvtransfn`

- `pg_catalog.pg_aggregate.aggordered`
- `pg_catalog.pg_aggregate.aggprelimfn`
- `pg_catalog.pg_am.amcanshrink`
- `pg_catalog.pg_am.amgetmulti`
- `pg_catalog.pg_am.amindexnulls`
- `pg_catalog.pg_amop.amopreqcheck`
- `pg_catalog.pg_authid.rolconfig`
- `pg_catalog.pg_authid.rolcreatorexthdfs`
- `pg_catalog.pg_authid.rolcreatewexthdfs`
- `pg_catalog.pg_class.relkeys`
- `pg_catalog.pg_class.relrefs`
- `pg_catalog.pg_class.reltoastidxid`
- `pg_catalog.pg_class.reltriggers`
- `pg_catalog.pg_class.relukeys`
- `pg_catalog.pg_database.datconfig`
- `pg_catalog.pg_exttable.fmterrtbl`

# Server Programmatic Interfaces

This section describes programmatic interfaces to the Greenplum Database server.

- [DataDirect ODBC Driver \(Tanzu Greenplum Only\)](#)
- [DataDirect JDBC Driver \(Tanzu Greenplum Only\)](#)
- [Greenplum Partner Connector API](#)
- [Background Worker Processes](#)

**Parent topic:** [Greenplum Database Reference Guide](#)

## DataDirect ODBC Drivers for VMware Tanzu Greenplum

ODBC drivers enable third party applications to connect via a common interface to the VMware Tanzu Greenplum Database system. This document describes how to install DataDirect Connect XE for ODBC drivers for VMware Tanzu Greenplum on either a Linux or Windows system. Unless specified otherwise, references to DataDirect Connect XE for ODBC refer to DataDirect Connect XE for ODBC and DataDirect Connect64 XE for ODBC.

The DataDirect ODBC Drivers for VMware Tanzu Greenplum are available for download from [VMware Tanzu Network](#).

## Prerequisites

- On Linux systems, install KornShell ([ksh](#)) if it is not available.
- Note the appropriate serial number and license key (use the same number for both the serial number and license key during the installation):

| Driver  | Serial Number | License Key  |
|---|---------------|--|
| DataDirect Connect XE for ODBC 7.1 drivers (32-bit drivers)   | 1076681728    | 77C2BCC3-654834A9-7D40E9A1-B2507904-AECA5E1B53F4DC95 |
| DataDirect Connect64 XE for ODBC 7.1 drivers (64-bit drivers) | 1076681984    | 77C2BCC3-654834A9-7D40E9A1-B2507904-AECA5E1B53F4DC95 |

## Supported Client Platforms

DataDirect Connect64 XE for ODBC drivers for Greenplum support the following 64-bit client platforms:

- AIX 64: 7.1, 6.1, 5.3 Fixpack 5 or higher

- HP-UX IPF: 11i v3.0 (B.11.3X), 11i v2.0 (B.11.23)
- Linux Itanium: Red Hat Enterprise Linux (RHEL) 7.x, 6.x, RHEL 5.x, RHEL 4.x
- Linux x64: RHEL 7.x RHEL 6.x, RHEL 5.x, RHEL 4.x, SUSE Linux Enterprise Server (SLES) 15, SLES 12, SLES 11, SLES 10, Ubuntu 16.04
- Solaris on SPARC: 11 and 11 Express (Solaris 5.11), 10 (Solaris 5.10), 9 (Solaris 5.9), 8 (Solaris 5.8)
- Solaris x64: 11 (Solaris 5.11), 10 (Solaris 5.10)
- Windows x64: Windows 8, Windows 10, Windows Server 20016

DataDirect Connect XE for ODBC drivers for Greenplum support the following 32-bit client platforms:

- AIX 32: 7.1, 6.1, 5.3 Fixpack 5 or higher
- HP-UX IPF: 11i v3.0 (B.11.3X), 11i v2.0 (B.11.23)
- HP-UX PA-RISC: 11i v3 (B.11.3X), 11i v2 (B.11.23) 11i v1 (B.11.11), 11
- Linux x86: Red Hat Enterprise Linux (RHEL) 6.x, RHEL 5.x, RHEL 4.x, SUSE Linux Enterprise Server (SLES) 11, SLES 10, Ubuntu 16.04, Ubuntu 14.04
- Solaris on SPARC: 11 and 11 Express (Solaris 5.11), 10 (Solaris 5.10), 9 (Solaris 5.9), 8 (Solaris 5.8)
- Windows: Windows 8, Windows 10, Windows Server 20016

## Upgrading DataDirect ODBC Drivers

Beginning with Greenplum 6.22, the DataDirect ODBC Driver package was changed to no longer require acceptance of a separate licensing agreement. If you have installed a DataDirect ODBC driver version 7.1.6+7.16.389 or earlier, follow these instructions to upgrade to the new version 7.1.6+7.16.445 package.

### Upgrading DataDirect ODBC Drivers for Linux

Follow these steps to upgrade an older (version 7.1.6+7.16.389 or earlier) ODBC Driver on a Linux system:

1. Back up the ODBC Data Source Names (DSNs) by copying the `odbc.ini` file to safe location. For example, for a default installation:

```
$ cp /opt/Progress/DataDirect/Connect64_for_ODBC_71/odbc.ini /backup-path/odbc.ini
```

2. Uninstall the older ODBC driver by removing the installation directory:

```
$ rm -rf /opt/Progress/DataDirect/Connect64_for_ODBC_71
```

3. Install the new ODBC Driver by following the instructions in [Installing on Linux Systems](#).
4. Use a text editor to edit the newly-installed `/opt/Progress/DataDirect/Connect64_for_ODBC_71/odbc.ini` file and add the DSN entries

present in your backup `odbc.ini` file.

## Upgrading DataDirect ODBC Drivers for Windows

Follow these steps to upgrade an older (version 7.1.6+7.16.389 or earlier) ODBC Driver on a Windows system:

1. Back up the ODBC Data Source Names (DSNs) by saving the Windows Registry entries to safe location:
  1. Press **Win+r** and enter `regedit` to start the Windows Registry Editor.
  2. Navigate to and select the `HKEY_CURRENT_USER\Software\ODBC\ODBC.INI\ODBC Data Sources` entry.
  3. Copy any data source entries you want to preserve to a text file, so that you can create them after installing the new software version.
  4. Exit the Windows Registry Editor.
2. Uninstall the older ODBC driver using either of the following methods:
  - Run the uninstall application, which is installed by default to `C:\Program Files\Progress\DataDirect\Connect64_for_ODBC_71\Uninstall Progress DataDirect Connect64 ® and Connect64 XE for ODBC 7.1.exe` and follow the prompts to uninstall the software.
  - Delete the software directory, `C:\Program Files\Progress\DataDirect\Connect64_for_ODBC_71`.
3. Install the new ODBC Driver by following the instructions in [Installing on Windows Systems](#).
4. Re-configure any DSN entries that you preserved from the previous installation.

## Installing on Linux Systems

To install ODBC drivers on your client:

1. Log into [VMware Tanzu Network](#) and download the correct ODBC driver for your operating system. The following Linux and UNIX files are available:
  - `PROGRESS_DATADIRECT_ODBC_GREENPLUM_7.1.6.HOTFIX_LINUX_64.tar.gz`
  - `PROGRESS_DATADIRECT_ODBC_GREENPLUM_7.1.6.HOTFIX_LINUX_32.tar.gz`
  - `PROGRESS_DATADIRECT_ODBC_GREENPLUM_7.1.6.HOTFIX_AIX_64.tar.gz`
  - `PROGRESS_DATADIRECT_ODBC_GREENPLUM_7.1.6.HOTFIX_AIX_32.tar.gz`
2. Follow the instructions in [Verifying the Greenplum Database Software Download](#) to verify the integrity of the **Progress DataDirect ODBC Driver** software.
3. Unpack the files. For example:

```
$ tar -zxvf PROGRESS_DATADIRECT_ODBC_GREENPLUM_7.1.6.HOTFIX_LINUX_64.tar.gz
```

The files are extracted to the current directory.

4. Execute the installer as the root user:

```
$ ./PROGRESS_DATADIRECT_ODBC_LINUX_64_INSTALL.bin
```

5. On the **Install Directory** screen, click **Restore Default** to install the ODBC driver to a default location, then click **Next**. **Note:** If you do not click **Restore Default**, then the installer installs the ODBC driver files into a user-specific directory.
6. On the **Install Type** screen, select **OEM/License Installation** and click **Next**.
7. Type the license key `77C2BCC3-654834A9-7D40E9A1-B2507904-AECA5E1B53F4DC95` into the **License key # / Control #** field and click **Validate**. Click **Next** after the key validation completes.
8. On the follow-on **Product Registration** screen, enter a **User Name**, **Company Name**, and **Serial Number** to register the driver installation. Use the serial number `1076681728` for the 32-bit driver, or `1076681984` for the 64-bit driver. Click **Next** to continue.
9. Click **Install** on the **Pre-Installation Summary** screen to install the software.

## Configuring the Driver on Linux

After you install the driver software, perform these steps to configure the driver.

