About vSphere Security

_vSphere Security_ provides information about securing your vSphere® environment for VMware® vCenter® Server and VMware ESXi.

To help you protect your vSphere environment, this documentation describes security features available in the vSphere environment and the measures that you can take to safeguard your environment from attack.

**Intended Audience**

This information is for experienced Windows or Linux system administrators who are familiar with virtual machine technology and datacenter operations.
Updated Information

This vSphere Security document is updated with each release of the product or when necessary.

This table provides the update history of the vSphere Security document.

<table>
<thead>
<tr>
<th>Revision</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>14 AUG 2020</td>
<td>At VMware, we value inclusion. To foster this principle within our customer, partner, and internal community, we are replacing some of the terminology in our content. We have updated this guide to remove instances of non-inclusive language.</td>
</tr>
</tbody>
</table>
| EN-001517-04 | - Corrected port for vSphere Replication in TCP and UDP Ports  
- Removed information about DSA keys from Upload an SSH Key Using a vifs Command  
- Added clarification to Configure SSL Timeouts. Also added a note that a timeout longer than the default is not recommended. |
| EN-001517-03 | - Updated Edit the vCenter Single Sign-On Password Policy. Password policies apply to both administrator users and other users. |
| EN-001517-02 | - Added information about Multiple Permission Settings.  
- Updated Add Members to a vCenter Single Sign-On Group. You cannot add groups to groups.  
- Added PCI and PCIe Devices and ESXi.  
- Added warning that administrators should not delete groups that are predefined in the vsphere.local domain to Managing vCenter Single Sign-On Users and Groups. |
| EN-001517-01 | - Updated vCenter Single Sign-On user management topics to include an additional step. |
| EN-001517-00 | Initial release. |
Security in the vSphere Environment

To secure your vSphere environment, you must become familiar with many aspects of security including authentication, authorization, users and permissions, and aspects of securing vCenter Server systems, ESXi hosts, and virtual machines.

A high level overview of different areas of vSphere that require attention helps you plan your security strategy. You also benefit from additional vSphere Security resources on the VMware website.

This chapter includes the following topics:

- Security and the Virtualization Layer
- Security and the Virtual Networking Layer
- Security Resources and Information

Security and the Virtualization Layer

VMware designed the virtualization layer, or VMkernel, to run virtual machines. It controls the hardware that hosts use and schedules the allocation of hardware resources among the virtual machines. Because the VMkernel is fully dedicated to supporting virtual machines and is not used for other purposes, the interface to the VMkernel is strictly limited to the API required to manage virtual machines.

ESXi provides additional VMkernel protection with the following features:

**Memory Hardening**

The ESXi kernel, user-mode applications, and executable components such as drivers and libraries are located at random, non-predictable memory addresses. Combined with the non-executable memory protections made available by microprocessors, this provides protection that makes it difficult for malicious code to use memory exploits to take advantage of vulnerabilities.

**Kernel Module Integrity**

Digital signing ensures the integrity and authenticity of modules, drivers and applications as they are loaded by the VMkernel. Module signing allows ESXi to identify the providers of
modules, drivers, or applications and whether they are VMware-certified. VMware software and certain third-party drivers are signed by VMware.

**Trusted Platform Module (TPM)**

vSphere uses Intel Trusted Platform Module/Trusted Execution Technology (TPM/TXT) to provide remote attestation of the hypervisor image based on hardware root of trust. The hypervisor image consists of the following elements:

- ESXi software (hypervisor) in VIB (package) format
- Third-party VIBs
- Third-party drivers

To leverage this capability, your ESXi system must have TPM and TXT enabled.

When TPM and TXT are enabled, ESXi measures the entire hypervisor stack when the system boots and stores these measurements in the Platform Configuration Registers (PCR) of the TPM. The measurements include the VMkernel, kernel modules, drivers, native management applications that run on ESXi, and any boot-time configuration options. All VIBs that are installed on the system are measured.

Third-party solutions can use this feature to build a verifier that detects tampering of the hypervisor image, by comparing the image with an image of the expected known good values. vSphere does not provide a user interface to view these measurements.

The measurements are exposed in a vSphere API. An event log is provided as part of the API, as specified by the Trusted Computing Group (TCG) standard for TXT.

**Security and the Virtual Networking Layer**

The virtual networking layer includes virtual network adapters and virtual switches. ESXi relies on the virtual networking layer to support communications between virtual machines and their users. In addition, hosts use the virtual networking layer to communicate with iSCSI SANs, NAS storage, and so forth.

The methods you use to secure a virtual machine network depend on which guest operating system is installed, whether the virtual machines operate in a trusted environment, and a variety of other factors. Virtual switches provide a substantial degree of protection when used with other common security practices, such as installing firewalls.

ESXi also supports IEEE 802.1q VLANs, which you can use to further protect the virtual machine network or storage configuration. VLANs let you segment a physical network so that two machines on the same physical network cannot send packets to or receive packets from each other unless they are on the same VLAN.

**Security Resources and Information**

You can find additional information about security on the VMware Web site.
The table lists security topics and the location of additional information about these topics.

Table 1-1. VMware Security Resources on the Web

</tbody>
</table>
vCenter Single Sign-On is an authentication broker and security token exchange. When a user is authenticated with vCenter Single Sign-On, that user can access all installed vCenter services to which the user has been granted access. Because traffic is encrypted for all communications and only authenticated users can be granted access, your environment is secure.

Install or upgrade vCenter Single Sign-On before you install or upgrade any other vSphere components. See the vSphere Installation and Setup or the vSphere Upgrade documentation.

For information on replacing certificates for services that use vCenter Single Sign-On, see Chapter 3 vSphere Security Certificates and Encryption.

This chapter includes the following topics:

- How vCenter Single Sign-On Protects Your Environment
- vCenter Single Sign-On Components
- How vCenter Single Sign-On Affects vCenter Server Installation
- How vCenter Single Sign-On Affects vCenter Server Upgrades
- Using vCenter Single Sign-On with vSphere
- Configuring vCenter Single Sign-On
- Managing vCenter Single Sign-On Users and Groups
- Troubleshooting vCenter Single Sign-On

How vCenter Single Sign-On Protects Your Environment

vCenter Single Sign-On allows vSphere components to communicate with each other through a secure token mechanism instead of requiring users to authenticate separately with each component.

vCenter Single Sign-On uses a combination of STS (Security Token Service), SSL for secure traffic, and authentication through Active Directory or OpenLDAP, as shown in the following illustration.
1 A user logs in to the vSphere Web Client with a user name and password to access the vCenter Server system or another vCenter service.

The user can also log in without a password and check the Use Windows session authentication checkbox. The checkbox becomes available after you install the VMware Client Integration Plugin.

2 The vSphere Web Client passes the login information to the vCenter Single Sign-On service, which checks the SAML token of the vSphere Web Client. If the vSphere Web Client has a valid token, vCenter Single Sign-On then checks whether the user is in the configured identity source (for example Active Directory).

- If only the user name is used, vCenter Single Sign-On checks in the default domain.
- If a domain name is included with the user name (DOMAIN\user1), vCenter Single Sign-On checks that domain.

3 If the user is in the identity source, vCenter Single Sign-On returns a token that represents the user to the vSphere Web Client.

4 The vSphere Web Client passes the token to the vCenter Server system.

5 vCenter Server checks with the vCenter Single Sign-On server that the token is valid and not expired.

6 The vCenter Single Sign-On server returns the token to the vCenter Server system.

The user can now authenticate to vCenter Server and view and modify any objects that the user has permissions for.

**Note** Initially, each user is assigned the No Access permission. A vCenter Server administrator must assign the user at least Read Only permissions before the user can log in. See Assign Permissions in the vSphere Web Client and Chapter 5 vCenter User Management Tasks.
vCenter Single Sign-On Components

vCenter Single Sign-On includes the Security Token Service (STS), an administration server, and vCenter Lookup Service, as well as the VMware Directory Service (vmdir).

The components are deployed as part of installation.

STS (Security Token Service)

STS certificates enable a user who has logged on through vCenter Single Sign-On to use any vCenter service that vCenter Single Sign-On supports without authenticating to each one. The STS service issues Security Assertion Markup Language (SAML) tokens. These security tokens represent the identity of a user in one of the identity source types supported by vCenter Single Sign-On.

Administration server

The administration server allows users with administrator privileges to vCenter Single Sign-On to configure the vCenter Single Sign-On server and manage users and groups from the vSphere Web Client. Initially, only the user administrator@vsphere.local has these privileges.

vCenter Lookup Service

vCenter Lookup Service contains topology information about the vSphere infrastructure, enabling vSphere components to connect to each other securely. Unless you are using Simple Install, you are prompted for the Lookup Service URL when you install other vSphere components. For example, the Inventory Service and the vCenter Server installers ask for the Lookup Service URL and then contact the Lookup Service to find vCenter Single Sign-On. After installation, the Inventory Service and vCenter Server system are registered in vCenter Lookup Service so other vSphere components, like the vSphere Web Client, can find them.

VMware Directory Service

Directory service associated with the vsphere.local domain. This service is a multi-tenanted, peer-replicating directory service that makes an LDAP directory available on port 11711. In multisite mode, an update of VMware Directory Service content in one VMware Directory Service instance results in the automatic update of the VMware Directory Service instances associated with all other vCenter Single Sign-On nodes.

How vCenter Single Sign-On Affects vCenter Server Installation

Starting with version 5.1, vSphere includes a vCenter Single Sign-On component as part of the vCenter Server management infrastructure. This change affects vCenter Server installation.

Authentication by vCenter Single Sign-On makes the VMware cloud infrastructure platform more secure by allowing the vSphere software components to communicate with each other through a secure token exchange mechanism.
For the first installation of vCenter Server, you must install all components. In subsequent installations in the same environment, or if you add services, you do not have to install vCenter Single Sign-On. One vCenter Single Sign-On server can serve your entire vSphere environment. After you install vCenter Single Sign-On once, you can connect all new vCenter Server instances to the same vCenter Single Sign-On service. You must install an Inventory Service instance for each vCenter Server instance.

**Simple Install**

The Simple Install option installs vCenter Single Sign-On, the vSphere Web Client, vCenter Inventory Service, and vCenter Server on the same host or virtual machine. Simple Install is appropriate for most deployments.

**Custom Install**

If you want to customize the location and setup of each component, you can install the components separately by performing a custom install and selecting the individual installation options, in the following order:

1. vCenter Single Sign-On
2. vSphere Web Client
3. vCenter Inventory Service
4. vCenter Server

You can install each component on a different host or virtual machine.

If you decide on installing multiple vCenter Server systems, you can point to the same vCenter Single Sign-On service for each vCenter Server.

**Installing in Multiple Locations**

Unlike vCenter Single Sign-On version 5.1, vCenter Single Sign-On 5.5 synchronizes authentication data across locations.

If you install vCenter Server systems in multiple locations, you can install a vCenter Single Sign-On server in each location. When you install the second and subsequent instances of vCenter Single Sign-On, you can point those instances to the first vCenter Single Sign-On instance during installation. The two instances synchronize their VMware Directory Service instances. Changes to one instance are propagated to the other instance.
Figure 2-2. Installing vCenter Single Sign-On in Multiple Locations

How vCenter Single Sign-On Affects vCenter Server Upgrades

Which users can log in to vCenter Server after an upgrade depends on the version that you are upgrading from and the deployment configuration.

In upgrades to vCenter Server 5.0 and earlier, which do not include a vCenter Single Sign-On service, both the local operating system users and Active Directory users that are registered with vCenter Server continue to work with the upgraded vCenter Server.

This behavior changes if you are upgrading from a version that does not include vCenter Single Sign-On to a version that does include vCenter Single Sign-On: vCenter Server version 5.1 or vCenter Server version 5.5.

Note With vCenter Single Sign-On, local operating system users become far less important than the users in a directory service such as Active Directory. As a result, it is not always possible, or even desirable, to keep local operating system users as authenticated users.

After the upgrade from a version earlier than version 5.1, you might be prompted for the administrator of the root folder in the vSphere inventory hierarchy during installation. This might happen because of changes in user stores from pre-5.1 versions to 5.1 and later versions of vSphere. See Hierarchical Inheritance of Permissions.

Simple Install Upgrade

A Simple Install upgrade installs or upgrades a single vCenter Server and related components.
If you upgrade to vCenter Server 5.5 from a vCenter Server version that does not include vCenter Single Sign-On, vCenter Single Sign-On recognizes existing local operating system users. In addition, the user administrator@vsphere.local can log in as an administrator user to vCenter Single Sign-On and vCenter Server. If your previous installation supported Active Directory users, you can add the Active Directory domain as an identity source.

If you upgrade vCenter Single Sign-On and vCenter Server, vCenter Single Sign-On recognizes existing local operating system users. In addition, the user administrator@vsphere.local can log in to vCenter Single Sign-On and vCenter Server as an administrator user. If your previous installation included an Active Directory domain as an identity source, that identity source is still available after the upgrade. Because vCenter Server supports only one default identity source, users might have to specify the domain when they log in (DOMAIN\user).

**Custom Upgrade**

A custom upgrade might install different vCenter Server components on different machines or install a second vCenter Server system on the same machine. You also use Custom Install to upgrade an environment that is installed in different locations.

If you upgrade to vCenter Server 5.5 from a vCenter Server version that does not include vCenter Single Sign-On, and you install vCenter Single Sign-On on a different machine than vCenter Server, vCenter Single Sign-On does not recognize existing local operating system users. The user administrator@vsphere.local can log in to vCenter Single Sign-On and vCenter Server as an administrator user. If your previous installation supported Active Directory users, you can add the Active Directory domain as an identity source.

If you are upgrading vCenter Server from a version that includes vCenter Single Sign-On in multisite mode, and if the different vCenter Server systems use Linked mode, you must resynchronize first. You can then upgrade all vCenter Single Sign-On instances and maintain Linked Mode functionality. Linked Mode is required for a single view of all vCenter Server systems. Multisite vCenter Single Sign-On is supported only if all nodes are the same version.

If you are upgrading vCenter Server from a version that includes vCenter Single Sign-On in high availability mode, you must upgrade all of the vCenter Single Sign-On high availability instances. Perform the upgrade first, and configure high availability by protecting both vCenter Server and vCenter Single Sign-On with VMware HA or VMware Heartbeat after the upgrade is complete.

**Note**  When you install the vCenter Single Sign-On component that is included with vCenter Server version 5.5 in multiple locations, the VMware Directory Service is updated for all vCenter Single Sign-On instances if you make a change in one location.

**Using vCenter Single Sign-On with vSphere**

When a user logs in to a vSphere component, vCenter Single Sign-On is used for authentication. Users must be authenticated with vCenter Single Sign-On and must have been granted vCenter Server permissions to view and manage vSphere objects.
When users log in to the vSphere Web Client, they are first authenticated by vCenter Single Sign-On. For authenticated users, vCenter Server checks the permissions. What a user can see, and what a user can do, is determined by vSphere permission settings for vCenter Server and ESXi and by the applications in the environment. vCenter Server administrators assign those permissions from the Manage > Permissions interface in the vSphere Web Client, not through vCenter Single Sign-On. See Chapter 4 vSphere Users and Permissions and Chapter 5 vCenter User Management Tasks.

vCenter Single Sign-On and vCenter Server Users

Using the vSphere Web Client, users authenticate to vCenter Single Sign-On by entering their credentials on the vSphere Web Client login page. After connecting to vCenter Server, authenticated users can view all of the vCenter Server instances or other vSphere services for which they have permissions. No further authentication is required. The actions that authenticated users can perform on objects depend on the user's vCenter Server permissions on those objects. See Chapter 4 vSphere Users and Permissions and Chapter 5 vCenter User Management Tasks.

After installation, the administrator@vsphere.local user has administrator access to both vCenter Single Sign-On and vCenter Server. That user can then add identity sources, set the default identity source, and manage users and groups in the vCenter Single Sign-On domain (vsphere.local).

While most vCenter Single Sign-On management tasks require vCenter Single Sign-On administrator credentials, all users that can authenticate to vCenter Single Sign-On can reset their password, even if the password has expired. See Reset an Expired vCenter Single Sign-On Password.

vCenter Single Sign-On Administrator Users

The vCenter Single Sign-On administrative interface is accessible from the vSphere Web Client. To configure vCenter Single Sign-On and manage vCenter Single Sign-On users and groups, the user administrator@vsphere.local or a user with vCenter Single Sign-On administrator privileges must log in to the vSphere Web Client. Upon authentication, that user can access the vCenter Single Sign-On administration interface to manage identity sources and default domains, specify password policies, and perform other administrative tasks. See Configuring vCenter Single Sign-On.

Note  You cannot rename the administrator@vsphere.local user. For improved security, consider creating additional users in the vsphere.local domain and assigning them administrative privileges. You can then stop using administrator@vsphere.local.
Authentication in Different Versions of vSphere

If a user connects to a vCenter Server system version 5.0.x or earlier, vCenter Server authenticates the user by validating the user against an Active Directory domain or against the list of local operating system users. In vCenter Server 5.1 and later, users authenticate through vCenter Single Sign-On.

**Note** You cannot use the vSphere Web Client to manage vCenter Server version 5.0 or earlier. Upgrade vCenter Server to version 5.1 or later.

ESXi Users

ESXi 5.1 is not integrated with vCenter Single Sign-On. You add the ESXi host to an Active Directory domain explicitly. See [Add an ESXi Host to an Active Directory Domain](#).

You can still create local ESXi users with the vSphere Client, vCLI, or PowerCLI. vCenter Server is not aware of users that are local to ESXi and ESXi is not aware of vCenter Server users.

Login Behavior

When a user logs in to a vCenter Server system from the vSphere Web Client, the login behavior depends on whether the user is in the default domain.

- Users who are in the default domain can log in with their user name and password.
- Users who are in a domain that has been added to vCenter Single Sign-On as an identity source but is not the default domain can log in to vCenter Server but must specify the domain in one of the following ways.
  - Including a domain name prefix, for example, MYDOMAIN\user1
  - Including the domain, for example, user1@mydomain.com
- Users who are in a domain that is not a vCenter Single Sign-On identity source cannot log in to vCenter Server. If the domain that you add to vCenter Single Sign-On is part of a domain hierarchy, Active Directory determines whether users of other domains in the hierarchy are authenticated or not.

Configuring vCenter Single Sign-On

vCenter Single Sign-On lets you add identity sources, manage default domains, configure a password policy, and edit the lockout policy.
You configure vCenter Single Sign-On from the vSphere Web Client. To configure vCenter Single Sign-On, you must have vCenter Single Sign-On administrator privileges. Having vCenter Single Sign-On administrator privileges is different from having the Administrator role on vCenter Server or ESXi. By default, only the user administrator@vsphere.local has administrator privileges on the vCenter Single Sign-On server in a new installation.

- **Reset an Expired vCenter Single Sign-On Password**
  By default, vCenter Single Sign-On passwords for user accounts expire after 90 days. The vSphere Web Client provides a warning when a password is about to expire. You can reset an expired password from the vSphere Web Client.

- **Edit the vCenter Single Sign-On Password Policy**
  The vCenter Single Sign-On password policy is a set of rules and restrictions on the format and expiration of vCenter Single Sign-On user passwords. The password policy applies only to users in the vCenter Single Sign-On domain (vsphere.local).

- **Edit the vCenter Single Sign-On Lockout Policy**
  A vCenter Single Sign-On lockout policy specifies the conditions under which a user's vCenter Single Sign-On account is locked when the user attempts to log in with incorrect credentials. You can edit the lockout policy.

- **Edit the vCenter Single Sign-On Token Policy**
  The vCenter Single Sign-On token policy specifies the clock tolerance, renewal count, and other token properties. You can edit the vCenter Single Sign-On token policy to ensure that the token specification conforms to your corporation's security standards.

- **Identity Sources for vCenter Server with vCenter Single Sign-On**
  Identity sources allow you to attach one or more domains to vCenter Single Sign-On. A domain is a repository for users and groups that the vCenter Single Sign-On server can use for user authentication.

- **Set the Default Domain for vCenter Single Sign-On**
  Each vCenter Single Sign-On identity source is associated with a domain. vCenter Single Sign-On uses the default domain to authenticate a user who logs in without a domain name. Users who belong to a domain that is not the default domain must include the domain name when they log in.

- **Add a vCenter Single Sign-On Identity Source**
  Users can log in to vCenter Server only if they are in a domain that has been added as a vCenter Single Sign-On identity source. vCenter Single Sign-On administrator users can add identity sources from the vSphere Web Client.

- **Edit a vCenter Single Sign-On Identity Source**
  vSphere users are defined in an identity source. You can edit the details of an identity source that is associated with vCenter Single Sign-On.
- **Remove a vCenter Single Sign-On Identity Source**
  vSphere users are defined in an identity source. You can remove an identity source from the list of registered identity sources.

- **Refresh the Security Token Service (STS) Root Certificate**
  vCenter Single Sign-On provides a Security Token Service (STS). The Security Token Service is a Web service that issues, validates, and renews security tokens. You can manually refresh the existing Security Token Service certificate when it expires or changes.

- **Determine the Expiration Date of an SSL Certificate**
  CA-signed SSL certificates expire after a predefined lifespan. Knowing when a certificate expires lets you replace or renew the certificate before the expiration date.

- **Determine Whether a Certificate is Being Used**
  Before you start with certificate replacement, you can check whether the certificates you have are already being used. You can use the **Compute Usage** feature to determine whether or not the system is using a certificate.

- **Use vCenter Single Sign-On with Windows Session Authentication**
  You can use vCenter Single Sign-On with Windows Session Authentication (SSPI). To make the checkbox on the login page available, you must install the Client Integration Plug-in.

**Reset an Expired vCenter Single Sign-On Password**

By default, vCenter Single Sign-On passwords for user accounts expire after 90 days. The vSphere Web Client provides a warning when a password is about to expire. You can reset an expired password from the vSphere Web Client.

In vSphere 5.5 and later, a user with an expired password is prompted to reset the password upon login. To reset passwords for earlier versions of vCenter Single Sign-On, see the documentation for that version of the product.

**Prerequisites**

You must know the current, expired password corresponding to the user name.

**Procedure**

1. Go to the vSphere Web Client URL.
2. When prompted, provide the user name, the current password, and the new password.

   If you are unable to log in, contact a vCenter Single Sign-On system administrator for assistance.

**Edit the vCenter Single Sign-On Password Policy**

The vCenter Single Sign-On password policy is a set of rules and restrictions on the format and expiration of vCenter Single Sign-On user passwords. The password policy applies only to users in the vCenter Single Sign-On domain (vsphere.local).
Procedure

1 Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.

Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.

2 Browse to Administration > Single Sign-On > Configuration.

3 Click the Policies tab and select Password Policies.

4 Click Edit.

5 Edit the password policy parameters.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Password policy description. Required.</td>
</tr>
<tr>
<td>Maximum lifetime</td>
<td>Maximum number of days that a password can exist before the user must change it.</td>
</tr>
<tr>
<td>Restrict re-use</td>
<td>Number of the user’s previous passwords that cannot be selected. For example, if a user cannot reuse any of the last five passwords, type 5.</td>
</tr>
<tr>
<td>Maximum length</td>
<td>Maximum number of characters that are allowed in the password.</td>
</tr>
<tr>
<td>Minimum length</td>
<td>Minimum number of characters required in the password. The minimum length must be no less than the combined minimum of alphabetic, numeric, and special character requirements.</td>
</tr>
<tr>
<td>Character requirements</td>
<td>Minimum number of different character types that are required in the password.</td>
</tr>
<tr>
<td>- Special: &amp; # %</td>
<td></td>
</tr>
<tr>
<td>- Alphabetic: A b c D</td>
<td></td>
</tr>
<tr>
<td>- Uppercase: A B C</td>
<td></td>
</tr>
<tr>
<td>- Lowercase: a b c</td>
<td></td>
</tr>
<tr>
<td>- Numeric: 1 2 3</td>
<td></td>
</tr>
<tr>
<td>The minimum number of alphabetic characters must be no less than the combined uppercase and lowercase requirements.</td>
<td></td>
</tr>
<tr>
<td>The following characters are not supported in passwords: non-ASCII characters, semicolon (;), double quotation mark (&quot;), single quotation mark (’), circumflex (^), and backslash.</td>
<td></td>
</tr>
<tr>
<td>Identical adjacent characters</td>
<td>Maximum number of identical adjacent characters that are allowed in the password. The number must be greater than 0. For example, if you enter 1, the following password is not allowed: p@$$.word.</td>
</tr>
</tbody>
</table>

6 Click OK.

Edit the vCenter Single Sign-On Lockout Policy

A vCenter Single Sign-On lockout policy specifies the conditions under which a user's vCenter Single Sign-On account is locked when the user attempts to log in with incorrect credentials. You can edit the lockout policy.
If a user logs in to vsphere.local multiple times with the wrong password, the user is locked out. The lockout policy allows you to specify the maximum number of failed login attempts and how much time can elapse between failures. The policy also specifies how much time must elapse before the account is automatically unlocked.

**Procedure**

1. Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.

   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.

2. Browse to **Administration > Single Sign-On > Configuration**.

3. Click the **Policies** tab and select **Lockout Policy**.

4. Click **Edit**.

5. Edit the parameters.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Description of the lockout policy. Currently a required field.</td>
</tr>
<tr>
<td>Max number of failed login attempts</td>
<td>Maximum number of failed login attempts that are allowed before the account is locked.</td>
</tr>
<tr>
<td>Time interval between failures (seconds)</td>
<td>Time period in which failed login attempts must occur to trigger a lockout.</td>
</tr>
<tr>
<td>Unlock time (seconds)</td>
<td>Amount of time that the account remains locked. If you enter 0, the administrator must unlock the account explicitly.</td>
</tr>
</tbody>
</table>

6. Click **OK**.

**Edit the vCenter Single Sign-On Token Policy**

The vCenter Single Sign-On token policy specifies the clock tolerance, renewal count, and other token properties. You can edit the vCenter Single Sign-On token policy to ensure that the token specification conforms to your corporation’s security standards.

**Procedure**

1. Log in to the vSphere Web Client.

2. Select **Administration > Single Sign-On**, and select **Configuration**.

3. Click the **Policies** tab and select **Token Policy**.

   The vSphere Web Client displays the current configuration settings. If you have not modified the default settings, vCenter Single Sign-On uses them.
4 Edit the token policy configuration parameters.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Clock tolerance</strong></td>
<td>Time difference, in milliseconds, that vCenter Single Sign-On tolerates between a client clock and the domain controller clock. If the time difference is greater than the specified value, vCenter Single Sign-On declares the token invalid.</td>
</tr>
<tr>
<td><strong>Maximum token renewal count</strong></td>
<td>Maximum number of times that a token can be renewed. After the maximum number of renewal attempts, a new security token is required.</td>
</tr>
<tr>
<td><strong>Maximum token delegation count</strong></td>
<td>Holder-of-key tokens can be delegated to services in the vSphere environment. A service that uses a delegated token performs the service on behalf of the principal that provided the token. A token request specifies a DelegateTo identity. The DelegateTo value can either be a solution token or a reference to a solution token. This value specifies how many times a single holder-of-key token can be delegated.</td>
</tr>
<tr>
<td><strong>Maximum bearer token lifetime</strong></td>
<td>Bearer tokens provide authentication based only on possession of the token. Bearer tokens are intended for short-term, single-operation use. A bearer token does not verify the identity of the user or entity that is sending the request. This value specifies the lifetime value of a bearer token before the token has to be reissued.</td>
</tr>
<tr>
<td><strong>Maximum holder-of-key token lifetime</strong></td>
<td>Holder-of-key tokens provide authentication based on security artifacts that are embedded in the token. Holder-of-key tokens can be used for delegation. A client can obtain a holder-of-key token and delegate that token to another entity. The token contains the claims to identify the originator and the delegate. In the vSphere environment, a vCenter Server obtains delegated tokens on a user’s behalf and uses those tokens to perform operations. This value determines the lifetime of a holder-of-key token before the token is marked invalid.</td>
</tr>
</tbody>
</table>

5 Click **OK**.

**Identity Sources for vCenter Server with vCenter Single Sign-On**

Identity sources allow you to attach one or more domains to vCenter Single Sign-On. A domain is a repository for users and groups that the vCenter Single Sign-On server can use for user authentication.

An identity source is a collection of user and group data. The user and group data is stored in Active Directory, OpenLDAP, or locally to the operating system of the machine where vCenter Single Sign-On is installed. Upon installation, every instance of vCenter Single Sign-On has the Local OS identity source identity source vsphere.local. This identity source is internal to vCenter Single Sign-On.

A vCenter Single Sign-On administrator user can create vCenter Single Sign-On users and groups.
Types of Identity Sources

vCenter Server versions earlier than version 5.1 supported Active Directory and local operating system users as user repositories. As a result, local operating system users could always authenticate to the vCenter Server system. vCenter Server version 5.1 and version 5.5 uses vCenter Single Sign-On for authentication. See the vSphere 5.1 documentation for a list of supported identity sources with vCenter Single Sign-On 5.1. vCenter Single Sign-On 5.5 supports the following types of user repositories as identity sources, but supports only one default identity source.

- Active Directory versions 2003 and later. vCenter Single Sign-On allows you to specify a single Active Directory domain as an identity source. The domain can have child domains or be a forest root domain. Shown as Active Directory (Integrated Windows Authentication) in the vSphere Web Client.

- Active Directory over LDAP. vCenter Single Sign-On supports multiple Active Directory over LDAP identity sources. This identity source type is included for compatibility with the vCenter Single Sign-On service included with vSphere 5.1. Shown as Active Directory as an LDAP Server in the vSphere Web Client.

- OpenLDAP versions 2.4 and later. vCenter Single Sign-On supports multiple OpenLDAP identity sources. Shown as OpenLDAP in the vSphere Web Client.

- Local operating system users. Local operating system users are local to the operating system where the vCenter Single Sign-On server is running. The local operating system identity source exists only in Simple vCenter Server installation and in Custom installations with a standalone vCenter Single Sign-On deployment. The local operating system identity source is not available in deployments with multiple vCenter Single Sign-On instances. Only one local operating system identity source is allowed. Shown as localos in the vSphere Web Client.

- vCenter Single Sign-On system users. Exactly one system identity source named vsphere.local is created when you install vCenter Single Sign-On. Shown as vsphere.local in the vSphere Web Client.

Note At any time, only one default domain exists. If a user from a non-default domain logs in, that user must add the domain name (DOMAIN\user) to authenticate successfully.

vCenter Single Sign-On identity sources are managed by vCenter Single Sign-On administrator users.

You can add identity sources to a vCenter Single Sign-On server instance. Remote identity sources are limited to Active Directory and OpenLDAP server implementations.

Login Behavior

When a user logs in to a vCenter Server system from the vSphere Web Client, the login behavior depends on whether the user is in the default domain.

- Users who are in the default domain can log in with their user name and password.
Users who are in a domain that has been added to vCenter Single Sign-On as an identity source but is not the default domain can log in to vCenter Server but must specify the domain in one of the following ways.

- Including a domain name prefix, for example, MYDOMAIN\user1
- Including the domain, for example, user1@mydomain.com

Users who are in a domain that is not a vCenter Single Sign-On identity source cannot log in to vCenter Server. If the domain that you add to vCenter Single Sign-On is part of a domain hierarchy, Active Directory determines whether users of other domains in the hierarchy are authenticated or not.

vCenter Single Sign-On does not propagate permissions that result from nested groups from dissimilar identity sources. For example, if you add the Domain Administrators group to the Local Administrators group, the permissions are not propagated because Local OS and Active Directory are separate identity sources.

**Set the Default Domain for vCenter Single Sign-On**

Each vCenter Single Sign-On identity source is associated with a domain. vCenter Single Sign-On uses the default domain to authenticate a user who logs in without a domain name. Users who belong to a domain that is not the default domain must include the domain name when they log in.

When a user logs in to a vCenter Server system from the vSphere Web Client, the login behavior depends on whether the user is in the default domain.

- Users who are in the default domain can log in with their user name and password.
- Users who are in a domain that has been added to vCenter Single Sign-On as an identity source but is not the default domain can log in to vCenter Server but must specify the domain in one of the following ways.
  - Including a domain name prefix, for example, MYDOMAIN\user1
  - Including the domain, for example, user1@mydomain.com
- Users who are in a domain that is not a vCenter Single Sign-On identity source cannot log in to vCenter Server. If the domain that you add to vCenter Single Sign-On is part of a domain hierarchy, Active Directory determines whether users of other domains in the hierarchy are authenticated or not.

**Procedure**

1. Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.
   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.
2. Browse to **Administration > Single Sign-On > Configuration**.
3 On the **Identity Sources** tab, select an identity source and click the **Set as Default Domain** icon.

In the domain display, the default domain shows (default) in the Domain column.

### Add a vCenter Single Sign-On Identity Source

Users can log in to vCenter Server only if they are in a domain that has been added as a vCenter Single Sign-On identity source. vCenter Single Sign-On administrator users can add identity sources from the vSphere Web Client.

An identity source can be a native Active Directory (Integrated Windows Authentication) domain or an OpenLDAP directory service. For backward compatibility, Active Directory as an LDAP Server is also available.

Immediately after installation, the following default identity sources and users are available:

**localos**

All local operating system users. These users can be granted permissions to vCenter Server. If you are upgrading, those users who already have permissions keep those permissions.

**vsphere.local**

Contains the vCenter Single Sign-On internal users.

#### Procedure

1 Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.

   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.

2 Browse to **Administration > Single Sign-On > Configuration**.

3 On the **Identity Sources** tab, click the **Add Identity Source** icon.

4 Select the type of identity source and enter the identity source settings.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active Directory (Integrated Windows Authentication)</td>
<td>Use this option for native Active Directory implementations. The machine on which the vCenter Single Sign-On service is running must be in an Active Directory domain if you want to use this option. See <a href="#">Active Directory Identity Source Settings</a>.</td>
</tr>
<tr>
<td>Active Directory as an LDAP Server</td>
<td>This option is available for backward compatibility. It requires that you specify the domain controller and other information. See <a href="#">Active Directory LDAP Server and OpenLDAP Server Identity Source Settings</a>.</td>
</tr>
</tbody>
</table>
Option | Description
---|---
OpenLDAP | Use this option for an OpenLDAP identity source. See Active Directory LDAP Server and OpenLDAP Server Identity Source Settings.
LocalOS | Use this option to add the local operating system as an identity source. You are prompted only for the name of the local operating system. If you select this option, all users on the specified machine are visible to vCenter Single Sign-On, even if those users are not part of another domain.

**Note**  If the user account is locked or disabled, authentications and group and user searches in the Active Directory domain will fail. The user account must have read-only access over the User and Group OU, and must be able to read user and group attributes. This is the default Active Directory domain configuration for user permissions. VMware recommends using a special service user.

5 If you configured an Active Directory as an LDAP Server or an OpenLDAP identity source, click **Test Connection** to ensure that you can connect to the identity source.

6 Click **OK**.

**What to do next**

When an identity source is added, all users can be authenticated but have the **No access** permission. A user with vCenter Server **Modify permissions** privileges can assign permissions to users or groups of users to enable them to log in to vCenter Server. See Assign Permissions in the vSphere Web Client.

**Active Directory Identity Source Settings**

If you select the Active Directory (Integrated Windows Authentication) identity source type, you can either use the local machine account as your SPN (Service Principal Name) or specify an SPN explicitly.

Select **Use machine account** to speed up configuration. If you expect to rename the local machine on which vCenter Single Sign-On runs, specifying an SPN explicitly is preferable.

**Table 2-1. Add Identity Source Settings**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domain name</td>
<td>FDQN of the domain. Do not provide an IP address in this field.</td>
</tr>
<tr>
<td>Use machine account</td>
<td>Select this option to use the local machine account as the SPN. When you select this option, you specify only the domain name. Do not select this option if you expect to rename this machine.</td>
</tr>
<tr>
<td>Use SPN</td>
<td>Select this option if you expect to rename the local machine. You must specify an SPN, a user who can authenticate with the identity source, and a password for the user.</td>
</tr>
</tbody>
</table>
Table 2-1. Add Identity Source Settings (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service Principal</td>
<td>SPN that helps Kerberos to identify the Active Directory service. Include the domain in the name, for example, STS/example.com. You might have to run setspn -S to add the user you want to use. See the Microsoft documentation for information on setspn. The SPN must be unique across the domain. Running setspn -S checks that no duplicate is created.</td>
</tr>
<tr>
<td>User Principal Name</td>
<td>Name of a user who can authenticate with this identity source. Use the email address format, for example, <a href="mailto:jchin@mydomain.com">jchin@mydomain.com</a>. You can verify the User Principal Name with the Active Directory Service Interfaces Editor (ADSI Edit).</td>
</tr>
<tr>
<td>Password</td>
<td>Password for the user who is used to authenticate with this identity source, which is the user who is specified in User Principal Name. Include the domain name, for example, <a href="mailto:jdoe@example.com">jdoe@example.com</a>.</td>
</tr>
</tbody>
</table>

Active Directory LDAP Server and OpenLDAP Server Identity Source Settings

The Active Directory as an LDAP Server identity source is available for backward compatibility. Use the Active Directory (Integrated Windows Authentication) option for a setup that requires less input. The OpenLDAP Server identity source is available for environments that use OpenLDAP.