1. Change to the installation directory for your driver. For example:

```
$ cd /opt/Progress/DataDirect/Connect64_for_ODBC_71/
```

2. Set the `LD_LIBRARY_PATH`, `ODBCINI` and `ODBCINST` environment variables with the command:

```
$ source odbc.sh
```

3. Open the `odbc.ini` file and create a new DSN entry. You can use the existing "Greenplum Wire Protocol" entry as a template.

```
$ vi $ODBCINI
```

You must edit the following entries to add values that match your system:

| Entry      | Description              |
|------------|--------------------------|
| Database   | Greenplum database name. |
| HostName   | Master host name.        |
| PortNumber | Master host port number. |
| LogonID    | Greenplum Database user. |
| Password   | Password.                |

4. Verify the driver version:

```
$ cd /opt/Progress/DataDirect/Connect64_for_ODBC_71/bin
$ **./ddtestlib ddgplm27.so**
Load of ddgplm27.so successful, qehandle is 0x15C9EC0
File version: 07.16.0389 (B0562, U0408)
```

## Testing the Driver Connection on Linux

To test the DSN connection:

1. Execute the example utility to test the DSN connection, entering the Greenplum Wire Protocol data source name and the credentials of a Greenplum user. For example:

```
$ cd /opt/Progress/DataDirect/Connect64_for_ODBC_71/samples/example
$ ./example
./example DataDirect Technologies, Inc. ODBC Example Application.
Enter the data source name : **Greenplum Wire Protocol**
Enter the user name       : **gpadmin**
Enter the password       : **gpadmin**

Enter SQL statements (Press ENTER to QUIT)
SQL>
```

2. Enter the following select statement to confirm database connectivity:

```
Enter SQL statements (Press ENTER to QUIT)
SQL> select version();

version
PostgreSQL 8.3.23 (Greenplum Database 5.0.0 build commit:8c709516061cfff5476c03d
6e2da99aae42722ae1) on x86_64-pc-linux-gnu, compiled by GCC gcc (GCC) 6.2.0 com
piled on Sep  1 2017 22:39:53

Enter SQL statements (Press ENTER to QUIT)
SQL>
```

3. Press the ENTER key to exit the example application.

## Installing on Windows Systems

To install ODBC drivers on your client:

1. Log into [VMware Tanzu Network](#) and download the correct ODBC driver for your operating system (32-bit or 64-bit). The following Windows files are available:
  - PROGRESS\_DATADIRECT\_CONNECT64\_ODBC\_7.1.6+7.16.445.HOTFIX\_WIN\_64.zip
  - PROGRESS\_DATADIRECT\_CONNECT\_ODBC\_7.1.6+7.16.445.HOTFIX\_WIN\_32.zip
2. Follow the instructions in [Verifying the Greenplum Database Software Download](#) to verify the integrity of the **Progress DataDirect ODBC Driver** software.
3. Uncompress the installer.
4. Double-click `PROGRESS_DATADIRECT_ODBC__WIN_64.exe` or `PROGRESS_DATADIRECT_ODBC__WIN_32.exe` file to launch the install wizard.
5. If necessary, permit the InstallAnywhere installer to run.
6. Click **Next** at the Introduction screen to begin the installation.
7. On the **Install Directory** screen, either modify the installation path or accept the default path, `C:\Program Files\Progress\DataDirect\Connect64_for_ODBC_71`. Click **Next**.

8. Select **OEM or Licensed Installation** as the installation type and click **Next**.
9. Type the license key `77C2BCC3-654834A9-7D40E9A1-B2507904-AECA5E1B53F4DC95` into the **License key # / Control #** field and click **Validate**. Click **Next** after the key validation completes.
10. Select **Create a default Data Source** and click **Next**.
11. Verify the selected installation options, and click **Install** to begin installation. The installation process may take several minutes.
12. Select **Done** to complete installing the driver package.

## Verifying the Version on Windows

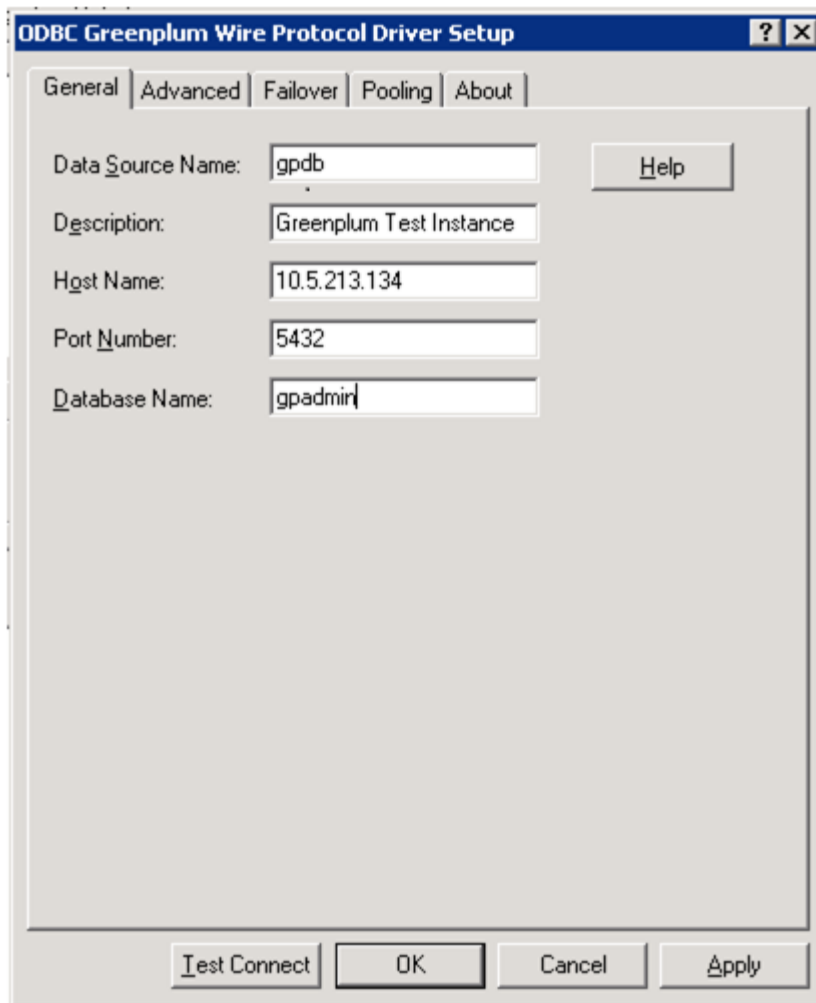

To verify your driver version:

1. Select **Start > All Programs > DataDirect > ODBC Administrator** to open the Windows ODBC Administrator.
2. Click the **Drivers** tab, and scroll down to DataDirect <version> Greenplum Wire Protocol. Ensure that you see the expected version number.

## Configuring and Testing the Driver on Windows

To configure and test a DSN connection to a Greenplum Database:

1. Open the ODBC Administrator.
2. Select the **System DSN** tab.
3. Select **Add**.
4. Select **DataDirect 7.1 Greenplum Wire Protocol** and click **Finish**.
5. Enter the details for your chosen Greenplum Database instance. For example:

Recommended: Set the Max Long Varchar size.

Select the **Advanced** tab.

In **Max Long Varchar Size**, enter 8192 then select **Apply**.

6. Select **Test Connect**.
7. Enter your user name and password, then select **OK**.
8. You should see the confirmation message **Connection Established!**

If your connection fails, check the following for accuracy:

- Host Name
- Port Number
- Database Name
- User Name
- Password
- Greenplum instance is active

## DataDirect Driver Documentation

For more information on working with Data Direct, see documentation that is installed with the driver. By default, you can access the installed documentation by using a Web browser to open the file `/opt/Progress/DataDirect/Connect64_for_ODBC_71/help/index.html`.

Documentation is also available online at <https://www.progress.com/documentation/datadirect-connectors>. Titles include:

- [User's Guide](#)
- [Reference](#)
- [Troubleshooting Guide](#)
- [Installation Help](#)
- [Windows Readme](#)
- [UNIX/Linux Readme](#)

## DataDirect JDBC Driver for VMware Tanzu Greenplum

DataDirect JDBC drivers are compliant with the Type 4 architecture, but provide advanced features that define them as Type 5 drivers. Additionally, the drivers consistently support the latest database features and are fully compliant with Java™ SE 8 and JDBC 4.0 functionality.

The DataDirect JDBC Driver for VMware Tanzu Greenplum is available for download from [VMware Tanzu Network](#).

- [Prerequisites](#)
- [Downloading the DataDirect JDBC Driver](#)
- [Obtaining Version Details for the Driver](#)
- [Usage Information](#)
- [Configuring Prepared Statement Execution](#)
- [DataDirect Driver Documentation](#)

## Prerequisites

- The DataDirect JDBC Driver requires Java SE 5 or higher. See [System and Product Requirements](#) in the DataDirect documentation for information and requirements associated with specific features of the JDBC driver.
- The license key is embedded in the `greenplum.jar` file itself. You do not need to apply a specific license key to the driver to activate it.

**Parent topic:** [DataDirect JDBC Driver for VMware Tanzu Greenplum](#)

## Downloading the DataDirect JDBC Driver

To install the JDBC driver on your client:

1. Log into [VMware Tanzu Network](#) and download the DataDirect JDBC driver file: `PROGRESS_DATADIRECT_JDBC_DRIVER_PIVOTAL_GREENPLUM_5.1.4.zip`.

2. Follow the instructions in [Verifying the Greenplum Database Software Download](#) to verify the integrity of the **Progress DataDirect JDBC Driver** software.
3. Extract the downloaded ZIP file.
4. Add the full path to the `PROGRESS_DATADIRECT_JDBC_DRIVER_PIVOTAL_GREENPLUM_5.1.4.jar` to your Java CLASSPATH environment variable, or add it to your classpath with the `-classpath` option when executing a Java application.

**Parent topic:** [DataDirect JDBC Driver for VMware Tanzu Greenplum](#)

## Obtaining Version Details for the Driver

To view the JDBC driver version information:

1. Change to the directory that contains the downloaded `PROGRESS_DATADIRECT_JDBC_DRIVER_PIVOTAL_GREENPLUM_5.1.4.jar` driver file. For example:

```
$ cd /opt/Progress/DataDirect/Connect_for_JDBC_51/lib
```

2. Execute the data source class to display the version information.

For Linux/Unix systems:

```
$ java -classpath PROGRESS_DATADIRECT_JDBC_DRIVER_PIVOTAL_GREENPLUM_5.1.4.jar c
om.pivotal.jdbc.GreenplumDriver
[Pivotal][Greenplum JDBC Driver]Driver Version: 5.1.4.000223 (F000432.U000208)
```

For Windows systems:

```
java -classpath .;\greenplum.jar com.pivotal.jdbc.GreenplumDriver
[Pivotal][Greenplum JDBC Driver]Driver Version: 5.1.4.000223 (F000432.U000208)
```

**Parent topic:** [DataDirect JDBC Driver for VMware Tanzu Greenplum](#)

## Usage Information

The JDBC driver is provided in the `greenplum.jar` file. Use the following data source class and connection URL information with the driver.

| Property          | Description  |
|-------------------|--|
| Driver File Name  | greenplum.jar  |
| Data Source Class | com.pivotal.jdbc.GreenplumDriver                       |
| Connection URL    | jdbc:pivotal:greenplum://host:port;DatabaseName=<name> |

| Property        | Description   |
|-----------------|---|
| Driver Defaults | FetchTWFSasTime=true<br>MaxLongVarcharSize=8190<br>MaxNumericPrecision=28<br>MaxNumericScale=6<br>PrepareThreshold=0<br>ResultSetMetadataOptions=1<br>SupportsCatalogs=true |

Parent topic: [DataDirect JDBC Driver for VMware Tanzu Greenplum](#)

## Configuring Prepared Statement Execution

The DataDirect JDBC driver version 5.1.4.000270 (F000450.U000214) introduced support for the `PrepareThreshold` connection property. This property specifies the number of prepared statement executions to be performed before the driver switches to using server-side prepared statements.

The `PrepareThreshold` default value is 0, always use server-side prepare for prepared statements. This setting preserves the behavior of previous versions of the JDBC driver.

When the `PrepareThreshold` value is greater than 1, it specifies on which execution of a prepared statement the driver starts using server-side prepared statements.

**Note:** `statement.executeBatch()` always uses server-side prepare for prepared statements. This matches the behavior of the PostgreSQL open source JDBC driver.

Refer to [PrepareThreshold](#) in the DataDirect documentation for additional information about this connection property.

### Limitation

When the `PrepareThreshold` value is greater than one and the prepared statement includes parameterized operations, the driver does not send any SQL prepare calls during `connection.prepareStatement()`. The driver instead sends the query all at once, at execution time. This requires that the driver determine the data types of every column *before* it sends the query to the server. While the driver can make this determination for many data types, it cannot for the JDBC types that can be mapped to multiple Greenplum data types:

- BIT VARYING
- BOOLEAN
- JSON
- TIME WITH TIME ZONE
- UUIDCOL

To work around this limitation, set `PrepareThreshold` to 0 when a prepared statement uses parameterized values with any of the above data types. And use `ResultSet.getMetaData()` to determine if any of the above types are used in a query in advance of submitting the prepared statement.

**Note:** GPORCA does not support prepared statements that have parameterized values, and will fall back to using the Postgres Planner.

**Parent topic:** [DataDirect JDBC Driver for VMware Tanzu Greenplum](#)

## DataDirect Driver Documentation

For more information on working with the Data Direct JDBC driver, see documentation available online at <https://www.progress.com/documentation/datadirect-connectors>. Titles include:

## Greenplum Partner Connector API

With the Greenplum Partner Connector API (GPPC API), you can write portable Greenplum Database user-defined functions (UDFs) in the C and C++ programming languages. Functions that you develop with the GPPC API require no recompilation or modification to work with older or newer Greenplum Database versions.

Functions that you write to the GPPC API can be invoked using SQL in Greenplum Database. The API provides a set of functions and macros that you can use to issue SQL commands through the Server Programming Interface (SPI), manipulate simple and composite data type function arguments and return values, manage memory, and handle data.

You compile the C/C++ functions that you develop with the GPPC API into a shared library. The GPPC functions are available to Greenplum Database users after the shared library is installed in the Greenplum Database cluster and the GPPC functions are registered as SQL UDFs.

**Note:** The Greenplum Partner Connector is supported for Greenplum Database versions 4.3.5.0 and later.

This topic contains the following information:

- [Using the GPPC API](#)
  - [Requirements](#)
  - [Header and Library Files](#)
  - [Data Types](#)
  - [Function Declaration, Arguments, and Results](#)
  - [Memory Handling](#)
  - [Working With Variable-Length Text Types](#)
  - [Error Reporting and Logging](#)
  - [SPI Functions](#)
  - [About Tuple Descriptors and Tuples](#)

- [Set-Returning Functions](#)
- [Table Functions](#)
- [Limitations](#)
- [Sample Code](#)
- [Building a GPPC Shared Library with PGXS](#)
- [Registering a GPPC Function with Greenplum Database](#)
- [Packaging and Deployment Considerations](#)
- [GPPC Text Function Example](#)
- [GPPC Set-Returning Function Example](#)

## Using the GPPC API

The GPPC API shares some concepts with C language functions as defined by PostgreSQL. Refer to [C-Language Functions](#) in the PostgreSQL documentation for detailed information about developing C language functions.

The GPPC API is a wrapper that makes a C/C++ function SQL-invokable in Greenplum Database. This wrapper shields GPPC functions that you write from Greenplum Database library changes by normalizing table and data manipulation and SPI operations through functions and macros defined by the API.

The GPPC API includes functions and macros to:

- Operate on base and composite data types.
- Process function arguments and return values.
- Allocate and free memory.
- Log and report errors to the client.
- Issue SPI queries.
- Return a table or set of rows.
- Process tables as function input arguments.

## Requirements

When you develop with the GPPC API:

- You must develop your code on a system with the same hardware and software architecture as that of your Greenplum Database hosts.
- You must write the GPPC function(s) in the C or C++ programming languages.
- The function code must use the GPPC API, data types, and macros.
- The function code must *not* use the PostgreSQL C-Language Function API, header files, functions, or macros.
- The function code must *not* `#include` the `postgres.h` header file or use `PG_MODULE_MAGIC`.

- You must use only the GPPC-wrapped memory functions to allocate and free memory. See [Memory Handling](#).
- Symbol names in your object files must not conflict with each other nor with symbols defined in the Greenplum Database server. You must rename your functions or variables if you get error messages to this effect.

## Header and Library Files

The GPPC header files and libraries are installed in `$GPHOME`:

- `$GPHOME/include/gppc.h` - the main GPPC header file
- `$GPHOME/include/gppc_config.h` - header file defining the GPPC version
- `$GPHOME/lib/libgppc.[a, so, so.1, so.1.2]` - GPPC archive and shared libraries

## Data Types

The GPPC functions that you create will operate on data residing in Greenplum Database. The GPPC API includes data type definitions for equivalent Greenplum Database SQL data types. You must use these types in your GPPC functions.

The GPPC API defines a generic data type that you can use to represent any GPPC type. This data type is named `GppcDatum`, and is defined as follows:

```
typedef int64_t GppcDatum;
```

The following table identifies each GPPC data type and the SQL type to which it maps.

| SQL Type           | GPPC Type    | GPPC Oid for Type |
|--------------------|--------------|-------------------|
| boolean            | GppcBool     | GppcOidBool       |
| char (single byte) | GppcChar     | GppcOidChar       |
| int2/smallint      | GppcInt2     | GppcOidInt2       |
| int4/integer       | GppcInt4     | GppcOidInt4       |
| int8/bigint        | GppcInt8     | GppcOidInt8       |
| float4/real        | GppcFloat4   | GppcOidFloat4     |
| float8/double      | GppcFloat8   | GppcOidFloat8     |
| text               | *GppcText    | GppcOidText       |
| varchar            | *GppcVarChar | GppcOidVarChar    |
| char               | *GppcBpChar  | GppcOidBpChar     |
| bytea              | *GppcBytea   | GppcOidBytea      |
| numeric            | *GppcNumeric | GppcOidNumeric    |
| date               | GppcDate     | GppcOidDate       |
| time               | GppcTime     | GppcOidTime       |

| SQL Type    | GPPC Type       | GPPC Oid for Type  |
|-------------|-----------------|--------------------|
| timetz      | *GppcTimeTz     | GppcOidTimeTz      |
| timestamp   | GppcTimestamp   | GppcOidTimestamp   |
| timestampTz | GppcTimestampTz | GppcOidTimestampTz |
| anytable    | GppcAnyTable    | GppcOidAnyTable    |
| oid         | GppcOid         |                    |

The GPPC API treats text, numeric, and timestamp data types specially, providing functions to operate on these types.

Example GPPC base data type declarations:

```
GppcText      message;
GppcInt4      arg1;
GppcNumeric   total_sales;
```

The GPPC API defines functions to convert between the generic `GppcDatum` type and the GPPC specific types. For example, to convert from an integer to a datum:

```
GppcInt4 num = 13;
GppcDatum num_dat = GppcInt4GetDatum(num);
```

## Composite Types

A composite data type represents the structure of a row or record, and is comprised of a list of field names and their data types. This structure information is typically referred to as a tuple descriptor. An instance of a composite type is typically referred to as a tuple or row. A tuple does not have a fixed layout and can contain null fields.

The GPPC API provides an interface that you can use to define the structure of, to access, and to set tuples. You will use this interface when your GPPC function takes a table as an input argument or returns table or set of record types. Using tuples in table and set returning functions is covered later in this topic.