If you are configuring an OpenLDAP identity source, see VMware Knowledge Base article 2064977 for additional requirements.

Table 2-2. Active Directory as an LDAP Server and OpenLDAP Settings

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

Edit a vCenter Single Sign-On Identity Source

vSphere users are defined in an identity source. You can edit the details of an identity source that is associated with vCenter Single Sign-On.

Procedure

1. Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.
   
   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.

2. Browse to Administration > Single Sign-On > Configuration.

3. Click the Identity Sources tab.

4. Right-click the identity source in the table and select Edit Identity Source.

5. Edit the identity source settings. The available options depend on the type of identity source you selected.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active Directory (Integrated Windows Authentication)</td>
<td>Use this option for native Active Directory implementations. The machine on which the vCenter Single Sign-On service is running must be in an Active Directory domain if you want to use this option. See Active Directory Identity Source Settings.</td>
</tr>
<tr>
<td>Active Directory as an LDAP Server</td>
<td>This option is available for backward compatibility. It requires that you specify the domain controller and other information. See Active Directory LDAP Server and OpenLDAP Server Identity Source Settings.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>OpenLDAP</td>
<td>Use this option for an OpenLDAP identity source. See Active Directory LDAP Server and OpenLDAP Server Identity Source Settings.</td>
</tr>
<tr>
<td>LocalOS</td>
<td>Use this option to add the local operating system as an identity source. You are prompted only for the name of the local operating system. If you select this option, all users on the specified machine are visible to vCenter Single Sign-On, even if those users are not part of another domain.</td>
</tr>
</tbody>
</table>

6. Click **Test Connection** to ensure that you can connect to the identity source.

7. Click **OK**.

### Remove a vCenter Single Sign-On Identity Source

vSphere users are defined in an identity source. You can remove an identity source from the list of registered identity sources.

**Procedure**

1. Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.

   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.

2. Browse to **Administration > Single Sign-On > Configuration**.

3. On the **Identity Sources** tab, select an identity source and click the **Delete Identity Source** icon.

4. Click **Yes** when prompted to confirm.

### Refresh the Security Token Service (STS) Root Certificate

vCenter Single Sign-On provides a Security Token Service (STS). The Security Token Service is a Web service that issues, validates, and renews security tokens. You can manually refresh the existing Security Token Service certificate when it expires or changes.

STS certificates expire or change periodically and must be updated or refreshed. In some environments, your system administrator might implement automatic updates of the certificate. Otherwise, you can update the certificate manually.

**Note** The vCenter Certificate Automation Tool can only replace the SSL certificates. The tool cannot be used to replace the STS certificates.

**Procedure**

1. Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.

   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.

2. Browse to **Administration > Single Sign-On > Configuration**.
3 Select the Certificates tab, then the STS Signing subtab, and click Add STS Signing Certificate.

4 Click Browse to browse to the key store JKS file that contains the new certificate and click Open.

   If the key store file is valid, the STS certificate table is populated with the certificate information.

5 Click OK.

Results

The new certificate information appears on the STS Signing tab.

What to do next

Restart the vSphere Web Client service.

Determine the Expiration Date of an SSL Certificate

CA-signed SSL certificates expire after a predefined lifespan. Knowing when a certificate expires lets you replace or renew the certificate before the expiration date.

Procedure

1 Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.

   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.

2 Browse to Administration > Single Sign-On > Configuration.

3 Click the Certificates tab, and then the Identity Sources TrustStore subtab.

4 Find the certificate and verify the expiration date in the Valid To text box.

   You might see a warning at the top of the tab which indicates that a certificate is about to expire.

What to do next

Renew or replace SSL certificates that are getting close to their expiration date.

Determine Whether a Certificate is Being Used

Before you start with certificate replacement, you can check whether the certificates you have are already being used. You can use the Compute Usage feature to determine whether or not the system is using a certificate.
Procedure

1 Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.

   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.

2 Browse to Administration > Single Sign-On > Configuration.

3 Click the Certificates tab, and then the Identity Sources TrustStore subtab.

4 Click Compute Usage.

   For each certificate in the list, the vSphere Web Client communicates with each registered LDAPs identity source to determine whether a valid connection exists.

5 The Used By Domain column shows whether a certificate is in use, and helps you determine whether you can safely remove a certificate.

Use vCenter Single Sign-On with Windows Session Authentication

You can use vCenter Single Sign-On with Windows Session Authentication (SSPI). To make the checkbox on the login page available, you must install the Client Integration Plug-in.

Using SSPI speeds up login for the user who is currently logged in to a machine.

Prerequisites

Your Windows domain must be set up properly.

Procedure

1 Navigate to the vSphere Web Client login page.

2 If the Use Windows session authentication check box is not available, click Download the Client Integration Plug-in at the bottom of the login page.

3 If the browser blocks the installation by issuing certificate errors or by running a pop-up blocker, follow the Help instructions for your browser to resolve the problem.

4 Close other browsers if you are prompted to do so.

   After installation, the plug-in is available for all browsers.

5 Exit and restart your browser.

   After the restart, you can select the Use Windows session authentication check box.

Managing vCenter Single Sign-On Users and Groups

A vCenter Single Sign-On administrator user can manage users and groups in the vsphere.local domain from the vSphere Web Client.
The vCenter Single Sign-On administrator user can perform the following tasks.

**Note**  Do not delete any of the groups that are predefined in the vsphere.local domain. Unexpected errors with authentication might result.

- **Add vCenter Single Sign-On Users**
  Users listed on the **Users** tab in the vSphere Web Client are internal to vCenter Single Sign-On and belong to the vsphere.local domain.

- **Disable and Enable vCenter Single Sign-On Users**
  When a vCenter Single Sign-On user account is disabled, the user cannot log in to the vCenter Single Sign-On server until the account is enabled by an administrator. You can disable and enable users from the vSphere Web Client interface.

- **Delete a vCenter Single Sign-On User**
  You can delete users that are in the vsphere.local domain from the vSphere Web Client. You cannot delete local operating system users or users in another domain from the vSphere Web Client.

- **Edit a vCenter Single Sign-On User**
  You can change the password or other details of a vCenter Single Sign-On user from the vSphere Web Client. You cannot rename users in the vsphere.local domain. That means you cannot rename administrator@vsphere.local.

- **Add a vCenter Single Sign-On Group**
  In the vSphere Web Client, groups listed on the **Groups** tab are internal to vCenter Single Sign-On. A group lets you create a container for a collection of group members (principals).

- **Edit a vCenter Single Sign-On Group**
  You can change the description of a vCenter Single Sign-On group in the vSphere Web Client. You cannot change the name of the group.

- **Add Members to a vCenter Single Sign-On Group**
  You can add new members to a vCenter Single Sign-On group from the vSphere Web Client.

- **Remove Members from a vCenter Single Sign-On Group**
  You can remove members from a vCenter Single Sign-On group from the vSphere Web Client. When you remove a member (user or group) from a local group, you do not delete the member from the system.

- **Delete vCenter Single Sign-On Application Users**
  vCenter Single Sign-On recognizes vCenter services such as vCenter Server, vCenter Inventory Server, and the vSphere Web Client and grants privileges to those services as application users.
Change Your vCenter Single Sign-On Password

Users in the local domain, vsphere.local by default, can change their vCenter Single Sign-On passwords from a Web interface. Users in other domains change their passwords following the rules for that domain.

Add vCenter Single Sign-On Users

Users listed on the Users tab in the vSphere Web Client are internal to vCenter Single Sign-On and belong to the vsphere.local domain.

You can select other domains and view information about the users in those domains, but you cannot add users to other domains from the vCenter Single Sign-On management interface of the vSphere Web Client.

Procedure

1. Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.
   
   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.

2. Click Home, and browse to Administration > Single Sign-On > Users and Groups.

3. If vsphere.local is not the currently selected domain, select it from the dropdown menu.
   
   You cannot add users to other domains.

4. On the Users tab, click the New User icon.

5. Type a user name and password for the new user.
   
   You cannot change the user name after you create a user.

   The password must meet the password policy requirements for the system.

6. (Optional) Type the first name and last name of the new user.

7. (Optional) Enter an email address and description for the user.

8. Click OK.

Results

When you add a user, that user initially has no permissions to perform management operations.

What to do next

Add the user to a group in the vsphere.local domain, for example, to the administrator group. See Add Members to a vCenter Single Sign-On Group.

Disable and Enable vCenter Single Sign-On Users

When a vCenter Single Sign-On user account is disabled, the user cannot log in to the vCenter Single Sign-On server until the account is enabled by an administrator. You can disable and enable users from the vSphere Web Client interface.
Disabled user accounts remain available in the vCenter Single Sign-On system, but the user cannot log in or perform operations on the server. Users with administrator privileges can disable and enable users from the vCenter Users and Groups page.

Prerequisites
You must be a member of the vCenter Single Sign-On Administrators group to disable and enable vCenter Single Sign-On users.

Procedure
1. Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.
   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.
2. Click Home, and browse to Administration > Single Sign-On > Users and Groups.
3. Select a user, click the Disable icon, and click Yes when prompted.
4. To enable the user again, right-click the user, select Enable, and click Yes when prompted.

Delete a vCenter Single Sign-On User
You can delete users that are in the vsphere.local domain from the vSphere Web Client. You cannot delete local operating system users or users in another domain from the vSphere Web Client.

Caution   If you delete the administrator user in the vsphere.local domain, you can no longer log in to vCenter Single Sign-On. Reinstall vCenter Server and its components.

Procedure
1. Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.
   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.
2. Click Home, and browse to Administration > Single Sign-On > Users and Groups.
3. Select the Users tab, and select the vsphere.local domain.
4. In the list of users, select the user that you want to delete and click the Delete icon.
   Proceed with caution. You cannot undo this action.

Edit a vCenter Single Sign-On User
You can change the password or other details of a vCenter Single Sign-On user from the vSphere Web Client. You cannot rename users in the vsphere.local domain. That means you cannot rename administrator@vsphere.local.

You can create additional users with the same privileges as administrator@vsphere.local. vCenter Single Sign-On users are stored in the vCenter Single Sign-On vsphere.local domain.
You can review the vCenter Single Sign-On password policies from the vSphere Web Client. Log in as administrator@vsphere.local and select **Configuration > Policies > Password Policies**.

**Procedure**

1. Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.
   
   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.

2. Click **Home**, and browse to **Administration > Single Sign-On > Users and Groups**.

3. Click the **Users** tab.

4. Right-click the user and select **Edit User**.

5. Make changes to the user.
   
   You cannot change the user name of the user.
   
   The password must meet the password policy requirements for the system.

6. Click **OK**.

**Add a vCenter Single Sign-On Group**

In the vSphere Web Client, groups listed on the **Groups** tab are internal to vCenter Single Sign-On. A group lets you create a container for a collection of group members (principals).

When you add a vCenter Single Sign-On group from the vCenter Single Sign-On administration interface, the group is added to the vsphere.local domain.

**Procedure**

1. Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.
   
   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.

2. Click **Home**, and browse to **Administration > Single Sign-On > Users and Groups**.

3. Select the **Groups** tab and click the **New Group** icon.

4. Enter a name and description for the group.
   
   You cannot change the group name after you create the group.

5. Click **OK**.

**What to do next**

- Add members to the group.

**Edit a vCenter Single Sign-On Group**

You can change the description of a vCenter Single Sign-On group in the vSphere Web Client. You cannot change the name of the group.
vCenter Single Sign-On groups are stored in the vCenter Single Sign-On database, which runs on the system where vCenter Single Sign-On is installed. These groups are part of the vsphere.local domain.

**Procedure**

1. Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.
   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.

2. Click **Home**, and browse to **Administration > Single Sign-On > Users and Groups**.

3. Click the **Groups** tab.

4. Right-click the group to edit and select **Edit Group**.

5. Edit the description for the group.
   You cannot change the group name after you create the group.

6. Click **OK**.

**Add Members to a vCenter Single Sign-On Group**

You can add new members to a vCenter Single Sign-On group from the vSphere Web Client.

You can add members of Microsoft Active Directory or OpenLDAP groups to a vCenter Single Sign-On group. You cannot add groups from external identity sources to a vCenter Single Sign-On group.

Groups that are listed on the **Groups** tab in the vSphere Web Client are internal to vCenter Single Sign-On and are part of the vsphere.local domain.

**Procedure**

1. Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.
   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.

2. Click **Home**, and browse to **Administration > Single Sign-On > Users and Groups**.

3. Click the **Groups** tab and click the group (for example, Administrators).

4. In the Group Members area, click the **Add Members** icon.

5. Select the identity source that contains the member to add to the group.

6. **(Optional)** Enter a search term and click **Search**.

7. Select the member and click **Add**.
   You can simultaneously add multiple members.

8. Click **OK**.
Remove Members from a vCenter Single Sign-On Group

You can remove members from a vCenter Single Sign-On group from the vSphere Web Client. When you remove a member (user or group) from a local group, you do not delete the member from the system.

Procedure

1. Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.
   
   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.

2. Click Home, and browse to Administration > Single Sign-On > Users and Groups.

3. Select the Groups tab and click the group.

4. In the list of group members, select the user or group that you want to remove and click the Remove Member icon.

5. Click OK.

Results

The user is removed from the group, but is still available in the system.

Delete vCenter Single Sign-On Application Users

vCenter Single Sign-On recognizes vCenter services such as vCenter Server, vCenter Inventory Server, and the vSphere Web Client and grants privileges to those services as application users.

When you uninstall an vCenter service, the service is removed from the list of vCenter Single Sign-On application users as part of uninstallation by default. If you forcefully remove an application, or if the system becomes unrecoverable while the application user is still in the system, you can remove the application user explicitly from the vSphere Web Client.

Important If you remove an application, the application no longer has access to vCenter Single Sign-On.

Procedure

1. Log in to the vSphere Web Client as administrator@vsphere.local or as another user with vCenter Single Sign-On administrator privileges.
   
   Users with vCenter Single Sign-On administrator privileges are in the CAAdmins group.

2. Browse to Administration > Single Sign-On > Users and Groups.

3. Click the Applications Users tab, and click the application user name.

4. Click the Delete Application User icon.

5. Click Yes.
Results

The application (or solution) no longer has access to vCenter Server and cannot function as a vCenter service.

Change Your vCenter Single Sign-On Password

Users in the local domain, vsphere.local by default, can change their vCenter Single Sign-On passwords from a Web interface. Users in other domains change their passwords following the rules for that domain.

The password policy that is defined in the vCenter Single Sign-On configuration interface determines when your password expires. By default, vCenter Single Sign-On passwords expire after 90 days, but your system administrator might change this default depending on the policy of your organization. The vSphere Web Client reminds you when your password is about to expire. You can reset an expired password if you know the old password.

**Note**  You can change a password only if it is not expired.

If the password is expired, the administrator of the local domain, administrator@vsphere.local by default, can reset the password by using the `dir-cli password reset` command. Only members of the Administrator group for the vCenter Single Sign-On domain can reset passwords.

Procedure

1. From a Web browser, connect to the vSphere Web Client or the Platform Services Controller.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere Web Client</td>
<td><code>https://vc_hostname_or_IP/vsphere-client</code></td>
</tr>
<tr>
<td>Platform Services Controller</td>
<td><code>https://psc_hostname_or_IP/psc</code></td>
</tr>
<tr>
<td></td>
<td>In an embedded deployment, the Platform Services Controller host name or IP address is the same as the vCenter Server host name or IP address.</td>
</tr>
</tbody>
</table>

2. Specify the user name and password for administrator@vsphere.local or another member of the vCenter Single Sign-On Administrators group.

   If you specified a different domain during installation, log in as administrator@mydomain.

3. In the upper navigation pane, to the left of the Help menu, click your user name to pull down the menu.

   As an alternative, you can select **Single Sign-On > Users and Groups** and select **Edit User** from the right-button menu.

4. Select **Change Password** and type your current password.

5. Type a new password and confirm it.

   The password must conform to the password policy.

6. Click **OK**.
Troubleshooting vCenter Single Sign-On

Configuring vCenter Single Sign-On can be a complex process.

The following topics provide a starting point for troubleshooting vCenter Single Sign-On. Search this documentation center and the VMware Knowledge Base system for additional pointers.

vCenter Single Sign-On Installation Fails

In a Windows environment, vCenter Single Sign-On installation might fail for several reasons.

Problem

The vCenter Single Sign-On installation fails in a Windows environment.

Cause

Multiple causes of an installation failure.

Solution

1. Verify that all installation setup prerequisites are met.
   At the time the installation fails, the installer displays a message similar to ####:
   Installation failed due to....

2. At a command line, run the following command to gather a vCenter Single Sign-On support bundle.

   C:\Windows\System32\cscript.exe "SSO Server\scripts\sso-support.wsf" /z

3. Click OK

4. View the logs in %TEMP%\vminst.log for details about the failure and possible solutions.
   For a complete list of logs, see VMware Knowledge Base article 2033430.

Determining the Cause of a Lookup Service Error

vCenter Single Sign-On installation displays an error referring to the vCenter Server or the vSphere Web Client.

Problem

vCenter Server and Web Client installers show the error Could not contact Lookup Service. Please check VM_sssoreg.log....

Cause

This problem has several causes, including unsynchronized clocks on the host machines, firewall blocking, and services that must be started.
Solution

1. Verify that the clocks on the host machines running vCenter Single Sign-On, vCenter Server, and the Web Client are synchronized.

2. View the specific log file found in the error message.
   In the message, system temporary folder refers to %TEMP%.

3. Within the log file, search for the following messages.
   The log file contains output from all installation attempts. Locate the last message that shows Initializing registration provider...

<table>
<thead>
<tr>
<th>Message</th>
<th>Cause and solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>java.net.ConnectException: Connection timed out: connect</td>
<td>The IP address is incorrect, a firewall is blocking access to vCenter Single Sign-On, or vCenter Single Sign-On is overloaded. Ensure that a firewall is not blocking the vCenter Single Sign-On port (by default 7444) and that the machine on which vCenter Single Sign-On is installed has adequate free CPU, I/O, and RAM capacity.</td>
</tr>
<tr>
<td>java.net.ConnectException: Connection refused: connect</td>
<td>The IP address or FQDN is incorrect and the vCenter Single Sign-On has not started or has started within the past minute. Verify that vCenter Single Sign-On is working by checking the status of vCenter Single Sign-On service (Windows) and vmware-sso daemon (Linux). Restart the service. If this does not correct the problem, see the recovery section of the vSphere troubleshooting guide.</td>
</tr>
<tr>
<td>Unexpected status code: 404. SSO Server failed during initialization</td>
<td>Restart vCenter Single Sign-On. If this does not correct the problem, see the Recovery section of the vSphere Troubleshooting Guide.</td>
</tr>
<tr>
<td>The error shown in the UI begins with Could not connect to vCenter Single Sign-On.</td>
<td>You also see the return code SslHandshakeFailed. This is an uncommon error. It indicates that the provided IP address or FQDN that resolves to vCenter Single Sign-On host was not the one used when you installed vCenter Single Sign-On. In %TEMP%/VM_ssoReg.log, find the line that contains the following message. host name in certificate did not match: &lt;install-configured FQDN or IP&gt; != &lt;A&gt; or &lt;B&gt; or &lt;C&gt; where A was the FQDN you entered during the vCenter Single Sign-On installation, and B and C are system-generated allowable alternatives. Correct the configuration to use the FQDN on the right of the != sign in the log file. In most cases, use the FQDN that you specified during vCenter Single Sign-On installation. If none of the alternatives are possible in your network configuration, recover your vCenter Single Sign-On SSL configuration.</td>
</tr>
</tbody>
</table>

Unable to Log In Using Active Directory Domain Authentication

You log in to a vCenter Server component from the vSphere Web Client. You use your Active Directory user name and password. Authentication fails.
Problem
You add an Active Directory identity source to vCenter Single Sign-On, but users cannot log in to vCenter.

Cause
Users use their user name and password to log in to the default domain. For all other domains, users must include the domain name (user@domain or DOMAIN\user).

If you are using the vCenter Server Appliance, other problems might exist.

Solution
For all vCenter Single Sign-On deployments, you can change the default identity source. After that change, users can log in to the default identity source with username and password only.

If you are using the vCenter Server Appliance, and changing the default identity source does not resolve the issue, perform the following additional troubleshooting steps.

1. Synchronize the clocks between the vCenter Server Appliance and the Active Directory domain controllers.

2. Verify that each domain controller has a pointer record (PTR) in the Active Directory domain DNS service and that the PTR record information matches the DNS name of the controller. When using the vCenter Server Appliance, you can run the following commands to perform the task:

   a. To list the domain controllers run the following command:

   ```
   # dig SRV _ldap._tcp.my-ad.com
   ```

   The relevant addresses are in the answer section, as in the following example:

   ```
   ;; ANSWER SECTION:
   _ldap._tcp.my-ad.com. (...) my-controller.my-ad.com
   ... *
   ```

   b. For each domain controller, verify forward and reverse resolution by running the following command:

   ```
   # dig my-controller.my-ad.com
   ```

   The relevant addresses are in the answer section, as in the following example:

   ```
   ;; ANSWER SECTION:
   my-controller.my-ad.com (...) IN A controller IP address
   ... *
   ```

   ```
   # dig -x <controller IP address>
   ```
The relevant addresses are in the answer section, as in the following example:

"; ANSWER SECTION:
IP-in-reverse.in-addr.arpa. (...) IN PTR my_controller.my-ad.com"

3 If that does not resolve the problem, remove the vCenter Server Appliance from the Active Directory domain and then rejoin the domain.

4 Restart vCenter Single Sign-On.

vCenter Server Login Fails Because the User Account is Locked

When you log in to vCenter Server from the vSphere Web Client login page, an error indicates that the account is locked.

Problem

After several failed attempts, you cannot log in to the vSphere Web Client using vCenter Single Sign-On. You see the message that your account is locked.

Cause

You exceeded the maximum number of failed login attempts.

Solution

◆ If you log in as a user from the system domain (vsphere.local), ask your vCenter Single Sign-On administrator to unlock your account. As an alternative, you can wait until your account is unlocked, if the lock is set to expire in the password policy.

◆ If you log in as a user from an Active Directory or LDAP domain, ask your Active Directory or LDAP administrator to unlock your account.
ESXi and vCenter Server components communicate securely over SSL to ensure confidentiality, data integrity and authentication. Data is private, protected, and cannot be modified in transit without detection.

By default, vSphere services use the certificates that are created as part of the installation process and stored on each system. These default certificates are unique and make it possible to begin using the software, but they are not signed by a trusted certificate authority (CA).

To receive the full benefit of certificate checking, particularly if you intend to use SSL connections over the Internet, install new certificates that are signed by a valid internal certificate authority or purchase a certificate from a trusted security authority.

This chapter includes the following topics:

- Certificates Used in vSphere
- Certificate Replacement Overview
- Certificate Automation Tool Deployment Options
- Replacing vCenter Certificates With the vCenter Certificate Automation Tool
- Replace vCenter Server Appliance Certificates
- Replace vCenter Server Heartbeat Certificates

Certificates Used in vSphere

Different types of certificates are used for different purposes in your vSphere environment.

SAML Tokens Issued by vCenter Single Sign-On STS Service

STS certificates enable a user who has logged on through vCenter Single Sign-On to use any vCenter Service that vCenter Single Sign-On supports without authenticating to each one. The STS service issues Security Assertion Markup Language (SAML) tokens. These security tokens represent the identity of a user in one of the of the identity source types supported by vCenter Single Sign-On. See How vCenter Single Sign-On Protects Your Environment.
The vCenter Single Sign-On service deploys an Identity Provider which issues SAML Tokens used throughout the vSphere for authentication purposes. A SAML token is a piece of XML that represents the user’s identity (user name, first, last name). In addition the SAML token contains group membership information so that the SAML token could be used for authorization operations. When vCenter Single Sign-On issues SAML tokens, it signs each token with the certificate chain so that clients of vCenter Single Sign-On can verify that the SAML token comes from a trusted source.

**SSL Certificates**

SSL certificates secure communication throughout your vSphere environment. The client verifies the authenticity of the certificate presented during the SSL handshake phase, before encryption. This verification protects against man-in-the-middle attacks.

VMware products use standard X.509 version 3 (X.509v3) certificates to encrypt session information that is sent over Secure Socket Layer (SSL) protocol connections between components.

vSphere components include default certificates. You can replace the default certificates with self-signed or CA-signed certificates. For the vCenter core components, you can use the Certificate Automation Tool.

**SSH Keys**

SSH keys are used to control access to the ESXi hosts that are using the Secure Shell (SSH) protocol. See [Uploading an SSH Key to Your ESXi Host](#).

**Cipher Strength**

To encrypt data, the sending component, such as a gateway or redirector, applies cryptographic algorithms, or ciphers, to alter the data before transmitting it. The receiving component uses a key to decrypt the data, returning it to its original form. Several ciphers are in use, and the level of security that each provides is different. One measure of a cipher’s ability to protect data is its cipher strength—the number of bits in the encryption key. The larger the number, the more secure the cipher.

Administrators specify the desired cipher strength when they prepare a certificate request. Company policy might dictate the cipher strength that the administrator chooses.

256-bit AES encryption and 1024-bit RSA for key exchange are the default for the following connections.

- vSphere Web Client connections to vCenter Server and to ESXi through the management interface.
- SDK connections to vCenter Server and to ESXi.
- Connections to the virtual machine virtual machine console.
- Direct SSH connections to ESXi.
Certificate Replacement Overview

For the core vCenter components, you can generate certificate requests and replace the default certificates with self-signed or CA-signed certificates by using the Certificate Automation Tool. You can also generate the requests, create the certificates, and replace the certificates from the command line without the tool.

Where to Find Information

How you want to replace certificates determines where you can find information. You can perform certificate replacement in several ways.

- Use the Certificate Replacement tool in your Windows environment, as described in this document.
- Replace certificates on Windows explicitly, as explained in VMware Knowledge Base article 2058519.
- Replace certificates on the vCenter Server Appliance, as explained in VMware Knowledge Base article 2057223.

If you want to use certificates that are signed by a CA, you must generate a certificate request (CSR) for each component. You can use the tool to generate the CSRs. See Preparing Your Environment for a list of certificate requirements.

Certificate Replacement Tool Overview

The Certificate Automation Tool is a command-line tool that helps you replace the certificates for the core vCenter components listed below. In most cases, you replace the default certificates with custom certificates. You use the tool after you install all vCenter components. If you add a new component to your vSphere environment, you can run the tool again to perform certificate replacement for the new component. When you run the tool on a vCenter component such as the vCenter Server system or the vCenter Single Sign-On server, it performs the following tasks.

- Prompts you for required input.
- Validates the input (x.509 certificate and URL formats).
- Updates the SSL certificate of a component and the corresponding LookupService entries of the services that are exposed by the components if necessary.
- Restarts the corresponding service if necessary.
- Updates the trust of the component to all other components that it connects to. Restarts the component if necessary.
Provides the next steps to the user where necessary.

**Note**  Certificate replacement with the tool has been tested with vCenter Single Sign-On, vCenter Inventory Service, vCenter Server, vSphere Web Client, vSphere Update Manager, vCenter Log Browser and vCenter Orchestrator. If you have to perform a certificate replacement with another vSphere component, the instructions in VMware documentation or the VMware Knowledge base for that product. You might have to update certificates on one of the supported components as part of the process.

The tool supports the following vCenter components:

- vCenter Single Sign-On
- vCenter Inventory Service
- vCenter Server
- vSphere Web Client
- vSphere Update Manager
- vCenter Log Browser
- vCenter Orchestrator

Each component must have an SSL certificate and a solution user certificate. Most components use the same certificate for both purposes. On Windows, the solution user certificates must be unique, so a unique SSL certificate for each component is required.

**Upgrades**

If you replaced the default certificates in vSphere version 5.0 or version 5.1, and you upgrade to vSphere version 5.5, the certificates are migrated. If you are upgrading and you want to replace the default certificates, you can run the Certificate Automation Tool after the upgrade.

**Certificate Automation Tool Deployment Options**

The vCenter Certificate Automation Tool automates certificate renewal for core vCenter components on Windows operating systems.

The tool supports several deployment options. How the tool interacts with the user depends on the deployment option. See Certificate Replacement Overview

**All Services on One Machine**

You can edits the ssl-environment.bat file and enter environment-specific information, and run the tool on the machine without being prompted. As an alternative, you can run the tool and provide input when prompted.
Each Service on a Separate Machine

If each service runs on a separate machine or virtual machine in your environment, follow the steps below to update certificates. If some of these services run on the same machine, follow the information in the Update Planner list that is generated by the Certificate Automation Tool. If you are not including some of the services in your environment, you can skip the corresponding steps.

1. Install and run the tool on one machine. The tool generates the update planner list.
2. Install and run the tool on the machine on which vCenter Single Sign-on is running to update the vCenter Single Sign-On SSL certificate.
3. Install and run the tool on the Inventory Service machine. The tool performs these tasks:
   a. Updates the trust from vCenter Inventory Service to vCenter Single Sign-On.
   b. Updates the vCenter Inventory Service SSL certificate.
4. Install and run the tool on the machine on which vCenter Server is running. The tool performs these tasks:
   a. Updates the trust from the vCenter Server service to the vCenter Single Sign-On service.
   b. Updates the vCenter Server SSL certificate.
   c. Updates the trust from the vCenter Server to the vCenter Inventory Service.
   d. Updates the trust from the vCenter Server to the vSphere Update Manager.
5. Install and run the tool on the vCenter Orchestrator machine. The tool performs these tasks:
   a. Updates the trust from the vCenter Orchestrator service to the vCenter Single Sign-On service.
   b. Updates the trust from the vCenter Orchestrator service to the vCenter Server service.
   c. Updates the vCenter Orchestrator SSL certificate.
6. Install and run the tool on the vSphere Web Client machine. The tool performs these tasks:
   a. Updates the trust from the vSphere Web Client to the vCenter Single Sign-On service.
   b. Updates the trust from the vSphere Web Client to the vCenter Inventory Service and restarts the service.
   c. Updates the trust from the vSphere Web Client to the vCenter Server service and restarts the service.
   d. Updates the trust from the vSphere Web Client to the vCenter Orchestrator service and restarts the service.
   e. Updates the vSphere Web Client SSL certificate.

You have to restart the vSphere Web Client to complete the updates of the trust relationships.
7 Install and run the tool on the Log Browser machine. The vSphere Web Client and the vCenter Log Browser always run on the same machine. The tool performs these tasks.
   a Updates the trust from the Log Browser service to the vCenter Single Sign-On service.
   b Updates the Log Browser SSL certificate.
8 Install and run the tool on the vSphere Update Manager machine.
   The tool updates the vSphere Update Manager SSL certificate. As part of the certificate update, the vCenter Server trust to vSphere Update Manager is updated.

Mixed Mode Deployment

In a mixed mode deployment, for example, when two services are on one machine and three services are on a second machine, you can run the tool as if each service were on a different machine.

Replacing vCenter Certificates With the vCenter Certificate Automation Tool

You can replace the default vCenter SSL certificates with CA-signed or self-signed certificates if company policy requires it. The vCenter Certificate Automation Tool is a command-line tool that helps you replace certificates in the correct order for the core vCenter services in your environment. You can use the tool to generate certificate requests, generate an update plan, and perform the update.

Each vSphere service has an identity, which is used to create an x509 certificate. You can replace the certificates for the core vCenter components with the vCenter Certificate Automation Tool. You can replace certificates for other vCenter components manually.

- Use the vCenter Certificate Automation Tool to replace SSL certificates for vCenter components that are installed on supported Windows operating systems. The tool helps you generate certificate requests and to plan the process of replacing certificates. The tool supports vCenter Single Sign-On, vCenter Inventory Service, vCenter Server, vSphere Web Client, vSphere Update Manager, vCenter Log Browser and vCenter Orchestrator.

- If you are using other vSphere components, see VMware documentation or the VMware Knowledge Base for certificate replacement information.

- If you are using a third-party component, you must replace the certificates manually. See VMware Knowledge Base article 2058519.

- If you are using the vCenter Server Appliance, replace SSL certificates manually. Some services share certificates. See VMware Knowledge Base article 2057223.
Replacing the certificates consists of several tasks.

Procedure

1. **Preparing Your Environment**
   Before you run the vCenter Certificate Automation Tool, verify that you are running on one of the supported operating systems and verify that you have the correct platform, that the certificates meet requirement, and that your system setup meets requirements.

2. **Install the vCenter Certificate Automation Tool**
   You install the vCenter Certificate Automation Tool on each machine on which a vCenter core component resides. To do the initial planning, you can install the tool on a single machine.

3. **Predefine Default Values for vCenter Certificate Automation Tool**
   Predefining default values in a configuration file for the tool helps prevent typing errors and saves time. With default values predefined, the tool no longer prompts you for those values. You cannot specify default passwords.

4. **Generate Certificate Requests and Set Up CA Signed Certificates**
   If you want to use trusted certificates that are generated by a CA (Certificate Authority), you must create certificate requests and submit them to a CA.

5. **Run the Update Planner**
   The update planner, part of the vCenter Certificate Automation Tool, allows you to determine the correct order for certificate replacement. Follow the steps in the order that the tool recommends for best results.

6. **Run the Tool to Update SSL Certificates and Trusts**
   After you obtain the SSL certificates and you generate the list of update steps, you can run the tool to replace the existing certificates, reestablish trust, and optionally restart some of the services.

7. **Rolling Back Your Updates**
   Each update operation successfully performs the update for one certificate and key, or fails in a way that preserves the original state. If an update fails, you might need to roll back the failed step.

**Preparing Your Environment**

Before you run the vCenter Certificate Automation Tool, verify that you are running on one of the supported operating systems and verify that you have the correct platform, that the certificates meet requirement, and that your system setup meets requirements.

Review the Known Issues listed in VMware Knowledge Base Article 2057340.
Supported Platforms
The tool has been tested on the following Windows operating systems.

- Windows 2008 R2 SP1
- Windows 2012 Standard
- Windows 2012 R2

Tool and Product Versions
Different versions of the tool are supported with different versions of vSphere.

- Version 1.0 of the tool is supported with vSphere 5.1
- Version 1.0.1 of the tool is supported with vSphere 5.1 Update 1
- Version 5.5 of the tool is supported with vSphere 5.5

Certificate Requirements
You can obtain the CA-signed certificates before you run the tool, or you can have the tool generate the certificate requests for you. Before you run the tool to replace certificates, make sure that certificates meet the following requirements:

- The SSL certificate for each vSphere component has a unique base DN.
- The certificates and private keys meet these requirements:
  - Private key algorithm: RSA
  - Private key length >= 1024
  - Private key standard: PKCS#1 or PKCS#8
  - Private key storage: PEM
- Recommended certificate signature algorithm:
  - sha256WithRSAEncryption 1.2.840.113549.1.1.11
  - sha384WithRSAEncryption 1.2.840.113549.1.1.12
  - sha512WithRSAEncryption 1.2.840.113549.1.1.13

  **Note**  The algorithms md2WithRSAEncryption 1.2.840.113549.1.1.2, md5WithRSAEncryption 1.2.840.113549.1.1.4, and sha1WithRSAEncryption 1.2.840.113549.1.1.5 are not recommended. The algorithm RSASSA-PSS with OID 1.2.840.113549.1.1.10 is not supported.

- The certificate chain format meets these requirements:
  - Single PEM file that does not contain any comments.
  - The file starts with the header of the first certificate, that is, -----BEGIN CERTIFICATE-----.
  - Self-signed certificates are ordered from the leaf to the root.
  - No extra certificates are in the file.
The certificate chain is complete.

The path or file name for certificates and keys does not contain any of the following special characters:
- ^ (caret)
- % (percent)
- & (ampersand)
- ; (semicolon)
- ) (closing parenthesis)

The tool exits, throws an exception, or reports that certificate or key files are not found if it encounters those characters.

**System Requirements**

Install all vCenter components, obtain administrator permissions, and shut down dependent solutions, as follows:

- Verify that all vCenter components that require certificate updates are installed and running, and that you have access to the server for each component.
- Verify that you have administrative privileges on the server or servers that you are running the tool on. Although nonadministrator users can download and launch the tool, all operations fail without the proper permissions.
- Shut down the following dependent solutions that are running in the environment:
  - VMware Site Recovery Manager
  - vSphere Data Recovery
  - vCloud Director
  - Any third-party solution which might be connecting to vCenter Server

**Install the vCenter Certificate Automation Tool**

You install the vCenter Certificate Automation Tool on each machine on which a vCenter core component resides. To do the initial planning, you can install the tool on a single machine.

Install the tool on each physical or virtual machine on which a service is running whose certificate update is planned. You can install the tool in several configurations. See Certificate Automation Tool Deployment Options.

**Note** Different versions of the tool are supported with different versions of vSphere.

- Version 1.0 of the tool is supported with vSphere 5.1
- Version 1.0.1 of the tool is supported with vSphere 5.1 Update 1
- Version 5.5 of the tool is supported with vSphere 5.5
Prerequisites

- Verify that all requirements are met. See Preparing Your Environment.
- Obtain certificates for each machine on which a vSphere component resides before you install the tool, or use the tool to generate Certificate Signing Requests (CSRs) and obtain certificates from your Certificate Authority. See Generate Certificate Requests and Set Up CA Signed Certificates.