## Function Declaration, Arguments, and Results

The GPPC API relies on macros to declare functions and to simplify the passing of function arguments and results. These macros include:

| Task                           | Macro Signature  | Description   |
|--------------------------------|--|---|
| Make a function SQL-invokable  | <code>GPPC_FUNCTION_INFO (function\_name)</code>           | Glue to make function <code>function\_name</code> SQL-invokable.  |
| Declare a function             | <code>GppcDatum function\_name (GPPC_FUNCTION_ARGS)</code> | Declare a GPPC function named <code>function\_name</code> ; every function must have this same signature. |
| Return the number of arguments | <code>GPPC_NARGS ()</code>                                 | Return the number of arguments passed to the function.  |

| Task  | Macro Signature   | Description  |
|---|---|--|
| Fetch an argument                             | <code>GPPC_GETARG_&lt;ARGTYPE&gt;(arg\_num)</code>      | Fetch the value of argument number <code>arg\_num</code> (starts at 0), where <code>&lt;ARGTYPE&gt;</code> identifies the data type of the argument. For example, <code>GPPC_GETARG_FLOAT8(0)</code> .                                 |
| Fetch and make a copy of a text-type argument | <code>GPPC_GETARG_&lt;ARGTYPE&gt;_COPY(arg\_num)</code> | Fetch and make a copy of the value of argument number <code>arg\_num</code> (starts at 0). <code>&lt;ARGTYPE&gt;</code> identifies the text type (text, varchar, bpchar, bytea). For example, <code>GPPC_GETARG_BYTEA_COPY(1)</code> . |
| Determine if an argument is NULL              | <code>GPPC_ARGISNULL(arg\_num)</code>                   | Return whether or not argument number <code>arg\_num</code> is NULL.   |
| Return a result                               | <code>GPPC_RETURN_&lt;ARGTYPE&gt;(return\_val)</code>   | Return the value <code>return\_val</code> , where <code>&lt;ARGTYPE&gt;</code> identifies the data type of the return value. For example, <code>GPPC_RETURN_INT4(131)</code> .   |

When you define and implement your GPPC function, you must declare it with the GPPC API using the two declarations identified above. For example, to declare a GPPC function named `add_int4s()`:

```
GPPC_FUNCTION_INFO(add_int4s);
GppcDatum add_int4s(GPPC_FUNCTION_ARGS);

GppcDatum
add_int4s(GPPC_FUNCTION_ARGS)
{
    // code here
}
```

If the `add_int4s()` function takes two input arguments of type `int4`, you use the `GPPC_GETARG_INT4(arg\_num)` macro to access the argument values. The argument index starts at 0. For example:

```
GppcInt4 first_int = GPPC_GETARG_INT4(0);
GppcInt4 second_int = GPPC_GETARG_INT4(1);
```

If `add_int4s()` returns the sum of the two input arguments, you use the `GPPC_RETURN_INT8(return\_val)` macro to return this sum. For example:

```
GppcInt8 sum = first_int + second_int;
GPPC_RETURN_INT8(sum);
```

The complete GPPC function:

```
GPPC_FUNCTION_INFO(add_int4s);
GppcDatum add_int4s(GPPC_FUNCTION_ARGS);

GppcDatum
add_int4s(GPPC_FUNCTION_ARGS)
{
    // get input arguments
    GppcInt4 first_int = GPPC_GETARG_INT4(0);
    GppcInt4 second_int = GPPC_GETARG_INT4(1);

    // add the arguments
    GppcInt8 sum = first_int + second_int;
```

```
// return the sum
GPPC_RETURN_INT8(sum);
}
```

## Memory Handling

The GPPC API provides functions that you use to allocate and free memory, including text memory. You must use these functions for all memory operations.

| Function Name   | Description                                 |
|---|---|
| <code>void *GppcAlloc( size_t num )</code>              | Allocate num bytes of uninitialized memory. |
| <code>void *GppcAlloc0( size_t num )</code>             | Allocate num bytes of 0-initialized memory. |
| <code>void *GppcRealloc( void *ptr, size_t num )</code> | Resize pre-allocated memory.                |
| <code>void GppcFree( void *ptr )</code>                 | Free allocated memory.                      |

After you allocate memory, you can use system functions such as `memcpy()` to set the data.

The following example allocates an array of `GppcDatums` and sets the array to datum versions of the function input arguments:

```
GppcDatum *values;
int attnum = GPPC_NARGS();

// allocate memory for attnum values
values = GppcAlloc( sizeof(GppcDatum) * attnum );

// set the values
for( int i=0; i<attnum; i++ ) {
    GppcDatum d = GPPC_GETARG_DATUM(i);
    values[i] = d;
}
```

When you allocate memory for a GPPC function, you allocate it in the current context. The GPPC API includes functions to return, create, switch, and reset memory contexts.

| Function Name   | Description  |
|---|--|
| <code>GppcMemoryContext GppcGetCurrentMemoryContext(void)</code>                    | Return the current memory context.                 |
| <code>GppcMemoryContext GppcMemoryContextCreate(GppcMemoryContext parent)</code>    | Create a new memory context under parent.          |
| <code>GppcMemoryContext GppcMemoryContextSwitchTo(GppcMemoryContext context)</code> | Switch to the memory context context.              |
| <code>void GppcMemoryContextReset(GppcMemoryContext context)</code>                 | Reset (free) the memory in memory context context. |

Greenplum Database typically calls a SQL-invoked function in a per-tuple context that it creates and deletes every time the server backend processes a table row. Do not assume that memory allocated in the current memory context is available across multiple function calls.

## Working With Variable-Length Text Types

The GPPC API supports the variable length text, varchar, blank padded, and byte array types. You must use the GPPC API-provided functions when you operate on these data types. Variable text manipulation functions provided in the GPPC API include those to allocate memory for, determine string length of, get string pointers for, and access these types:

| Function Name  | Description   |
|--|---|
| <code>GppcText GppcAllocText( size_t len )</code>                | Allocate len bytes of memory for the varying length type.                                   |
| <code>GppcVarChar GppcAllocVarChar( size_t len )</code>          |   |
| <code>GppcBpChar GppcAllocBpChar( size_t len )</code>            |   |
| <code>GppcBytea GppcAllocBytea( size_t len )</code>              |   |
| <code>size_t GppcGetTextLength( GppcText s )</code>              | Return the number of bytes in the memory chunk.   |
| <code>size_t GppcGetVarCharLength( GppcVarChar s )</code>        |   |
| <code>size_t GppcGetBpCharLength( GppcBpChar s )</code>          |   |
| <code>size_t GppcGetByteaLength( GppcBytea b )</code>            |   |
| <code>char *GppcGetTextPointer( GppcText s )</code>              | Return a string pointer to the head of the memory chunk. The string is not null-terminated. |
| <code>char *GppcGetVarCharPointer( GppcVarChar s )</code>        |   |
| <code>char *GppcGetBpCharPointer( GppcBpChar s )</code>          |   |
| <code>char *GppcGetByteaPointer( GppcBytea b )</code>            |   |
| <code>char *GppcTextGetCString( GppcText s )</code>              | Return a string pointer to the head of the memory chunk. The string is null-terminated.     |
| <code>char *GppcVarCharGetCString( GppcVarChar s )</code>        |   |
| <code>char *GppcBpCharGetCString( GppcBpChar s )</code>          |   |
| <code>GppcText *GppcCStringGetText( const char *s )</code>       | Build a varying-length type from a character string.  |
| <code>GppcVarChar *GppcCStringGetVarChar( const char *s )</code> |   |
| <code>GppcBpChar *GppcCStringGetBpChar( const char *s )</code>   |   |

Memory returned by the `GppcGet<VLEN_ARGTYPE>Pointer()` functions may point to actual database content. Do not modify the memory content. The GPPC API provides functions to allocate memory

for these types should you require it. After you allocate memory, you can use system functions such as `memcpy()` to set the data.

The following example manipulates text input arguments and allocates and sets result memory for a text string concatenation operation:

```
GppcText first_textstr = GPPC_GETARG_TEXT(0);
GppcText second_textstr = GPPC_GETARG_TEXT(1);

// determine the size of the concatenated string and allocate
// text memory of this size
size_t arg0_len = GppcGetTextLength(first_textstr);
size_t arg1_len = GppcGetTextLength(second_textstr);
GppcText retstring = GppcAllocText(arg0_len + arg1_len);

// construct the concatenated return string; copying each string
// individually
memcpy(GppcGetTextPointer(retstring), GppcGetTextPointer(first_textstr), arg0_len);
memcpy(GppcGetTextPointer(retstring) + arg0_len, GppcGetTextPointer(second_textstr), arg1_len);
```

## Error Reporting and Logging

The GPPC API provides error reporting and logging functions. The API defines reporting levels equivalent to those in Greenplum Database:

```
typedef enum GppcReportLevel
{
    GPPC_DEBUG1           = 10,
    GPPC_DEBUG2           = 11,
    GPPC_DEBUG3           = 12,
    GPPC_DEBUG4           = 13,
    GPPC_DEBUG            = 14,
    GPPC_LOG              = 15,
    GPPC_INFO             = 17,
    GPPC_NOTICE           = 18,
    GPPC_WARNING          = 19,
    GPPC_ERROR            = 20,
} GppcReportLevel;
```

(The Greenplum Database `client_min_messages` server configuration parameter governs the current client logging level. The `log_min_messages` configuration parameter governs the current log-to-logfile level.)

A GPPC report includes the report level, a report message, and an optional report callback function.

Reporting and handling functions provide by the GPPC API include:

| Function Name                            | Description  |
|--|--|
| <code>GppcReport()</code>                | Format and print/log a string of the specified report level. |
| <code>GppcInstallReportCallback()</code> | Register/install a report callback function.                 |

| Function Name                 | Description                                |
|-------------------------------|--|
| GppcUninstallReportCallback() | Uninstall a report callback function.      |
| GppcGetReportLevel()          | Retrieve the level from an error report.   |
| GppcGetReportMessage()        | Retrieve the message from an error report. |
| GppcCheckForInterrupts()      | Error out if an interrupt is pending.      |

The `GppcReport()` function signature is:

```
void GppcReport(GppcReportLevel elevel, const char *fmt, ...);
```

`GppcReport()` takes a format string input argument similar to `printf()`. The following example generates an error level report message that formats a GPPC text argument:

```
GppcText  uname = GPPC_GETARG_TEXT(1);
GppcReport(GPPC_ERROR, "Unknown user name: %s", GppcTextGetCString(uname));
```

Refer to the [GPPC example code](#) for example report callback handlers.

## SPI Functions

The Greenplum Database Server Programming Interface (SPI) provides writers of C/C++ functions the ability to run SQL commands within a GPPC function. For additional information on SPI functions, refer to [Server Programming Interface](#) in the PostgreSQL documentation.

The GPPC API exposes a subset of PostgreSQL SPI functions. This subset enables you to issue SPI queries and retrieve SPI result values in your GPPC function. The GPPC SPI wrapper functions are:

| SPI Function Name       | GPPC Function Name   | Description   |
|-------------------------|--|---|
| SPI_connect()           | GppcSPIConnect()   | Connect to the Greenplum Database server programming interface.                               |
| SPI_finish()            | GppcSPIFinish()  | Disconnect from the Greenplum Database server programming interface.                          |
| SPI_exec()              | GppcSPIExec()  | Run a SQL statement, returning the number of rows.  |
| SPI_getvalue()          | GppcSPIGetValue()  | Retrieve the value of a specific attribute by number from a SQL result as a character string. |
| GppcSPIGetDatum()       | Retrieve the value of a specific attribute by number from a SQL result as a <code>GppcDatum</code> . |   |
| GppcSPIGetValueByName() | Retrieve the value of a specific attribute by name from a SQL result as a character string.          |   |
| GppcSPIGetDatumByName() | Retrieve the value of a specific attribute by name from a SQL result as a <code>GppcDatum</code> .   |   |

When you create a GPPC function that accesses the server programming interface, your function should comply with the following flow:

```
GppcSPIConnect();
GppcSPIExec(...)
// process the results - GppcSPIGetValue(...), GppcSPIGetDatum(...)
GppcSPIFinish();
```

You use `GppcSPIExec()` to run SQL statements in your GPPC function. When you call this function, you also identify the maximum number of rows to return. The function signature of `GppcSPIExec()` is:

```
GppcSPIResult GppcSPIExec(const char *sql_statement, long rcount);
```

`GppcSPIExec()` returns a `GppcSPIResult` structure. This structure represents SPI result data. It includes a pointer to the data, information about the number of rows processed, a counter, and a result code. The GPPC API defines this structure as follows:

```
typedef struct GppcSPIResultData
{
    struct GppcSPITupleTableData *tuptable;
    uint32_t processed;
    uint32_t current;
    int rescode;
} GppcSPIResultData;
typedef GppcSPIResultData *GppcSPIResult;
```

You can set and use the `current` field in the `GppcSPIResult` structure to examine each row of the `tuptable` result data.

The following code excerpt uses the GPPC API to connect to SPI, run a simple query, loop through query results, and finish processing:

```
GppcSPIResult result;
char *attname = "id";
char *query = "SELECT i, 'foo' || i AS val FROM generate_series(1, 10)i ORDER BY 1";
bool isnull = true;

// connect to SPI
if( GppcSPIConnect() < 0 ) {
    GppcReport(GPPC_ERROR, "cannot connect to SPI");
}

// execute the query, returning all rows
result = GppcSPIExec(query, 0);

// process result
while( result->current < result->processed ) {
    // get the value of attname column as a datum, making a copy
    datum = GppcSPIGetDatumByName(result, attname, &isnull, true);

    // do something with value

    // move on to next row
    result->current++;
}

// complete processing
```

```
GppcSPIFinish();
```

## About Tuple Descriptors and Tuples

A table or a set of records contains one or more tuples (rows). The structure of each attribute of a tuple is defined by a tuple descriptor. A tuple descriptor defines the following for each attribute in the tuple:

- attribute name
- object identifier of the attribute data type
- byte length of the attribute data type
- object identifier of the attribute modifier

The GPPC API defines an abstract type, `GppcTupleDesc`, to represent a tuple/row descriptor. The API also provides functions that you can use to create, access, and set tuple descriptors:

| Function Name                              | Description   |
|--|---|
| <code>GppcCreateTemplateTupleDesc()</code> | Create an empty tuple descriptor with a specified number of attributes.   |
| <code>GppcTupleDescInitEntry()</code>      | Add an attribute to the tuple descriptor at a specified position.   |
| <code>GppcTupleDescNattrs()</code>         | Fetch the number of attributes in the tuple descriptor.   |
| <code>GppcTupleDescAttrName()</code>       | Fetch the name of the attribute in a specific position (starts at 0) in the tuple descriptor.                           |
| <code>GppcTupleDescAttrType()</code>       | Fetch the type object identifier of the attribute in a specific position (starts at 0) in the tuple descriptor.         |
| <code>GppcTupleDescAttrLen()</code>        | Fetch the type length of an attribute in a specific position (starts at 0) in the tuple descriptor.                     |
| <code>GppcTupleDescAttrTypmod()</code>     | Fetch the type modifier object identifier of an attribute in a specific position (starts at 0) in the tuple descriptor. |

To construct a tuple descriptor, you first create a template, and then fill in the descriptor fields for each attribute. The signatures for these functions are:

```
GppcTupleDesc GppcCreateTemplateTupleDesc(int natts);
void GppcTupleDescInitEntry(GppcTupleDesc desc, uint16_t attno,
                           const char *attname, GppcOid typid, int32_t typmod);
```

In some cases, you may want to initialize a tuple descriptor entry from an attribute definition in an existing tuple. The following functions fetch the number of attributes in a tuple descriptor, as well as the definition of a specific attribute (by number) in the descriptor:

```
int GppcTupleDescNattrs(GppcTupleDesc tupdesc);
const char *GppcTupleDescAttrName(GppcTupleDesc tupdesc, int16_t attno);
GppcOid GppcTupleDescAttrType(GppcTupleDesc tupdesc, int16_t attno);
int16_t GppcTupleDescAttrLen(GppcTupleDesc tupdesc, int16_t attno);
int32_t GppcTupleDescAttrTypmod(GppcTupleDesc tupdesc, int16_t attno);
```

The following example initializes a two attribute tuple descriptor. The first attribute is initialized with the definition of an attribute from a different descriptor, and the second attribute is initialized to a boolean type attribute:

```
GppcTupleDesc      tdesc;
GppcTupleDesc      indesc = some_input_descriptor;

// initialize the tuple descriptor with 2 attributes
tdesc = GppcCreateTemplateTupleDesc(2);

// use third attribute from the input descriptor
GppcTupleDescInitEntry(tdesc, 1,
    GppcTupleDescAttrName(indesc, 2),
    GppcTupleDescAttrType(indesc, 2),
    GppcTupleDescAttrTypmod(indesc, 2));

// create the boolean attribute
GppcTupleDescInitEntry(tdesc, 2, "is_active", GppcOidBool, 0);
```

The GPPC API defines an abstract type, [GppcHeapTuple](#), to represent a tuple/record/row. A tuple is defined by its tuple descriptor, the value for each tuple attribute, and an indicator of whether or not each value is NULL.

The GPPC API provides functions that you can use to set and access a tuple and its attributes:

| Function Name                             | Description  |
|---|--|
| <a href="#">GppcHeapFormTuple()</a>       | Form a tuple from an array of <a href="#">GppcDatumS</a> .                           |
| <a href="#">GppcBuildHeapTupleDatum()</a> | Form a <a href="#">GppcDatum</a> tuple from an array of <a href="#">GppcDatumS</a> . |
| <a href="#">GppcGetAttributeByName()</a>  | Fetch an attribute from the tuple by name.   |
| <a href="#">GppcGetAttributeByNum()</a>   | Fetch an attribute from the tuple by number (starts at 1).                           |

The signatures for the tuple-building GPPC functions are:

```
GppcHeapTuple GppcHeapFormTuple(GppcTupleDesc tupdesc, GppcDatum *values, bool *nulls);
GppcDatum     GppcBuildHeapTupleDatum(GppcTupleDesc tupdesc, GppcDatum *values, bool *nulls);
```

The following code excerpt constructs a [GppcDatum](#) tuple from the tuple descriptor in the above code example, and from integer and boolean input arguments to a function:

```
GppcDatum intarg = GPPC_GETARG_INT4(0);
GppcDatum boolarg = GPPC_GETARG_BOOL(1);
GppcDatum result, values[2];
bool nulls[2] = { false, false };

// construct the values array
values[0] = intarg;
values[1] = boolarg;
result = GppcBuildHeapTupleDatum( tdesc, values, nulls );
```

## Set-Returning Functions

Greenplum Database UDFs whose signatures include `RETURNS SETOF RECORD` or `RETURNS TABLE( ... )` are set-returning functions.