Procedure

1. Download the vCenter Certificate Automation Tool.
   The download is located in the Drivers and Tools section of the VMware vSphere download page.
2. For initial planning, copy the downloaded ZIP file to one machine and generate the Update Planner list.
3. Depending on your deployment, you might copy the downloaded ZIP file to each machine on which a vCenter core component resides.
4. Unzip the file into any directory, preserving the directory structure.

What to do next

You can predefine your preferred default values, see Predefine Default Values for vCenter Certificate Automation Tool, or respond to the prompts when you run the tool.

If a newer version of the tool becomes available, you can download and unzip that version of the tool to a different directory and delete the old version of the tool.

Predefine Default Values for vCenter Certificate Automation Tool

Predefining default values in a configuration file for the tool helps prevent typing errors and saves time. With default values predefined, the tool no longer prompts you for those values. You cannot specify default passwords.

Predefining default values is not required, but might help speed up the process later. If the tool does not encounter defaults, it prompts you.

Prerequisites

- Verify that the vCenter Certificate Automation Tool is not running. The tool reads the values in ssl-environment.bat when you start it.

Procedure

1. Open ssl-environment.bat in a text editor.
Specify parameters that you want to change for each vSphere component that requires updated certificates.

For example, for vCenter Server, you can edit the vc_cert_chain, vc_private_key, and vc_username parameters.

Save and close ssl-environment.bat.

Start the tool.

The tool picks up your default values each time you start it.

Results

The vCenter Certificate Automation Tool saves the information and uses it to automatically prefill required input.

What to do next

Generate certificate requests if necessary, or run the update planner if you deployed on multiple machines to plan your certificate update tasks. See Run the Update Planner.

Generate Certificate Requests and Set Up CA Signed Certificates

If you want to use trusted certificates that are generated by a CA (Certificate Authority), you must create certificate requests and submit them to a CA.

You can create the certificate requests manually, or use the vCenter Certificate Automation Tool to generate certificate requests for each component. See VMware KB article 2061934 for detailed instruction on manual generation and replacement.

For increased security, generate each certificate and private key on the machine where it will be used.

Note This procedure explains how to prepare your CA-signed certificates. The tool also works with self-signed certificates.

Procedure

1. You can use the tool to generate the certificate requests for each of the following services if you are using them in your environment.
   - vCenter Single Sign-On service
   - vCenter Inventory Service
   - vCenter Server
   - vCenter Orchestrator
   - vSphere Web Client
   - vCenter Log Browser
   - vCenter Update Manager
2  Submit the certificate requests to the CA that you are using.
   The CA returns the generated certificates and keys.

3  When you later supply the certificates and keys to the tool, the tool generates the PFX and JKS files that are required by the vCenter Single Sign-On infrastructure and places them in the correct location.

What to do next
- Run the tool to generate update planner information.

Run the Update Planner

The update planner, part of the vCenter Certificate Automation Tool, allows you to determine the correct order for certificate replacement. Follow the steps in the order that the tool recommends for best results.

Procedure
1  Log into a machine on which the vCenter Certificate Automation Tool is installed.

2  From a command line, navigate to the location to which you unzipped the tool and run the following command.

   ```
   ssl-updater.bat
   ```

3  When prompted, select 1. Plan your steps to update SSL certificates.

4  Enter the numbers that correspond to the services that you want to update.
   - To update more than one SSL certificate, separate the numbers with a comma. For example, to update the SSL certificates on vCenter Single Sign-On, vCenter Server, and the vSphere Web Client, type: 1, 3, 4
   - To update the certificate on all services that are supported by the tool, type 8.

The vSphere Web Client and the vCenter Log Browser always run on the same machine.

| Note | Enter all of the services you intend to update. If you leave out some services initially and run the Update Planner again later, the steps might be incorrect and the update might fail. |

The Update Planner displays the tasks to perform and the order to perform them in.

5  Save the Update Planner output to a text file.

Sample output for an environment where all certificates will be replaced is shown below.

1. Go to the machine with Single Sign-On installed and
   - Update the Single Sign-On SSL certificate.

2. Go to the machine with Inventory Service installed and
   - Update Inventory Service trust to Single Sign-On.

3. Go to the machine with Inventory Service installed and
- Update the Inventory Service SSL certificate.

4. Go to the machine with vCenter Server installed and
- Update vCenter Server trust to Single Sign-On.

5. Go to the machine with vCenter Server installed and
- Update the vCenter Server SSL certificate.

6. Go to the machine with vCenter Server installed and
- Update vCenter Server trust to Inventory Service.

7. Go to the machine with Inventory Service installed and
- Update the Inventory Service trust to vCenter Server.

8. Go to the machine with vCenter Orchestrator installed and
- Update vCenter Orchestrator trust to Single Sign-On.

9. Go to the machine with vCenter Orchestrator installed and
- Update vCenter Orchestrator trust to vCenter Server.

10. Go to the machine with vCenter Orchestrator installed and
- Update the vCenter Orchestrator SSL certificate.

11. Go to the machine with vSphere Web Client installed and
- Update vSphere Web Client trust to Single Sign-On.

12. Go to the machine with vSphere Web Client installed and
- Update vSphere Web Client trust to Inventory Service.

13. Go to the machine with vSphere Web Client installed and
- Update vSphere Web Client trust to vCenter Server.

14. Go to the machine with vSphere Web Client installed and
- Update the vSphere Web Client SSL certificate.

15. Go to the machine with Log Browser installed and
- Update the Log Browser trust to Single Sign-On.

16. Go to the machine with Log Browser installed and
- Update the Log Browser SSL certificate.

17. Go to the machine with vSphere Update Manager installed and
- Update the vSphere Update Manager SSL certificate.

18. Go to the machine with vSphere Update Manager installed and
- Update vSphere Update Manager trust to vCenter Server.

Type 9 to return to the main menu.

What to do next

Update certificates and trusts. See Run the Tool to Update SSL Certificates and Trusts.
Run the Tool to Update SSL Certificates and Trusts

After you obtain the SSL certificates and you generate the list of update steps, you can run the tool to replace the existing certificates, reestablish trust, and optionally restart some of the services.

See Certificate Automation Tool Deployment Options for an overview of how the tool proceeds in different deployments.

The tool gives you a list of update tasks and specifies the machine on which to perform each task. If you select a task, the tool prompts for input to perform that task. For example, to update the Inventory Service, you select Inventory Service from the menu. The tool prompts you for information that it requires to update the Inventory Service Trust to Single Sign-On, and to update the Inventory Service SSL Certificate options.

Perform the tasks in sequence. If the update planner instructs you to perform tasks on multiple machines, keep the tool running on each machine to avoid entering information again.

Procedure

1. Move to the first machine on the task list and start the tool by running `ssl-updater.bat`.
   - The tool does not list machines by name but points you to the machine on which a service is running.

2. Select Update SSL certificate.

3. When prompted, specify the service whose certificate you want to update.
   - If you prespecified the default, the tool does not prompt you.
     - To update multiple SSL certificates, update the certificate for one service and then proceed to the next service on the machine where it is deployed. The SSL certificate for each vSphere component must be unique.

4. When prompted, type the requested information, such as the locations of the new SSL chain and private key, passwords and so on.

5. Continue until you have provided all information.

6. Check the planner for the next step.
   - You might have to deploy and start the tool on a different machine to update some of the services.

7. After you have completed your update plan, you can close the command prompt window to end your session.

Rolling Back Your Updates

Each update operation successfully performs the update for one certificate and key, or fails in a way that preserves the original state. If an update fails, you might need to roll back the failed step.
Before beginning the update process, the vCenter Certificate Automation Tool saves a copy of the existing certificate information in a backup folder, ensuring that you can roll back to the previously used certificate to keep the entire system up and running.

You can use the tool's menu item to let you roll back to the original.

Note After rolling back the vCenter Server certificate, you must update the vCenter Server trust to VMware Update Manager again.

Replace vCenter Server Appliance Certificates

You can replace vCenter Server Appliance certificates. Because the Certificate Automation Tool is supported only on Windows, you must replace the certificates by hand.

Replacing the default SSL certificate and key with a self-signed or CA-signed certificate on vCenter Server Appliance is a manual process. You cannot use the Certificate Automation Tool to update the certificate and key on Linux.

Prerequisites

Obtain certificate files (including the certificate and private key).

Procedure

1. Follow the steps in VMware Knowledge Base article 2057223.

Replace vCenter Server Heartbeat Certificates

If you have a problem with the current certificate, or if your corporate security policy requires doing so, you can replace default vCenter Server Heartbeat certificates.

Prerequisites

1. Install OpenSSL on the system where you intend to replace the certificate.
2. Obtain the certificate files rui.crt, rui.key, and rui.pfx.

Procedure

1. Download the SSLImport.jar utility from the VMware Knowledge Base article Replacing SSL Certificates for vCenter Server Heartbeat 6.x (KB 2013041).
2. Follow the steps in the knowledge base article to replace the certificate.
vSphere Users and Permissions

vCenter Single Sign-On supports authentication, which means it determines whether a user can access vSphere components at all. In addition, each user must be authorized to view or manipulate vSphere objects.

vCenter Server allows fine-grained control over authorization with permissions and roles. Review first the background information about hierarchical inheritance of permissions, permission validation, and related topics. You can then move on to vCenter Server User Management Tasks (Chapter 5 vCenter User Management Tasks).

This chapter includes the following topics:
- Hierarchical Inheritance of Permissions
- Multiple Permission Settings
- Permission Validation
- Using Roles to Assign Privileges
- Best Practices for Roles and Permissions
- Required Privileges for Common Tasks
- Password Requirements
- vCenter Server User Directory Settings

Hierarchical Inheritance of Permissions

When you assign a permission to an object, you can choose whether the permission propagates down the object hierarchy. You set propagation for each permission. Propagation is not universally applied. Permissions defined for a child object always override the permissions that are propagated from parent objects.

The figure illustrates inventory hierarchy and the paths by which permissions can propagate.
Figure 4-1. vSphere Inventory Hierarchy

- root folder
- data center folder
  - data center
    - VM folder
      - template
        - virtual machine
        - vApp
        - vApp
        - vApp
      - virtual machine
    - host folder
      - host
      - resource pool
        - virtual machine
        - virtual machine
        - vApp
    - network folder
      - standard switch
      - VDS
        - datastore
    - datastore folder
      - datastore
      - distributed port group
      - datastore cluster
  - resource pool
  - cluster
Most inventory objects inherit permissions from a single parent object in the hierarchy. For example, a datastore inherits permissions from either its parent datastore folder or parent datacenter. Virtual machines inherit permissions from both the parent virtual machine folder and the parent host, cluster, or resource pool simultaneously. To restrict a user’s privileges on a virtual machine, you must set permissions on both the parent folder and the parent host, cluster, or resource pool for that virtual machine.

To set permissions for a distributed switch and its associated distributed port groups, set permissions on a parent object, such a folder or datacenter. You must also select the option to propagate these permissions to child objects.

Permissions take several forms in the hierarchy:

**Managed entities**

You can define permissions on managed entities.

- Clusters
- Datacenters
- Datastores
- Datastore clusters
- Folders
- Hosts
- Networks (except vSphere Distributed Switches)
- Distributed port groups
- Resource pools
- Templates
- Virtual machines
- vSphere vApps

**Global entities**

Global entities derive permissions from the root vCenter Server system.

- Custom fields
- Licenses
- Roles
- Statistics intervals
- Sessions
Multiple Permission Settings

Objects might have multiple permissions, but only one permission for each user or group. For example, one permission might specify that Group A has Administrator privileges on an object. Another permission might specify that Group B might have Virtual Machine Administrator privileges on the same object.

If an object inherits permissions from two parent objects, the permissions on one object are added to the permissions on the other object. For example, if a virtual machine is in a virtual machine folder and also belongs to a resource pool, that virtual machine inherits all permission settings from both the virtual machine folder and the resource pool.

Permissions applied on a child object always override permissions that are applied on a parent object. See Example 2: Child Permissions Overriding Parent Permissions.

If multiple group permissions are defined on the same object and a user belongs to two or more of those groups, two situations are possible:

- If no permission is defined for the user on that object, the user is assigned the set of privileges assigned to the groups for that object.
- If a permission is defined for the user on that object, the user's permission takes precedence over all group permissions.

Example 1: Inheritance of Multiple Permissions

This example illustrates how an object can inherit multiple permissions from groups that are granted permission on a parent object.

In this example, two permissions are assigned on the same object for two different groups.

- Role 1 can power on virtual machines.
- Role 2 can take snapshots of virtual machines.
- Group A is granted Role 1 on VM Folder, with the permission set to propagate to child objects.
- Group B is granted Role 2 on VM Folder, with the permission set to propagate to child objects.
- User 1 is not assigned specific privileges.

User 1, who belongs to groups A and B, logs on. User 1 can both power on and take snapshots of VM A and VM B.
Example 2: Child Permissions Overriding Parent Permissions

This example illustrates how permissions that are assigned on a child object can override permissions that are assigned on a parent object. You can use this overriding behavior to restrict user access to particular areas of the inventory.

In this example, permissions are defined on two different objects for two different groups.

- Role 1 can power on virtual machines.
- Role 2 can take snapshots of virtual machines.
- Group A is granted Role 1 on VM Folder, with the permission set to propagate to child objects.
- Group B is granted Role 2 on VM B.

User 1, who belongs to groups A and B, logs on. Because Role 2 is assigned at a lower point in the hierarchy than Role 1, it overrides Role 1 on VM B. User 1 can power on VM A, but not take snapshots. User 1 can take snapshots of VM B, but not power it on.
User 1 is granted No Access role on VM Folder.

User 1, who belongs to group A, logs on. The No Access role granted to User 1 on VM Folder overrides the role assigned to the group. User 1 has no access to VM Folder or VMs A and B.

Figure 4-4. Example 3: User Permissions Overriding Group Permissions

Permission Validation

vCenter Server and ESXi hosts that use Active Directory regularly validate users and groups against the Windows Active Directory domain. Validation occurs whenever the host system starts and at regular intervals specified in the vCenter Server settings.

For example, if user Smith was assigned permissions and in the domain the user’s name was changed to Smith2, the host concludes that Smith no longer exists and removes permissions for that user when the next validation occurs.

Similarly, if user Smith is removed from the domain, all permissions are removed when the next validation occurs. If a new user Smith is added to the domain before the next validation occurs, the new user Smith receives all the permissions the old user Smith was assigned.

Using Roles to Assign Privileges

A role is a predefined set of privileges. Privileges define individual rights that a user requires to perform actions and read properties.

When you assign permissions to a user or group, you pair the user or group with a role and associate that pairing with an inventory object. A single user might have different roles for different objects in the inventory. For example, if you have two resource pools in your inventory, Pool A and Pool B, you might assign a particular user the Virtual Machine User role on Pool A and the Read Only role on Pool B. These assignments allow that user to turn on virtual machines in Pool A, but to only view virtual machines in Pool B.

The roles created on a host are separate from the roles created on a vCenter Server system. When you manage a host using vCenter Server, the roles that are created through vCenter Server are available. If you connect directly to the host, the roles created directly on the host are available.

vCenter Server and ESXi hosts provide default system roles and sample roles:

System roles
System roles are permanent. You cannot edit the privileges associated with these roles.

Sample roles

VMware provides sample roles for convenience as guidelines and suggestions. You can modify or remove these roles.

See Roles in vCenter Server and ESXi for information on creating, cloning, and editing roles.

All roles permit the user to schedule tasks by default. Users can schedule only tasks they have permission to perform at the time the tasks are created.

Note Changes to permissions and roles take effect immediately, even if the users involved are logged in. The exception is searches, where permission changes take effect after the user has logged out and logged back in.

Best Practices for Roles and Permissions

Use best practices for roles and permissions to maximize the security and manageability of your vCenter Server environment.

VMware recommends the following best practices when configuring roles and permissions in your vCenter Server environment:

- Where possible, grant permissions to groups rather than individual users.
- Grant permissions only where needed. Using the minimum number of permissions makes it easier to understand and manage your permissions structure.
- If you assign a restrictive role to a group, check that the group does not contain the Administrator user or other users with administrative privileges. Otherwise, you could unintentionally restrict administrators' privileges in parts of the inventory hierarchy where you have assigned that group the restrictive role.
- Use folders to group objects. For example, if you want to grant modify permission to one set of hosts and view permission to another set of hosts to a group of users, place each set of hosts in a folder.
- Use caution when granting a permission at the root vCenter Server level. Users with permissions at the root level have access to global data on vCenter Server, such as roles, custom attributes, vCenter Server settings, and licenses. Changes to licenses and roles propagate to all vCenter Server systems in a Linked Mode group, even if the user does not have permissions on all of the vCenter Server systems in the group.
- In most cases, enable propagation on permissions. This ensures that when new objects are inserted into the inventory hierarchy, they inherit permissions and are accessible to users.
- Use the No Access role to mask specific areas of the hierarchy if you do not want for certain users or groups to have access.
Required Privileges for Common Tasks

Many tasks require permissions on more than one object in the inventory. You can review the privileges required to perform the tasks and, where applicable, the appropriate sample roles.

The following table lists common tasks that require more than one privilege. You can use the Applicable Roles on the inventory objects to grant permission to perform these tasks, or you can create your own roles with the equivalent required privileges.

Table 4-1. Required Privileges for Common Tasks

<table>
<thead>

vSphere Security
### Password Requirements

Password requirements differ for vCenter Server and for ESXi hosts.

#### vCenter Server Passwords

In vCenter Server, password requirements are dictated by vCenter Single Sign-On or by the configured identity source, which can be Active Directory, OpenLDAP, or the local operating system for the vCenter Single Sign-On server. See [Edit the vCenter Single Sign-On Password Policy](#), or see the relevant Active Directory or OpenLDAP documentation.

#### ESXi Passwords

By default, ESXi enforces requirements for user passwords.

Your user password must meet the following length requirements.

- Passwords containing characters from one or two character classes must be at least eight characters long.
- Passwords containing characters from three character classes must be at least seven characters long.
- Passwords containing characters from all four character classes must be at least six characters long.

When you create a password, include a mix of characters from four character classes: lowercase letters, uppercase letters, numbers, and special characters such as an underscore or dash.

---

<table>
<thead>
<tr>
<th>Task</th>
<th>Required Privileges</th>
<th>Applicable Role</th>
</tr>
</thead>
<tbody>
<tr>
<td>On the destination datastore (if different from the source): Datastore.Allocate space</td>
<td>Datastore Consumer or Administrator</td>
<td></td>
</tr>
<tr>
<td>Migrate a virtual machine with Storage vMotion</td>
<td>On the virtual machine or folder of virtual machines: Resource.Migrate powered on virtual machine</td>
<td>Resource Pool Administrator or Administrator</td>
</tr>
<tr>
<td>Datastore.Allocate space</td>
<td></td>
<td>Datastore Consumer or Administrator</td>
</tr>
<tr>
<td>Move a host into a cluster</td>
<td>On the host:</td>
<td>Administrator</td>
</tr>
<tr>
<td>Host.Inventory.Add host to cluster</td>
<td></td>
<td></td>
</tr>
<tr>
<td>On the destination cluster:</td>
<td>Host.Inventory.Add host to cluster</td>
<td>Administrator</td>
</tr>
<tr>
<td>Datastore.Allocate space</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The password cannot contain the words root, admin, or administrator in any form.

**Note** An uppercase character that begins a password does not count toward the number of character classes used. A number that ends a password does not count toward the number of character classes used.

You can also use a passphrase, which is a phrase consisting of at least three words, each of which is 8 to 40 characters long.

**Example: Creating Acceptable ESXi Passwords**

The following password candidates meet the requirements of ESXi.

- xQaTEhbU: Contains eight characters from two character classes.
- xQaT3pb: Contains seven characters from three character classes.
- xQaT3#: Contains six characters from four character classes.

The following password candidates do not meet the requirements of ESXi.

- Xqat3hb: Begins with an uppercase character, reducing the effective number of character classes to two. Eight characters are required when you use only two character classes.
- xQaTEh2: Ends with a number, reducing the effective number of character classes to two. Eight characters are required when you use only two character classes.

**vCenter Server User Directory Settings**

You can limit the number of results returned when you search for users and groups and set a user directory timeout for vCenter Server.

vCenter Server systems that use a directory service regularly validate users and groups against the user directory domain. Validation occurs at regular intervals specified in the vCenter Server settings. For example, if user Smith was assigned permissions and in the domain the user's name was changed to Smith2, the host concludes that Smith no longer exists and removes permissions for that user when the next validation occurs.

Similarly, if user Smith is removed from the domain, all permissions are removed when the next validation occurs. If a new user Smith is added to the domain before the next validation occurs, the new user Smith receives all the permissions the old user Smith was assigned.
vCenter User Management Tasks

Users in the vCenter environment must be authenticated, and they must be authorized to view and change vSphere objects. Administrators perform user management tasks from the vSphere Web Client.

This chapter includes the following topics:

- Managing Permissions for vCenter Components
- Roles in vCenter Server and ESXi
- Adjust the Search List in Large Domains in the vSphere Web Client

Managing Permissions for vCenter Components

Permissions are access roles that consist of a user and the user's assigned role for an object such as a virtual machine or ESXi host. Permissions grant users the right to perform the activities specified by the role on the object to which the role is assigned.

For example, to configure memory for the host, you must grant a role to a user that includes the Host.Configuration.Memory Configuration privilege. By assigning different roles to users for different objects, you control the tasks that users can perform in your vSphere environment.

Users other than root and vpxuser initially have no permissions on any objects, which means they cannot view these objects or perform operations on them. A user with Administrator privileges must assign permissions to these users to allow them to perform tasks.

The list of privileges is the same for ESXi and vCenter Server. See Chapter 11 Defined Privileges for a complete list of privileges.

Multiple Permissions

Many tasks require permissions on more than one object.

Permissions applied on a child object always override permissions that are applied on a parent object. Virtual machine folders and resource pools are equivalent levels in the hierarchy. If you assign propagating permissions to a user or group on a virtual machine's folder and its resource pool, the user has the privileges propagated from the resource pool and from the folder.
If multiple group permissions are defined on the same object and the user belongs to two or more of those groups, two situations are possible:

- If no permission is defined for the user on that object, the user is assigned the set of privileges assigned to the groups for that object.
- If a permission is defined for the user on that object, the user's permission takes precedence over all group permissions.

**Permission Examples**

These rules can help you determine where you must assign permissions to allow particular operations:

- Any operation that consumes storage space, such as creating a virtual disk or taking a snapshot, requires the **Datastore.Allocate Space** privilege on the target datastore, as well as the privilege to perform the operation itself.
- Moving an object in the inventory hierarchy requires appropriate privileges on the object itself, the source parent object (such as a folder or cluster), and the destination parent object.
- Each host and cluster has its own implicit resource pool that contains all the resources of that host or cluster. Deploying a virtual machine directly to a host or cluster requires the **Resource.Assign Virtual Machine to Resource Pool** privilege.

**Assign Permissions in the vSphere Web Client**

After you create users and groups and define roles, you must assign the users and groups and their roles to the relevant inventory objects. You can assign the same permissions at one time on multiple objects by moving the objects to a folder and setting the permissions on the folder.

Permissions assigned from the vSphere Web Client must match permissions, including case, in ActiveDirectory precisely. If you upgraded from earlier versions of vSphere, check for case inconsistencies if you experience problems with groups.

**Prerequisites**

**Permissions.Modify permission** on object whose permissions you want to modify.

**Procedure**

1. Browse to the object in the vSphere Web Client object navigator.
2. Click the **Manage** tab and select **Permissions**.
3. Click **Add Permission**.
4. Click **Add**.
5 Identify the user or group that will have the permission.
   a Select the domain where the user or group is located from the Domain drop-down menu.
   b Type a name in the Search box or select a name from the list.
      The system searches user names, group names, and descriptions.
   c Select the user or group and click Add.
      The name is added to either the Users or Groups list.
   d (Optional) Click Check Names to verify that the user or group exists in the database.
   e Click OK.

6 Select a role from the Assigned Role drop-down menu.
   The roles that are assigned to the object appear in the menu. The privileges contained in the role are listed in the section below the role title.

7 (Optional) Deselect the Propagate to Child Objects check box.
   The role is applied only to the selected object and does not propagate to the child objects.

8 Verify that the users and groups are assigned to the appropriate permissions and click OK.
   The server adds the permission to the list of permissions for the object.
   The list of permissions references all users and groups that have roles assigned to the object and indicates where in the vCenter Server hierarchy the role is assigned.

Change Permissions in the vSphere Web Client

After a user or group and role pair is set for an inventory object, you can change the role paired with the user or group or change the setting of the Propagate check box. You can also remove the permission setting.

Procedure

1 Browse to the object in the vSphere Web Client object navigator.

2 Click the Manage tab and select Permissions.

3 Click the line item to select the user or group and role pair.

4 Click Change role on permission.

5 Select a role for the user or group from the Assigned Role drop-down menu.

6 To propagate the privileges to the children of the assigned inventory object, click the Propagate check box and click OK.
Remove Permissions in the vSphere Web Client

Removing a permission for a user or group does not remove the user or group from the list of those available. It also does not remove the role from the list of available items. It removes the user or group and role pair from the selected inventory object.

Procedure

1. Browse to the object in the vSphere Web Client object navigator.
2. Click the Manage tab and select Permissions.
3. Click the appropriate line item to select the user or group and role pair.
4. Click Remove permission.

Results

vCenter Server removes the permission setting.

Change Permission Validation Settings in the vSphere Web Client

vCenter Server periodically validates its user and group lists against the users and groups in the user directory. It then removes users or groups that no longer exist in the domain. You can disable validation or change the interval between validations.

Procedure

1. Browse to the vCenter Server system in the vSphere Web Client object navigator.
2. Select the Manage tab and click Settings.
3. Click General and click Edit.
4. Select User directory.
5. (Optional) Deselect the Validation check box to disable validation.
   Validation is enabled by default. Users and groups are validated when vCenter Server system starts, even if validation is disabled.
6. (Optional) If validation is enabled, enter a validation period to specify a time, in minutes, between validations.
7. Click OK.

Roles in vCenter Server and ESXi

vCenter Server grants access to an object only to users who are assigned permissions for the object. When you assign a user permissions for the object, you pair the user with a role. A role is a predefined set of privileges.
vCenter Server provides three default roles. You cannot change the privileges associated with the default roles. The default roles are organized as a hierarchy; each role inherits the privileges of the previous role. For example, the Administrator role inherits the privileges of the Read Only role. Roles that you create do not inherit privileges from any of the default roles.

You can create custom roles for vCenter Server and all object it manages, or for individual hosts.

**vCenter Server Custom Roles (Recommended)**

You can create custom roles by using the role-editing facilities in the vSphere Web Client to create privilege sets that match your user needs.

**ESXi Custom Roles**

You can create custom roles for individual hosts by using a CLI or the vSphere Client. Custom host roles are not accessible from vCenter Server.

If you manage ESXi hosts through vCenter Server, maintaining custom roles in both the host and vCenter Server can result in confusion and misuse. In most cases, defining vCenter Server roles is recommended.

**Note** When you add a custom role and do not assign any privileges to it, the role is created as a Read Only role with three system-defined privileges: System.Anonymous, System.View, and System.Read.

### Create a Role in the vSphere Web Client

VMware recommends that you create roles to suit the access control needs of your environment.

If you create or edit a role on a vCenter Server system that is part of a connected group in Linked Mode, the changes that you make are propagated to all other vCenter Server systems in the group. Assignments of roles to specific users and objects are not shared across linked vCenter Server systems.

**Prerequisites**

Verify that you are logged in as a user with Administrator privileges.

**Procedure**

1. Browse to **Administration > Role Manager** in the vSphere Web Client.
2. Select a vCenter Server system from the drop-down menu.
3. Click **Create role action**.
4. Type a name for the new role.
5. Select privileges for the role and click **OK**.
**Edit a Role in the vSphere Web Client**

When you edit a role, you can change the privileges selected for that role. When completed, these privileges are applied to any user or group that is assigned the edited role.

If you create or edit a role on a vCenter Server system that is part of a connected group in Linked Mode, the changes you make are propagated to all other vCenter Server systems in the group. Assignments of roles to specific users and objects are not shared across linked vCenter Server systems.

**Prerequisites**

Verify that you are logged in as a user with Administrator privileges.

**Procedure**

1. Browse to Administration > Role Manager in the vSphere Web Client.
2. Select a vCenter Server system from the drop-down menu.
3. Select a role and click **Edit role action**.
4. Select privileges for the role and click **OK**.

**Clone a Role in the vSphere Web Client**

You can make a copy of an existing role, rename it, and edit it. When you make a copy, the new role is not applied to any users or groups and objects. You must assign the role to users or groups and objects.

If you create or edit a role on a vCenter Server system that is part of a connected group in Linked Mode, the changes you make are propagated to all other vCenter Server systems in the group. Assignments of roles to specific users and objects are not shared across linked vCenter Server systems.

**Prerequisites**

Verify that you are logged in as a user with Administrator privileges.

**Procedure**

1. Browse to Administration > Role Manager in the vSphere Web Client.
2. Select a vCenter Server system from the drop-down menu.
3. Click **Clone role action**.
4. Type a name for the cloned role.
5. Select privileges for the role and click **OK**.
Adjust the Search List in Large Domains in the vSphere Web Client

If you have domains with thousands of users or groups, or if searches take a long time to complete, adjust the search settings.

**Note** This procedure applies only to vCenter Server user lists. ESXi host user lists cannot be searched in the same way.

**Procedure**

1. Browse to the vCenter Server system in the vSphere Web Client object navigator.
2. Select the **Manage** tab and click **Settings**.
3. Click **General** and click **Edit**.
4. Select **User directory**.
5. Change the values as needed.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>User directory timeout</strong></td>
<td>Timeout interval in seconds for connecting to the Active Directory server. This value specifies the maximum amount of time vCenter Server allows a search to run on the selected domain. Searching large domains can take a long time.</td>
</tr>
<tr>
<td><strong>Query limit</strong></td>
<td>Select the checkbox to set a maximum number of users and groups that vCenter Server displays.</td>
</tr>
<tr>
<td><strong>Query limit size</strong></td>
<td>Specifies the maximum number of users and groups vCenter Server displays from the selected domain in the Select Users or Groups dialog box. If you enter 0 (zero), all users and groups appear.</td>
</tr>
</tbody>
</table>

6. Click **OK**.
Securing vCenter Server Systems

Securing vCenter Server includes ensuring security of the host where vCenter Server is running, following best practices for assigning privileges and roles, and verifying the integrity of the clients that connect to vCenter Server.

This chapter includes the following topics:

- Hardening the vCenter Server Host Operating System
- Best Practices for vCenter Server Privileges
- Enable Certificate Checking and Verify Host Thumbprints in the vSphere Web Client
- Removing Expired or Revoked Certificates and Logs from Failed Installations
- Enable SSL Certificate Validation Over Network File Copy
- Limiting vCenter Server Network Connectivity

Hardening the vCenter Server Host Operating System

Protect the host where vCenter Server is running against vulnerabilities and attacks by ensuring that the operating system of the host (Windows or Linux) is as secure as possible.

- Maintain a supported operating system, database, and hardware for the vCenter Server system. If vCenter Server is not running on a supported operating system, it might not run properly, making vCenter Server vulnerable to attacks.
- Keep the vCenter Server system properly patched. By staying up-to-date with operating system patches, the server is less vulnerable to attack.
- Provide operating system protection on the vCenter Server host. Protection includes antivirus and anti-malware software.
- On each Windows computer in the infrastructure, ensure that Remote Desktop (RDP) Host Configuration settings are set to ensure the highest level of encryption according to industry-standard guidelines or internal guidelines.

For operating system and database compatibility information, see the vSphere Compatibility Matrixes.
Best Practices for vCenter Server Privileges

Strictly control vCenter Server administrator privileges to increase security for the system.

- Full administrative rights to vCenter Server should be removed from the local Windows administrator account and granted to a special-purpose local vCenter Server administrator account. Grant full vSphere administrative rights only to those administrators who are required to have it. Do not grant this privilege to any group whose membership is not strictly controlled.

- Avoid allowing users to log in directly to the vCenter Server system. Allow only those users who have legitimate tasks to perform to log into the system and ensure that these events are audited.

- Install vCenter Server using a service account instead of a Windows account. You can use a service account or a Windows account to run vCenter Server. Using a service account allows you to enable Windows authentication for SQL Server, which provides more security. The service account must be an administrator on the local machine.

- Check for privilege reassignment when you restart vCenter Server. If the user or user group that is assigned the Administrator role on the root folder of the server cannot be verified as a valid user or group, the Administrator privileges are removed and assigned to the local Windows Administrators group.

- Grant minimal privileges to the vCenter Server database user. The database user requires only certain privileges specific to database access. In addition, some privileges are required only for installation and upgrade. These can be removed after the product is installed or upgraded.

Restrict Use of the Administrator Privilege

By default, vCenter Server grants full administrator privileges to the administrator of the local system, which can be accessed by domain administrators. To minimize risk of this privilege being abused, remove administrative rights from the local operating system's administrator account and assign these rights to a special-purpose local vSphere administrator account. Use the local vSphere account to create individual user accounts.

Grant the Administrator privilege only to administrators who are required to have it. Do not grant the privilege to any group whose membership is not strictly controlled.

Procedure

1. Create a user account that you will use to manage vCenter Server (for example, vi-admin).
   - Ensure that the user does not belong to any local groups, such as the Administrators group.

2. Log into the vCenter Server system as the local operating system administrator and grant the role of global vCenter Server administrator to the user account you created (for example, vi-admin).

3. Log out of vCenter Server and log in with the user account you created (vi-admin).
4 Verify that the user can perform all tasks available to a vCenter Server administrator.
5 Remove the administrator privileges that are assigned to the local operating system administrator user or group.

**Restrict Use of the Administrator Role**

Secure the vCenter Server Administrator role and assign it only to certain users.

Protect the vCenter Server administrator user from regular use by relying on user accounts associated with specific individuals.

**Prerequisites**
- Create a user account to manage vCenter Server and assign full vCenter Server administrator privileges to the user. See Managing Permissions for vCenter Components.
- Remove vCenter Server administrator privileges from the local operating system administrator.

**Procedure**
1 Log in to the vCenter Server system as the vCenter Server administrator you created (for example, vi-admin).
2 Grant full administrator privileges to the minimum number of individuals required.
3 Log out as the vCenter Server administrator.

**What to do next**
Protect the vCenter Server administrator account password. For example, create a password with two halves, each half of which is known to only one person, or lock a printout of the password in a safe.

**Enable Certificate Checking and Verify Host Thumbprints in the vSphere Web Client**

To prevent man-in-the-middle attacks and to fully use the security that certificates provide, certificate checking is enabled by default. You can verify that certificate checking is enabled in the vSphere Web Client.

**Note** vCenter Server certificates are preserved across upgrades.

**Procedure**
1 Browse to the vCenter Server system in the vSphere Web Client object navigator.
2 Select the Manage tab, click Settings, and click General.
3 Click Edit.
4 Click SSL Settings and verify that vCenter requires verified host SSL certificates is selected.
5 If there are hosts that require manual validation, compare the thumbprints listed for the hosts to the thumbprints in the host console.

To obtain the host thumbprint, use the Direct Console User Interface (DCUI).
  a Log in to the direct console and press F2 to access the System Customization menu.
  b Select **View Support Information**.

    The host thumbprint appears in the column on the right.

6 If the thumbprint matches, select the **Verify** check box next to the host.

    Hosts that are not selected will be disconnected after you click **OK**.

7 Click **OK**.

Removing Expired or Revoked Certificates and Logs from Failed Installations

Leaving expired or revoked certificates or leaving vCenter Server installation logs for failed installation on your vCenter Server system can compromise your environment.

Removing expired or revoked certificates is required for the following reasons.

- If expired or revoked certificates are not removed from the vCenter Server system, the environment can be subject to a MiTM attack
- In certain cases, a log file that contains the database password in plain text is created on the system if vCenter Server installation fails. An attacker who breaks into the vCenter Server system, might gain access to this password and, at the same time, access to the vCenter Server database.

Enable SSL Certificate Validation Over Network File Copy

Network File Copy (NFC) provides a file-type-aware FTP service for vSphere components. ESXi uses NFC for operations such as copying and moving data between datastores by default. You can disable and reenable SSL certificate validation for NFC operations.

When SSL over NFC is enabled, connections between vSphere components over NFC are secure. This connection can help prevent man-in-the-middle attacks within a datacenter.

Because using NFC over SSL causes some performance degradation, you might consider disabling this advanced setting in some development environments.

**Procedure**

1 Connect to the vCenter Server with the vSphere Web Client.

2 Select the **Settings** tab, and click **Advanced Settings**.

3 Click **Edit**.
At the bottom of the dialog, enter the following Key and Value.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key</td>
<td>nfc.useSSL</td>
</tr>
<tr>
<td>Value</td>
<td>true</td>
</tr>
</tbody>
</table>

Click **OK**.