The GPPC API provides support for returning sets (for example, multiple rows/tuples) from a GPPC function. Greenplum Database calls a set-returning function (SRF) once for each row or item. The function must save enough state to remember what it was doing and to return the next row on each call. Memory that you allocate in the SRF context must survive across multiple function calls.

The GPPC API provides macros and functions to help keep track of and set this context, and to allocate SRF memory. They include:

| Function/Macro Name                       | Description  |
|---|--|
| <code>GPPC_SRF_RESULT_DESCRIPTOR()</code> | Get the output row tuple descriptor for this SRF. The result tuple descriptor is determined by an output table definition or a <code>DESCRIBE</code> function. |
| <code>GPPC_SRF_IS_FIRSTCALL()</code>      | Determine if this is the first call to the SRF.  |
| <code>GPPC_SRF_FIRSTCALL_INIT()</code>    | Initialize the SRF context.  |
| <code>GPPC_SRF_PERCALL_SETUP()</code>     | Restore the context on each call to the SRF.   |
| <code>GPPC_SRF_RETURN_NEXT()</code>       | Return a value from the SRF and continue processing.   |
| <code>GPPC_SRF_RETURN_DONE()</code>       | Signal that SRF processing is complete.  |
| <code>GppSRFAlloc()</code>                | Allocate memory in this SRF context.   |
| <code>GppSRFAlloc0()</code>               | Allocate memory in this SRF context and initialize it to zero.   |
| <code>GppSRFSave()</code>                 | Save user state in this SRF context.   |
| <code>GppSRFRestore()</code>              | Restore user state in this SRF context.  |

The `GppFuncCallContext` structure provides the context for an SRF. You create this context on the first call to your SRF. Your set-returning GPPC function must retrieve the function context on each invocation. For example:

```
// set function context
GppFuncCallContext fctx;
if (GPPC_SRF_IS_FIRSTCALL()) {
    fctx = GPPC_SRF_FIRSTCALL_INIT();
}
fctx = GPPC_SRF_PERCALL_SETUP();
// process the tuple
```

The GPPC function must provide the context when it returns a tuple result or to indicate that processing is complete. For example:

```
GPPC_SRF_RETURN_NEXT(fctx, result_tuple);
// or
GPPC_SRF_RETURN_DONE(fctx);
```

Use a `DESCRIBE` function to define the output tuple descriptor of a function that uses the `RETURNS SETOF RECORD` clause. Use the `GPPC_SRF_RESULT_DESC()` macro to get the output tuple descriptor of a function that uses the `RETURNS TABLE(...)` clause.

Refer to the [GPPC Set-Returning Function Example](#) for a set-returning function code and deployment example.

## Table Functions

The GPPC API provides the `GppcAnyTable` type to pass a table to a function as an input argument, or to return a table as a function result.

Table-related functions and macros provided in the GPPC API include:

| Function/Macro Name                     | Description                               |
|---|---|
| <code>GPPC_GETARG_ANYTABLE()</code>     | Fetch an anytable function argument.      |
| <code>GPPC_RETURN_ANYTABLE()</code>     | Return the table.                         |
| <code>GppcAnyTableGetTupleDesc()</code> | Fetch the tuple descriptor for the table. |
| <code>GppcAnyTableGetNextTuple()</code> | Fetch the next row in the table.          |

You can use the `GPPC_GETARG_ANYTABLE()` macro to retrieve a table input argument. When you have access to the table, you can examine the tuple descriptor for the table using the `GppcAnyTableGetTupleDesc()` function. The signature of this function is:

```
GppcTupleDesc GppcAnyTableGetTupleDesc(GppcAnyTable t);
```

For example, to retrieve the tuple descriptor of a table that is the first input argument to a function:

```
GppcAnyTable    intbl;
GppcTupleDesc   in_desc;

intbl = GPPC_GETARG_ANYTABLE(0);
in_desc = GppcAnyTableGetTupleDesc(intbl);
```

The `GppcAnyTableGetNextTuple()` function fetches the next row from the table. Similarly, to retrieve the next tuple from the table above:

```
GppcHeapTuple   ntuple;

ntuple = GppcAnyTableGetNextTuple(intbl);
```

## Limitations

The GPPC API does not support the following operators with Greenplum Database version 5.0.x:

- integer || integer

- integer = text
- text < integer

## Sample Code

The `gppc test` directory in the Greenplum Database github repository includes sample GPPC code:

- `gppc_demo/` - sample code exercising GPPC SPI functions, error reporting, data type argument and return macros, set-returning functions, and encoding functions
- `tabfunc_gppc_demo/` - sample code exercising GPPC table and set-returning functions

## Building a GPPC Shared Library with PGXS

You compile functions that you write with the GPPC API into one or more shared libraries that the Greenplum Database server loads on demand.

You can use the PostgreSQL build extension infrastructure (PGXS) to build the source code for your GPPC functions against a Greenplum Database installation. This framework automates common build rules for simple modules. If you have a more complicated use case, you will need to write your own build system.

To use the PGXS infrastructure to generate a shared library for functions that you create with the GPPC API, create a simple `Makefile` that sets PGXS-specific variables.

**Note:** Refer to [Extension Building Infrastructure](#) in the PostgreSQL documentation for information about the `Makefile` variables supported by PGXS.

For example, the following `Makefile` generates a shared library named `sharedlib_name.so` from two C source files named `src1.c` and `src2.c`:

```
MODULE_big = sharedlib_name
OBJS = src1.o src2.o
PG_CPPFLAGS = -I$(shell $(PG_CONFIG) --includedir)
SHLIB_LINK = -L$(shell $(PG_CONFIG) --libdir) -lgppc

PG_CONFIG = pg_config
PGXS := $(shell $(PG_CONFIG) --pgxs)
include $(PGXS)
```

`MODULE_big` identifies the base name of the shared library generated by the `Makefile`.

`PG_CPPFLAGS` adds the Greenplum Database installation include directory to the compiler header file search path.

`SHLIB_LINK` adds the Greenplum Database installation library directory to the linker search path. This variable also adds the GPPC library (`-lgppc`) to the link command.

The `PG_CONFIG` and `PGXS` variable settings and the `include` statement are required and typically reside in the last three lines of the `Makefile`.

## Registering a GPPC Function with Greenplum Database

Before users can invoke a GPPC function from SQL, you must register the function with Greenplum Database.

Registering a GPPC function involves mapping the GPPC function signature to a SQL user-defined function. You define this mapping with the `CREATE FUNCTION .. AS` command specifying the GPPC shared library name. You may choose to use the same name or differing names for the GPPC and SQL functions.

Sample `CREATE FUNCTION ... AS` syntax follows:

```
CREATE FUNCTION <sql_function_name>(<arg>[, ...]) RETURNS <return_type>
  AS '<shared_library_path>'[, '<gppc_function_name>']
  LANGUAGE C STRICT [WITH (DESCRIBE=<describe_function>)];
```

You may omit the shared library `.so` extension when you specify `shared\_library\_path`.

The following command registers the example `add_int4s()` function referenced earlier in this topic to a SQL UDF named `add_two_int4s_gppc()` if the GPPC function was compiled and linked in a shared library named `gppc_try.so`:

```
CREATE FUNCTION add_two_int4s_gppc(int4, int4) RETURNS int8
  AS 'gppc_try.so', 'add_int4s'
  LANGUAGE C STRICT;
```

## About Dynamic Loading

You specify the name of the GPPC shared library in the SQL `CREATE FUNCTION ... AS` command to register a GPPC function in the shared library with Greenplum Database. The Greenplum Database dynamic loader loads a GPPC shared library file into memory the first time that a user invokes a user-defined function linked in that shared library. If you do not provide an absolute path to the shared library in the `CREATE FUNCTION ... AS` command, Greenplum Database attempts to locate the library using these ordered steps:

1. If the shared library file path begins with the string `$libdir`, Greenplum Database looks for the file in the PostgreSQL package library directory. Run the `pg_config --pkglibdir` command to determine the location of this directory.
2. If the shared library file name is specified without a directory prefix, Greenplum Database searches for the file in the directory identified by the `dynamic_library_path` server configuration parameter value.
3. The current working directory.

## Packaging and Deployment Considerations

You must package the GPPC shared library and SQL function registration script in a form suitable for deployment by the Greenplum Database administrator in the Greenplum cluster. Provide specific deployment instructions for your GPPC package.

When you construct the package and deployment instructions, take into account the following:

- Consider providing a shell script or program that the Greenplum Database administrator runs to both install the shared library to the desired file system location and register the

GPPC functions.

- The GPPC shared library must be installed to the same file system location on the master host and on every segment host in the Greenplum Database cluster.
- The `gpadmin` user must have permission to traverse the complete file system path to the GPPC shared library file.
- The file system location of your GPPC shared library after it is installed in the Greenplum Database deployment determines how you reference the shared library when you register a function in the library with the `CREATE FUNCTION ... AS` command.
- Create a `.sql` script file that registers a SQL UDF for each GPPC function in your GPPC shared library. The functions that you create in the `.sql` registration script must reference the deployment location of the GPPC shared library. Include this script in your GPPC deployment package.
- Document the instructions for running your GPPC package deployment script, if you provide one.
- Document the instructions for installing the GPPC shared library if you do not include this task in a package deployment script.
- Document the instructions for installing and running the function registration script if you do not include this task in a package deployment script.

## GPPC Text Function Example

In this example, you develop, build, and deploy a GPPC shared library and register and run a GPPC function named `concat_two_strings`. This function uses the GPPC API to concatenate two string arguments and return the result.

You will develop the GPPC function on your Greenplum Database master host. Deploying the GPPC shared library that you create in this example requires administrative access to your Greenplum Database cluster.

Perform the following procedure to run the example:

1. Log in to the Greenplum Database master host and set up your environment. For example:

```
$ ssh gpadmin@<gpmaster>
gpadmin@gpmaster$ . /usr/local/greenplum-db/greenplum_path.sh
```

2. Create a work directory and navigate to the new directory. For example:

```
gpadmin@gpmaster$ mkdir gppc_work
gpadmin@gpmaster$ cd gppc_work
```

3. Prepare a file for GPPC source code by opening the file in the editor of your choice. For example, to open a file named `gppc_concat.c` using `vi`:

```
gpadmin@gpmaster$ vi gppc_concat.c
```

4. Copy/paste the following code into the file:

```

#include <stdio.h>
#include <string.h>
#include "gppc.h"

// make the function SQL-invokable
GPPC_FUNCTION_INFO(concat_two_strings);

// declare the function
GppcDatum concat_two_strings(GPPC_FUNCTION_ARGS);

GppcDatum
concat_two_strings(GPPC_FUNCTION_ARGS)
{
    // retrieve the text input arguments
    GppcText arg0 = GPPC_GETARG_TEXT(0);
    GppcText arg1 = GPPC_GETARG_TEXT(1);

    // determine the size of the concatenated string and allocate
    // text memory of this size
    size_t arg0_len = GppcGetTextLength(arg0);
    size_t arg1_len = GppcGetTextLength(arg1);
    GppcText retstring = GppcAllocText(arg0_len + arg1_len);

    // construct the concatenated return string
    memcpy(GppcGetTextPointer(retstring), GppcGetTextPointer(arg0), arg0_len);
    memcpy(GppcGetTextPointer(retstring) + arg0_len, GppcGetTextPointer(arg1),
    arg1_len);

    GPPC_RETURN_TEXT( retstring );
}

```

The code declares and implements the `concat_two_strings()` function. It uses GPPC data types, macros, and functions to get the function arguments, allocate memory for the concatenated string, copy the arguments into the new string, and return the result.

5. Save the file and exit the editor.
6. Open a file named `Makefile` in the editor of your choice. Copy/paste the following text into the file:

```

MODULE_big = gppc_concat
OBJS = gppc_concat.o

PG_CONFIG = pg_config
PGXS := $(shell $(PG_CONFIG) --pgxs)

PG_CPPFLAGS = -I$(shell $(PG_CONFIG) --includedir)
SHLIB_LINK = -L$(shell $(PG_CONFIG) --libdir) -lgppc
include $(PGXS)

```

7. Save the file and exit the editor.
8. Build a GPPC shared library for the `concat_two_strings()` function. For example:

```

gpadmin@gpmaster$ make all

```

The `make` command generates a shared library file named `gppc_concat.so` in the current working directory.

- Copy the shared library to your Greenplum Database installation. You must have Greenplum Database administrative privileges to copy the file. For example:

```
gpadmin@gpmaster$ cp gppc_concat.so /usr/local/greenplum-db/lib/postgresql/
```

- Copy the shared library to every host in your Greenplum Database installation. For example, if `seghostfile` contains a list, one-host-per-line, of the segment hosts in your Greenplum Database cluster:

```
gpadmin@gpmaster$ gpscp -v -f seghostfile /usr/local/greenplum-db/lib/postgresql/gppc_concat.so =:/usr/local/greenplum-db/lib/postgresql/gppc_concat.so
```

- Open a `psql` session. For example:

```
gpadmin@gpmaster$ psql -d testdb
```

- Register the GPPC function named `concat_two_strings()` with Greenplum Database, For example, to map the Greenplum Database function `concat_with_gppc()` to the GPPC `concat_two_strings()` function:

```
testdb=# CREATE FUNCTION concat_with_gppc(text, text) RETURNS text
AS 'gppc_concat', 'concat_two_strings'
LANGUAGE C STRICT;
```

- Run the `concat_with_gppc()` function. For example:

```
testdb=# SELECT concat_with_gppc( 'happy', 'monday' );
concat_with_gppc
-----
happymonday
(1 row)
```

## GPPC Set-Returning Function Example

In this example, you develop, build, and deploy a GPPC shared library. You also create and run a `.sql` registration script for a GPPC function named `return_tbl()`. This function uses the GPPC API to take an input table with an integer and a text column, determine if the integer column is greater than 13, and returns a result table with the input integer column and a boolean column identifying whether or not the integer is greater than 13. `return_tbl()` utilizes GPPC API reporting and SRF functions and macros.

You will develop the GPPC function on your Greenplum Database master host. Deploying the GPPC shared library that you create in this example requires administrative access to your Greenplum Database cluster.

Perform the following procedure to run the example:

- Log in to the Greenplum Database master host and set up your environment. For example:

```
$ ssh gpadmin@<gpmaster>
gpadmin@gpmaster$ . /usr/local/greenplum-db/greenplum_path.sh
```

2. Create a work directory and navigate to the new directory. For example:

```
gpadmin@gpmaster$ mkdir gppc_work
gpadmin@gpmaster$ cd gppc_work
```

3. Prepare a source file for GPPC code by opening the file in the editor of your choice. For example, to open a file named `gppc_concat.c` using `vi`:

```
gpadmin@gpmaster$ vi gppc_rettbl.c
```

4. Copy/paste the following code into the file:

```
#include <stdio.h>
#include <string.h>
#include "gppc.h"

// initialize the logging level
GppcReportLevel level = GPPC_INFO;

// make the function SQL-invokable and declare the function
GPPC_FUNCTION_INFO(return_tbl);
GppcDatum return_tbl(GPPC_FUNCTION_ARGS);

GppcDatum
return_tbl(GPPC_FUNCTION_ARGS)
{
    GppcFuncCallContext fctx;
    GppcAnyTable        intbl;
    GppcHeapTuple       intuple;
    GppcTupleDesc       in_tupdesc, out_tupdesc;
    GppcBool             resbool = false;
    GppcDatum            result, boolres, values[2];
    bool                 nulls[2] = {false, false};

    // single input argument - the table
    intbl = GPPC_GETARG_ANYTABLE(0);

    // set the function context
    if (GPPC_SRF_IS_FIRSTCALL()) {
        fctx = GPPC_SRF_FIRSTCALL_INIT();
    }
    fctx = GPPC_SRF_PERCALL_SETUP();

    // get the tuple descriptor for the input table
    in_tupdesc = GppcAnyTableGetTupleDesc(intbl);

    // retrieve the next tuple
    intuple = GppcAnyTableGetNextTuple(intbl);
    if( intuple == NULL ) {
        // no more tuples, conclude
        GPPC_SRF_RETURN_DONE(fctx);
    }

    // get the output tuple descriptor and verify that it is
```

```

// defined as we expect
out_tupdesc = GPPC_SRF_RESULT_DESC();
if (GppcTupleDescNattrs(out_tupdesc) != 2 ||
    GppcTupleDescAttrType(out_tupdesc, 0) != GppcOidInt4 ||
    GppcTupleDescAttrType(out_tupdesc, 1) != GppcOidBool) {
    GppcReport(GPPC_ERROR, "INVALID out_tupdesc tuple");
}

// log the attribute names of the output tuple descriptor
GppcReport(level, "output tuple descriptor attr0 name: %s", GppcTupleDescAttrName(out_tupdesc, 0));
GppcReport(level, "output tuple descriptor attr1 name: %s", GppcTupleDescAttrName(out_tupdesc, 1));

// retrieve the attribute values by name from the tuple
bool text_isnull, int_isnull;
GppcDatum intdat = GppcGetAttributeByName(intuple, "id", &int_isnull);
GppcDatum textdat = GppcGetAttributeByName(intuple, "msg", &text_isnull);

// convert datum to specific type
GppcInt4 intarg = GppcDatumGetInt4(intdat);
GppcReport(level, "id: %d", intarg);
GppcReport(level, "msg: %s", GppcTextGetCString(GppcDatumGetText(textdat)));

// perform the >13 check on the integer
if( !int_isnull && (intarg > 13) ) {
    // greater than 13?
    resbool = true;
    GppcReport(level, "id is greater than 13!");
}

// values are datums; use integer from the tuple and
// construct the datum for the boolean return
values[0] = intdat;
boolres = GppcBoolGetDatum(resbool);
values[1] = boolres;

// build a datum tuple and return
result = GppcBuildHeapTupleDatum(out_tupdesc, values, nulls);
GPPC_SRF_RETURN_NEXT(fctx, result);
}

```

The code declares and implements the `return_tbl()` function. It uses GPPC data types, macros, and functions to fetch the function arguments, examine tuple descriptors, build the return tuple, and return the result. The function also uses the SRF macros to keep track of the tuple context across function calls.

5. Save the file and exit the editor.
6. Open a file named `Makefile` in the editor of your choice. Copy/paste the following text into the file:

```

MODULE_big = gppc_rettbl
OBJS = gppc_rettbl.o

PG_CONFIG = pg_config

```

```
PGXS := $(shell $(PG_CONFIG) --pgxs)

PG_CPPFLAGS = -I$(shell $(PG_CONFIG) --includedir)
SHLIB_LINK = -L$(shell $(PG_CONFIG) --libdir) -lgppc
include $(PGXS)
```

7. Save the file and exit the editor.
8. Build a GPPC shared library for the `return_tbl()` function. For example:

```
gpadmin@gpmaster$ make all
```

The `make` command generates a shared library file named `gppc_rettbl.so` in the current working directory.