**Limiting vCenter Server Network Connectivity**

For improved security, avoid putting the vCenter Server system on any network other than the management network, and ensure that vSphere management traffic is on a restricted network. By limiting network connectivity, you limit certain types of attack.

vCenter Server requires access to the management network only. Avoid putting the vCenter Server system on other networks such as your production network or storage network, or on any network with access to the Internet. vCenter Server does not need access to the network where vMotion operates.

vCenter Server requires network connectivity to the following systems.

- All ESXi hosts.
- The vCenter Server database.
- Other vCenter Server systems (linked mode only)
- Systems that are authorized to run management clients. For example, the vSphere Web Client, a Windows system where you use the PowerCLI, or any other SDK-based client.
- Systems that run add-on components such as VMware vSphere Update Manager.
- Infrastructure services such as DNS, Active Directory, and NTP.
- Other systems that run components that are essential to functionality of the vCenter Server system.

Use a local firewall on the Windows system where vCenter Server system is running or use a network firewall. Include IP-based access restrictions so that only necessary components can communicate with the vCenter Server system.

**Restricting the Use of Linux Clients**

Communications between client components and vCenter Server system or ESXi hosts are protected by SSL-based encryption by default. Linux versions of these components do not perform certificate validation, so you should restrict the use of these clients.
Even if you have replaced the self-signed certificates on the vCenter Server system and the ESXi hosts with legitimate certificates signed by your local root certificate authority or a third party CA, communications with Linux clients are still vulnerable to man-in-the-middle attacks. The following components are vulnerable when they run on the Linux operating system.

- vCLI commands
- vSphere SDK for Perl scripts
- Programs written using the vSphere SDK

You can relax the restriction against using Linux clients if you enforce proper controls.

- Restrict management network access to authorized systems only.
- Use firewalls to ensure that only authorized hosts are allowed to access vCenter Server.
- Use jump-box systems to ensure that Linux clients are behind the jump.

**Verifying the Integrity of the vSphere Web Client**

vSphere Web Client extensions run at the same privilege level as the user who is logged in. A malicious extension can masquerade as a useful plug-in and perform harmful operations such as stealing credentials or changing the system configuration. To increase security, use a vSphere Web Client installation that includes only authorized extensions from trusted sources.

A vCenter installation includes the vSphere Web Client extensibility framework, which provides the ability to extend the vSphere Web Client with menu selections or toolbar icons that provide access to vCenter add-on components or external, Web-based functionality. This flexibility results in a risk of introducing unintended capabilities. For example, if an administrator installs a plug-in in an instance of the vSphere Web Client, the plug-in can then execute arbitrary commands with the privilege level of that administrator.

To protect against potential compromise, do not install any vSphere Web Client plug-ins that do not come from a trusted source.

**Examine Installed Plug-Ins**

vSphere Web Client extensions run at the same privilege level as the user who is logged in. A malicious extension can masquerade as a useful plug-in and perform harmful operations such as stealing credentials or changing the system configuration. To increase security, use a vSphere Web Client installation that includes only authorized extensions from trusted sources.

A vCenter installation includes the vSphere Web Client extensibility framework, which provides the ability to extend the vSphere Web Client with menu selections or toolbar icons that provide access to vCenter add-on components or external, Web-based functionality. This flexibility results in a risk of introducing unintended capabilities. For example, if an administrator installs a plug-in in an instance of the vSphere Web Client, the plug-in can then execute arbitrary commands with the privilege level of that administrator.

To protect against potential compromise of your vSphere Web Client you can periodically examine all installed plug-ins and make sure that all plug-ins come from a trusted source.
Prerequisites

You must have privileges to access the vCenter Single Sign-On server. These privileges differ from vCenter Server privileges.

Procedure

1. Log in to the vSphere Web Client as administrator@vsphere.local or a user with vCenter Single Sign-On privileges.
2. From the Home page, select Administration, and then select Client Plug-Ins under Solutions.
3. Examine the list of client plug-ins.

Remove the tcpdump Package from the vCenter Server Virtual Appliance

By default, the vCenter Server virtual appliance includes the tcpdump package. You can remove that package if security considerations require it.

The tcpdump package allows administrators to analyze TCP packets for troubleshooting and testing. However, in some situations security considerations require a removal of the package. For example, you must remove the package to ensure compliance with GEN003865 in the DIS STIG, run the following command as root to remove the tcpdump package from the system:

Procedure

1. Log in to the vCenter Server Virtual Appliance as root.
2. Run the following command.
   
   `rpm -e tcpdump`
Securing ESXi Hosts

Restricting access to the services and ports on an ESXi host is critical to protecting against unauthorized intrusion in your vSphere environment.

If a host is compromised, the virtual machines on that host are now threatened to be compromised as well. Restrict access to services and ports, an ESXi host is protected with a firewall. Using the ESXi lockdown mode and limiting access to the ESXi Shell can further contribute to a more secure environment.

This chapter includes the following topics:

- General ESXi Security Recommendations
- ESXi Firewall Configuration
- Assigning Permissions for ESXi
- Using Active Directory to Manage ESXi Users
- Replacing ESXi SSL Certificates and Keys
- Uploading an SSH Key to Your ESXi Host
- Using the ESXi Shell
- Lockdown Mode
- Using vSphere Authentication Proxy
- Replace the Authentication Proxy Certificate for the ESXi Host
- Modifying ESXi Web Proxy Settings
- vSphere Auto Deploy Security Considerations
- Managing ESXi Log Files

General ESXi Security Recommendations

To protect the host against unauthorized intrusion and misuse, VMware imposes constraints on several parameters, settings, and activities. You can loosen the constraints to meet your configuration needs. If you do, make sure that you are working in a trusted environment and that
you have taken enough other security measures to protect the network as a whole and the devices connected to the host.

Consider the following recommendations when evaluating host security and administration.

- **Limit user access.**
  
  To improve security, restrict user access to the Direct Console User Interface (DCUI) and the ESXi Shell and enforce access security policies, for example, by setting up password restrictions.
  
  The ESXi Shell has privileged access to certain parts of the host. Provide only trusted users with ESXi Shell login access.

- **Use the vSphere Client to administer standalone ESXi hosts.**
  
  Whenever possible, use the vSphere Client or a third-party network management tool to administer your ESXi hosts instead of working through the command-line interface as the root user. Using the vSphere Client lets you limit the accounts with access to the ESXi Shell, safely delegate responsibilities, and set up roles that prevent administrators and users from using capabilities they do not need.

- **Use the vSphere Web Client to administer ESXi hosts that are managed by a vCenter Server.**
  
  Do not access managed hosts directly with the vSphere Client, and do not make changes to managed hosts from the host’s DCUI.

- **Use only VMware sources to upgrade ESXi components.**
  
  The host runs a variety of third-party packages to support management interfaces or tasks that you must perform. VMware does not support upgrading these packages from anything other than a VMware source. If you use a download or patch from another source, you might compromise management interface security or functions. Regularly check third-party vendor sites and the VMware knowledge base for security alerts.

In addition to implementing the firewall, risks to the hosts are mitigated using other methods.

- **ESXi runs only services essential to managing its functions, and the distribution is limited to the features required to run ESXi.**

- **By default, all ports not specifically required for management access to the host are closed. You must specifically open ports if you need additional services.**

- **By default, weak ciphers are disabled and all communications from clients are secured by SSL. The exact algorithms used for securing the channel depend on the SSL handshake. Default certificates created on ESXi use PKCS#1 SHA-256 With RSA encryption as the signature algorithm.**

- **The Tomcat Web service, used internally by ESXi to support access by Web clients, has been modified to run only those functions required for administration and monitoring by a Web client. As a result, ESXi is not vulnerable to the Tomcat security issues reported in broader use.**
VMware monitors all security alerts that could affect ESXi security and issues a security patch if needed.

Insecure services such as FTP and Telnet are not installed, and the ports for these services are closed by default. Because more secure services such as SSH and SFTP are easily available, always avoid using these insecure services in favor of their safer alternatives. For example, use Telnet with SSL instead of Telnet to access virtual serial ports. If you must use insecure services and have implemented sufficient protection for the host, you must explicitly open ports to support them.

**Note**  Follow the VMware security advisories at [http://www.vmware.com/security/](http://www.vmware.com/security/).

**ESXi Networking Security Recommendations**

Isolation of network traffic is essential to a secure ESXi environment. Different networks require different access and level of isolation.

Your ESXi host uses several networks. Use appropriate security measures for each network, and isolate traffic for specific applications and functions. For example, ensure that vSphere vMotion traffic does not travel over networks where virtual machines are located. Isolation prevents snooping. Having separate networks also is recommended for performance reasons.

- vSphere infrastructure networks are used for features such as VMware vSphere vMotion®, VMware vSphere Fault Tolerance, and storage. These networks are considered to be isolated for their specific functions and often are not routed outside a single physical set of server racks.

- A management network isolates client traffic, command-line interface (CLI) or API traffic, and third-party software traffic from normal traffic. This network should be accessible only by system, network, and security administrators. Use jump box or virtual private network (VPN) to secure access to the management network. Strictly control access within this network to potential sources of malware.

- Virtual machine traffic can flow over one or many networks. You can enhance the isolation of virtual machines by using virtual firewall solutions that set firewall rules at the virtual network controller. These settings travel with a virtual machine as it migrates from host to host within your vSphere environment.

**Disable the Managed Object Browser (MOB)**

The managed object browser provides a way to explore the VMkernel object model. However, attackers can use this interface to perform malicious configuration changes or actions. The managed object browser lets you change the host configuration. This interface is used primarily for debugging the vSphere Web Services SDK.

**Procedure**

1. Connect directly to the host using the ESXi Shell.
2 (Optional) Determine if the managed object browser (MOB) is enabled by running the following command.

```bash
vim-cmd proxysvc/service_list
```

If the service is running, the following text appears in the list of services:

```plaintext
... 
serverNamespace = '/mob',
accessMode = "httpsWithRedirect",
pipeName = "'/var/run/vmware/proxy-mob'',
... 
```

3 Disable the service by running the following command.

```bash
vim-cmd proxysvc/remove_service "mob" "httpsWithRedirect"
```

Changes are effective immediately and persist across reboots.

**Results**

The managed object browser is no longer available for diagnostics. Some third-party tools use this interface to gather information.

**What to do next**

After you disable the managed object browser, perform tests to verify that third-party applications still function as expected.

To reenable the service, run the following command.

```bash
vim-cmd proxysvc/add_np_service "mob" httpsWithRedirect /var/run/vmware/proxy-mob
```

**Disable Authorized (SSH) Keys**

Authorized keys allow you to enable access to an ESXi host through SSH without requiring user authentication. To increase host security, do not allow users to access a host using authorized keys.

A user is considered trusted if their public key is in the `/etc/ssh/keys-root/authorized_keys` file on a host. Trusted remote users are allowed to access the host without providing a password.

**Procedure**

- For day-to-day operations, disable SSH on ESXi hosts.
- If SSH is enabled, even temporarily, monitor the contents of the `/etc/ssh/keys-root/authorized_keys` file to ensure that no users are allowed to access the host without proper authentication.
- Monitor the `/etc/ssh/keys-root/authorized_keys` file to verify that it is empty and no SSH keys have been added to the file.
- If you find that the `/etc/ssh/keys-root/authorized_keys` file is not empty, remove any keys.
Results

Disabling remote access with authorized keys might limit your ability to run commands remotely on a host without providing a valid login. For example, this can prevent you from running an unattended remote script.

Configure SSL Timeouts

You can configure SSL timeouts for ESXi by editing a configuration file on the ESXi host. Timeout periods can be set for two types of idle connections:

- The Read Timeout setting applies to connections that have completed the SSL handshake process with port 443 of ESXi.
- The Handshake Timeout setting applies to connections that have not completed the SSL handshake process with port 443 of ESXi.

Both connection timeouts are set in milliseconds.

Idle connections are disconnected after the timeout period. By default, fully established SSL connections have a timeout of infinity.

**Note** Using a longer timeout than the default is not recommended.

Procedure

1. Log in to the ESXi Shell as a user with administrator privileges.
2. Change to the directory `/etc/vmware/rhttpproxy/`.
3. Use a text editor to open the `config.xml` file.
4. In the `<http>` section, enter the `<readTimeoutMs>` value in milliseconds.
   - If the `<readTimeoutMs>` tag does not exist you can create it.
5. In the `<ssl>` section, enter the `<handshakeTimeoutMs>` value in milliseconds.
   - If the `<handshakeTimeoutMs>` tag does not exist you can create it.
6. Save your changes and close the file.
7. Restart the `rhttpproxy` process:
   ```bash
   /etc/init.d/rhttpproxy restart
   ```

Example: Configuration File

The following section from the file `/etc/vmware/rhttpproxy/config.xml` shows where to add the SSL timeout settings.

```xml
<vmacore>
  ...
  <http>
    ...
    <readTimeoutMs>20000</readTimeoutMs>
```
Check the Acceptance Levels of Hosts and VIBs

To protect the integrity of the ESXi host, do not allow users to install unsigned (community-supported) VIBs. An unsigned VIB contains code that is not certified by, accepted by, or supported by VMware or its partners. Community-supported VIBs do not have a digital signature.

You can use ESXCLI commands to set an acceptance level for a host. The host's acceptance level must be the same or less restrictive than the acceptance level of any VIB you want to add to the host. To protect the security and integrity of your ESXi hosts, do not allow unsigned (CommunitySupported) VIBs to be installed on hosts in production systems.

The following acceptance levels are supported.

**VMwareCertified**

The VMwareCertified acceptance level has the most stringent requirements. VIBs with this level go through thorough testing fully equivalent to VMware in-house Quality Assurance testing for the same technology. Today, only IOVP drivers are published at this level. VMware takes support calls for VIBs with this acceptance level.

**VMwareAccepted**

VIBs with this acceptance level go through verification testing, but the tests do not fully test every function of the software. The partner runs the tests and VMware verifies the result. Today, CIM providers and PSA plugins are among the VIBs published at this level. VMware directs support calls for VIBs with this acceptance level to the partner's support organization.

**PartnerSupported**

VIBs with the PartnerSupported acceptance level are published by a partner that VMware trusts. The partner performs all testing. VMware does not verify the results. This level is used for a new or nonmainstream technology that partners want to enable for VMware systems. Today, driver VIB technologies such as Infiniband, ATAoE, and SSD are at this level with nonstandard hardware drivers. VMware directs support calls for VIBs with this acceptance level to the partner's support organization.

**CommunitySupported**
The Community Supported acceptance level is for VIBs created by individuals or companies outside of VMware partner programs. VIBs at this level have not gone through any VMware-approved testing program and are not supported by VMware Technical Support or by a VMware partner.

Procedure

1. Connect to each ESXi host and verify that the acceptance level is set to VMwareCertified or VMwareAccepted by running the following command.

   ```
esxcli software acceptance get
   ```

2. If the host acceptance level is not VMwareCertified or VMwareAccepted, determine whether any of the VIBs are not at the VMwareCertified or VMwareAccepted level by running the following commands.

   ```
esxcli software vib list
   esxcli software vib get -n vibname
   ```

3. Remove any VIBs that are at the PartnerSupported or CommunitySupported level by running the following command.

   ```
esxcli software vib remove --vibname vib
   ```

4. Change the acceptance level of the host by running the following command.

   ```
esxcli software acceptance set --level acceptance_level
   ```

Add an ESXi Host to an Active Directory Domain

Because ESXi does not support vCenter Single Sign-On, it does not support the identity sources you set up with vCenter Single Sign-On. You can add an ESXi host to an Active Directory Domain from the vSphere Web Client.

Procedure

1. In the vSphere Web Client, select the ESXi host.

2. In the Settings tab, select Authentication Services in the System area.

3. Click Join Domain, supply the domain settings, and click OK.

PCI and PCIe Devices and ESXi

Using the VMware DirectPath I/O feature to pass through a PCI or PCIe device to a virtual machine results in a potential security vulnerability. The vulnerability can be triggered by buggy or malicious code, such as a device driver, running in privileged mode in the guest OS. Industry-standard hardware and firmware does not currently have sufficient error containment support to make it possible for ESXi to fully close the vulnerability.
VMware recommends that you use PCI or PCIe passthrough to a virtual machine only if the virtual machine is owned and administered by a trusted entity. You must be sure that this entity does not attempt to crash or exploit the host from the virtual machine.

Your host might be compromised in one of the following ways.

- The guest OS might generate an unrecoverable PCI or PCIe error. Such an error does not corrupt data, but can crash the ESXi host. Such errors might occur because of bugs or incompatibilities in the hardware devices that are being passed through, or because of problems with drivers in the guest OS.

- The guest OS might generate a Direct Memory Access (DMA) operation that causes an IOMMU page fault on the ESXi host, for example, if the DMA operation targets an address outside the virtual machine's memory. On some machines, host firmware configures IOMMU faults to report a fatal error through a non-maskable interrupt (NMI), which causes the ESXi host to crash. This problem might occur because of problems with the drivers in the guest OS.

- If the operating system on the ESXi host is not using interrupt remapping, the guest OS might inject a spurious interrupt into the ESXi host on any vector. ESXi currently uses interrupt remapping on Intel platforms where it is available; interrupt mapping is part of the Intel VT-d feature set. ESXi does not use interrupt mapping on AMD platforms. A spurious interrupt most likely results in a crash of the ESXi host; however, other ways to exploit these interrupts might exist in theory.

### ESXi Firewall Configuration

ESXi includes a firewall between the management interface and the network. The firewall is enabled by default.

At installation time, the ESXi firewall is configured to block incoming and outgoing traffic, except traffic for the default services listed in TCP and UDP Ports.

**Note**  The firewall also allows Internet Control Message Protocol (ICMP) pings and communication with DHCP and DNS (UDP only) clients.

You can manage ESXi firewall ports as follows:

- From the security profile for each host.

- Using ESXCLI commands to modify firewall rules, from the command line or in scripts. See ESXi Firewall Configuration.
Using a custom VIB if the port you want to open is not included in the security profile. You create custom VIBs with the vibauthor tool available from VMware Labs. To install the custom VIB, you have to change the acceptance level of the the ESXi host to CommunitySupported. See VMware Knowledge Base Article 2007381.

**Note** If you engage VMware Technical Support to investigate a problem on an ESXi host with a CommunitySupported VIB installed, VMware Support might request that this CommunitySupported VIB be uninstalled as a troubleshooting step to determine if that VIB is related to the problem being investigated.

You can view supported services and management agents that are required to operate the host in the host's Security Profile section in the vSphere Web Client.

**Note** The behavior of the NFS Client rule set (nfsClient) is different from other rule sets. When the NFS Client rule set is enabled, all outbound TCP ports are open for the destination hosts in the list of allowed IP addresses. See NFS Client Rule Set Behavior for more information.

### Manage ESXi Firewall Settings

You can configure incoming and outgoing firewall connections for a service or a management agent from the vSphere Web Client or at the command line.

**Note** If different services have overlapping port rules, enabling one service might implicitly enable overlapping services. You can specify which IP addresses are allowed to access each service on the host to avoid this problem.

#### Procedure

1. Browse to the host in the vSphere Web Client inventory.
2. Click the Manage tab and click Settings.
3. Click Security Profile.
   - The vSphere Web Client displays a list of active incoming and outgoing connections with the corresponding firewall ports.
4. In the Firewall section, click Edit.
   - The display shows firewall rule sets, which include the name of the rule and the associated information.
5. Select the rule sets to enable, or deselect the rule sets to disable.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Incoming Ports and Outgoing Ports</td>
<td>The ports that the vSphere Web Client opens for the service</td>
</tr>
<tr>
<td>Protocol</td>
<td>Protocol that a service uses.</td>
</tr>
<tr>
<td>Daemon</td>
<td>Status of daemons associated with the service</td>
</tr>
</tbody>
</table>
For some services, you can manage service details.

- Use the **Start**, **Stop**, or **Restart** buttons to change the status of a service temporarily.
- Change the Startup Policy to have the service start with the host or with port usage.

For some services, you can explicitly specify IP addresses from which connections are allowed.

See [Add Allowed IP Addresses in the vSphere Web Client](#).

Click **OK**.

**Add Allowed IP Addresses in the vSphere Web Client**

By default, the firewall for each service allows access to all IP addresses. To restrict traffic, change each service to allow traffic only from your management subnet. You might also deselect some services if your environment does not use them.

You can use the vSphere Web Client, vCLI, or PowerCLI to update the Allowed IP list for a service. By default, all IP addresses are allowed.

**Procedure**

1. Browse to the host in the vSphere Web Client inventory.
2. Click the **Manage** tab and click **Settings**.
3. Under System, click **Security Profile**.
4. In the Firewall section, click **Edit** and select a service from the list.
5. In the Allowed IP Addresses section, deselect **Allow connections from any IP address** and enter the IP addresses of networks that are allowed to connect to the host.

Separate IP addresses with commas. You can use the following address formats:

- 192.168.0.0/24
- 192.168.1.2, 2001::1/64
- fd3e:29a6:0a81:e478::/64

6. Click **OK**.

**NFS Client Rule Set Behavior**

The NFS Client rule set behaves differently than other ESXi firewall rule sets. ESXi configures NFS Client settings when you mount or unmount an NFS datastore.

When you add or mount an NFS datastore, ESXi checks the state of the NFS Client (nfsClient) firewall rule set.

- If the NFS Client rule set is disabled, ESXi enables the rule set and disables the Allow All IP Addresses policy by setting the `allowedAll` flag to FALSE. The IP address of the NFS server is added to the allowed list of outgoing IP addresses.
If the NFS Client rule set is enabled, the state of the rule set and the allowed IP address policy are not changed. The IP address of the NFS server is added to the allowed list of outgoing IP addresses.

When you remove or unmount an NFS datastore, ESXi performs one of the following actions.

- If ESXi is mounted on any NFS datastore, the IP address of the unmounted NFS server is removed from the list of allowed outgoing IP addresses and the NFS Client rule set remains enabled.
- If ESXi is not mounted on any NFS datastore, the IP address of the unmounted NFS server is removed from the list of allowed outgoing IP addresses and the NFS Client rule set is disabled.

**Note** If you manually enable the NFS Client rule set or manually set the Allow All IP Addresses policy, either before or after you add an NFS datastore to the system, your settings are overridden when the last NFS datastore is unmounted. The NFS Client rule set is disabled when all NFS datastores are unmounted.

### Automating Service Behavior Based on Firewall Settings

ESXi can automate whether services start based on the status of firewall ports.

Automation helps ensure that services start if the environment is configured to enable their function. For example, starting a network service only if some ports are open can help avoid the situation where services are started, but are unable to complete the communications required to complete their intended purpose.

In addition, having accurate information about the current time is a requirement for some protocols, such as Kerberos. The NTP service is a way of getting accurate time information, but this service only works when required ports are opened in the firewall. The service cannot achieve its goal if all ports are closed. The NTP services provide an option to configure the conditions when the service starts or stops. This configuration includes options that account for whether firewall ports are opened, and then start or stop the NTP service based on those conditions. Several possible configuration options exist, all of which are also applicable to the SSH server.

**Note** The settings described in this section only apply to service settings configured through the vSphere Web Client or applications created with the vSphere Web services SDK. Configurations made through other means, such as the ESXi Shell or configuration files in `/etc/init.d/`, are not affected by these settings.

- **Start automatically if any ports are open, and stop when all ports are closed**: The default setting for these services that VMware recommends. If any port is open, the client attempts to contact the network resources pertinent to the service in question. If some ports are open, but the port for a particular service is closed, the attempt fails, but there is little drawback to such a case. If and when the applicable outgoing port is opened, the service begins completing its tasks.
- **Start and stop with host**: The service starts shortly after the host starts and closes shortly before the host shuts down. Much like **Start automatically if any ports are open, and stop when all ports are closed**, this option means that the service regularly attempts to complete its tasks, such as contacting the specified NTP server. If the port was closed but is subsequently opened, the client begins completing its tasks shortly thereafter.

- **Start and stop manually**: The host preserves the user-determined service settings, regardless of whether ports are open or not. When a user starts the NTP service, that service is kept running as long as the host is powered on. If the service is started and the host is powered off, the service is stopped as part of the shutdown process, but as soon as the host is powered on, the service is started again, preserving the user-determined state.

**Note** ESXi firewall automates when rule sets are enabled or disabled based on the service startup policy. When a service starts, its corresponding rule set is enabled. When a service stops, the rule set is disabled.

---

**ESXi Firewall Commands**

You can configure the ESXi firewall at the command line.

**Firewall Configuration Using the ESXi Shell**

The vSphere Web Client graphical user interface provides the preferred means of performing many configuration tasks. However, you can use the ESXi Shell or vSphere CLI commands to configure ESXi at the command line if necessary. See *Getting Started with vSphere Command-Line Interfaces*

**Table 7-1. Firewall Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>esxcli network firewall get</td>
<td>Returns the enabled or disabled status of the firewall and lists default actions.</td>
</tr>
<tr>
<td>esxcli network firewall set --default-action</td>
<td>Set to true to set the default action to pass, set to fals to set the default action to drop.</td>
</tr>
<tr>
<td>esxcli network firewall set --enabled</td>
<td>Enable or disable the ESXi firewall.</td>
</tr>
<tr>
<td>esxcli network firewall load</td>
<td>Load the firewall module and rule set configuration files.</td>
</tr>
<tr>
<td>esxcli network firewall refresh</td>
<td>Refresh the firewall configuration by reading the rule set files if the firewall module is loaded.</td>
</tr>
<tr>
<td>esxcli network firewall unload</td>
<td>Destroy filters and unload the firewall module.</td>
</tr>
<tr>
<td>esxcli network firewall ruleset list</td>
<td>List rule sets information.</td>
</tr>
<tr>
<td>esxcli network firewall ruleset set --allowed-all</td>
<td>Set to true to allow all access to all IPs, set to false to use a list of allowed IP addresses.</td>

### Assigning Permissions for ESXi

For ESXi, permissions are defined as access roles that consist of a user and the user's assigned role for an object such as a virtual machine or ESXi host. Permissions grant users the right to perform the activities specified by the role on the object to which the role is assigned.

The *vSphere Single Host Management* document explains how you can perform permission validation and assign and remove permissions with the vSphere Client. This document discusses the different types of permissions.

### Specify Users with DCUI Access in Lockdown Mode

You can specify which users can log into a host that is in lockdown mode. DCUI Access users do not need to have full administrative privileges on the host. You grant the DCUI Access privilege in Advanced Settings in the vSphere Web Client.

In versions of vSphere earlier than vSphere 5.1, the root user can log into the DCUI on a host that is in lockdown mode. In vSphere 5.1, you can specify which local ESXi users are allowed to log in to the DCUI when the host is in lockdown mode. These special users do not need to have full administrative privileges on the host. Specifying users other than the anonymous root user allows you to log which users have performed operations on the host while it is in lockdown mode.

**Important** When you disable lockdown mode using the DCUI, all users with the DCUI Access privilege are granted the Administrator role on the host.

**Procedure**

1. Browse to the host in the vSphere Web Client object navigator.
2. Click the Manage tab and select Settings.
3. Click Advanced System Settings and select the setting DCUI.Access.
4. Click Edit and enter the user names, separated by commas.
   - By default, the root user is specified. You can remove root from the list of DCUI access users, as long as you specified at least one other user.
5. Click OK.
Multiple Permission Settings

Objects might have multiple permissions, but only one permission for each user or group. For example, one permission might specify that Group A has Administrator privileges on an object. Another permission might specify that Group B might have Virtual Machine Administrator privileges on the same object.

If an object inherits permissions from two parent objects, the permissions on one object are added to the permissions on the other object. For example, if a virtual machine is in a virtual machine folder and also belongs to a resource pool, that virtual machine inherits all permission settings from both the virtual machine folder and the resource pool.

Permissions applied on a child object always override permissions that are applied on a parent object. See Example 2: Child Permissions Overriding Parent Permissions.

If multiple group permissions are defined on the same object and a user belongs to two or more of those groups, two situations are possible:

- If no permission is defined for the user on that object, the user is assigned the set of privileges assigned to the groups for that object.
- If a permission is defined for the user on that object, the user's permission takes precedence over all group permissions.

Example 1: Inheritance of Multiple Permissions

This example illustrates how an object can inherit multiple permissions from groups that are granted permission on a parent object.

In this example, two permissions are assigned on the same object for two different groups.

- Role 1 can power on virtual machines.
- Role 2 can take snapshots of virtual machines.
- Group A is granted Role 1 on VM Folder, with the permission set to propagate to child objects.
- Group B is granted Role 2 on VM Folder, with the permission set to propagate to child objects.
- User 1 is not assigned specific privileges.

User 1, who belongs to groups A and B, logs on. User 1 can both power on and take snapshots of VM A and VM B.
Example 2: Child Permissions Overriding Parent Permissions

This example illustrates how permissions that are assigned on a child object can override permissions that are assigned on a parent object. You can use this overriding behavior to restrict user access to particular areas of the inventory.

In this example, permissions are defined on two different objects for two different groups.

- Role 1 can power on virtual machines.
- Role 2 can take snapshots of virtual machines.
- Group A is granted Role 1 on VM Folder, with the permission set to propagate to child objects.
- Group B is granted Role 2 on VM B.

User 1, who belongs to groups A and B, logs on. Because Role 2 is assigned at a lower point in the hierarchy than Role 1, it overrides Role 1 on VM B. User 1 can power on VM A, but not take snapshots. User 1 can take snapshots of VM B, but not power it on.
User 1 is granted No Access role on VM Folder.

User 1, who belongs to group A, logs on. The No Access role granted to User 1 on VM Folder overrides the role assigned to the group. User 1 has no access to VM Folder or VMs A and B.

Figure 7-3. Example 3: User Permissions Overriding Group Permissions

root User Permissions

Create a non-root user account for local admin access.

By default each ESXi host has a single root user account with full administrator privileges that can be used for local administration and to connect the host to vCenter Server. Sharing a common root account can make it easier to break into an ESXi host.

Create at least one named user account and assign it full administrative privileges and use this account instead of the root account. Set a highly complex password for the root account and limit the use of the root account. (Do not remove the root user itself.)

**Important** If you remove the access permissions for the root user, you must first create another permission at the root level that has a different user assigned to the Administrator role.

**Note** In vSphere 5.1 and later, only the root user and no other user with administrator privileges is permitted to add a host to vCenter Server.

Assigning the Administrator role to a different user helps you maintain security through traceability. The vSphere Client logs all actions that the Administrator role user initiates as events, providing you with an audit trail. If all administrators log in as the root user, you cannot tell which administrator performed an action. If you create multiple permissions at the root level—each associated with a different user—you can track the actions of each administrator.

**vpxuser Permissions**

The vpxuser permission is used for vCenter Server when managing activities for the host.

vCenter Server has Administrator privileges on the host that it manages. For example, vCenter Server can move virtual machines to and from hosts and perform configuration changes needed to support virtual machines.
The vCenter Server administrator can perform most of the same tasks on the host as the root user and also schedule tasks, work with templates, and so forth. However, the vCenter Server administrator cannot directly create, delete, or edit local users and groups for hosts. These tasks can only be performed by a user with Administrator permissions directly on each host.

**Note**  You cannot manage the vpxuser using Active Directory.

**Caution**  Do not change vpxuser in any way. Do not change its password. Do not change its permissions. If you do so, you might experience problems when working with hosts through vCenter Server.

**Ensure that vpxuser Password Meets Policy**

When you add a host to the vCenter Server inventory, vCenter Server creates a special user account called vpxuser on the host. vpxuser is a privileged account that acts as a proxy for all actions initiated through vCenter Server. Ensure that the default settings for the vpxuser password meet the requirements of your organization's password policy.

By default, vCenter Server generates a new vpxuser password every 30 days using OpenSSL crypto libraries as a source of randomness. The password is 32 characters long and is guaranteed to contain at least one symbol from four character classes: symbols (-/:=@\^\_-{}~), digits (1-9), uppercase letters, and lowercase letters. Ensuring that the password expires periodically limits the amount of time an attacker can use the vpxuser password if it is compromised.

You can change the default value for password expiration and for password length to meet your password policy. Using shorter passwords and allowing less frequent password changes makes your environment less secure.

**Important**  To preclude the possibility that vCenter Server is locked out of the ESXi host, the password aging policy must not be shorter than the interval that is set to automatically change the vpxuser password.

**Procedure**

1. To change the password length policy, edit the vpxd.hostPasswordLength parameter in the vCenter Server configuration file on the system where vCenter Server is running.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Default Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows</td>
<td>C:\Documents and Settings\All Users\Application Data\VMware VirtualCenter\vpxd.cfg</td>
</tr>
<tr>
<td>Linux</td>
<td>/etc/vmware-vpx/vpxd.cfg</td>
</tr>
</tbody>
</table>
2  To change the password aging requirement, use the Advanced Settings dialog box in the vSphere Web Client.
   a  Browse to the vCenter Server system in the vSphere Web Client inventory.
   b  Click the Manage tab and click Settings.
   c  Select Advanced Settings
   d  Click Edit and locate the VirtualCenter.VimPasswordExpirationInDays parameter.
   e  Type the new value and click OK.
3  Restart vCenter Server.

dcui User Permissions

The dcui user runs on hosts and acts with Administrator rights. This user’s primary purpose is to configure hosts for lockdown mode from the Direct Console User Interface (DCUI).

This user acts as an agent for the direct console and cannot be modified or used by interactive users.

Using Active Directory to Manage ESXi Users

You can configure ESXi to use a directory service such as Active Directory to manage users. Creating local user accounts on each host presents challenges with having to synchronize account names and passwords across multiple hosts. Join ESXi hosts to an Active Directory domain to eliminate the need to create and maintain local user accounts. Using Active Directory for user authentication simplifies the ESXi host configuration and reduces the risk for configuration issues that could lead to unauthorized access.

When you use Active Directory, users supply their Active Directory credentials and the domain name of the Active Directory server when adding a host to a domain.

Configure a Host to Use Active Directory in the vSphere Web Client

You can configure a host to use a directory service such as Active Directory to manage users and groups.

When you add an ESXi host to Active Directory all user and group accounts are assigned full administrative access to the host if the group ESX Admins exists. If you do not want to make full administrative access available, see VMware Knowledge Base article 1025569 for a workaround.

Note  When you define user account settings in Active Directory, you can limit the computers that a user can log in to by the computer name. By default, no equivalent restrictions are set on a user account. If you set this limitation, LDAP Bind requests for the user account fail with the message LDAP binding not successful, even if the request is from a listed computer. You can avoid this issue by adding the netBIOS name for the Active Directory server to the list of computers that the user account can log in to.
Prerequisites

- Verify that you have an Active Directory domain. See your directory server documentation.
- Verify that the host name of ESXi is fully qualified with the domain name of the Active Directory forest.

\[ \text{fully qualified domain name} = \text{host_name} \cdot \text{domain_name} \]

Procedure

1. Synchronize the time between ESXi and the directory service system using NTP. See the VMware Knowledge Base for information about how to synchronize ESXi time with a Microsoft Domain Controller.

2. Ensure that the DNS servers you configured for the host can resolve the host names for the Active Directory controllers.
   a. Browse to the host in the vSphere Web Client object navigator.
   b. Click the Manage tab and click Networking.
   c. Click DNS, and verify that the host name and DNS server information for the host are correct.

What to do next

Use the vSphere Web Client to join a directory service domain.

Add a Host to a Directory Service Domain in the vSphere Web Client

To use a directory service, you must join the host to the directory service domain.

You can enter the domain name in one of two ways:

- \( \text{name.tld} \) (for example, \( \text{domain.com} \)): The account is created under the default container.
- \( \text{name.tld/container/path} \) (for example, \( \text{domain.com/OU1/OU2} \)): The account is created under a particular organizational unit (OU).

To use the vSphere Authentication Proxy service, see Use vSphere Authentication Proxy to Add a Host to a Domain in the vSphere Web Client.

Procedure

1. Browse to the host in the vSphere Web Client inventory.
2. Click the Manage tab and click Settings.
4. Click Join Domain.
5. Enter a domain.
   Use the form \( \text{name.tld} \) or \( \text{name.tld/container/path} \).
Enter the user name and password of a directory service user who has permissions to join the host to the domain, and click OK.

Click OK to close the Directory Services Configuration dialog box.

View Directory Service Settings in the vSphere Web Client

You can view the type of directory server, if any, the host uses to authenticate users and the directory server settings.

Procedure

1. Browse to the host in the vSphere Web Client inventory.
2. Click the Manage tab and click Settings.
   The Authentication Services page displays the directory service and domain settings.

Replacing ESXi SSL Certificates and Keys

Your company's security policy might require that you replace the default ESXi SSL certificate with a trusted certificate on each host. You can also regenerate a self-signed certificate and key if the default certificate and key were accidentally deleted.

SSL certificates are used to vouch for the identity of the components involved in the communication and to secure communication between vSphere components.

By default, vSphere components use the self-signed certificate and key that are created during installation. Self-signed certificates are as secure as certificates that are issued by an external Certificate Authority as long as the user validates the certificate and its thumbprint when the warning dialog appears.

Replace self-signed certificates with certificates from a trusted CA, either a commercial CA or an organizational CA, if company policy requires it. Consider also replacing certificates to avoid having users get used to clicking through browser warnings. The warning might be an indication of a man-in-the-middle attack, and only inspection of the certificate and thumbprint can guard against such attacks.

You can replace the default certificates with trusted certificates in a number of ways.

- Replace a Default ESXi Certificate and Key from the ESXi Shell
- Replace a Default ESXi Certificate and Key by Using the vifs Command
- Replace a Default ESXi Certificate and Key Using HTTPS PUT

If you accidentally deleted the default self-signed certificate and key or you changed the host name, you can generate a new self-signed certificate and key from the ESXi Shell. See Generate New Self-Signed Certificates for ESXi.
Preparing Your Environment for ESXi Certificate Replacement

If you plan to replace the default certificate and key with a certificate and key from a certificate authority, ensure that your environment has the required software installed.

Your environment does not have to meet these requirements if you use self-signed certificates.

- Microsoft CA (2000 or higher), with Web Server template
- Microsoft Visual C++ 2008 Redistributable Package (x86) installed on the system where you will generate the certificate-signing request
- OpenSSL 0.98r or higher installed on the system where you will generate the certificate-signing request
- Putty or other SSH client (recommended)
- WinSCP or other SFTP/SCP client
- vCenter Server
- ESXi 5.1 or later

Generate New Self-Signed Certificates for ESXi

You typically generate new certificates only if you change the host name or accidentally delete the certificate. Under certain circumstances, you must force the host to generate new certificates.

Note To receive the full benefit of certificate checking, particularly if you intend to use encrypted remote connections externally, do not use a self signed certificate. Instead, install new certificates that are signed by a valid internal certificate authority or purchase a certificate from a trusted security authority.

Procedure

1. Log in to the ESXi Shell as a user with administrator privileges.
2. In the directory /etc/vmware/ssl, back up any existing certificates by renaming them using the following commands.
   ```
   mv rui.crt orig.rui.crt
   mv rui.key orig.rui.key
   ```
   Note If you are regenerating certificates because you have deleted them, this step is unnecessary.
3. Run the command /sbin/generate-certificates to generate new certificates.
4 Restart the host.

Generating the certificates places them in the correct location. You can alternatively put the host into maintenance mode, install the new certificate, and then use the Direct Console User Interface (DCUI) to restart the management agents.

5 Confirm that the host successfully generated new certificates by using the following command and comparing the time stamps of the new certificate files with `orig.rui.crt` and `orig.rui.key`.

```
ls -la
```

What to do next

Consider replacing the self-signed certificate and key with a trusted certificate and key.

Replace a Default ESXi Certificate and Key from the ESXi Shell

ESXi uses automatically generated certificates that are created as part of the installation process. These certificates are unique and make it possible to begin using the server, but they are not verifiable and they are not signed by a trusted certificate authority (CA). This topic explains how to replace the default certificates with self-signed or CA-signed certificates.

Using default certificates might not comply with the security policy of your organization. If you require a certificate from a trusted certificate authority, you can replace the default certificate.

**Note** If the host has Verify Certificates enabled, replacing the default certificate might cause vCenter Server to stop managing the host. Disconnect and reconnect the host if vCenter Server cannot verify the new certificate.

ESXi supports only X.509 certificates to encrypt session information sent over SSL connections between server and client components.

**Prerequisites**

- If you want to use CA-signed certificates, generate the certificate request, send it to the certificate authority, and store the certificates you receive in a location that the host can access.
- If necessary, enable the ESXi Shell or enable SSH traffic from the vSphere Web Client. See [Use the vSphere Web Client to Enable Access to the ESXi Shell](#).
- All file transfers and other communications occur over a secure HTTPS session. The user who is used to authenticate the session must have the privilege `Host.Config.AdvancedConfig` on the host. For more information on ESXi privileges, see the [vSphere Single Host Management](#) publication.

**Procedure**

1 Log in to the ESXi Shell, either directly from the DCUI or from an SSH client, as a user with administrator privileges.
2 In the directory `/etc/vmware/ssl`, rename the existing certificates using the following commands.

```bash
mv rui.crt orig.rui.crt
mv rui.key orig.rui.key
```

3 Copy the certificates you want to use to `/etc/vmware/ssl`.

4 Rename the new certificate and key to `rui.crt` and `rui.key`.

5 Restart the host after you install the new certificate.

Alternatively, you can put the host into maintenance mode, install the new certificate, use the Direct Console User Interface (DCUI) to restart the management agents, and set the host to exit maintenance mode.

Replace a Default ESXi Certificate and Key by Using the vifs Command

ESXi uses automatically generated certificates that are created as part of the installation process. These certificates are unique and make it possible to begin using the server, but they are not verifiable and they are not signed by a trusted certificate authority (CA).

Using default certificates might not comply with the security policy of your organization. If you require a certificate from a trusted certificate authority, you can replace the default certificate.

**Note** If the host has Verify Certificates enabled, replacing the default certificate might cause vCenter Server to stop managing the host. Disconnect and reconnect the host if vCenter Server cannot verify the new certificate.

ESXi supports only X.509 certificates to encrypt session information sent over SSL connections between server and client components.

**Prerequisites**

All file transfers and other communications occur over a secure HTTPS session. The user who is used to authenticate the session must have the privilege `Host.Config.AdvancedConfig` on the host. For more information on ESXi privileges, see the *vSphere Single Host Management* publication.

**Procedure**

1 Back up the existing certificates.

2 Generate a certificate request following the instructions from the certificate authority.

3 At the command line, use the vifs command to upload the certificate to the appropriate location on the host.

```bash
vifs --server hostname --username username --put rui.crt /host/ssl_cert
vifs --server hostname --username username --put rui.key /host/ssl_key
```
4 Restart the host.

Alternatively, you can put the host into maintenance mode, install the new certificate, and then use the Direct Console User Interface (DCUI) to restart the management agents.

**Replace a Default ESXi Certificate and Key Using HTTPS PUT**

You can use third-party applications to upload certificates and key. Applications that support HTTPS PUT operations work with the HTTPS interface that is included with ESXi.

**Procedure**

1 In your upload application, open the file.

2 Publish the file to one of these locations.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Certificates</td>
<td><a href="https://hostname/host/ssl_cert">https://hostname/host/ssl_cert</a></td>
</tr>
<tr>
<td>Keys</td>
<td><a href="https://hostname/host/ssl_key">https://hostname/host/ssl_key</a></td>
</tr>
</tbody>
</table>

The location `/host/ssl_cert` and `host/ssl_key` link to the certificate files in `/etc/vmware/ssl`.

3 In the Direct Console User Interface (DCUI), use the Restart Management Agents operation to initiate the settings.

**Uploading an SSH Key to Your ESXi Host**

You can use SSH keys to restrict, control, and secure access to an ESXi host. By using an SSH key, you can allow trusted users or scripts to log in to a host without specifying a password.

You can copy the SSH key to the host by using the vifs vSphere CLI command. See *Getting Started with vSphere Command-Line Interfaces* for information on installing and using the vSphere CLI command set. It is also possible to use HTTPS PUT to copy the SSK key to the host.

Instead of generating the keys externally and uploading them, you can create the keys on the the ESXi host and download them. See VMware Knowledge Base article 1002866.

Enabling SSH and adding SSH keys to the host has inherent risks and is not recommended in a hardened environment. See Disable Authorized (SSH) Keys.

**Note** For ESXi 5.0 and earlier, a user with an SSH key can access the host even when the host is in lockdown mode. This is fixed in ESXi 5.1.
Upload an SSH Key Using a vifs Command

If you decide you want to use authorized keys to log in to a host with SSH, you can upload authorized keys with a vifs command.

**Note** Because authorized keys allow SSH access without requiring user authentication, consider carefully whether you want to use SSH keys in your environment.

Authorized keys allow you to authenticate remote access to a host. When users or scripts try to access a host with SSH, the key provides authentication without a password. With authorized keys you can automate authentication, which is useful when you write scripts to perform routine tasks.

You can upload the following types of SSH keys to a host.

- Authorized keys file for root user
- RSA key
- RSA public key

Starting with the vSphere 6.0 Update 2 release, DSS/DSA keys are no longer supported.

**Important** Do not modify the `/etc/ssh/sshd_config` file.

**Procedure**

- At the command line or an administration server, use the vifs command to upload the SSH key to appropriate location on the ESXi host.

  ```
  vifs --server hostname --username username --put filename /host/ssh_host_dsa_key_pub
  ```

<table>
<thead>
<tr>
<th>Type of key</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authorized key files for the root user</td>
<td><code>/host/ssh_root_authorized_keys</code></td>
</tr>
<tr>
<td></td>
<td>You must have full administrator privileges to upload this file.</td>
</tr>
<tr>
<td>RSA keys</td>
<td><code>/host/ssh_host_rsa_key</code></td>
</tr>
<tr>
<td>RSA public keys</td>
<td><code>/host/ssh_host_rsa_key_pub</code></td>
</tr>
</tbody>
</table>

Upload an SSH Key Using HTTPS PUT

You can use authorized keys to log in to a host with SSH. You can upload authorized keys with HTTPS PUT.

Authorized keys allow you to authenticate remote access to a host. When users or scripts try to access a host with SSH, the key provides authentication without a password. With authorized keys you can automate authentication, which is useful when you write scripts to perform routine tasks.
You can upload the following types of SSH keys to a host using HTTPS PUT:

- Authorized keys file for root user
- DSA key
- DSA public key
- RSA key
- RSA public key

**Important** Do not modify the `/etc/ssh/sshd_config` file.

**Procedure**

1. In your upload application, open the key file.
2. Publish the file to the following locations.

<table>
<thead>
<tr>
<th>Type of key</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authorized key files for the root user</td>
<td>https://hostname_or_IP_address/host/ssh_root_authorized_keys</td>
</tr>
<tr>
<td></td>
<td>You must have full administrator privileges on the host to upload this file.</td>
</tr>
<tr>
<td>DSA keys</td>
<td>https://hostname_or_IP_address/host/ssh_host_dsa_key</td>
</tr>
<tr>
<td>DSA public keys</td>
<td>https://hostname_or_IP_address/host/ssh_host_dsa_key_pub</td>
</tr>
<tr>
<td>RSA keys</td>
<td>https://hostname_or_IP_address/host/ssh_host_rsa_key</td>
</tr>
<tr>
<td>RSA public keys</td>
<td>https://hostname_or_IP_address/host/ssh_host_rsa_key_pub</td>
</tr>
</tbody>
</table>

**Using the ESXi Shell**

The ESXi Shell (formerly Tech Support Mode or TSM) is disabled by default on ESXi. You can enable local and remote access to the shell if necessary.

Enable the ESXi Shell for troubleshooting only. The ESXi Shell can be enabled and disabled whether or not the host is running in lockdown mode.

**ESXi Shell**

- Enable this service to access the ESXi Shell locally.

**SSH**

- Enable this service to access the ESXi Shell remotely using SSH.

**Direct Console UI (DCUI)**

When you enable this service while running in lockdown mode, you can log in locally to the direct console user interface as the root user and disable lockdown mode. You can then access the host using a direct connection to the vSphere Client or by enabling the ESXi Shell.
The root user and users with the Administrator role can access the ESXi Shell. Users who are in the Active Directory group ESX Admins are automatically assigned the Administrator role. By default, only the root user can execute system commands (such as vmware -v) using the ESXi Shell.

**Note**  Do not enable the ESXi Shell until it is required.

- **Use the vSphere Web Client to Enable Access to the ESXi Shell**
  You can use the vSphere Web Client to enable local and remote (SSH) access to the ESXi Shell and to set the idle timeout and availability timeout.

- **Use the Direct Console User Interface (DCUI) to Enable Access to the ESXi Shell**
  The Direct Console User Interface (DCUI) allows you to interact with the host locally using text-based menus. Evaluate carefully whether the security requirements of your environment support enabling the Direct Console User Interface.

- **Log in to the ESXi Shell for Troubleshooting**
  Perform ESXi configuration tasks with the vSphere Web Client. the vSphere CLI, or vSphere PowerCLI. Log in to the ESXi Shell (formerly Tech Support Mode or TSM) for troubleshooting purposes only.

- **SSH Security**
  You can use SSH to remotely log in to the ESXi Shell and perform troubleshooting tasks for the host.

**Use the vSphere Web Client to Enable Access to the ESXi Shell**

You can use the vSphere Web Client to enable local and remote (SSH) access to the ESXi Shell and to set the idle timeout and availability timeout.

**Note**  Access the host by using the vSphere Web Client, remote command-line tools (vCLI and PowerCLI), and published APIs. Do not enable remote access to the host using SSH unless special circumstances require that you enable SSH access.

**Prerequisites**

If you want to use an authorized SSH key, you can upload it. See [Uploading an SSH Key to Your ESXi Host](#).

**Procedure**

1. Browse to the host in the vSphere Web Client inventory.
2. Click the **Manage** tab and click **Settings**.
3. Under System, select **Security Profile**.
4. In the Services panel, click **Edit**.
5 Select a service from the list.
   - ESXi Shell
   - SSH
   - Direct Console UI

6 Click Service Details and select the startup policy **Start and stop manually**.
   When you select **Start and stop manually**, the service does not start when you reboot the host. If you want the service to start when you reboot the host, select **Start and stop with host**.

7 Select **Start** to enable the service.

8 Click **OK**.

**What to do next**

Set the availability and idle timeouts for the ESXi Shell. See [Create a Timeout for ESXi Shell Availability in the vSphere Web Client](#) and [Create a Timeout for Idle ESXi Shell Sessions in the vSphere Web Client](#)

### Create a Timeout for ESXi Shell Availability in the vSphere Web Client

The ESXi Shell is disabled by default. You can set an availability timeout for the ESXi Shell to increase security when you enable the shell.

The availability timeout setting is the amount of time that can elapse before you must log in after the ESXi Shell is enabled. After the timeout period, the service is disabled and users are not allowed to log in.

**Procedure**

1 Browse to the host in the vSphere Web Client inventory.
2 Click the **Manage** tab and click **Settings**.
3 Under System, select **Advanced System Settings**.
4 Select UserVars.ESXiShellTimeOut and click the **Edit** icon.
5 Enter the idle timeout setting.
   You must restart the SSH service and the ESXi Shell service for the timeout to take effect.
6 Click **OK**.

**Results**

If you are logged in when the timeout period elapses, your session will persist. However, after you log out or your session is terminated, users are not allowed to log in.
Create a Timeout for Idle ESXi Shell Sessions in the vSphere Web Client

If a user enables the ESXi Shell on a host, but forgets to log out of the session, the idle session remains connected indefinitely. The open connection can increase the potential for someone to gain privileged access to the host. You can prevent this by setting a timeout for idle sessions.

The idle timeout is the amount of time that can elapse before a user is logged out of an idle interactive session. You can control the amount of time for both local and remote (SSH) session from the Direct Console Interface (DCUI) or from the vSphere Web Client.

Procedure

1. Browse to the host in the vSphere Web Client inventory.
2. Click the Manage tab and click Settings.
4. Select UserVars.ESXiShellInteractiveTimeOut, click the Edit icon, and enter the timeout setting.
5. Restart the ESXi Shell service and the SSH service for the timeout to take effect.

Results

If the session is idle, users are logged out after the timeout period elapses.

Use the Direct Console User Interface (DCUI) to Enable Access to the ESXi Shell

The Direct Console User Interface (DCUI) allows you to interact with the host locally using text-based menus. Evaluate carefully whether the security requirements of your environment support enabling the Direct Console User Interface.

You can use the Direct Console User Interface to enable local and remote access to the ESXi Shell.

Note  Changes made to the host using the Direct Console User Interface, the vSphere Web Client, ESXCLI, or other administrative tools are committed to permanent storage every hour or upon graceful shutdown. Changes might be lost if the host fails before they are committed.

Procedure

1. From the Direct Console User Interface, press F2 to access the System Customization menu.
2. Select Troubleshooting Options and press Enter.
3. From the Troubleshooting Mode Options menu, select a service to enable.
   - Enable ESXi Shell
   - Enable SSH
4. Press Enter to enable the service.
5 Press Esc until you return to the main menu of the Direct Console User Interface.

What to do next

Set the availability and idle timeouts for the ESXi Shell. See Create a Timeout for ESXi Shell Availability in the Direct Console User Interface and Create a Timeout for Idle ESXi Shell Sessions.

Create a Timeout for ESXi Shell Availability in the Direct Console User Interface

The ESXi Shell is disabled by default. You can set an availability timeout for the ESXi Shell to increase security when you enable the shell.

The availability timeout setting is the amount of time that can elapse before you must log in after the ESXi Shell is enabled. After the timeout period, the service is disabled and users are not allowed to log in.

Procedure

1 From the Troubleshooting Mode Options menu, select Modify ESXi Shell and SSH timeouts and press Enter.

2 Enter the availability timeout.

   You must restart the SSH service and the ESXi Shell service for the timeout to take effect.

3 Press Enter and press Esc until you return to the main menu of the Direct Console User Interface.

4 Click OK.

Results

If you are logged in when the timeout period elapses, your session will persist. However, after you log out or your session is terminated, users are not allowed to log in.

Create a Timeout for Idle ESXi Shell Sessions

If a user enables the ESXi Shell on a host, but forgets to log out of the session, the idle session remains connected indefinitely. The open connection can increase the potential for someone to gain privileged access to the host. You can prevent this by setting a timeout for idle sessions.

The idle timeout is the amount of time that can elapse before the user is logged out of an idle interactive sessions. Changes to the idle timeout apply the next time a user logs in to the ESXi Shell and do not affect existing sessions.

You can specify the timeout from the Direct Console User Interface in seconds, or from the vSphere Web Client in minutes.

Procedure

1 From the Troubleshooting Mode Options menu, select Modify ESXi Shell and SSH timeouts and press Enter.
2 Enter the idle timeout, in seconds.
   You must restart the SSH service and the ESXi Shell service for the timeout to take effect.
3 Press Enter and press Esc until you return to the main menu of the Direct Console User Interface.

Results
If the session is idle, users are logged out after the timeout period elapses.

Log in to the ESXi Shell for Troubleshooting
Perform ESXi configuration tasks with the vSphere Web Client. the vSphere CLI, or vSphere PowerCLI. Log in to the ESXi Shell (formerly Tech Support Mode or TSM) for troubleshooting purposes only.

Procedure
1 Log in to the ESXi Shell using one of the following methods.
   - If you have direct access to the host, press Alt+F1 to open the login page on the machine's physical console.
   - If you are connecting to the host remotely, use SSH or another remote console connection to start a session on the host.
2 Enter a user name and password recognized by the host.

SSH Security
You can use SSH to remotely log in to the ESXi Shell and perform troubleshooting tasks for the host.
SSH configuration in ESXi is enhanced to provide a high security level.

Version 1 SSH protocol disabled
VMware does not support Version 1 SSH protocol and uses Version 2 protocol exclusively. Version 2 eliminates certain security problems present in Version 1 and provides you with a safe way to communicate with the management interface.

Improved cipher strength
SSH supports only 256-bit and 128-bit AES ciphers for your connections.
These settings are designed to provide solid protection for the data you transmit to the management interface through SSH. You cannot change these settings.
Lockdown Mode

To increase the security of your ESXi hosts, you can put them in lockdown mode. In lockdown mode, all operations must be performed through vCenter Server. Only the vpxuser user has authentication permissions, no other users can perform operations against the host directly.

When a host is in lockdown mode, you cannot run vSphere CLI commands from an administration server, from a script, or from vMA against the host. External software or management tools might not be able to retrieve or modify information from the ESXi host.

**Note** Users can be assigned DCUI access privileges explicitly via the DCUI Access advanced configuration option. The option has DCUI.Access as the key, and a comma-separated list of ESXi users as the value. Users in the list which can access the DCUI at any time, even if these users are not administrators (Admin role), and even when the host is in lockdown mode.

Enabling or disabling lockdown mode affects which types of users are authorized to access host services, but it does not affect the availability of those services. In other words, if the ESXi Shell, SSH, or Direct Console User Interface (DCUI) services are enabled, they will continue to run whether or not the host is in lockdown mode.

You can enable lockdown mode using the **Add Host** wizard to add a host to vCenter Server, using the vSphere Web Client to manage a host, or using the Direct Console User Interface (DCUI).

**Note** If you enable or disable lockdown mode using the Direct Console User Interface (DCUI), permissions for users and groups on the host are discarded. To preserve these permissions, you must enable and disable lockdown mode using the vSphere Web Client connected to vCenter Server.

Lockdown mode is available only on ESXi hosts that have been added to vCenter Server.

Lockdown Mode Behavior

Enabling lockdown mode affects which users are authorized to access host services.

**Users Logged in When Lockdown Mode Is Enabled**

Users who were logged in to the ESXi Shell before lockdown mode was enabled remain logged in and can run commands. However, these users cannot disable lockdown mode. No other users, including the root user and users with the Administrator role on the host, can use the ESXi Shell to log in to a host that is in lockdown mode.

**Access Through vCenter Server**

Users with administrator privileges on the vCenter Server system can use the vSphere Web Client to disable lockdown mode for hosts that are managed by the vCenter Server system.
Access From the DCUI

Users granted the DCUI Access privilege can always log directly into the host using the Direct Console User Interface (DCUI) to disable lockdown mode, even if the user does not have the Administrator role on the host. You must use Advanced Settings to grant the DCUI Access privilege.

**Note** When you disable lockdown mode using the DCUI, all users with the DCUI Access privilege are granted the Administrator role on the host.

Root users or users with the Administrator role on the host cannot log directly into the host with the DCUI if they have not been granted the DCUI Access privilege. If the host is not managed by vCenter Server or if the host is unreachable, only DCUI Access users can log into the DCUI and disable lockdown mode. If the DCUI service is stopped, you must reinstall ESXi.

Lockdown Mode Services for Different Users

The following table shows the services that are available to different types of users when the host is running in lockdown mode and in normal mode. As a rule, changes can be made only through vCenter Server. The root user can make changes from the Direct Console Interface, but not from the ESXi Shell or through an SSH session.

<table>
<thead>
<tr>
<th>Service</th>
<th>Normal Mode</th>
<th>Lockdown Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere WebServices API</td>
<td>All users, based on ESXi permissions</td>
<td>vCenter only (vpxuser)</td>
</tr>
<tr>
<td>CIM Providers</td>
<td>Root users and users with Admin role on the host</td>
<td>vCenter only (ticket)</td>
</tr>
<tr>
<td>Direct Console UI (DCUI)</td>
<td>Root users and users with Admin role on the host</td>
<td>Root users</td>
</tr>
<tr>
<td>ESXi Shell</td>
<td>Root users and users with Admin role on the host</td>
<td>No users</td>
</tr>
<tr>
<td>SSH</td>
<td>Root users and users with Admin role on the host</td>
<td>No users</td>
</tr>
</tbody>
</table>

Enable Lockdown Mode Using the vSphere Web Client

Enable lockdown mode to require that all configuration changes go through vCenter Server. You can also enable or disable lockdown mode through the Direct Console User Interface (DCUI).

**Procedure**

1. Browse to the host in the vSphere Web Client inventory.
2. Click the **Manage** tab and click **Settings**.
3. Under System, select **Security Profile**.
4. In the Lockdown Mode panel, click **Edit**.
5  Select **Enable Lockdown Mode**.

6  Click **OK**.

### Enable Lockdown Mode from the Direct Console User Interface

You can enable lockdown mode from the Direct Console User Interface (DCUI).

**Note**  If you enable or disable lockdown mode using the Direct Console User Interface, permissions for users on the host are discarded. To preserve these permissions, you must enable and disable lockdown mode using a vSphere Web Client connected to vCenter Server.

#### Procedure

1. At the Direct Console User Interface of the host, press F2 and log in.
2. Scroll to the **Configure Lockdown Mode** setting and press Enter.
3. Press Esc until you return to the main menu of the Direct Console User Interface.

### Specify Users with DCUI Access in Lockdown Mode

You can specify which users can log into a host that is in lockdown mode. DCUI Access users do not need to have full administrative privileges on the host. You grant the DCUI Access privilege in Advanced Settings in the vSphere Web Client.

In versions of vSphere earlier than vSphere 5.1, the root user can log into the DCUI on a host that is in lockdown mode. In vSphere 5.1, you can specify which local ESXi users are allowed to log in to the DCUI when the host is in lockdown mode. These special users do not need to have full administrative privileges on the host. Specifying users other than the anonymous root user allows you to log which users have performed operations on the host while it is in lockdown mode.

**Important**  When you disable lockdown mode using the DCUI, all users with the DCUI Access privilege are granted the Administrator role on the host.

#### Procedure

1. Browse to the host in the vSphere Web Client object navigator.
2. Click the **Manage** tab and select **Settings**.
3. Click **Advanced System Settings** and select the setting **DCUI.Access**.
4. Click **Edit** and enter the user names, separated by commas.
   
   By default, the root user is specified. You can remove root from the list of DCUI access users, as long as you specified at least one other user.

5. Click **OK**.
Using vSphere Authentication Proxy

When you use the vSphere Authentication Proxy, you do not need to transmit Active Directory credentials to the host. Users supply the domain name of the Active Directory server and the IP address of the authentication proxy server when they add a host to a domain.

Install the vSphere Authentication Proxy Service

To use the vSphere Authentication Proxy service for authentication, you must install the service on a host machine.

You can install the vSphere Authentication Proxy on the same machine as the associated vCenter Server, or on a different machine that has a network connection to the vCenter Server. The vSphere Authentication Proxy is not supported with vCenter Server versions earlier than version 5.0.

The vSphere Authentication Proxy service binds to an IPv4 address for communication with vCenter Server, and does not support IPv6. vCenter Server can be on an IPv4-only, IPv4/IPv6 mixed-mode, or IPv6-only host machine, but the machine that connects to vCenter Server through the vSphere Client must have an IPv4 address for the vSphere Authentication Proxy service to work.

Prerequisites

- Verify that you have administrator privileges on the host machine where you install the vSphere Authentication Proxy service.
- Verify that the host machine has Windows Installer 3.0 or later.
- Verify that the host machine has a supported processor and operating system. The vSphere Authentication Proxy supports the same processors and operating systems as vCenter Server.
- Verify that the host machine has a valid IPv4 address. You can install vSphere Authentication Proxy on an IPv4-only or IPv4/IPv6 mixed-mode host machine, but you cannot install vSphere Authentication Proxy on an IPv6-only host machine.
- If you are installing vSphere Authentication Proxy on a Windows Server 2008 R2 host machine, download and install the Windows hotfix described in Windows KB Article 981506 on the support.microsoft.com Web site. If this hotfix is not installed, the Authentication Proxy Adapter fails to initialize. This problem is accompanied by error messages in camadapter.log similar to Failed to bind CAM website with CTL and Failed to initialize CAMAdapter.

Gather the following information to complete the installation:

- The location where you will install the vSphere Authentication Proxy, if you are not using the default location.
- The IP address or host name, HTTP port, and credentials for the vCenter Server system that the vSphere Authentication Proxy will connect to.
The host name or IP address to identify the vSphere Authentication Proxy host machine on the network.

### Procedure

1. On the host machine where you will install the vSphere Authentication Proxy service, install the .NET Framework 3.5.
2. Install vSphere Auto Deploy.
   
   You do not have to install Auto Deploy on the same host machine as the vSphere Authentication Proxy service.
3. Add the host machine where you will install the authentication proxy service to the domain.
4. Use the Domain Administrator account to log in to the host machine.
5. In the software installer directory, double-click the autorun.exe file to start the installer.
6. Select **VMware vSphere Authentication Proxy** and click **Install**.
7. Follow the wizard prompts to complete the installation.
   
   During installation, the authentication service registers with the vCenter Server instance where Auto Deploy is registered.

### Results

The authentication proxy service is installed on the host machine.

- **Note** When you install the vSphere Authentication Proxy service, the installer creates a domain account with appropriate privileges to run the authentication proxy service. The account name begins with the prefix CAM- and has a 32-character, randomly generated password associated with it. The password is set to never expire. Do not change the account settings.

### What to do next

Configure the host to use the authentication proxy service to join the domain.

**Configure a Host to Use the vSphere Authentication Proxy for Authentication**

After you install the vSphere Authentication Proxy service (CAM service), you must configure the host to use the authentication proxy server to authenticate users.

- **Prerequisites**

  Install the vSphere Authentication Proxy service (CAM service) on a host as described in [Install the vSphere Authentication Proxy Service](#).
Procedure

1. Use the IIS manager on the host to set up the DHCP range.

   Setting the range allows hosts that are using DHCP in the management network to use the authentication proxy service.

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>For IIS 6</td>
<td>a. Browse to <strong>Computer Account Management Web Site</strong>.</td>

</tr>
</tbody>
</table>

**Authenticating vSphere Authentication Proxy to ESXi**

Before you use the vSphere Authentication Proxy to connect ESXi to a domain, you must authenticate the vSphere Authentication Proxy server to ESXi. If you use Host Profiles to connect a domain with the vSphere Authentication Proxy server, you do not need to authenticate the server. The host profile authenticates the proxy server to ESXi.

To authenticate ESXi to use the vSphere Authentication Proxy, export the server certificate from the vSphere Authentication Proxy system and import it to ESXi. You need only authenticate the server once.

**Note** By default, ESXi must authenticate the vSphere Authentication Proxy server when using it to join a domain. Make sure that this authentication functionality is enabled at all times. If you must disable authentication, you can use the Advanced Settings dialog box to set the `UserVars.ActiveDirectoryVerifyCAMCertificate` attribute to 0.
Export vSphere Authentication Proxy Certificate

To authenticate the vSphere Authentication Proxy to ESXi, you must provide ESXi with the proxy server certificate.

Prerequisites

Install the vSphere Authentication Proxy service on a host as described in Install the vSphere Authentication Proxy Service.

Procedure

1. On the authentication proxy server system, use the IIS Manager to export the certificate.

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>For IIS 6</td>
<td>a. Right-click Computer Account Management Web Site.</td>
</tr>
<tr>
<td>For IIS 7</td>
<td>a. Click Computer Account Management Web Site in the left pane.</td>
</tr>
<tr>
<td></td>
<td>b. Select Bindings to open the Site Bindings dialog box.</td>
</tr>
<tr>
<td></td>
<td>c. Select https binding.</td>
</tr>
<tr>
<td></td>
<td>d. Select Edit &gt; View SSL Certificate.</td>
</tr>
</tbody>
</table>

2. Select Details > Copy to File.

3. Select the options Do Not Export the Private Key and Base-64 encoded X.509 (CER).

What to do next

Import the certificate to ESXi.

Import a Proxy Server Certificate to ESXi in the vSphere Web Client

To authenticate the vSphere Authentication Proxy server to ESXi, upload the proxy server certificate to ESXi.

You use the vSphere Web Client user interface to upload the vSphere Authentication Proxy server certificate to ESXi.

Prerequisites

Install the vSphere Authentication Proxy service on a host as described in Install the vSphere Authentication Proxy Service.

Export the vSphere Authentication Proxy server certificate as described in Export vSphere Authentication Proxy Certificate.
Procedure

1. Upload the certificate for the authentication proxy server to a temporary location accessible to the host.
   a. In the vSphere Web Client, browse to a datastore accessible to the host and click the Manage tab.
   b. Click Files and click Upload File.

2. Browse to the certificate and select Open.
   To upload or download files from a datastore, you must have the Client Integration Plug-in installed on the system where you use the vSphere Web Client.

3. Browse to the host and click the Manage tab.

4. Select the Configuration tab and click Authentication Services.

5. Click Import Certificate.

6. Enter the full path to the authentication proxy server certificate file on the host and the IP address of the authentication proxy server.
   Use the form [datastore name] file path to enter the path to the proxy server.

7. Click Import.

What to do next

Set up the host to use vSphere Authentication Proxy server to authenticate users.

Use vSphere Authentication Proxy to Add a Host to a Domain in the vSphere Web Client

When you join a host to a directory service domain, you can use the vSphere Authentication Proxy server for authentication instead of transmitting user-supplied Active Directory credentials.

You can enter the domain name in one of two ways:

- name.tld (for example, domain.com): The account is created under the default container.
- name.tld/container/path (for example, domain.com/OU1/OU2): The account is created under a particular organizational unit (OU).

Prerequisites

- Connect to a vCenter Server system with the vSphere Web Client.
- If ESXi is configured with a DHCP address, set up the DHCP range.
- If ESXi is configured with a static IP address, verify that its associated profile is configured to use the vSphere Authentication Proxy service to join a domain so that the authentication proxy server can trust the ESXi IP address.
If ESXi is using a self-signed certificate, verify that the host has been added to vCenter Server. This allows the authentication proxy server to trust ESXi.

If ESXi is using a CA-signed certificate and is not provisioned by Auto Deploy, verify that the CA certificate has been added to the local trust certificate store of the authentication proxy server as described in Configure a Host to Use the vSphere Authentication Proxy for Authentication.

Authenticate the vSphere Authentication Proxy server to the host.

**Procedure**

1. Browse to the host in the vSphere Web Client and click the Manage tab.
2. Click Settings and select Authentication Services.
3. Click Join Domain.
4. Enter a domain.
   - Use the form name.tld or name.tld/container/path.
5. Select Using Proxy Server.
6. Enter the IP address of the authentication proxy server.
7. Click OK.

Replace the Authentication Proxy Certificate for the ESXi Host

You can import a certificate from a trusted certificate authority from the vSphere Web Client

**Prerequisites**

- Upload the authentication proxy certificate file to the ESXi host.

**Procedure**

1. In the vSphere Web Client, select the ESXi host.
2. In the Settings tab, select Authentication Services in the System area.
3. Click Import Certificate.
4. Enter the SSL certificate path and the vSphere Authentication Proxy server.
Modifying ESXi Web Proxy Settings

When you modify Web proxy settings, you have several encryption and user security guidelines to consider.

**Note**  Restart the host process after making any changes to host directories or authentication mechanisms.

- Do not set up certificates using a password or pass phrases. ESXi does not support passwords or pass phrases, also known as encrypted keys. If you set up a pass word or pass phrase, ESXi processes cannot start correctly.

- You can configure the Web proxy so that it searches for certificates in a location other than the default location. This capability proves useful for companies that prefer to centralize their certificates on a single machine so that multiple hosts can use the certificates.

**Caution**  If certificates are not stored locally on the host—for example, if they are stored on an NFS share—the host cannot access those certificates if ESXi loses network connectivity. As a result, a client connecting to the host cannot successfully participate in a secure SSL handshake with the host.

- To support encryption for user names, passwords, and packets, SSL is enabled by default for vSphere Web services SDK connections. If you want to configure the these connections so that they do not encrypt transmissions, disable SSL for your vSphere Web Services SDK connection by switching the connection from HTTPS to HTTP.

  Consider disabling SSL only if you created a fully trusted environment for these clients, where firewalls are in place and transmissions to and from the host are fully isolated. Disabling SSL can improve performance, because you avoid the overhead required to perform encryption.

- To protect against misuse of ESXi services, most internal ESXi services are accessible only through port 443, the port used for HTTPS transmission. Port 443 acts as a reverse proxy for ESXi. You can see a list of services on ESXi through an HTTP welcome page, but you cannot directly access the Storage Adapters services without proper authorization.

  You can change this configuration so that individual services are directly accessible through HTTP connections. Do not make this change unless you are using ESXi in a fully trusted environment.

- When you upgrade vCenter Server, the certificate remains in place.

**Change Security Settings for a Web Proxy Service**

You can change the security configuration so that individual services are directly accessible through HTTP connections.

To configure security settings for vSphere 5.0 and earlier, see Change Security Settings for a Web Proxy Service 5.0 and earlier.
Procedure

1. Log in to the ESXi Shell as a user with administrator privileges.
2. Change to the /etc/vmware/rhttpproxy directory.
3. Use a text editor to open the endpoints.conf file.
4. Change the security settings as required.
   
   For example, you might want to modify entries for services that use HTTPS to add the option of HTTP access.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connection-type</td>
<td>Acceptable values include:</td>
</tr>
<tr>
<td>remote</td>
<td></td>
</tr>
<tr>
<td>namedpipe</td>
<td></td>
</tr>
<tr>
<td>localtunnel</td>
<td></td>
</tr>
<tr>
<td>remotetunnel</td>
<td></td>
</tr>
<tr>
<td>namedpipetunnel</td>
<td></td>
</tr>
<tr>
<td>endpoint-address</td>
<td>For local and localtunnel, supply the port number.</td>
</tr>
<tr>
<td></td>
<td>For remote and remotetunnel, supply the HostName/IP_address:Port.</td>
</tr>
<tr>
<td></td>
<td>For namedpipe and namedpipetunnel, supply the location of the name pipe in the file system.</td>
</tr>
<tr>
<td>HTTP Access mode</td>
<td>Forms of communication the service permits. Acceptable values include:</td>
</tr>
<tr>
<td>allow</td>
<td>Allow HTTP access.</td>
</tr>
<tr>
<td>redirect</td>
<td>If the Endpoint address is a local port, then the client is redirected to 443. If the Endpoint address is a remote host, then the client is redirected to that host.</td>
</tr>
<tr>
<td>reject</td>
<td>No HTTP access.</td>
</tr>
<tr>
<td>HTTPS Access mode</td>
<td>Acceptable values include:</td>
</tr>
<tr>
<td>allow</td>
<td>Allow HTTPS access.</td>
</tr>
<tr>
<td>reject</td>
<td>Do not allow HTTPS access.</td>
</tr>
</tbody>
</table>

5. Save your changes and close the file.

Example

The following example shows a completed endpoints.conf file.

```bash
# Endpoint Connection-type Endpoint-address HTTP-access-Mode HTTPS-access-mode
/local 8309 redirect allow
/sdk local 8307 redirect allow
/client/clients.xml local 8309 allow allow
/ui local 8308 redirect allow
/vpxa local 8889 reject allow
/mob namedpipe /var/run/vmware/proxy-mob redirect allow
/wsman local 8889 redirect allow
/sdkTunnel namedpipetunnel /var/run/vmware/proxy-sdk-tunnel allow reject
```
What to do next

After you make the changes to the endpoints.conf file, make the reverse proxy reload the new endpoints by using the command `kill -HUP <pid_of_rhttpproxy>`

Change Security Settings for a Web Proxy Service 5.0 and earlier

You can change the security configuration so that individual services are directly accessible through HTTP connections.

These steps are for version 5.0 and earlier. Beginning with 5.1, the file that needs to be modified is completely different. For instructions to modify the new file, see Change Security Settings for a Web Proxy Service.

Procedure

1. Log in to the ESXi Shell as a user with administrator privileges.
2. Change to the `/etc/vmware/hostd` directory.
3. Use a text editor to open the `proxy.xml` file.

   The contents of the file typically appears as follows.

   ```xml
   <ConfigRoot>
   <EndpointList>
     <length>10</length>
     <type>vim.ProxyService.EndpointSpec[]</type>
     <e id="0">
       <type>vim.ProxyService.LocalServiceSpec</type>
       <accessMode>httpsWithRedirect</accessMode>
       <port>8309</port>
       <serverNamespace>/</serverNamespace>
     </e>
     <e id="1">
       <type>vim.ProxyService.LocalServiceSpec</type>
       <accessMode>httpAndHttps</accessMode>
       <port>8309</port>
       <serverNamespace>/client/clients.xml</serverNamespace>
     </e>
     <e id="2">
       <type>vim.ProxyService.LocalServiceSpec</type>
       <accessMode>httpAndHttps</accessMode>
       <port>12001</port>
       <serverNamespace>/ha-nfc</serverNamespace>
     </e>
     <e id="3">
       <type>vim.ProxyService.NamedPipeServiceSpec</type>
       <accessMode>httpsWithRedirect</accessMode>
       <pipeName>/var/run/vmware/proxy-mob</pipeName>
       <serverNamespace>/mob</serverNamespace>
     </e>
   </EndpointList>
   </ConfigRoot>
   ```
Change the security settings as required.

For example, you might want to modify entries for services that use HTTPS to add the option of HTTP access.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>ID number for the server ID XML tag. ID numbers must be unique within the HTTP area.</td>
</tr>
<tr>
<td>_type</td>
<td>Name of the service you are moving.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>accessmode</td>
<td>Forms of communication the service permits. Acceptable values include:</td>
</tr>
<tr>
<td></td>
<td>- httpOnly – The service is accessible only over plain-text HTTP connections.</td>
</tr>
<tr>
<td></td>
<td>- httpsOnly – The service is accessible only over HTTPS connections.</td>
</tr>
<tr>
<td></td>
<td>- httpsWithRedirect – The service is accessible only over HTTPS connections. Requests over HTTP are redirected to the appropriate HTTPS URL.</td>
</tr>
<tr>
<td></td>
<td>- httpAndHttps – The service is accessible both over HTTP and HTTPS connections.</td>
</tr>
<tr>
<td>port</td>
<td>Port number assigned to the service. You can assign a different port number to the service.</td>
</tr>
<tr>
<td>serverNamespace</td>
<td>Namespace for the server that provides this service, for example /sdk or /mob.</td>
</tr>
</tbody>
</table>

5. Save your changes and close the file.

6. Restart the hostd process:

   /etc/init.d/hostd restart

**vSphere Auto Deploy Security Considerations**

To best protect your environment, be aware of security risks that might exist when you use Auto Deploy with host profiles.

**Networking Security**

Secure your network as you would for any other PXE-based deployment method. vSphere Auto Deploy transfers data over SSL to prevent casual interference and snooping. However, the authenticity of the client or of the Auto Deploy server is not checked during a PXE boot.

You can greatly reduce the security risk of Auto Deploy by completely isolating the network where Auto Deploy is used.

**Boot Image and Host Profile Security**

The boot image that the vSphere Auto Deploy server downloads to a machine can have the following components.

- The VIB packages that the image profile consists of are always included in the boot image.
- The host profile and host customization are included in the boot image if Auto Deploy rules are set up to provision the host with a host profile or a host customization setting.
  - The administrator (root) password and user passwords that are included with host profile and host customization are MD5 encrypted.
  - Any other passwords associated with profiles are in the clear. If you set up Active Directory by using host profiles, the passwords are not protected.
Use the vSphere Authentication Service for setting up Active Directory to avoid exposing the Active Directory passwords. If you set up Active Directory using host profiles, the passwords are not protected.

- The host's public and private SSL key and certificate are included in the boot image.

Managing ESXi Log Files

Log files are an important component of troubleshooting attacks and obtaining information about breaches of host security. Logging to a secure, centralized log server can help prevent log tampering. Remote logging also provides a long-term audit record.

Take the following measures to increase the security of the host.

- Configure persistent logging to a datastore. By default, the logs on ESXi hosts are stored in the in-memory file system. Therefore, they are lost when you reboot the host, and only 24 hours of log data is stored. When you enable persistent logging, you have a dedicated record of server activity available for the host.
- Remote logging to a central host allows you to gather log files onto a central host, where you can monitor all hosts with a single tool. You can also do aggregate analysis and searching of log data, which might reveal information about things like coordinated attacks on multiple hosts.
- Configure remote secure syslog on ESXi hosts using a remote command line such as vCLI or PowerCLI, or using an API client.
- Query the syslog configuration to make sure that a valid syslog server has been configured, including the correct port.

Configure Syslog on ESXi Hosts

All ESXi hosts run a syslog service (vmsyslogd), which logs messages from the VMkernel and other system components to log files.

You can use the vSphere Web Client or the esxcli system syslog vCLI command to configure the syslog service.

For more information about using vCLI commands, see Getting Started with vSphere Command-Line Interfaces.

Procedure

1. In the vSphere Web Client inventory, select the host.
2. Click the Manage tab.
3. In the System panel, click Advanced System Settings.
4. Locate the Syslog section of the Advanced System Settings list.
5 To set up logging globally, select the setting to change and click the Edit icon.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syslog.global.defaultRotate</td>
<td>Sets the maximum number of archives to keep. You can set this number globally and for individual subloggers.</td>
</tr>
<tr>
<td>Syslog.global.defaultSize</td>
<td>Sets the default size of the log, in KB, before the system rotates logs. You can set this number globally and for individual subloggers.</td>
</tr>
<tr>
<td>Syslog.global.LogDir</td>
<td>Directory where logs are stored. The directory can be located on mounted NFS or VMFS volumes. Only the /scratch directory on the local file system is persistent across reboots. The directory should be specified as [datastorename]/path_to_file where the path is relative to the root of the volume backing the datastore. For example, the path [storage1]/systemlogs maps to the path /vmfs/volumes/storage1/systemlogs.</td>
</tr>
<tr>
<td>Syslog.global.logDirUnique</td>
<td>Selecting this option creates a subdirectory with the name of the ESXi host under the directory specified by Syslog.global.LogDir. A unique directory is useful if the same NFS directory is used by multiple ESXi hosts.</td>
</tr>
<tr>
<td>Syslog.global.LogHost</td>
<td>Remote host to which syslog messages are forwarded and port on which the remote host receives syslog messages. You can include the protocol and the port, for example, ssl://hostName1:514. UDP (default), TCP, and SSL are supported. The remote host must have syslog installed and correctly configured to receive the forwarded syslog messages. See the documentation for the syslog service installed on the remote host for information on configuration.</td>
</tr>
</tbody>
</table>

6 (Optional) To overwrite the default log size and log rotation for any of the logs.

a Click the name of the log you that want to customize.

b Click the Edit icon and enter the number of rotations and log size you want.

7 Click OK.

Results

Changes to the syslog options take effect immediately.

**ESXi Log File Locations**

ESXi records host activity in log files, using a syslog facility.

<table>
<thead>
<tr>
<th>Component</th>
<th>Location</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMkernel</td>
<td>/var/log/vmkernel.log</td>
<td>Records activities related to virtual machines and ESXi.</td>
</tr>
<tr>
<td>VMkernel warnings</td>
<td>/var/log/vmkwarning.log</td>
<td>Records activities related to virtual machines.</td>
</tr>
<tr>
<td>VMkernel summary</td>
<td>/var/log/vmksummary.log</td>
<td>Used to determine uptime and availability statistics for ESXi (comma separated).</td>
</tr>
<tr>
<td>Component</td>
<td>Location</td>
<td>Purpose</td>
</tr>
<tr>
<td>----------------------------</td>
<td>---------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ESXi host agent log</td>
<td>/var/log/hostd.log</td>
<td>Contains information about the agent that manages and configures the ESXi host and its virtual machines.</td>
</tr>
<tr>
<td>vCenter agent log</td>
<td>/var/log/vpxa.log</td>
<td>Contains information about the agent that communicates with vCenter Server (if the host is managed by vCenter Server).</td>
</tr>
<tr>
<td>Shell log</td>
<td>/var/log/shell.log</td>
<td>Contains a record of all commands typed into the ESXi Shell as well as shell events (for example, when the shell was enabled).</td>
</tr>
<tr>
<td>Authentication</td>
<td>/var/log/auth.log</td>
<td>Contains all events related to authentication for the local system.</td>
</tr>
<tr>
<td>System messages</td>
<td>/var/log/syslog.log</td>
<td>Contains all general log messages and can be used for troubleshooting. This information was formerly located in the messages log file.</td>
</tr>
<tr>
<td>Virtual machines</td>
<td>The same directory as the affected virtual machine's configuration files, named vmware.log and vmware*.log. For example, /vmfs/volumes/ datastore/virtual machine/ vwmare.log</td>
<td>Contains virtual machine power events, system failure information, tools status and activity, time sync, virtual hardware changes, vMotion migrations, machine clones, and so on.</td>
</tr>
</tbody>
</table>

**Securing Fault Tolerance Logging Traffic**

When you enable Fault Tolerance (FT), VMware vLockstep captures inputs and events that occur on a Primary VM and sends them to the Secondary VM, which is running on another host.

This logging traffic between the Primary and Secondary VMs is unencrypted and contains guest network and storage I/O data, as well as the memory contents of the guest operating system. This traffic can include sensitive data such as passwords in plaintext. To avoid such data being divulged, ensure that this network is secured, especially to avoid "man-in-the-middle" attacks. For example, use a private network for FT logging traffic.
Securing Virtual Machines

The guest operating system that runs in the virtual machine is subject to the same security risks as a physical system. Secure virtual machines as you would secure physical machines.

This chapter includes the following topics:

- General Virtual Machine Protection
- Disable Unnecessary Functions Inside Virtual Machines
- Use Templates to Deploy Virtual Machines
- Prevent Virtual Machines from Taking Over Resources
- Limit Informational Messages from Virtual Machines to VMX Files
- Prevent Virtual Disk Shrinking in the vSphere Web Client
- Minimize Use of Virtual Machine Console
- Configuring Logging Levels for the Guest Operating System

General Virtual Machine Protection

A virtual machine is, in most respects, the equivalent of a physical server. Employ the same security measures in virtual machines that you do for physical systems.

Keep all security measures up-to-date, including applying appropriate patches. It is especially important to keep track of updates for dormant virtual machines that are powered off, because it can be easy to overlook them. For example, ensure that antivirus, anti-spy ware, intrusion detection, and other protection are enabled for every virtual machine in your virtual infrastructure. You should also ensure that you have enough space for the virtual machine logs.

Installing Anti-Virus Software

Because each virtual machine hosts a standard operating system, you must protect it from viruses by installing antivirus software. Depending on how you are using the virtual machine, you might also want to install a software firewall.

Stagger the schedule for virus scans, particularly in deployments with a large number of virtual machines. Performance of systems in your environment degrades significantly if you scan all virtual machines simultaneously.
Because software firewalls and antivirus software can be virtualization-intensive, you can balance the need for these two security measures against virtual machine performance, especially if you are confident that your virtual machines are in a fully trusted environment.

**Configure Logging Levels for the Guest Operating System**

Virtual machines can write troubleshooting information into a virtual machine log file stored on the VMFS volume. Virtual machine users and processes can abuse logging either on purpose or inadvertently so that large amounts of data flood the log file. Over time, the log file can consume enough file system space to cause a denial of service.

To prevent this problem, consider modifying logging settings for virtual machine guest operating systems. These settings can limit the total size and number of log files. Normally, a new log file is created each time you reboot a host, so the file can grow to be quite large. You can ensure new log file creation happens more frequently by limiting the maximum size of the log files. VMware recommends saving 10 log files, each one limited to 100KB. These values are large enough to capture sufficient information to debug most problems that might occur.

Each time an entry is written to the log, the size of the log is checked. If it is over the limit, the next entry is written to a new log. If the maximum number of log files exists, the oldest log file is deleted. A Denial of Service attack that avoids these limits could be attempted by writing an enormous log entry, but each log entry is limited in size to 4KB, so no log files are ever more than 4KB larger than the configured limit.

**Disable Unnecessary Functions Inside Virtual Machines**

Any service running in a virtual machine provides the potential for attack. By disabling unnecessary system components that are not necessary to support the application or service running on the system, you reduce the number of components that can be attacked.

Virtual machines do not usually require as many services or functions as physical servers. When you virtualize a system, evaluate whether a particular service or function is necessary.

**Procedure**

- Disable unused services in the operating system.
  
  For example, if the system runs a file server, turn off any Web services.

- Disconnect unused physical devices, such as CD/DVD drives, floppy drives, and USB adaptors.
  
  See [Removing Unnecessary Hardware Devices](#).

- Turn off screen savers.

- Do not run the X Window system on Linux, BSD, or Solaris guest operating systems unless it is necessary.
Removing Unnecessary Hardware Devices

Any enabled or connected device represents a potential attack channel. Users and processes without privileges on a virtual machine can connect or disconnect hardware devices, such as network adapters and CD-ROM drives. Attackers can use this capability to breach virtual machine security. Removing unnecessary hardware devices can help prevent attacks.

Use the following guidelines to increase virtual machine security.

- Ensure that unauthorized devices are not connected and remove any unneeded or unused hardware devices.
- Disable unnecessary virtual devices from within a virtual machine. An attacker with access to a virtual machine can connect a disconnected CD-ROM drive and access sensitive information on the media left in the drive, or disconnect a network adapter to isolate the virtual machine from its network, resulting in a denial of service.
- Ensure that no device is connected to a virtual machine if it is not required. Serial and parallel ports are rarely used for virtual machines in a datacenter environment, and CD/DVD drives are usually connected only temporarily during software installation.
- For less commonly used devices that are not required, either the parameter should not be present or its value must be false. Ensure that the following parameters are either not present or set to false unless the device is required.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Device</th>
</tr>
</thead>
<tbody>
<tr>
<td>floppyX.present</td>
<td>false</td>
<td>floppy drives</td>
</tr>
<tr>
<td>serialX.present</td>
<td>false</td>
<td>serial ports</td>
</tr>
<tr>
<td>parallelX.present</td>
<td>false</td>
<td>parallel ports</td>
</tr>
<tr>
<td>usb.present</td>
<td>false</td>
<td>USB controller</td>

</tr>
</tbody>
</table>

Disable Unexposed Features

VMware virtual machines are designed to work on both vSphere systems and hosted virtualization platforms such as Workstation and Fusion. Certain VMX parameters do not need to be enabled when you run a virtual machine on a vSphere system. Disable these parameters to reduce the potential for vulnerabilities.

Prerequisites

Turn off the virtual machine.

Procedure

1. Find the virtual machine in the vSphere Web Client inventory.
   a. To find a virtual machine, select a datacenter, folder, cluster, resource pool, or host.
   b. Click the Related Objects tab and click Virtual Machines.
2 Right-click the virtual machine and click **Edit Settings**.

3 Select **VM Options**.

4 Click **Advanced** and click **Edit Configuration**.

5 Add or edit the following parameters.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>isolation.tools.unity.push.update.disable</td>
<td>TRUE</td>
</tr>
<tr>
<td>isolation.tools.ghi.launchmenu.change</td>
<td>TRUE</td>
</tr>
<tr>
<td>isolation.tools.memSchedFakeSampleStats.disable</td>
<td>TRUE</td>
</tr>
<tr>
<td>isolation.tools.getCreds.disable</td>
<td>TRUE</td>
</tr>
<tr>
<td>isolation.tools.ghi.autologon.disable</td>
<td>TRUE</td>
</tr>
<tr>
<td>isolation.bios.bbs.disable</td>
<td>TRUE</td>
</tr>
<tr>
<td>isolation.tools.hgfsServerSet.disable</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

6 Click **OK**.

**Results**

Setting `isolation.tools.hgfsServerSet.disable` to true disables registration of the guest's HGFS server with the host. APIs that use HGFS to transfer files to and from the guest operating system, such as some VIx commands or the VMware Tools auto-upgrade utility, will not function.

**Disable Copy and Paste Operations Between Guest Operating System and Remote Console**

Copy and paste operations between the guest operating system and remote console are disabled by default. For a secure environment, retain the default setting. If you require copy and paste operations, you must enable them using the vSphere Client.

**Prerequisites**

Turn off the virtual machine.

**Procedure**

1 Log into a vCenter Server system using the vSphere Web Client.

2 Right-click the virtual machine and click **Edit Settings**.

3 Click **VM Options**, and click **Edit Configuration**.
4 Ensure that the following values are in the Name and Value columns, or click Add Row to add them.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>isolation.tools.copy.disable</td>
<td>true</td>
</tr>
<tr>
<td>isolation.tools.paste.disable</td>
<td>true</td>
</tr>
</tbody>
</table>

These options override any settings made in the guest operating system’s VMware Tools control panel.

5 Click OK.

6 (Optional) If you made changes to the configuration parameters, restart the virtual machine.

**Limiting Exposure of Sensitive Data Copied to the Clipboard**

Copy and paste operations are disabled by default for hosts to prevent exposing sensitive data that has been copied to the clipboard.

When copy and paste is enabled on a virtual machine running VMware Tools, you can copy and paste between the guest operating system and remote console. As soon as the console window gains focus, non-privileged users and processes running in the virtual machine can access the clipboard for the virtual machine console. If a user copies sensitive information to the clipboard before using the console, the user—perhaps unknowingly—exposes sensitive data to the virtual machine. To prevent this problem, copy and paste operations for the guest operating system are disabled by default.

It is possible to enable copy and paste operations for virtual machines if necessary.

**Restrict Users from Running Commands Within a Virtual Machine**

By default, the vCenter Server Administrator role lets users interact with files and programs within a virtual machine’s guest operating system. To reduce the risk of breaching guest confidentiality, availability, or integrity, create a nonguest access role without the Guest Operations privilege.

For security, be as restrictive about allowing access to the virtual datacenter as you are to the physical datacenter. To avoid giving users full administrator access, apply the nonguest access role to users who require administrator privileges, but who are not authorized to interact with files and programs within a guest operating system.

For example, a configuration might include a virtual machine on the infrastructure that has sensitive information on it. Tasks such as migration with vMotion and Storage vMotion require that the IT role has access to the virtual machine. In this case, you want to disable some remote operations within a guest OS to ensure that the IT role cannot access the sensitive information.

**Prerequisites**

Verify that you have Administrator privileges on the vCenter Server system where you create the role.
Procedure

1. Log in to the vSphere Web Client as a user who has **Administrator** privileges on the vCenter Server system where you will create the role.

2. Click **Administration** and select **Access > Roles**.

3. Click the **Create role** icon and type a name for the role. For example, type **Administrator No Guest Access**.

4. Select **All Privileges**.

6. Click OK.

**What to do next**

Assign users who require **Administrator** privileges without guest access privileges to the newly created role, ensuring that these users are removed from the default Administrator role.

**Prevent a Virtual Machine User or Process from Disconnecting Devices in the vSphere Web Client**

Users and processes without root or administrator privileges within virtual machines have the capability to connect or disconnect devices, such as network adaptors and CD-ROM drives, as well as the ability to modify device settings. To increase virtual machine security, remove these devices. If you do not want to permanently remove a device, you can prevent a virtual machine user or process from connecting or disconnecting the device from within the guest operating system.

**Prerequisites**

Turn off the virtual machine.

**Procedure**

1. Find the virtual machine in the vSphere Web Client inventory.
   a. To find a virtual machine, select a datacenter, folder, cluster, resource pool, or host.
   b. Click the **Related Objects** tab and click **Virtual Machines**.

2. Right-click the virtual machine and click **Edit Settings**.

3. Select **VM Options > Advanced** and click **Edit Configuration**.
4 Verify that the following values are in the Name and Value columns, or click Add Row to add them.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>isolation.device.connectable.disable</td>
<td>true</td>
</tr>
<tr>
<td>isolation.device.edit.disable</td>
<td>true</td>
</tr>
</tbody>
</table>

These options override any settings made in the guest operating system’s VMware Tools control panel.

5 Click OK to close the Configuration Parameters dialog box, and click OK again to close the Virtual Machine Properties dialog box.

### Limiting Guest Operating System Writes to Host Memory

The guest operating system processes send informational messages to the host through VMware Tools. If the amount of data the host stored as a result of these messages was unlimited, an unrestricted data flow would provide an opportunity for an attacker to stage a denial-of-service (DoS) attack.

The informational messages sent by guest operating processes are known as `setinfo` messages and typically contain name-value pairs that define virtual machine characteristics or identifiers that the host stores (for example, `ipaddress=10.17.87.224`). The configuration file containing these name-value pairs is limited to a size of 1MB, which prevents attackers from staging a DoS attack by writing software that mimics VMware Tools and filling the host's memory with arbitrary configuration data, which consumes space needed by the virtual machines.

If you require more than 1MB of storage for name-value pairs, you can change the value as required. You can also prevent the guest operating system processes from writing any name-value pairs to the configuration file.

### Modify Guest Operating System Variable Memory Limit in the vSphere Web Client

You can increase the guest operating system variable memory limit if large amounts of custom information are being stored in the configuration file.

**Prerequisites**

Turn off the virtual machine.

**Procedure**

1. Find the virtual machine in the vSphere Web Client inventory.
   a. To find a virtual machine, select a datacenter, folder, cluster, resource pool, or host.
   b. Click the Related Objects tab and click Virtual Machines.
2. Right-click the virtual machine and click Edit Settings.
3. Select VM Options > Advanced and click Edit Configuration.
4 Add or edit the parameter `tools.setInfo.sizeLimit` and set the value to the number of bytes.

5 Click **OK**.

**Prevent the Guest Operating System Processes from Sending Configuration Messages to the Host**

You can prevent guests from writing any name-value pairs to the configuration file. This is appropriate when guest operating systems must be prevented from modifying configuration settings.

**Prerequisites**

Turn off the virtual machine.

**Procedure**

1 Log in to a vCenter Server system using the vSphere Client.

2 Select the virtual machine in the inventory panel.

3 On the **Summary** tab, click **Edit Settings**.

4 Select **Options > Advanced > General** and click **Configuration Parameters**.

5 Click **Add Row** and type the following values in the Name and Value columns.

   - In the Name column: `isolation.tools.setinfo.disable`
   - In the Value column: `true`

6 Click **OK** to close the Configuration Parameters dialog box, and click **OK** again to close the Virtual Machine Properties dialog box.

**Use Templates to Deploy Virtual Machines**

When you manually install guest operating systems and applications on a virtual machine, you introduce a risk of misconfiguration. By using a template to capture a hardened base operating system image with no applications installed, you can ensure that all virtual machines are created with a known baseline level of security.

You can use templates that can contain a hardened, patched, and properly configured operating system to create other, application-specific templates, or you can use the application template to deploy virtual machines.

**Procedure**

- Provide templates for virtual machine creation that contain hardened, patched, and properly configured operating system deployments.

  If possible, deploy applications in templates as well. Ensure that the applications do not depend on information specific to the virtual machine to be deployed.
What to do next

You can convert a template to a virtual machine and back to a template in the vSphere Web Client, which makes updating templates easy. For more information about templates, see the *vSphere Virtual Machine Administration* documentation.

You can use vSphere Update Manager to automatically patch the operating system and certain applications in the template. See the *vSphere Update Manager* documentation.

**Prevent Virtual Machines from Taking Over Resources**

When one virtual machine consumes so much of the host resources that other virtual machines on the host cannot perform their intended functions, a Denial of Service (DoS) might occur. To prevent a virtual machine from causing a DoS, use host resource management features such as setting shares and limits to control the server resources that a virtual machine consumes.

By default, all virtual machines on a host share resources equally.

**Procedure**

- Use shares or reservations to guarantee resources to critical virtual machines.
  
  Limits constrain resource consumption by virtual machines that have a greater risk of being exploited or attacked, or that run applications that are known to have the potential to greatly consume resources.

What to do next

See the *vSphere Resource Management* documentation for information about shares and limits.

**Limit Informational Messages from Virtual Machines to VMX Files**

Limit informational messages from the virtual machine to the VMX file to avoid filling the datastore and causing a Denial of Service (DoS). A Denial of Service can occur when you do not control the size of a virtual machine's VMX file and the amount of information exceeds the datastore's capacity.

The configuration file containing the informational name-value pairs is limited to 1MB by default. This capacity is sufficient in most cases, but you can change this value if necessary. For example, you might increase the limit if large amounts of custom information are being stored in the configuration file.

**Note**  Consider carefully how much information you require. If the amount of information exceeds the datastore's capacity, a Denial of Service might result.

The default limit of 1MB is applied even when the sizeLimit parameter is not listed in the VMX file.
Procedure

1. On the ESXi system that hosts the virtual machine, browse to the VMX file.

   Virtual machine configuration files are located in the /vmfs/volumes/datastore directory, where datastore is the name of the storage device on which the virtual machine files reside. For example, /vmfs/volumes/vol1/vm-finance/.

2. Use a text editor to add or edit the following line in the VMX file:

   ```
   tools.setInfo.sizeLimit=104857
   ```

3. Save and close the file.

**Prevent Virtual Disk Shrinking in the vSphere Web Client**

Nonadministrative users in the guest operating system are able to shrink virtual disks. Shrinking a virtual disk reclams the disk's unused space. However, if you shrink a virtual disk repeatedly, the disk can become unavailable and cause a denial of service. To prevent this, disable the ability to shrink virtual disks.

**Prerequisites**

Turn off the virtual machine.

**Procedure**

1. Find the virtual machine in the vSphere Web Client inventory.
   
   a. To find a virtual machine, select a datacenter, folder, cluster, resource pool, or host.
   
   b. Click the **Related Objects** tab and click **Virtual Machines**.

2. Right-click the virtual machine and click **Edit Settings**.

3. Select **VM Options**.

4. Click **Advanced** and click **Edit Configuration**.

5. Add or edit the following parameters.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>isolation.tools.diskWiper.disable</td>
<td>TRUE</td>
</tr>
<tr>
<td>isolation.tools.diskShrink.disable</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

6. Click **OK**.

**Results**

When you disable this feature, you cannot shrink virtual machine disks when a datastore runs out of space.
Minimize Use of Virtual Machine Console

The virtual machine console provides the same function for a virtual machine that a monitor on a physical server provides. Users with access to the virtual machine console have access to virtual machine power management and removable device connectivity controls, which might allow a malicious attack on a virtual machine.

Procedure

- Use native remote management services, such as terminal services and SSH, to interact with virtual machines.
  
  Grant access to the virtual machine console only when necessary.

Configuring Logging Levels for the Guest Operating System

Virtual machines can write troubleshooting information into a virtual machine log file stored on the VMFS volume. Virtual machine users and processes can abuse logging either on purpose or inadvertently so that large amounts of data flood the log file. Over time, the log file can consume enough file system space to cause a denial of service.

To prevent this problem, consider modifying logging settings for virtual machine guest operating systems. These settings can limit the total size and number of log files. Normally, a new log file is created each time you reboot a host, so the file can grow to be quite large. You can ensure new log file creation happens more frequently by limiting the maximum size of the log files. VMware recommends saving 10 log files, each one limited to 100KB. These values are large enough to capture sufficient information to debug most problems that might occur.

Each time an entry is written to the log, the size of the log is checked. If it is over the limit, the next entry is written to a new log. If the maximum number of log files exists, the oldest log file is deleted. A DoS attack that avoids these limits could be attempted by writing an enormous log entry, but each log entry is limited in size to 4KB, so no log files are ever more than 4KB larger than the configured limit.

Limit the Number of Log Files in the vSphere Web Client

To prevent virtual machine users and processes from creating large numbers of log files, which can lead to denial of service, you can limit the number of the log files for a virtual machine. You cannot limit the log file size for individual virtual machines.

You can limit the number of log files for all virtual machines on a host by editing the /etc/vmware/config file. If the vmx.log.Keep0ld property is not defined in the file, you can add it. For example, to keep ten log files for each virtual machine, add the following to /etc/vmware/config:

```
vmx.log.keep0ld = "10"
```

You can also use a PowerCLI script to change this property on all the virtual machines on a host.
Prerequisites

Turn off the virtual machine.

Procedure

1. Find the virtual machine in the vSphere Web Client inventory.
   a. To find a virtual machine, select a datacenter, folder, cluster, resource pool, or host.
   b. Click the Related Objects tab and click Virtual Machines.

2. Right-click the virtual machine and click Edit Settings.

3. Select VM Options.

4. Click Advanced and click Edit Configuration.

5. Add or edit the vmx.log.keepOld parameter to specify the number of files to keep. For example, to keep 8 log files and begin deleting the oldest files as new ones are created, enter 8.

6. Click OK.

Disable Logging for the Guest Operating System in the vSphere Web Client

If you choose not to write troubleshooting information into a virtual machine log file stored on the VMFS volume, you can stop logging altogether.

If you disable logging for the guest operating system, be aware that you might not be able to gather adequate logs to allow troubleshooting. Further, VMware does not offer technical support for virtual machine problems if logging has been disabled.

Procedure

1. Find the virtual machine in the vSphere Web Client inventory.
   a. To find a virtual machine, select a datacenter, folder, cluster, resource pool, or host.
   b. Click the Related Objects tab and click Virtual Machines.

2. Right-click the virtual machine and click Edit Settings.

3. Select VM Options > Advanced.

4. In Settings, deselect Enable logging.

5. Click OK.
Securing vSphere Networking

Securing vSphere Networking is an essential part of protecting your environment. You secure different vSphere components in different ways. See the vSphere Networking documentation for detailed information about networking in the vSphere environment.

This chapter includes the following topics:

- Introduction to vSphere Network Security
- Securing the Network with Firewalls
- Secure the Physical Switch
- Securing Standard Switch Ports With Security Policies
- Securing Standard Switch MAC Addresses
- Standard Switch Protection and VLANs
- Secure vSphere Distributed Switches
- Securing Virtual Machines with VLANs
- Creating a Network DMZ on a Single ESXi Host
- Creating Multiple Networks Within a Single ESXi Host
- Internet Protocol Security
- Ensure Proper SNMP Configuration
- Use Virtual Switches on the vSphere Network Appliance Only If Required

Introduction to vSphere Network Security

Network security in the vSphere environment shares many characteristics of securing a physical network environment, but also includes some characteristics that apply only with virtual machines.

Firewalls

Add firewall protection to your virtual network by installing and configuring host-based firewalls on some or all of its virtual machines.
For efficiency, you can set up private virtual machine Ethernet networks or virtual networks. With virtual networks, you install a host-based firewall on a virtual machine at the head of the virtual network. This firewall serves as a protective buffer between the physical network adapter and the remaining virtual machines in the virtual network.

Because host-based firewalls can slow performance, balance your security needs against performance goals before you install host-based firewalls on virtual machines elsewhere in the virtual network.

See Securing the Network with Firewalls.

Segmentation

Keep different virtual machine zones within a host on different network segments. If you isolate each virtual machine zone on its own network segment, you minimize the risk of data leakage from one virtual machine zone to the next. Segmentation prevents various threats, including Address Resolution Protocol (ARP) spoofing, in which an attacker manipulates the ARP table to remap MAC and IP addresses, thereby gaining access to network traffic to and from a host. Attackers use ARP spoofing to generate man in the middle (MITM) attacks, perform denial of service (DoS) attacks, hijack the target system, and otherwise disrupt the virtual network.

Planning segmentation carefully lowers the chances of packet transmissions between virtual machine zones, which prevents sniffing attacks that require sending network traffic to the victim. Also, an attacker cannot use an insecure service in one virtual machine zone to access other virtual machine zones in the host. You can implement segmentation by using either of two approaches. Each approach has different benefits.

- Use separate physical network adapters for virtual machine zones to ensure that the zones are isolated. Maintaining separate physical network adapters for virtual machine zones is probably the most secure method and is less prone to misconfiguration after the initial segment creation.

- Set up virtual local area networks (VLANs) to help safeguard your network. Because VLANs provide almost all of the security benefits inherent in implementing physically separate networks without the hardware overhead, they offer a viable solution that can save you the cost of deploying and maintaining additional devices, cabling, and so forth. See Securing Virtual Machines with VLANs.

Preventing Unauthorized Access

If your virtual machine network is connected to a physical network, it can be subject to breaches just like a network that consists of physical machines. Even if the virtual machine network is isolated from any physical network, virtual machines in the network can be subject to attacks from other virtual machines in the network. The requirements for securing virtual machines are often the same as those for securing physical machines.
Virtual machines are isolated from each other. One virtual machine cannot read or write another virtual machine's memory, access its data, use its applications, and so forth. However, within the network, any virtual machine or group of virtual machines can still be the target of unauthorized access from other virtual machines and might require further protection by external means.

Securing the Network with Firewalls

Security administrators use firewalls to safeguard the network or selected components in the network from intrusion.

Firewalls control access to devices within their perimeter by closing all communication pathways, except for those that the administrator explicitly or implicitly designates as authorized. The pathways, or ports, that administrators open in the firewall allow traffic between devices on different sides of the firewall.

Important  The ESXi firewall in ESXi 5.5 does not allow per-network filtering of vMotion traffic. Therefore, you must install rules on your external firewall to ensure that no incoming connections can be made to the vMotion socket.

In a virtual machine environment, you can plan the layout for firewalls between components.

- Firewalls between physical machines such as vCenter Server systems and ESXi hosts.
- Firewalls between one virtual machine and another—for example, between a virtual machine acting as an external Web server and a virtual machine connected to your company's internal network.
- Firewalls between a physical machine and a virtual machine, such as when you place a firewall between a physical network adapter card and a virtual machine.

How you use firewalls in your ESXi configuration is based on how you plan to use the network and how secure any given component needs to be. For example, if you create a virtual network where each virtual machine is dedicated to running a different benchmark test suite for the same department, the risk of unwanted access from one virtual machine to the next is minimal. Therefore, a configuration where firewalls are present between the virtual machines is not necessary. However, to prevent interruption of a test run from an outside host, you might set up the configuration so that a firewall is present at the entry point of the virtual network to protect the entire set of virtual machines.

Firewalls for Configurations with vCenter Server

If you access ESXi hosts through vCenter Server, you typically protect vCenter Server using a firewall. This firewall provides basic protection for your network.

A firewall might lie between the clients and vCenter Server. Alternatively, depending on your deployment, vCenter Server and the clients can both be behind the firewall. The main point is to ensure that a firewall is present at what you consider to be an entry point for the system.
For a comprehensive list of TCP and UDP ports, including those for vSphere vMotion™ and vSphere Fault Tolerance, see TCP and UDP Ports.

Networks configured with vCenter Server can receive communications through the vSphere Web Client or third-party network management clients that use the SDK to interface with the host. During normal operation, vCenter Server listens for data from its managed hosts and clients on designated ports. vCenter Server also assumes that its managed hosts listen for data from vCenter Server on designated ports. If a firewall is present between any of these elements, you must ensure that the firewall has open ports to support data transfer.

You might also include firewalls at a variety of other access points in the network, depending on how you plan to use the network and the level of security various devices require. Select the locations for your firewalls based on the security risks that you have identified for your network configuration. The following is a list of firewall locations common to ESXi implementations.

- Between the vSphere Web Client or a third-party network-management client and vCenter Server.
- If your users access virtual machines through a Web browser, between the Web browser and the ESXi host.
- If your users access virtual machines through the vSphere Web Client, between the vSphere Web Client and the ESXi host. This connection is in addition to the connection between the vSphere Web Client and vCenter Server, and it requires a different port.
- Between vCenter Server and the ESXi hosts.
- Between the ESXi hosts in your network. Although traffic between hosts is usually considered trusted, you can add firewalls between them if you are concerned about security breaches from machine to machine.

If you add firewalls between ESXi hosts and plan to migrate virtual machines between the servers, perform cloning, or use vMotion, you must also open ports in any firewall that divides the source host from the target hosts so that the source and targets can communicate.

- Between the ESXi hosts and network storage such as NFS or iSCSI storage. These ports are not specific to VMware, and you configure them according to the specifications for your network.

**Connecting to vCenter Server Through a Firewall**

The port that vCenter Server uses to listen for data transfer from its clients is 443. If you have a firewall between vCenter Server and its clients, you must configure a connection through which vCenter Server can receive data from the clients.

To enable vCenter Server to receive data from the vSphere Web Client, open port 443 in the firewall to allow data transfer from the vSphere Web Client to vCenter Server. Contact the firewall system administrator for additional information on configuring ports in a firewall.
If you are using the vSphere Web Client and do not want to use port 443 as the port for vSphere Web Client-to-vCenter Server communication, you can switch to another port by changing the vCenter Server settings in the vSphere Web Client. To learn how to change these settings, see the vCenter Server and Host Management documentation.

**Firewalls for Configurations Without vCenter Server**

You can connect clients directly to your ESXi network instead of using vCenter Server.

Networks configured without vCenter Server receive communications through the vSphere Client, one of the vSphere command-line interfaces, the vSphere Web Services SDK, or third-party clients. For the most part, the firewall needs are the same as when a vCenter Server is present, but several key differences exist.

- As you would for configurations that include vCenter Server, be sure a firewall is present to protect your ESXi layer or, depending on your configuration, your clients and ESXi layer. This firewall provides basic protection for your network. The firewall ports you use are the same as those you use if vCenter Server is in place.
- Licensing in this type of configuration is part of the ESXi package that you install on each of the hosts. Because licensing is resident to the server, a separate license server is not required. This eliminates the need for a firewall between the license server and the ESXi network.

**Connecting ESXi Hosts Through Firewalls**

If you have a firewall between two ESXi hosts and you want to allow transactions between the hosts or use vCenter Server to perform any source or target activities, such as vSphere High Availability (vSphere HA) traffic, migration, cloning, or vMotion, you must configure a connection through which the managed hosts can receive data.

To configure a connection for receiving data, open ports for traffic from services such as vSphere High Availability, vMotion, and vSphere Fault Tolerance. See ESXi Firewall Configuration for a discussion of configuration files, vSphere Web Client access, and firewall commands. See TCP and UDP Ports for a list of ports. Refer to the firewall system administrator for additional information on configuring the ports.

**Connecting to the Virtual Machine Console Through a Firewall**

When you connect your client to ESXi hosts through vCenter Server, certain ports are required for user and administrator communication with virtual machine consoles. These ports support different client functions, interface with different layers on ESXi, and use different authentication protocols.

How you connect to the virtual machine console depends on whether you are using the vSphere Web Client or whether you are using a different client such as the vSphere SDK.
Connecting by Using the vSphere Web Client

When you are connecting with the vSphere Web Client, you always connect to the vCenter Server that manages the host, and access the virtual machine console from there.

The following ports are involved.

**Port 9443 and Port 9090**

The vSphere Web Client uses port 9443 for HTTPS communication with vCenter Server and port 9090 for HTTP communication with vCenter Server. Once users can access vCenter Server, they can also access individual ESXi hosts and virtual machines.

These ports can be changed during vSphere Web Client installation.

**Port 443 and Port 902**

Open ports 443 and 902 in the firewall to allow data transfer to ESXi hosts from vCenter Server if you have a firewall between your vCenter Server system and the ESXi host managed by vCenter Server.

**Figure 9-1. Port Use for vSphere Web Client Communications with an ESXi Host Managed by vCenter Server**

For additional information on configuring the ports, see the firewall system administrator.

Connecting Through vCenter Server with the vSphere Client

When you are connecting with the vSphere Client, the required ports depend on whether you connect directly to the ESXi host or you connect to a vCenter Server system.

**Port 443**

Port 443 connects clients such as the vSphere Web Services SDK to ESXi through the Tomcat Web service or the SDK. The host process multiplexes port 443 data to the appropriate recipient for processing.
When the vSphere SDK is connected directly to ESXi, it can use this port to support any management functions related to the host and its virtual machines. Port 443 is the port that clients such as the vSphere SDK assume is available when sending data to ESXi. VMware does not support configuring a different port for these connections.

**Port 902**

This is the port that vCenter Server assumes is available for receiving data from ESXi.

Port 902 connects vCenter Server to the host through the VMware Authorization Daemon (vmware-authd). This daemon multiplexes port 902 data to the appropriate recipient for processing. VMware does not support configuring a different port for this connection.

**Connecting Directly with the vSphere Client**

With the vSphere Client, you can connect directly to an ESXi host.

**Port 902**

The vSphere Client uses this port to provide a connection for guest operating system MKS activities on virtual machines. It is through this port that users interact with the guest operating systems and applications of the virtual machine. VMware does not support configuring a different port for this function.

**TCP and UDP Ports**

vCenter Server, ESXi hosts, and other network components are accessed using predetermined TCP and UDP ports. If you manage network components from outside a firewall, you might be required to reconfigure the firewall to allow access on the appropriate ports.

The table lists TCP and UDP ports, and the purpose and the type of each. Ports that are open by default at installation time are indicated by (Default). For an up to date list of ports of all vSphere components for the different versions of vSphere, see [http://kb.vmware.com/kb/1012382](http://kb.vmware.com/kb/1012382).

| 443 (Default) | The default port that the vCenter Server system uses to listen for connections from the vSphere Client. To enable the vCenter Server system to receive data from the vSphere Client, open port 443 in the firewall. The vCenter Server system also uses port 443 to monitor data transfer from SDK clients. This port is also used for the following services:  
- WS-Management (also requires port 80 to be open)  
- vSphere Client access to vSphere Update Manager  
- Third-party network management client connections to vCenter Server  
- Third-party network management clients access to hosts | Incoming TCP                     |
| 427 (Default) | The CIM client uses the Service Location Protocol, version 2 (SLPv2) to find CIM servers. | Incoming and outgoing UDP         |
| 513 (Default) | vCenter Server Appliance used for logging activity                       | Incoming UDP                      |
| 902 (Default) | The default port that the vCenter Server system uses to send data to managed hosts. Managed hosts also send a regular heartbeat over UDP port 902 to the vCenter Server system. This port must not be blocked by firewalls between the server and the hosts or between hosts. Port 902 must not be blocked between the vSphere Client and the hosts. The vSphere Client uses this port to display virtual machine consoles. | Incoming and outgoing TCP, outgoing UDP |
| 903    | Access a virtual machine console from the vSphere Client when the vSphere Client is connected directly to the ESXi host (no vCenter Server). MKS transactions (xinetd/vmware-authd-mks) | Incoming TCP                      |
| 2014   | RPC port for all VMCA (VMware Certificate Authority) APIs               |                                    |

In addition to the TCP and UDP ports, you can configure other ports depending on your needs.

## Secure the Physical Switch

Secure the physical switch on each ESXi host to prevent attackers from gaining access to the host and its virtual machines.

For best protection of your hosts, ensure that physical switch ports are configured with spanning tree disabled and ensure that the non-negotiate option is configured for trunk links between external physical switches and virtual switches in Virtual Switch Tagging (VST) mode.

### Procedure

1. Log in to the physical switch and ensure that spanning tree protocol is disabled or that Port Fast is configured for all physical switch ports that are connected to ESXi hosts.

2. For virtual machines that perform bridging or routing, check periodically that the first upstream physical switch port is configured with BPDU Guard and Port Fast disabled and with spanning tree protocol enabled.

   In vSphere 5.1 and later, to prevent the physical switch from potential Denial of Service (DoS) attacks, you can turn on the guest BPDU filter on the ESXi hosts.

3. Log in to the physical switch and ensure that Dynamic Trunking Protocol (DTP) is not enabled on the physical switch ports that are connected to the ESXi hosts.
4. Routinely check physical switch ports to ensure that they are properly configured as trunk ports if connected to virtual switch VLAN trunking ports.

**Securing Standard Switch Ports With Security Policies**

As with physical network adapters, a virtual machine network adapter can send frames that appear to be from a different machine or impersonate another machine so that it can receive network frames that are intended for that machine. Also, like physical network adapters, a virtual machine network adapter can be configured so that it receives frames targeted for other machines. Both scenarios present a security risk.

When you create a standard switch for your network, you add port groups in the vSphere Web Client to impose a policy for the virtual machines and VMkernel adapters for system traffic attached to the switch.

As part of adding a VMkernel port group or virtual machine port group to a standard switch, ESXi configures a security policy for the ports in the group. You can use this security policy to ensure that the host prevents the guest operating systems of its virtual machines from impersonating other machines on the network. This security feature is implemented so that the guest operating system responsible for the impersonation does not detect that the impersonation was prevented.

The security policy determines how strongly you enforce protection against impersonation and interception attacks on virtual machines. To correctly use the settings in the security profile, you must understand how virtual machine network adapters control transmissions and how attacks are staged at this level. See the Security Policy section in the *vSphere Networking* publication.

**Securing Standard Switch MAC Addresses**

You can secure standard switch traffic against Layer 2 attacks by restricting some of the MAC address modes.

Each virtual machine network adapter has an initial MAC address and an effective MAC address.

**Initial MAC address**

The initial MAC address is assigned when the adapter is created. Although the initial MAC address can be reconfigured from outside the guest operating system, it cannot be changed by the guest operating system.

**Effective MAC address**

Each adapter has an effective MAC address that filters out incoming network traffic with a destination MAC address that is different from the effective MAC address. The guest operating system is responsible for setting the effective MAC address and typically matches the effective MAC address to the initial MAC address.
Upon creating a virtual machine network adapter, the effective MAC address and initial MAC address are the same. The guest operating system can alter the effective MAC address to another value at any time. If an operating system changes the effective MAC address, its network adapter receives network traffic that is destined for the new MAC address.

When sending packets through a network adapter, the guest operating system typically places its own adapter effective MAC address in the source MAC address field of the Ethernet frames. It places the MAC address for the receiving network adapter in the destination MAC address field. The receiving adapter accepts packets only if the destination MAC address in the packet matches its own effective MAC address.

An operating system can send frames with an impersonated source MAC address. This means an operating system can stage malicious attacks on the devices in a network by impersonating a network adapter that the receiving network authorizes.

You can secure the traffic through the standard switches against this type of Layer 2 attacks by restricting the following modes:

- Promiscuous mode
- MAC address changes
- Forged transmission

To change any default settings for a port, you modify the security policy of the standard switch or of the port group from the vSphere Web Client.

### MAC Address Changes

The security policy of a virtual switch includes a MAC address changes option. This option affects traffic that a virtual machine receives.

When the Mac address changes option is set to Accept, ESXi accepts requests to change the effective MAC address to a different address than the initial MAC address.

When the Mac address changes option is set to Reject, ESXi does not honor requests to change the effective MAC address to a different address than the initial MAC address. This setting protects the host against MAC impersonation. The port that the virtual machine adapter used to send the request is disabled and the virtual machine adapter does not receive any more frames until the effective MAC address matches the initial MAC address. The guest operating system does not detect that the MAC address change request was not honored.

**Note** The iSCSI initiator relies on being able to get MAC address changes from certain types of storage. If you are using ESXi iSCSI with iSCSI storage, set the MAC address changes option to Accept.

In some situations, you might have a legitimate need for more than one adapter to have the same MAC address on a network—for example, if you are using Microsoft Network Load Balancing in unicast mode. When Microsoft Network Load Balancing is used in the standard multicast mode, adapters do not share MAC addresses.
Forged Transmissions

The **Forged transmits** option affects traffic that is transmitted from a virtual machine.

When the **Forged transmits** option is set to **Accept**, ESXi does not compare source and effective MAC addresses.

To protect against MAC impersonation, you can set the **Forged transmits** option to **Reject**. If you do, the host compares the source MAC address being transmitted by the guest operating system with the effective MAC address for its virtual machine adapter to see if they match. If the addresses do not match, the ESXi host drops the packet.

The guest operating system does not detect that its virtual machine adapter cannot send packets by using the impersonated MAC address. The ESXi host intercepts any packets with impersonated addresses before they are delivered, and the guest operating system might assume that the packets are dropped.

Promiscuous Mode Operation

Promiscuous mode eliminates any reception filtering that the virtual machine adapter performs so that the guest operating system receives all traffic observed on the wire. By default, the virtual machine adapter cannot operate in promiscuous mode.

Although promiscuous mode can be useful for tracking network activity, it is an insecure mode of operation, because any adapter in promiscuous mode has access to the packets even if some of the packets are received only by a particular network adapter. This means that an administrator or root user within a virtual machine can potentially view traffic destined for other guest or host operating systems.

**Note** In some situations, you might have a legitimate reason to configure a standard or a distributed virtual switch to operate in promiscuous mode, for example, if you are running network intrusion detection software or a packet sniffer.

Standard Switch Protection and VLANs

VMware standard switches provide safeguards against certain threats to VLAN security. Because of the way that standard switches are designed, they protect VLANs against a variety of attacks, many of which involve VLAN hopping.

Having this protection does not guarantee that your virtual machine configuration is invulnerable to other types of attacks. For example, standard switches do not protect the physical network against these attacks; they protect only the virtual network.

Standard switches and VLANs can protect against the following types of attacks.

**MAC flooding**

Flooding a switch with packets that contain MAC addresses tagged as having come from different sources. Many switches use a content-addressable memory table to learn and store the source address for each packet. When the table is full, the switch can enter a fully open...
state in which every incoming packet is broadcast on all ports, letting the attacker see all of the switch’s traffic. This state might result in packet leakage across VLANs.

Although VMware standard switches store a MAC address table, they do not get the MAC addresses from observable traffic and are not vulnerable to this type of attack.

802.1q and ISL tagging attacks

Force a switch to redirect frames from one VLAN to another by tricking the switch into acting as a trunk and broadcasting the traffic to other VLANs.

VMware standard switches do not perform the dynamic trunking required for this type of attack and, therefore, are not vulnerable.

Double-encapsulation attacks

Occur when an attacker creates a double-encapsulated packet in which the VLAN identifier in the inner tag is different from the VLAN identifier in the outer tag. For backward compatibility, native VLANs strip the outer tag from transmitted packets unless configured to do otherwise. When a native VLAN switch strips the outer tag, only the inner tag is left, and that inner tag routes the packet to a different VLAN than the one identified in the now-missing outer tag.

VMware standard switches drop any double-encapsulated frames that a virtual machine attempts to send on a port configured for a specific VLAN. Therefore, they are not vulnerable to this type of attack.

Multicast brute-force attacks

Involve sending large numbers of multicast frames to a known VLAN almost simultaneously to overload the switch so that it mistakenly allows some of the frames to broadcast to other VLANs.

VMware standard switches do not allow frames to leave their correct broadcast domain (VLAN) and are not vulnerable to this type of attack.

Spanning-tree attacks

Target Spanning-Tree Protocol (STP), which is used to control bridging between parts of the LAN. The attacker sends Bridge Protocol Data Unit (BPDU) packets that attempt to change the network topology, establishing themselves as the root bridge. As the root bridge, the attacker can sniff the contents of transmitted frames.

VMware standard switches do not support STP and are not vulnerable to this type of attack.

Random frame attacks

Involve sending large numbers of packets in which the source and destination addresses stay the same, but in which fields are randomly changed in length, type, or content. The goal of this attack is to force packets to be mistakenly rerouted to a different VLAN.

VMware standard switches are not vulnerable to this type of attack.
Because new security threats develop over time, do not consider this an exhaustive list of attacks. Regularly check VMware security resources on the Web to learn about security, recent security alerts, and VMware security tactics.

Secure vSphere Distributed Switches

Administrators have several options for securing a vSphere Distributed Switch in their vSphere environment.

Procedure

1. Verify that the Auto Expand feature for the distributed port groups with static binding is disabled.
   
   Auto Expand is enabled by default in vSphere 5.1 and later.
   
   To disable Auto Expand, configure the autoExpand property under the distributed port group with the vSphere Web Services SDK or with a command-line interface. See the vSphere API/SDK Documentation.

2. Ensure that all private VLAN IDs of any vSphere Distributed Switch are fully documented.

3. Ensure that no unused ports exist on a virtual port group associated with a vSphere Distributed Switch.

4. Protect virtual traffic against impersonation and interception Layer 2 attacks by configuring a security policy on port groups or ports.

   The security policy on distributed port groups and ports includes the following options:
   
   - Promiscuous mode (see Promiscuous Mode Operation)
   - MAC address changes (see MAC Address Changes)
   - Forged transmits (see Forged Transmissions)

   You can view and change the current settings by selecting Manage Distributed Port Groups from the right-button menu of the distributed switch and selecting Security in the wizard. See the vSphere Networking documentation.

Securing Virtual Machines with VLANS

The network can be one of the most vulnerable parts of any system. Your virtual machine network requires as much protection as your physical network. Using VLANS can improve networking security in your environment.

VLANS are an IEEE standard networking scheme with specific tagging methods that allow routing of packets to only those ports that are part of the VLAN. When properly configured, VLANS provide a dependable means for you to protect a set of virtual machines from accidental or malicious intrusions.
VLANs let you segment a physical network so that two machines in the network are unable to transmit packets back and forth unless they are part of the same VLAN. For example, accounting records and transactions are among a company's most sensitive internal information. In a company whose sales, shipping, and accounting employees all use virtual machines in the same physical network, you might protect the virtual machines for the accounting department by setting up VLANs.

In this configuration, all employees in the accounting department use virtual machines in VLAN A and the employees in sales use virtual machines in VLAN B.

The router forwards packets containing accounting data to the switches. These packets are tagged for distribution to VLAN A only. Therefore, the data is confined to Broadcast Domain A and cannot be routed to Broadcast Domain B unless the router is configured to do so.

This VLAN configuration prevents the sales force from intercepting packets destined for the accounting department. It also prevents the accounting department from receiving packets intended for the sales group. The virtual machines serviced by a single virtual switch can be in different VLANs.

**Security Considerations for VLANs**

The way you set up VLANs to secure parts of a network depends on factors such as the guest operating system and the way your network equipment is configured.
ESXi features a complete IEEE 802.1q-compliant VLAN implementation. VMware cannot make specific recommendations on how to set up VLANs, but there are factors to consider when using a VLAN deployment as part of your security enforcement policy.

**Secure VLANs**

Administrators have several options for securing the VLANs in their vSphere environment.

**Procedure**

1. Ensure that port groups are not configured to VLAN values that are reserved by upstream physical switches.
   
   Do not set VLAN IDs to values reserved for the physical switch.

2. Ensure that port groups are not configured to VLAN 4095 unless you are using for Virtual Guest Tagging (VGT).
   
   Three types of VLAN tagging exist in vSphere:
   - External Switch Tagging (EST)
   - Virtual Switch Tagging (VST) - The virtual switch tags with the configured VLAN ID the traffic that is incoming to the attached virtual machines and removes the VLAN tag from the traffic that is leaving them. To set up VST mode, assign a VLAN ID between 1 and 4095.
   - Virtual Guest Tagging (VGT) - Virtual machines handle VLAN traffic. To activate VGT mode, set the VLAN ID to 4095. On a distributed switch, you can also allow virtual machine traffic based on its VLAN by using the VLAN Trunking option.

3. Ensure that all VLANs on each virtual switch are fully documented and that each virtual switch has all required VLANs and only required VLANs.

**Creating a Network DMZ on a Single ESXi Host**

One example of how to use ESXi isolation and virtual networking features to configure a secure environment is the creation of a network demilitarized zone (DMZ) on a single host.
In this example, four virtual machines are configured to create a virtual DMZ on Standard Switch 2:

- Virtual Machine 1 and Virtual Machine 4 run firewalls and are connected to physical network adapters through standard switches. Both of these virtual machines are using multiple switches.
- Virtual Machine 2 runs a Web server, and Virtual Machine 3 runs as an application server. Both of these virtual machines are connected to one virtual switch.

The Web server and application server occupy the DMZ between the two firewalls. The conduit between these elements is Standard Switch 2, which connects the firewalls with the servers. This switch has no direct connection with any elements outside the DMZ and is isolated from external traffic by the two firewalls.

From an operational viewpoint, external traffic from the Internet enters Virtual Machine 1 through Hardware Network Adapter 1 (routed by Standard Switch 1) and is verified by the firewall installed on this machine. If the firewall authorizes the traffic, it is routed to the standard switch in the DMZ, Standard Switch 2. Because the Web server and application server are also connected to this switch, they can serve external requests.

Standard Switch 2 is also connected to Virtual Machine 4. This virtual machine provides a firewall between the DMZ and the internal corporate network. This firewall filters packets from the Web server and application server. If a packet is verified, it is routed to Hardware Network Adapter 2 through Standard Switch 3. Hardware Network Adapter 2 is connected to the internal corporate network.
When creating a DMZ on a single host, you can use fairly lightweight firewalls. Although a virtual machine in this configuration cannot exert direct control over another virtual machine or access its memory, all the virtual machines are still connected through a virtual network. This network could be used for virus propagation or targeted for other types of attacks. The security of the virtual machines in the DMZ is equivalent to separate physical machines connected to the same network.

Creating Multiple Networks Within a Single ESXi Host

The ESXi system is designed so that you can connect some groups of virtual machines to the internal network, others to the external network, and still others to both—all on the same host. This capability is an outgrowth of basic virtual machine isolation coupled with a well-planned use of virtual networking features.

Figure 9-4. External Networks, Internal Networks, and a DMZ Configured on a Single ESXi Host

In the figure, the system administrator configured a host into three distinct virtual machine zones: FTP server, internal virtual machines, and DMZ. Each zone serves a unique function.

FTPServer

Virtual Machine 1 is configured with FTP software and acts as a holding area for data sent to and from outside resources such as forms and collateral localized by a vendor.

This virtual machine is associated with an external network only. It has its own virtual switch and physical network adapter that connect it to External Network 1. This network is dedicated to servers that the company uses to receive data from outside sources. For example, the company uses External Network 1 to receive FTP traffic from vendors and allow vendors...
access to data stored on externally available servers though FTP. In addition to servicing Virtual Machine 1, External Network 1 services FTP servers configured on different ESXi hosts throughout the site.

Because Virtual Machine 1 does not share a virtual switch or physical network adapter with any virtual machines in the host, the other resident virtual machines cannot transmit packets to or receive packets from the Virtual Machine 1 network. This restriction prevents sniffing attacks, which require sending network traffic to the victim. More importantly, an attacker cannot use the natural vulnerability of FTP to access any of the host's other virtual machines.

**Internal virtual machines**

Virtual Machines 2 through 5 are reserved for internal use. These virtual machines process and store company-private data such as medical records, legal settlements, and fraud investigations. As a result, the system administrators must ensure the highest level of protection for these virtual machines.

These virtual machines connect to Internal Network 2 through their own virtual switch and network adapter. Internal Network 2 is reserved for internal use by personnel such as claims processors, in-house lawyers, or adjustors.

Virtual Machines 2 through 5 can communicate with one another through the virtual switch and with internal virtual machines elsewhere on Internal Network 2 through the physical network adapter. They cannot communicate with externally facing machines. As with the FTP server, these virtual machines cannot send packets to or receive packets from the other virtual machines' networks. Similarly, the host's other virtual machines cannot send packets to or receive packets from Virtual Machines 2 through 5.

**DMZ**

Virtual Machines 6 through 8 are configured as a DMZ that the marketing group uses to publish the company's external Web site.

This group of virtual machines is associated with External Network 2 and Internal Network 1. The company uses External Network 2 to support the Web servers that use the marketing and financial department to host the corporate Web site and other Web facilities that it hosts to outside users. Internal Network 1 is the conduit that the marketing department uses to publish content to the corporate Web site, post downloads, and maintain services like user forums.

Because these networks are separate from External Network 1 and Internal Network 2, and the virtual machines have no shared points of contact (switches or adapters), there is no risk of attack to or from the FTP server or the internal virtual machine group.

By capitalizing on virtual machine isolation, correctly configuring virtual switches, and maintaining network separation, the system administrator can house all three virtual machine zones in the same ESXi host and be confident that there will be no data or resource breaches.
The company enforces isolation among the virtual machine groups by using multiple internal and external networks and making sure that the virtual switches and physical network adapters for each group are completely separate from those of other groups.

Because none of the virtual switches straddle virtual machine zones, the system administrator succeeds in eliminating the risk of packet leakage from one zone to another. A virtual switch, by design, cannot leak packets directly to another virtual switch. The only way for packets to travel from one virtual switch to another is under the following circumstances:

- The virtual switches are connected to the same physical LAN.
- The virtual switches connect to a common virtual machine, which could be used to transmit packets.

Neither of these conditions occur in the sample configuration. If system administrators want to verify that no common virtual switch paths exist, they can check for possible shared points of contact by reviewing the network switch layout in the vSphere Web Client.

To safeguard the virtual machines’ resources, the system administrator lowers the risk of DoS and DDoS attacks by configuring a resource reservation and a limit for each virtual machine. The system administrator further protects the ESXi host and virtual machines by installing software firewalls at the front and back ends of the DMZ, ensuring that the host is behind a physical firewall, and configuring the networked storage resources so that each has its own virtual switch.

### Internet Protocol Security

Internet Protocol Security (IPsec) secures IP communications coming from and arriving at a host. ESXi hosts support IPsec using IPv6.

When you set up IPsec on a host, you enable authentication and encryption of incoming and outgoing packets. When and how IP traffic is encrypted depends on how you set up the system’s security associations and security policies.

A security association determines how the system encrypts traffic. When you create a security association, you specify the source and destination, encryption parameters, and a name for the security association.

A security policy determines when the system should encrypt traffic. The security policy includes source and destination information, the protocol and direction of traffic to be encrypted, the mode (transport or tunnel) and the security association to use.

### List Available Security Associations

ESXi can provide a list of all security associations available for use by security policies. The list includes both user created security associations and any security associations the VMkernel installed using Internet Key Exchange.

You can get a list of available security associations using the `esxcli` vSphere CLI command.
Procedure

- At the command prompt, enter the command `esxcli network ip ipsec sa list`.

Results

ESXi displays a list of all available security associations.

**Add a Security Association**

Add a security association to specify encryption parameters for associated IP traffic.

You can add a security association using the `esxcli` vSphere CLI command.

Procedure

- At the command prompt, enter the command `esxcli network ip ipsec sa add` with one or more of the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--sa-source= source address</code></td>
<td>Required. Specify the source address.</td>
</tr>
<tr>
<td><code>--sa-destination= destination address</code></td>
<td>Required. Specify the destination address.</td>
</tr>
<tr>
<td><code>--sa-mode= mode</code></td>
<td>Required. Specify the mode, either transport or tunnel.</td>
</tr>
<tr>
<td><code>--sa-spi= security parameter index</code></td>
<td>Required. Specify the security parameter index. The security parameter index identifies the security association to the host. It must be a hexadecimal with a 0x prefix. Each security association you create must have a unique combination of protocol and security parameter index.</td>
</tr>
<tr>
<td><code>--encryption-algorithm= encryption algorithm</code></td>
<td>Required. Specify the encryption algorithm using one of the following parameters.</td>
</tr>
<tr>
<td></td>
<td>- 3des-cbc</td>
</tr>
<tr>
<td></td>
<td>- aes128-cbc</td>
</tr>
<tr>
<td></td>
<td>- null</td>
</tr>
<tr>
<td></td>
<td>null provides no encryption.</td>
</tr>
<tr>
<td><code>--encryption-key= encryption key</code></td>
<td>Required when you specify an encryption algorithm. Specify the encryption key. You can enter keys as ASCII text or as a hexadecimal with a 0x prefix.</td>
</tr>
<tr>
<td><code>--integrity-algorithm= authentication algorithm</code></td>
<td>Required. Specify the authentication algorithm, either hmac-sha1 or hmac-sha2-256.</td>
</tr>
<tr>
<td><code>--integrity-key= authentication key</code></td>
<td>Required. Specify the authentication key. You can enter keys as ASCII text or as a hexadecimal with a 0x prefix.</td>
</tr>
<tr>
<td><code>--sa-name=name</code></td>
<td>Required. Provide a name for the security association.</td>
</tr>
</tbody>
</table>

Example: New Security Association Command

The following example contains extra line breaks for readability.

```
esxcli network ip ipsec sa add
   --sa-source 3ffe:501:ffff:0::a
```
Remove a Security Association

You can remove a security association from the host.

You can remove a security association using the `esxcli` vSphere CLI command.

Prerequisites

Be sure that the security association you want to use is not currently in use. If you try to remove a security association that is in use, the removal operation fails.

Procedure

- At the command prompt, enter the command

  `esxcli network ip ipsec sa remove --sa-name security_association_name`

List Available Security Policies

ESXi can provide a list of all security policies on the host.

You can get a list of available security policies using the `esxcli` vSphere CLI command.

Procedure

- At the command prompt, enter the command `esxcli network ip ipsec sp list`.

Results

The host displays a list of all available security policies.

Create a Security Policy

Create a security policy to determine when to use the authentication and encryption parameters set in a security association.

You can add a security policy using the `esxcli` vSphere CLI command.

Prerequisites

Before creating a security policy, add a security association with the appropriate authentication and encryption parameters as described in Add a Security Association.
Procedure

- At the command prompt, enter the command `esxcli network ip ipsec sp add` with one or more of the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--sp-source= source address</code></td>
<td>Required. Specify the source IP address and prefix length.</td>
</tr>
<tr>

</table>

Example: New Security Policy Command

The following example includes extra line breaks for readability.

```
esxcli network ip ipsec add
   --sp-source=2001:db8:1::/64
   --sp-destination=2002:db8:1::/64
   --source-port=23
   --destination-port=25
   --upper-layer-protocol=tcp
   --flow-direction=out
   --action=ipsec
   --sp-mode=transport
   --sa-name=sa1
   --sp-name=sp1
```
Remove a Security Policy

You can remove a security policy from the ESXi host.

You can remove a security policy using the esxcli vSphere CLI command.

Prerequisites

Be sure that the security policy you want to use is not currently in use. If you try to remove a security policy that is in use, the removal operation fails.

Procedure

1. At the command prompt, enter the command
   
esxcli network ip ipsec sp remove --sa-name security policy name.
   
   To remove all security policies, enter the command
   
esxcli network ip ipsec sp remove --remove-all.

Ensure Proper SNMP Configuration

If SNMP is not properly configured, monitoring information can be sent to a malicious host. The malicious host can then use this information to plan an attack.

Procedure

1. Run esxcli system snmp get to determine whether SNMP is currently used.
2. If your system does require SNMP, make sure that it is not running by running the esxcli system snmp set --enable true command.
3. If your system uses SNMP, see the Monitoring and Performance publication for setup information for SNMP 3.

   SNMP must be configured on each ESXi host. You can use vCLI, PowerCLI, or the vSphere Web Services SDK for configuration.

Use Virtual Switches on the vSphere Network Appliance Only If Required

If you are not using products that make use of the vSphere Network Appliance API (DvFilter), do not configure your host to send network information to a virtual machine. If the vSphere Network Appliance API is enabled, an attacker might attempt to connect a virtual machine to the filter. This connection might provide access to the network of other virtual machines on the host.

If you are using a product that makes use of this API, verify that the host is configured correctly. See the sections on DvFilter in Developing and Deploying vSphere Solutions, vServices, and ESX Agents. If your host is set up to use the API, make sure that the value of the Net.DVFilterBindIpAddress parameter matches the product that uses the API.
Procedure

1 To ensure that the Net.DVFilterBindIpAddress kernel parameter has the correct value, locate the parameter by using the vSphere Web Client.
   a Select the host and click the Manage tab.
   b Under System, select Advanced System Settings.
   c Scroll down to Net.DVFilterBindIpAddress and verify that the parameter has an empty value.

   The order of parameters is not strictly alphabetical. Scroll until you find the parameter.

2 If you are not using DvFilter settings, make sure that the value is blank.

3 If you are using DvFilter settings, make sure the value of the parameter matches the value that the product that uses the DvFilter is using.
Best Practices for Virtual Machine and Host Security

Consider basic security recommendations when creating and configuring hosts and virtual machines.

This chapter includes the following topics:

- Synchronizing Clocks on the vSphere Network
- Securing iSCSI Storage
- Masking and Zoning SAN Resources
- Control CIM-Based Hardware Monitoring Tool Access
- Verify That Sending Host Performance Data to Guests is Disabled

Synchronizing Clocks on the vSphere Network

Before you install vCenter Single Sign-On, install the vSphere Web Client, or deploy the vCenter Server Appliance, make sure that all machines on the vSphere network have their clocks synchronized.

If the clocks on vCenter Server network machines are not synchronized, SSL certificates, which are time-sensitive, might not be recognized as valid in communications between network machines. Unsynchronized clocks can result in authentication problems, which can cause the vSphere Web Client installation to fail or prevent the vCenter Server Appliance vpxd service from starting.

Make sure that any Windows host on which a vCenter component runs is synchronized with the NTP server. See the Knowledge Base article Timekeeping best practices for Windows, including NTP.

- **Synchronize ESX and ESXi Clocks with a Network Time Server**
  Before you install vCenter Single Sign-On, the vSphere Web Client, or the vCenter Server appliance, make sure all machines on the vSphere network have their clocks synchronized.
Synchronize the vCenter Server Appliance Clock with an NTP Server

Before you deploy the vCenter Server Appliance, make sure all machines on the network have their clocks synchronized. Unsynchronized clocks can cause installation and authentication errors.

Synchronize ESX and ESXi Clocks with a Network Time Server

Before you install vCenter Single Sign-On, the vSphere Web Client, or the vCenter Server appliance, make sure all machines on the vSphere network have their clocks synchronized.

Procedure

1. From the vSphere Web Client, connect to the vCenter Server.
2. Select the host in the inventory.
3. Select the Manage tab.
4. Select Settings.
5. In the System section, select Time Configuration.
6. Click Edit and set up the NTP server.
   a. Select Use Network Time Protocol (Enable NTP client).
   b. Set the NTP Service Startup Policy.
   c. Enter the IP addresses of the NTP servers to synchronize with.
   d. Click Start or Restart in the NTP Service Status section.
7. Click OK.

The host synchronizes with the NTP server.

Synchronize the vCenter Server Appliance Clock with an NTP Server

Before you deploy the vCenter Server Appliance, make sure all machines on the network have their clocks synchronized. Unsynchronized clocks can cause installation and authentication errors.

On systems that are joined to a Windows domain, the vCenter Server Appliance clock is synchronized automatically with the domain controller. On other systems, you can enable synchronizing the clock through VMware Tools. As an alternative, you can use this procedure.

Procedure

1. Open a Web browser and navigate to the vCenter Server Appliance Management Interface (https://vCenter-Appliance-IP-Address:5480/).
2. Log in as root.
3. From the vCenter Server tab, select the Time subtab.
4  Select one or more of the available options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>No synchronization</td>
<td>Does not perform synchronization.</td>
</tr>
<tr>
<td>NTP synchronization</td>
<td>Select this option and specify one or more NTP servers to configure the appliance to synchronize with an NTP server directly.</td>
</tr>
<tr>
<td>VMware Tools synchronization</td>
<td>Select this option to synchronize all virtual machines.</td>
</tr>
<tr>
<td>Active Directory synchronization</td>
<td>This option becomes available only if you add the appliance to an Active Directory domain. If you select this option, none of the other options is available.</td>
</tr>
</tbody>
</table>

5  Click **Save Settings**.

Results

The vCenter Server Appliance clock is synchronized with the NTP server.

Securing iSCSI Storage

The storage you configure for a host might include one or more storage area networks (SANs) that use iSCSI. When you configure iSCSI on a host, you can take several measures to minimize security risks.

iSCSI is a means of accessing SCSI devices and exchanging data records by using TCP/IP over a network port rather than through a direct connection to a SCSI device. In iSCSI transactions, blocks of raw SCSI data are encapsulated in iSCSI records and transmitted to the requesting device or user.

iSCSI SANs let you make efficient use of existing Ethernet infrastructures to provide hosts access to storage resources that they can dynamically share. iSCSI SANs provide an economical storage solution for environments that rely on a common storage pool to serve numerous users. As with any networked system, your iSCSI SANs can be subject to security breaches.

**Note**  The requirements and procedures for securing an iSCSI SAN are similar for the hardware iSCSI adapters you can use with hosts and for iSCSI configured directly through the host.

Securing iSCSI Devices Through Authentication

One means of securing iSCSI devices from unwanted intrusion is to require that the host, or initiator, be authenticated by the iSCSI device, or target, whenever the host attempts to access data on the target LUN.

The goal of authentication is to prove that the initiator has the right to access a target, a right granted when you configure authentication.

ESXi does not support Kerberos, Secure Remote Protocol (SRP), or public-key authentication methods for iSCSI. Additionally, it does not support IPsec authentication and encryption.
Use the vSphere Web Client to determine whether authentication is being performed and to configure the authentication method.

**Protecting an iSCSI SAN**

When you plan your iSCSI configuration, take measures to improve the overall security of the iSCSI SAN. Your iSCSI configuration is only as secure as your IP network, so by enforcing good security standards when you set up your network, you help safeguard your iSCSI storage.

The following are some specific suggestions for enforcing good security standards.

**Protect Transmitted Data**

A primary security risk in iSCSI SANs is that an attacker might sniff transmitted storage data.

Take additional measures to prevent attackers from easily seeing iSCSI data. Neither the hardware iSCSI adapter nor ESXi iSCSI initiator encrypts the data that they transmit to and from the targets, making the data more vulnerable to sniffing attacks.

Allowing your virtual machines to share standard switches and VLANs with your iSCSI configuration potentially exposes iSCSI traffic to misuse by a virtual machine attacker. To help ensure that intruders cannot listen to iSCSI transmissions, make sure that none of your virtual machines can see the iSCSI storage network.

If you use a hardware iSCSI adapter, you can accomplish this by making sure that the iSCSI adapter and ESXi physical network adapter are not inadvertently connected outside the host by virtue of sharing a switch or some other means. If you configure iSCSI directly through the ESXi host, you can accomplish this by configuring iSCSI storage through a different standard switch than the one used by your virtual machines.

In addition to protecting the iSCSI SAN by giving it a dedicated standard switch, you can configure your iSCSI SAN on its own VLAN to improve performance and security. Placing your iSCSI configuration on a separate VLAN ensures that no devices other than the iSCSI adapter have visibility into transmissions within the iSCSI SAN. Also, network congestion from other sources cannot interfere with iSCSI traffic.

**Secure iSCSI Ports**

When you run iSCSI devices, ESXi does not open any ports that listen for network connections. This measure reduces the chances that an intruder can break into ESXi through spare ports and gain control over the host. Therefore, running iSCSI does not present any additional security risks at the ESXi end of the connection.

Any iSCSI target device that you run must have one or more open TCP ports to listen for iSCSI connections. If any security vulnerabilities exist in the iSCSI device software, your data can be at risk through no fault of ESXi. To lower this risk, install all security patches that your storage equipment manufacturer provides and limit the devices connected to the iSCSI network.
Masking and Zoning SAN Resources

You can use zoning and LUN masking to separate SAN activity and restrict access to storage devices.

You can protect access to storage in your vSphere environment by using zoning and LUN masking with your SAN resources. For example, you might manage zones defined for testing independently within the SAN so they do not interfere with activity in the production zones. Similarly, you might set up different zones for different departments.

When you set up zones, take into account any host groups that are set up on the SAN device.

Zoning and masking capabilities for each SAN switch and disk array and the tools for managing LUN masking are vendor specific.

See your SAN vendor's documentation and the vSphere Storage documentation.

Control CIM-Based Hardware Monitoring Tool Access

The Common Information Model (CIM) system provides an interface that enables hardware-level management from remote applications using a set of standard APIs. To ensure that the CIM interface is secure, provide only the minimum access necessary to these applications. If an application has been provisioned with a root or full administrator account and the application is compromised, the full virtual environment might be compromised.

CIM is an open standard that defines a framework for agent-less, standards-based monitoring of hardware resources for ESXi. This framework consists of a CIM object manager, often called a CIM broker, and a set of CIM providers.

CIM provides are used as the mechanism to provide management access to device drivers and underlying hardware. Hardware vendors, including server manufacturers and specific hardware device vendors, can write providers to provide monitoring and management of their particular devices. VMware also writes providers that implement monitoring of server hardware, ESXi storage infrastructure, and virtualization-specific resources. These providers run inside the ESXi system and therefore are designed to be extremely lightweight and focused on specific management tasks. The CIM broker takes information from all CIM providers, and presents it to the outside world via standard APIs, the most common one being WS-MAN.

Do not provide root credentials to remote applications to access the CIM interface. Instead, create a service account specific to these applications and grant read-only access to CIM information to any local account defined on the ESXi system, as well as any role defined in vCenter Server.

Procedure

1. Create a service account specific to CIM applications.
2. Grant read-only access to CIM information to any local account defined on the ESXi system, as well as any role defined in vCenter Server.
3 (Optional) If the application requires write access to the CIM interface, create a role to apply to the service account with only two privileges:

- Host.Config.SystemManagement
- Host.CIM.CIMInteraction

This role can be local to the host or centrally defined on vCenter Server, depending on how the monitoring application works.

Results

When a user logs into the host with the service account you created for CIM applications, the user has only the privileges SystemManagement and CIMInteraction, or read-only access.

Verify That Sending Host Performance Data to Guests is Disabled

vSphere includes virtual machine performance counters on Windows operating systems where VMware Tools is installed. Performance counters allow virtual machine owners to do accurate performance analysis within the guest operating system. By default, vSphere does not expose host information to the guest virtual machine.

The ability to send host performance data to a guest virtual machine is disabled by default. This default setting prevents a virtual machine from obtaining detailed information about the physical host, and does not make host data available if a breach of security of the virtual machine occurs.

Note The procedure below illustrates the basic process. Use the vSphere or one of the vSphere command-line interfaces (vCLI, PowerCLI, and so on) for performing this task on all hosts simultaneously instead.

Procedure

1 On the ESXi system that hosts the virtual machine, browse to the VMX file.
   Virtual machine configuration files are located in the /vmfs/volumes/datastore directory, where datastore is the name of the storage device where the virtual machine files are stored.

2 In the VMX file, verify that the following parameter is set.
   tools.guestlib.enableHostInfo=FALSE

3 Save and close the file.

Results

You cannot retrieve performance information about the host from inside the guest virtual machine.
Defined Privileges

The following tables list the default privileges that, when selected for a role, can be paired with a user and assigned to an object. The tables in this appendix use VC to indicate vCenter Server and HC to indicate host client, a standalone ESXi or Workstation host.

When setting permissions, verify all the object types are set with appropriate privileges for each particular action. Some operations require access permission at the root folder or parent folder in addition to access to the object being manipulated. Some operations require access or performance permission at a parent folder and a related object.

vCenter Server extensions might define additional privileges not listed here. Refer to the documentation for the extension for more information on those privileges.

This chapter includes the following topics:

- Alarms
- Datacenter
- Datastore
- Datastore Cluster
- vSphere Distributed Switch
- ESX Agent Manager
- Extension
- Folder
- Global
- Host CIM
- Host Configuration
- Host Inventory
- Host Local Operations
- Host vSphere Replication
- Host Profile
Alarms

Alarms privileges control the ability to set and respond to alarms on inventory objects.

The table describes privileges needed to create, modify, and respond to alarms.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at
the folder level, you can propagate the privilege to one or more objects within the folder. The
object listed in the Required On column must have the privilege set, either directly or inherited.
### Table 11-1. Alarms Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alarms.Acknowledge alarm</td>
<td>Allows suppression of all alarm actions on all triggered alarms.</td>
<td>Object on which an alarm is defined</td>
</tr>
<tr>
<td>Alarms.Create alarm</td>
<td>Allows creation of a new alarm. When creating alarms with a custom action, privilege to perform the action is verified when the user creates the alarm.</td>
<td>Object on which an alarm is defined</td>
</tr>
<tr>
<td>Alarms.Disable alarm action</td>
<td>Allows stopping an alarm action from occurring after an alarm has been triggered. This does not disable the alarm.</td>
<td>Object on which an alarm is defined</td>
</tr>
<tr>
<td>Alarms.Modify alarm</td>
<td>Allows changing the properties of an alarm.</td>
<td>Object on which an alarm is defined</td>
</tr>
<tr>
<td>Alarms.Remove alarm</td>
<td>Allows deletion of an alarm.</td>
<td>Object on which an alarm is defined</td>
</tr>
<tr>
<td>Alarms.Set alarm status</td>
<td>Allows changing the status of the configured event alarm. The status can change to Normal, Warning, or Alert.</td>
<td>Object on which an alarm is defined</td>
</tr>
</tbody>
</table>

### Datacenter

Datacenter privileges control the ability to create and edit datacenters in the vSphere Web Client inventory.

The table describes the privileges required to create and edit datacenters. All datacenter privileges are used in vCenter Server only. The **Create datacenter** privilege is defined on datacenter folders or the root object. All other datacenter privileges are pair with datacenters, datacenter folders, or the root object.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

### Table 11-2. Datacenter Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datacenter.Create datacenter</td>
<td>Allows creation of new datacenter.</td>
<td>Datacenter folder or root object</td>
</tr>
<tr>
<td>Datacenter.Move datacenter</td>
<td>Allows moving a datacenter.</td>
<td>Datacenter, source and destination</td>
</tr>
<tr>
<td></td>
<td>Privilege must be present at both the source and destination.</td>
<td></td>
</tr>
<tr>
<td>Datacenter.Network profile configuration</td>
<td>Allows configuration of the network profile for a datacenter.</td>
<td>Datacenter</td>
</tr>
<tr>
<td>Datacenter.Query IP pool allocation</td>
<td>Allows configuration of a pool of IP addresses.</td>
<td>Datacenter</td>
</tr>
</tbody>
</table>
### Table 11-2. Datacenter Privileges (continued)

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datacenter.Reconfigure datacenter</td>
<td>Allows reconfiguration of a datacenter.</td>
<td>Datacenter</td>
</tr>
<tr>
<td>Datacenter.Release IP allocation</td>
<td>Allows releasing the assigned IP allocation for a datacenter.</td>
<td>Datacenter</td>
</tr>
<tr>
<td>Datacenter.Remove datacenter</td>
<td>Allows removal of a datacenter. In order to have permission to perform this operation, you must have this privilege assigned to both the object and its parent object.</td>
<td>Datacenter plus parent object</td>
</tr>
<tr>
<td>Datacenter RENAME datacenter</td>
<td>Allows changing the name of a datacenter.</td>
<td>Datacenter</td>
</tr>
</tbody>
</table>

### Datastore

Datastore privileges control the ability to browse, manage, and allocate space on datastores. The table describes the privileges required to work with datastores.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

### Table 11-3. Datastore Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datastore.Allocate space</td>
<td>Allows allocating space on a datastore for a virtual machine, snapshot, clone, or virtual disk.</td>
<td>Datastores</td>
</tr>
<tr>
<td>Datastore.Browse datastore</td>
<td>Allows browsing files on a datastore.</td>
<td>Datastores</td>
</tr>
<tr>
<td>Datastore.Configure datastore</td>
<td>Allows configuration of a datastore.</td>
<td>Datastores</td>
</tr>
<tr>
<td>Datastore.Low level file operations</td>
<td>Allows performing read, write, delete, and rename operations in the datastore browser.</td>
<td>Datastores</td>
</tr>
<tr>
<td>Datastore.Move datastore</td>
<td>Allows moving a datastore between folders. Privileges must be present at both the source and destination.</td>
<td>Datastore, source and destination</td>
</tr>
<tr>
<td>Datastore.Remove datastore</td>
<td>Allows removal of a datastore. This privilege is deprecated. To have permission to perform this operation, you must have this privilege assigned to both the object and its parent object.</td>
<td>Datastores</td>
</tr>
<tr>
<td>Datastore.Remove file</td>
<td>Allows deletion of files in the datastore. This privilege is deprecated. Assign the <strong>Low level file operations</strong> privilege.</td>
<td>Datastores</td>
</tr>
</tbody>
</table>

<td>datastore after the datastore has been resignatured.</td>
<td></td>
</tr>
</tbody>
</table>

Datastore Cluster

Datastore cluster privileges control the configuration of datastore clusters for Storage DRS.

The table describes privileges used for configuring datastore clusters.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-4. Datastore Cluster Privileges

<table>
<thead>

<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datastore cluster.Configure a datastore</td>
<td>Allows creation of and configuration of settings for datastore clusters for Storage DRS.</td>
<td>Datastore Clusters</td>
</tr>
</tbody>
</table>

vSphere Distributed Switch

vSphere Distributed Switch privileges control the ability to perform tasks related to the management of vSphere Distributed Switches.

The table describes the privileges required to create and configure vSphere Distributed Switches.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-5. vSphere Distributed Switch Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>

</tr>
<tr>
<td>vSphere Distributed Switch.Policy operation</td>
<td>Allows changing the policy of a vSphere Distributed Switch.</td>
<td>vSphere Distributed Switches</td>
</tr>
<tr>
<td>vSphere Distributed Switch.Port configuration operation</td>
<td>Allow changing the configuration of a port in a vSphere Distributed Switch.</td>
<td>vSphere Distributed Switches</td>
</tr>
<tr>
<td>vSphere Distributed Switch.Port setting operation</td>
<td>Allows changing the setting of a port in a vSphere Distributed Switch.</td>
<td>vSphere Distributed Switches</td>
</tr>
<tr>
<td>vSphere Distributed Switch.VSPAN operation</td>
<td>Allows changing the VSPAN configuration of a vSphere Distributed Switch.</td>
<td>vSphere Distributed Switches</td>
</tr>
</tbody>
</table>

ESX Agent Manager

ESX Agent Manager privileges control operations related to ESX Agent Manager and agent virtual machines.

The table describes privileges related to ESX Agent Manager and agent virtual machines.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-6. ESX Agent Manager

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESX Agent Manager.Config</td>
<td>Allows deployment of an agent virtual machine on a host or cluster.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>ESX Agent Manager.Modify</td>
<td>Allows modifications to an agent virtual machine such as powering off or deleting the virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>ESX Agent View.View</td>
<td>Allows viewing of an agent virtual machine.</td>
<td>Virtual machines</td>
</tr>
</tbody>
</table>

Extension

Extension privileges control the ability to install and manage extensions.

The table describes privileges required to install and manage plug-ins.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.
Table 11-7. Extension Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extension.Register extension</td>
<td>Allows registration of an extension (plug-in).</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Extension.Unregister extension</td>
<td>Allows unregistering an extension (plug-in).</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Extension.Update extension</td>
<td>Allows updates to an extension (plug-in).</td>
<td>Root vCenter Server</td>
</tr>
</tbody>
</table>

Folder

Folder privileges control the ability to create and manage folders.

The table describes privileges required to create and manage folders.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-8. Folder Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Folder.Create folder</td>
<td>Allows creation of a new folder.</td>
<td>Folders</td>
</tr>
<tr>
<td>Folder.Delete folder</td>
<td>Allows deletion of a folder. To have permission to perform this operation, you must have this privilege assigned to both the object and its parent object.</td>
<td>Folders</td>

<td>Folder.Move folder</td>
<td>Allows moving a folder. Privilege must be present at both the source and destination.</td>
<td>Folders</td>
</tr>
<tr>
<td>Folder.Rename folder</td>
<td>Allows changing the name of a folder.</td>
<td>Folders</td>
</tr>
</tbody>
</table>

Global

Global privileges control global tasks related to tasks, scripts, and extensions.

The table describes privileges required for global tasks in the vSphere Web Client.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-9. Global Privileges

<td>Allows viewing the health of vCenter Server components.</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Global.Licenses</td>
<td>Allows viewing installed licenses and adding or removing licenses.</td>
<td>Root host or vCenter Server</td>
</tr>
<tr>
<td>Global.Log event</td>
<td>Allows logging a user-defined event against a particular managed entity.</td>
<td>Any object</td>
</tr>
<tr>
<td>Global.Manage custom attributes</td>
<td>Allows adding, removing, or renaming custom field definitions.</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Global.Proxy</td>
<td>Allows access to an internal interface for adding or removing endpoints to or from the proxy.</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Global.Script action</td>
<td>Allows scheduling a scripted action in conjunction with an alarm.</td>
<td>Any object</td>
</tr>
<tr>
<td>Global.Service managers</td>
<td>Allows use of the resxtop command in the vSphere CLI.</td>
<td>Root host or vCenter Server</td>
</tr>
<tr>
<td>Global.Set custom attribute</td>
<td>Allows viewing, creating, or removing custom attributes for a managed object.</td>
<td>Any object</td>
</tr>
<tr>
<td>Global.Settings</td>
<td>Allows reading and modifying runtime vCenter Server configuration settings.</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Global.System tag</td>
<td>Allows adding or removing system tags.</td>
<td>Root vCenter Server</td>
</tr>
</tbody>
</table>

Host CIM

Host CIM privileges control the use of CIM for host health monitoring.

The table describes privileges used for CIM host health monitoring.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.
Table 11-10. Host CIM Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host.CIM.CIM Interaction</td>
<td>Allow a client to obtain a ticket to use for CIM services.</td>
<td>Hosts</td>
</tr>
</tbody>
</table>

**Host Configuration**

Host configuration privileges control the ability to configure hosts.

The table describes the privileges required to configure host settings.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-11. Host Configuration Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host.Configuration.Advanced Settings</td>
<td>Allows setting advanced options in host configuration.</td>
<td>Hosts</td>
</tr>
<tr>
<td>Host.Configuration.Change date and time settings</td>
<td>Allows changes to date and time settings on the host.</td>
<td>Hosts</td>
</tr>
<tr>
<td>Host.Configuration.Change PciPassthru settings</td>
<td>Allows changes to PciPassthru settings for a host.</td>
<td>Hosts</td>
</tr>
<tr>
<td>Host.Configuration.Change settings</td>
<td>Allows setting of lockdown mode on ESXi hosts. Lockdown mode is not supported on ESX hosts.</td>
<td>Hosts</td>
</tr>
<tr>
<td>Host.Configuration.Change SNMP settings</td>
<td>Allows configuring, restarting, and stopping the SNMP agent.</td>
<td>Hosts</td>
</tr>
<tr>
<td>Host.Configuration.Connection</td>
<td>Allows changes to the connection status of a host (connected or disconnected).</td>
<td>Hosts</td>
</tr>
<tr>
<td>Host.Configuration.Firmware</td>
<td>Allows updates to the ESXi host's firmware.</td>
<td>Hosts</td>
</tr>
<tr>
<td>Host.Configuration.Hyperthreading</td>
<td>Allows enabling and disabling hyperthreading in a host CPU scheduler.</td>
<td>Hosts</td>
</tr>
<tr>
<td>Host.Configuration.Image configuration</td>
<td>Allows changes to the image associated with a host.</td>
<td></td>
</tr>
<tr>
<td>Host.Configuration.Maintenance</td>
<td>Allows putting the host in and out of maintenance mode and shutting down and restarting the host.</td>
<td>Hosts</td>
</tr>
<tr>
<td>Host.Configuration.Memory configuration</td>
<td>Allows modifications to the host configuration</td>
<td>Hosts</td>
</tr>
<tr>
<td>Host.Configuration.Network configuration</td>
<td>Allows configuration of network, firewall, and vMotion network.</td>
<td>Hosts</td>
</tr>
<tr>
<td>Host.Configuration.Power</td>
<td>Allows configuration of host power management settings.</td>
<td>Hosts</td>
</tr>
</tbody>
</table>
Table 11-11. Host Configuration Privileges (continued)

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host.Configuration.Query patch</td>
<td>Allows querying for installable patches and installing patches on the host.</td>
<td>Hosts</td>
</tr>
<tr>
<td>Host.Configuration.Security profile and firewall</td>
<td>Allows configuration of Internet services, such as SSH, Telnet, SNMP, and of the host firewall.</td>
<td>Hosts</td>
</tr>
<tr>
<td>Host.Configuration.Storage partition configuration</td>
<td>Allows VMFS datastore and diagnostic partition management. Users with this privilege can scan for new storage devices and manage iSCSI.</td>
<td>Hosts</td>
</tr>
<tr>
<td>Host.Configuration.System Management</td>
<td>Allows extensions to manipulate the file system on the host.</td>
<td>Hosts</td>
</tr>
<tr>
<td>Host.Configuration.System resources</td>
<td>Allows updates to the configuration of the system resource hierarchy.</td>
<td>Hosts</td>
</tr>
<tr>
<td>Host.Configuration.Virtual machine autostart config.</td>
<td>Allows changes to the auto-start and auto-stop order of virtual machines on a single host.</td>
<td>Hosts</td>
</tr>
</tbody>
</table>

Host Inventory

Host inventory privileges control adding hosts to the inventory, adding hosts to clusters, and moving hosts in the inventory.

The table describes the privileges required to add and move hosts and clusters in the inventory.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-12. Host Inventory Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>

</tr>
<tr>
<td>Host.Inventory.Rename cluster</td>
<td>Allows renaming a cluster.</td>
<td>Clusters</td>
</tr>
</tbody>
</table>

Host Local Operations

Host local operations privileges control actions performed when the vSphere Client is connected directly to a host.

The table describes the privileges required for actions performed when the vSphere Client is connected directly to a single host.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-13. Host Local Operations Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>

</tr>
</tbody>
</table>
Host vSphere Replication

Host vSphere replication privileges control the use of replication for a host's virtual machines.

The table describes privileges used for virtual machine replication by VMware vCenter Site Recovery Manager™.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-14. Host vSphere Replication Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host.vSphere Replication.Manage</td>
<td>Allows management of virtual machine replication on this host.</td>
<td>Hosts</td>
</tr>
</tbody>
</table>

Host Profile

Host Profile privileges control operations related to creating and modifying host profiles.

The table describes privileges required for creating and modifying host profiles.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-15. Host Profile Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host profile.Clear</td>
<td>Allows clearing of profile related information.</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Host profile.Create</td>
<td>Allows creation of a host profile.</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Host profile.Delete</td>
<td>Allows deletion of a host profile.</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Host profile.Edit</td>
<td>Allows editing a host profile.</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Host profile.Export</td>
<td>Allows exporting a host profile</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Host profile.View</td>
<td>Allows viewing a host profile.</td>
<td>Root vCenter Server</td>
</tr>
</tbody>
</table>

Network

Network privileges control tasks related to network management.

The table describes privileges required for network management.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.
Table 11-16. Network Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network.Assign network</td>
<td>Allows assigning a network to a virtual machine.</td>
<td>Networks, Virtual Machines</td>
</tr>
<tr>
<td>Network.Configure</td>
<td>Allows configuring a network.</td>
<td>Networks, Virtual Machines</td>
</tr>
<tr>
<td>Network.Move network</td>
<td>Allows moving a network between folders.</td>
<td>Networks</td>
</tr>
<tr>
<td></td>
<td>Privilege must be present at both the source and destination.</td>
<td></td>
</tr>
<tr>
<td>Network.Remove</td>
<td>Allows removal of a network.</td>
<td>Networks</td>
</tr>
<tr>
<td></td>
<td>This privilege is deprecated.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>To have permission to perform this operation, you must have this privilege assigned to both the object and its parent object.</td>
<td></td>
</tr>
</tbody>
</table>

Performance

Performance privileges control modifying performance statistics settings.

The table describes privileges required to modify performance statistics settings.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-17. Performance Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Performance.Modify intervals</td>
<td>Allows creating, removing, and updating performance data collection intervals.</td>
<td>Root vCenter Server</td>
</tr>
</tbody>
</table>

Permissions

Permissions privileges control the assigning of roles and permissions.

The table describes permissions required for assigning roles and permissions.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.
Table 11-18. Permissions Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permissions.Modify</td>
<td>Allows defining one or more permission rules on an entity, or updating rules if rules are already present for the given user or group on the entity. To have permission to perform this operation, you must have this privilege assigned to both the object and its parent object.</td>
<td>Any object plus parent object</td>
</tr>
<tr>
<td>permission</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Permissions.Modify role</td>
<td>Allows updating a role's name and its privileges.</td>
<td>Any object</td>
</tr>
<tr>
<td>Permissions.Reassign role</td>
<td>Allows reassigning all permissions of a role to another role.</td>
<td>Any object</td>
</tr>
<tr>
<td>permissions</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Profile-driven Storage

Profile-driven storage privileges control operations related to storage profiles.

The table describes privileges required for viewing and updating storage profiles.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-19. Profile-driven Storage Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Profile-driven storage.View</td>
<td>Allows viewing of defined storage capabilities and storage profiles.</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Profile-driven storage.Update</td>
<td>Allows changes to be made to storage profiles, such as creating and updating storage capabilities and virtual machine storage profiles.</td>
<td>Root vCenter Server</td>
</tr>
</tbody>
</table>

Resource

Resource privileges control the creation and management of resource pools, as well as the migration of virtual machines.

The table describes privileges that control resource management and virtual machine migration.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.
### Table 11-20. Resource Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource.Apply recommendation</td>
<td>Allows accepting a suggestion by the server to perform a migration with vMotion.</td>
<td>Clusters</td>
</tr>
<tr>
<td>Resource.Assign vApp to resource pool</td>
<td>Allows assignment of a vApp to a resource pool.</td>
<td>Resource pools</td>
</tr>
<tr>
<td>Resource.Assign virtual machine to resource pool</td>
<td>Allows assignment of a virtual machine to a resource pool.</td>
<td>Resource pools</td>
</tr>
<tr>
<td>Resource.Create resource pool</td>
<td>Allows creation of resource pools.</td>
<td>Resource pools, clusters</td>
</tr>
<tr>
<td>Resource.Migrate powered off virtual machine</td>
<td>Allows migration of a powered off virtual machine to a different resource pool or host.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Resource.Migrate powered on virtual machine</td>
<td>Allows migration with vMotion of a powered on virtual machine to a different resource pool or host.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Resource.Modify resource pool</td>
<td>Allows changes to the allocations of a resource pool.</td>
<td>Resource pools</td>
</tr>
<tr>
<td>Resource.Move resource pool</td>
<td>Allows moving a resource pool. Priviliege must be present at both the source and destination.</td>
<td>Resource pools</td>
</tr>
<tr>
<td>Resource.Query vMotion</td>
<td>Allows querying the general vMotion compatibility of a virtual machine with a set of hosts.</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Resource.Relocate</td>
<td>Allows cold migration of a virtual machine’s execution to a specific resource pool or host.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Resource.Remove resource pool</td>
<td>Allows deletion of a resource pool. To have permission to perform this operation, you must have this privilege assigned to both the object and its parent object.</td>
<td>Resource pools</td>
</tr>
</tbody>
</table>

### Scheduled Task

Scheduled task privileges control creation, editing, and removal of scheduled tasks.

The table describes privileges required for creating and modifying scheduled tasks.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

### Table 11-21. Scheduled Task Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scheduled task.Create tasks</td>
<td>Allows scheduling of a task. Required in addition to the privileges to perform the scheduled action at the time of scheduling.</td>
<td>Any object</td>
</tr>
<tr>
<td>Scheduled task.Modify task</td>
<td>Allows reconfiguration of the scheduled task properties.</td>
<td>Any object</td>
</tr>
</tbody>
</table>
Table 11-21. Scheduled Task Privileges (continued)

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scheduled task.Remove task</td>
<td>Allows removal of a scheduled task from the queue.</td>
<td>Any object</td>
</tr>
<tr>
<td>Scheduled task.Run task</td>
<td>Allows running the scheduled task immediately. Creating and running a scheduled task also requires permission to perform the associated action.</td>
<td>Any object</td>
</tr>
</tbody>
</table>

Sessions

Sessions privileges control the ability of extensions to open sessions on the vCenter Server.

The table describes the privileges associated with sessions on vCenter Server.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-22. Session Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sessions.Impersonate user</td>
<td>Allow impersonation of another user. This capability is used by extensions.</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Sessions.Message</td>
<td>Allow setting of the global log in message.</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Sessions.Validate session</td>
<td>Allow verification of session validity.</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Sessions.View and stop sessions</td>
<td>Allow viewing sessions and forcing log out of one or more logged-on users.</td>
<td>Root vCenter Server</td>
</tr>
</tbody>
</table>

Storage Views

Storage Views privileges control the ability to configure and use storage views on vCenter Server.

The table describes privileges required to configure and use storage views.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-23. Storage Views Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Storage views.Configure service</td>
<td>Allows changing options such as the reports update interval and database connectivity information.</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Storage views.View</td>
<td>Allows viewing of the Storage Views tab.</td>
<td>Root vCenter Server</td>
</tr>
</tbody>
</table>
Tasks

Tasks privileges control the ability of extensions to create and update tasks on the vCenter Server.

The table describes privileges related to tasks.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-24. Tasks Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tasks.Create task</td>
<td>Allows an extension to create a user-defined task.</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Tasks.Update task</td>
<td>Allows an extension to update a user-defined task.</td>
<td>Root vCenter Server</td>
</tr>
</tbody>
</table>

vApp

vApp privileges control operations related to deploying and configuring a vApp.

The table describes privileges related to vApps.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-25. vApp Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>vApp.Add virtual machine</td>
<td>Allows adding a virtual machine to a vApp.</td>
<td>vApps</td>
</tr>
<tr>
<td>vApp.Assign resource pool</td>
<td>Allows assigning a resource pool to a vApp.</td>
<td>vApps</td>
</tr>
<tr>
<td>vApp.Assign vApp</td>
<td>Allows assigning a vApp to another vApp</td>
<td>vApps</td>
</tr>
<tr>
<td>vApp.Clone</td>
<td>Allows cloning of a vApp.</td>
<td>vApps</td>
</tr>
<tr>
<td>vApp.Create</td>
<td>Allows creation of a vApp.</td>
<td>vApps</td>
</tr>
<tr>
<td>vApp.Delete</td>
<td>Allows deletion of a vApp.</td>
<td>vApps</td>
</tr>
<tr>
<td></td>
<td>To have permission to perform this operation, you must have this privilege assigned to both the object and its parent object.</td>
<td></td>
</tr>
<tr>
<td>vApp.Export</td>
<td>Allows export of a vApp from vSphere.</td>
<td>vApps</td>
</tr>
<tr>
<td>vApp.Import</td>
<td>Allows import of a vApp into vSphere.</td>
<td>vApps</td>
</tr>
<tr>
<td>vApp.Move</td>
<td>Allows moving a vApp to a new inventory location.</td>
<td>vApps</td>
</tr>
<tr>
<td>vApp.Power Off</td>
<td>Allows power off operations on a vApp.</td>
<td>vApps</td>
</tr>
<tr>
<td>vApp.Power On</td>
<td>Allows power on operations on a vApp.</td>
<td>vApps</td>
</tr>
<tr>
<td>vApp.Rename</td>
<td>Allows renaming a vApp.</td>
<td>vApps</td>
</tr>
</tbody>
</table>
### Table 11-25. vApp Privileges (continued)

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>vApp.Suspend</td>
<td>Allows suspension of a vApp.</td>
<td>vApps</td>
</tr>
<tr>
<td>vApp.Unregister</td>
<td>Allows unregistering a vApp. To have permission to perform this operation, you must have this privilege assigned to both the object and its parent object.</td>
<td>vApps</td>
</tr>
<tr>
<td>vApp.View OVF Environment</td>
<td>Allows viewing the OVF environment of a powered-on virtual machine within a vApp.</td>
<td>vApps</td>
</tr>
<tr>
<td>vApp.vApp application configuration</td>
<td>Allows modification of a vApp’s internal structure, such as product information and properties.</td>
<td>vApps</td>
</tr>
<tr>
<td>vApp.vApp instance configuration</td>
<td>Allows modification of a vApp’s instance configuration, such as policies.</td>
<td>vApps</td>
</tr>
<tr>
<td>vApp.vApp managedBy configuration</td>
<td>Allows an extension or solution to mark a vApp as being managed by that extension or solution. No vSphere Web Client user interface elements are associated with this privilege.</td>
<td>vApps</td>
</tr>
<tr>
<td>vApp.vApp resource configuration</td>
<td>Allows modification of a vApp’s resource configuration. To have permission to perform this operation, you must have this privilege assigned to both the object and its parent object.</td>
<td>vApps</td>
</tr>
</tbody>
</table>

### vCenter Inventory Service Tagging

vCenter Inventory Service Tagging privileges control the ability to create and delete tags and tag categories, and assign and remove tags on vSphere inventory objects.

The table describes privileges related to tagging.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.
Table 11-26. vCenter Inventory Service Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>vCenter Inventory Service.Tagging.Assign or Unassign</td>
<td>Allows assignment or unassignment of a tag for an object in the vCenter</td>
<td>Any object</td>
</tr>
<tr>
<td>Inventory Service Tag</td>
<td>Server inventory.</td>
<td></td>
</tr>
<tr>
<td>vCenter Inventory Service.Tagging.Create</td>
<td>Allows creation of a tag category.</td>
<td>Any object</td>
</tr>
<tr>
<td>Inventory Service Tag Category</td>
<td></td>
<td></td>
</tr>
<tr>
<td>vCenter Inventory Service.Tagging.Delete</td>
<td>Allows deletion of a tag category.</td>
<td>Any object</td>
</tr>
<tr>
<td>Inventory Service Tag Category</td>
<td></td>
<td></td>
</tr>
<tr>
<td>vCenter Inventory Service.Tagging.Edit</td>
<td>Allows editing of a tag category.</td>
<td>Any object</td>
</tr>
<tr>
<td>Inventory Service Tag Category</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Virtual Machine Configuration

Virtual Machine Configuration privileges control the ability to configure virtual machine options and devices.

The table describes privileges required for configuring virtual machine options and devices.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-27. Virtual Machine Configuration Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual machine.Configuration.Add existing disk</td>
<td>Allows adding an existing virtual disk to a virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Add new disk</td>
<td>Allows creation of a new virtual disk to add to a virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Add or remove device</td>
<td>Allows addition or removal of any non-disk device.</td>
<td>Virtual machines</td>
</tr>
</tbody>
</table>
### Table 11-27. Virtual Machine Configuration Privileges (continued)

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual machine.Configuration.Advanced</td>
<td>Allows addition or modification of advanced parameters in the virtual machine’s configuration file.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Change CPU count</td>
<td>Allows changing the number of virtual CPUs.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Change resource</td>
<td>Allows changing the resource configuration of a set of virtual machine nodes in a given resource pool.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Configure managedBy</td>
<td>Allows an extension or solution to mark a virtual machine as being managed by that extension or solution.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Disk change tracking</td>
<td>Allows enabling or disabling of change tracking for the virtual machine’s disks.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Display connection settings</td>
<td>Allows configuration of virtual machine remote console options.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Extend virtual disk</td>
<td>Allows expansion of the size of a virtual disk.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Host USB device</td>
<td>Allows attaching a host-based USB device to a virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Memory</td>
<td>Allows changing the amount of memory allocated to the virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Modify device settings</td>
<td>Allows changing the properties of an existing device.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Query Fault Tolerance compatibility</td>
<td>Allows checking if a virtual machine is compatible for Fault Tolerance.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Query unowned files</td>
<td>Allows querying of unowned files.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Raw device</td>
<td>Allows adding or removing a raw disk mapping or SCSI pass through device. Setting this parameter overrides any other privilege for modifying raw devices, including connection states.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Reload from path</td>
<td>Allows changing a virtual machine configuration path while preserving the identity of the virtual machine. Solutions such as VMware vCenter Site Recovery Manager use this operation to maintain virtual machine identity during failover and failback.</td>
<td>Virtual machines</td>
</tr>
</tbody>
</table>
Table 11-27. Virtual Machine Configuration Privileges (continued)

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>

<tbody>
<tr>
<td>Virtual machine.Configuration.Remove disk</td>
<td>Allows removal of a virtual disk device.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Rename</td>
<td>Allows renaming a virtual machine or modifying the associated notes of a virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Reset guest information</td>
<td>Allows editing the guest operating system information for a virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Set annotation</td>
<td>Allows adding or editing a virtual machine annotation.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Swapfile placement</td>
<td>Allows changing the swapfile placement policy for a virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Unlock virtual machine</td>
<td>Allows decrypting a virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Configuration.Upgrade virtual machine compatibility</td>
<td>Allows upgrade of the virtual machine’s virtual machine compatibility version.</td>
<td>Virtual machines</td>
</tr>
</tbody>
</table>

Virtual Machine Guest Operations

Virtual Machine Guest operations privileges control the ability to interact with files and programs inside a virtual machine's guest operating system.

The table describes privileges required for virtual machine guest operations accessed through the VMware vSphere API. See the VMware vSphere API Reference documentation for more information on these operations.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.
Table 11-28. Virtual Machine Guest Operations

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Effective on Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual machine.Guest Operations.Guest Operation Modifications</td>
<td>Allows virtual machine guest operations that involve modifications to a guest operating system in a virtual machine, such as transferring a file to the virtual machine. No vSphere Web Client user interface elements are associated with this privilege.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Guest Operations.Guest Operation Program Execution</td>
<td>Allows virtual machine guest operations that involve executing a program in the virtual machine. No vSphere Web Client user interface elements are associated with this privilege.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Guest Operations.Guest Operation Queries</td>
<td>Allows virtual machine guest operations that involve querying the guest operating system, such as listing files in the guest operating system. No vSphere Web Client user interface elements are associated with this privilege.</td>
<td>Virtual machines</td>
</tr>
</tbody>
</table>

Virtual Machine Interaction

Virtual Machine Interaction privileges control the ability to interact with a virtual machine console, configure media, perform power operations, and install VMware Tools.

The table describes privileges required for virtual machine interaction.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-29. Virtual Machine Interaction

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual machine.Interaction.Answer question</td>
<td>Allows resolution of issues with virtual machine state transitions or runtime errors.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Interaction.Configure CD media</td>
<td>Allows configuration of a virtual DVD or CD-ROM device.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Interaction.Configure floppy media</td>
<td>Allows configuration of a virtual floppy device.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Interaction.Console interaction</td>
<td>Allows interaction with the virtual machine’s virtual mouse, keyboard, and screen.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Privilege Name</td>
<td>Description</td>
<td>Required On</td>
</tr>
<tr>
<td>---------------------------------------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>----------------------</td>
</tr>
<tr>
<td>Virtual machine.Interaction.Create screenshot</td>
<td>Allows creation of a virtual machine screen shot.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Interaction.Defragment all disks</td>
<td>