9. Copy the shared library to your Greenplum Database installation. You must have Greenplum Database administrative privileges to copy the file. For example:

```
gpadmin@gpmaster$ cp gppc_rettbl.so /usr/local/greenplum-db/lib/postgresql/
```

This command copies the shared library to `$libdir`

10. Copy the shared library to every host in your Greenplum Database installation. For example, if `seghostfile` contains a list, one-host-per-line, of the segment hosts in your Greenplum Database cluster:

```
gpadmin@gpmaster$ gpscp -v -f seghostfile /usr/local/greenplum-db/lib/postgresql/
gppc_rettbl.so =:/usr/local/greenplum-db/lib/postgresql/gppc_rettbl.so
```

11. Create a `.sql` file to register the GPPC `return_tbl()` function. Open a file named `gppc_rettbl_reg.sql` in the editor of your choice.
12. Copy/paste the following text into the file:

```
CREATE FUNCTION rettbl_gppc(anytable) RETURNS TABLE(id int4, thirteen bool)
AS 'gppc_rettbl', 'return_tbl'
LANGUAGE C STRICT;
```

13. Register the GPPC function by running the script you just created. For example, to register the function in a database named `testdb`:

```
gpadmin@gpmaster$ psql -d testdb -f gppc_rettbl_reg.sql
```

14. Open a `psql` session. For example:

```
gpadmin@gpmaster$ psql -d testdb
```

15. Create a table with some test data. For example:

```
CREATE TABLE gppc_testtbl( id int, msg text );
INSERT INTO gppc_testtbl VALUES (1, 'f1');
INSERT INTO gppc_testtbl VALUES (7, 'f7');
INSERT INTO gppc_testtbl VALUES (10, 'f10');
INSERT INTO gppc_testtbl VALUES (13, 'f13');
```

```
INSERT INTO gppc_testtbl VALUES (15, 'f15');
INSERT INTO gppc_testtbl VALUES (17, 'f17');
```

16. Run the `rettbl_gppc()` function. For example:

```
testdb=# SELECT * FROM rettbl_gppc(TABLE(SELECT * FROM gppc_testtbl));
 id | thirteen
----+-----
  1 | f
  7 | f
 13 | f
 15 | t
 17 | t
 10 | f
(6 rows)
```

## Developing a Background Worker Process

Greenplum Database can be extended to run user-supplied code in separate processes. Such processes are started, stopped, and monitored by `postgres`, which permits them to have a lifetime closely linked to the server's status. These processes have the option to attach to Greenplum Database's shared memory area and to connect to databases internally; they can also run multiple transactions serially, just like a regular client-connected server process. Also, by linking to `libpq` they can connect to the server and behave like a regular client application.

**Warning:** There are considerable robustness and security risks in using background worker processes because, being written in the `c` language, they have unrestricted access to data. Administrators wishing to enable modules that include background worker processes should exercise extreme caution. Only carefully audited modules should be permitted to run background worker processes.

Background workers can be initialized at the time that Greenplum Database is started by including the module name in the `shared_preload_libraries` server configuration parameter. A module wishing to run a background worker can register it by calling

`RegisterBackgroundWorker(BackgroundWorker *worker)` from its `_PG_init()`. Background workers can also be started after the system is up and running by calling the function `RegisterDynamicBackgroundWorker(BackgroundWorker *worker, BackgroundWorkerHandle **handle)`. Unlike `RegisterBackgroundWorker`, which can only be called from within the `postmaster`, `RegisterDynamicBackgroundWorker` must be called from a regular backend.

The structure `BackgroundWorker` is defined thus:

```
typedef void (*bgworker_main_type)(Datum main_arg);
typedef struct BackgroundWorker
{
    char          bgw_name[BGW_MAXLEN];
    int          bgw_flags;
    BgWorkerStartTime bgw_start_time;
    int          bgw_restart_time;      /* in seconds, or BGW_NEVER_RESTART */
    bgworker_main_type bgw_main;
    char          bgw_library_name[BGW_MAXLEN]; /* only if bgw_main is NULL */
    char          bgw_function_name[BGW_MAXLEN]; /* only if bgw_main is NULL */
}
```

```
Datum      bgw_main_arg;
int        bgw_notify_pid;
} BackgroundWorker;
```

`bgw_name` is a string to be used in log messages, process listings and similar contexts.

`bgw_flags` is a bitwise-or'd bit mask indicating the capabilities that the module wants. Possible values are `BGWORKER_SHMEM_ACCESS` (requesting shared memory access) and `BGWORKER_BACKEND_DATABASE_CONNECTION` (requesting the ability to establish a database connection, through which it can later run transactions and queries). A background worker using `BGWORKER_BACKEND_DATABASE_CONNECTION` to connect to a database must also attach shared memory using `BGWORKER_SHMEM_ACCESS`, or worker start-up will fail.

`bgw_start_time` is the server state during which `postgres` should start the process; it can be one of `BgWorkerStart_PostmasterStart` (start as soon as `postgres` itself has finished its own initialization; processes requesting this are not eligible for database connections), `BgWorkerStart_ConsistentState` (start as soon as a consistent state has been reached in a hot standby, allowing processes to connect to databases and run read-only queries), and `BgWorkerStart_RecoveryFinished` (start as soon as the system has entered normal read-write state). Note the last two values are equivalent in a server that's not a hot standby. Note that this setting only indicates when the processes are to be started; they do not stop when a different state is reached.

`bgw_restart_time` is the interval, in seconds, that `postgres` should wait before restarting the process, in case it crashes. It can be any positive value, or `BGW_NEVER_RESTART`, indicating not to restart the process in case of a crash.

`bgw_main` is a pointer to the function to run when the process is started. This function must take a single argument of type `Datum` and return `void`. `bgw_main_arg` will be passed to it as its only argument. Note that the global variable `MyBgworkerEntry` points to a copy of the `BackgroundWorker` structure passed at registration time. `bgw_main` may be NULL; in that case, `bgw_library_name` and `bgw_function_name` will be used to determine the entry point. This is useful for background workers launched after postmaster startup, where the postmaster does not have the requisite library loaded.

`bgw_library_name` is the name of a library in which the initial entry point for the background worker should be sought. It is ignored unless `bgw_main` is NULL. But if `bgw_main` is NULL, then the named library will be dynamically loaded by the worker process and `bgw_function_name` will be used to identify the function to be called.

`bgw_function_name` is the name of a function in a dynamically loaded library which should be used as the initial entry point for a new background worker. It is ignored unless `bgw_main` is NULL.

`bgw_notify_pid` is the PID of a Greenplum Database backend process to which the postmaster should send `SIGUSR1` when the process is started or exits. It should be 0 for workers registered at postmaster startup time, or when the backend registering the worker does not wish to wait for the worker to start up. Otherwise, it should be initialized to `MyProcPid`.

Once running, the process can connect to a database by calling `BackgroundWorkerInitializeConnection(char *dbname, char *username)`. This allows the process to run transactions and queries using the `SPi` interface. If `dbname` is NULL, the session is not connected to any particular database, but shared catalogs can be accessed. If `username` is NULL,

the process will run as the superuser created during `initdb`. `BackgroundWorkerInitializeConnection` can only be called once per background process, it is not possible to switch databases.

Signals are initially blocked when control reaches the `bgw_main` function, and must be unblocked by it; this is to allow the process to customize its signal handlers, if necessary. Signals can be unblocked in the new process by calling `BackgroundWorkerUnblockSignals` and blocked by calling `BackgroundWorkerBlockSignals`.

If `bgw_restart_time` for a background worker is configured as `BGW_NEVER_RESTART`, or if it exits with an exit code of 0 or is terminated by `TerminateBackgroundWorker`, it will be automatically unregistered by the postmaster on exit. Otherwise, it will be restarted after the time period configured via `bgw_restart_time`, or immediately if the postmaster reinitializes the cluster due to a backend failure. Backends which need to suspend execution only temporarily should use an interruptible sleep rather than exiting; this can be achieved by calling `WaitLatch()`. Make sure the `WL_POSTMASTER_DEATH` flag is set when calling that function, and verify the return code for a prompt exit in the emergency case that `postgres` itself has terminated.

When a background worker is registered using the `RegisterDynamicBackgroundWorker` function, it is possible for the backend performing the registration to obtain information regarding the status of the worker. Backends wishing to do this should pass the address of a `BackgroundWorkerHandle *` as the second argument to `RegisterDynamicBackgroundWorker`. If the worker is successfully registered, this pointer will be initialized with an opaque handle that can subsequently be passed to `GetBackgroundWorkerPid(BackgroundWorkerHandle *, pid_t *)` or `TerminateBackgroundWorker(BackgroundWorkerHandle *)`. `GetBackgroundWorkerPid` can be used to poll the status of the worker: a return value of `BGWH_NOT_YET_STARTED` indicates that the worker has not yet been started by the postmaster; `BGWH_STOPPED` indicates that it has been started but is no longer running; and `BGWH_STARTED` indicates that it is currently running. In this last case, the PID will also be returned via the second argument. `TerminateBackgroundWorker` causes the postmaster to send `SIGTERM` to the worker if it is running, and to unregister it as soon as it is not.

In some cases, a process which registers a background worker may wish to wait for the worker to start up. This can be accomplished by initializing `bgw_notify_pid` to `MyProcPid` and then passing the `BackgroundWorkerHandle *` obtained at registration time to `WaitForBackgroundWorkerStartup(BackgroundWorkerHandle *handle, pid_t *)` function. This function will block until the postmaster has attempted to start the background worker, or until the postmaster dies. If the background runner is running, the return value will be `BGWH_STARTED`, and the PID will be written to the provided address. Otherwise, the return value will be `BGWH_STOPPED` or `BGWH_POSTMASTER_DIED`.

The `worker_spi` contrib module contains a working example, which demonstrates some useful techniques.

The maximum number of registered background workers is limited by `max-worker-processes`.
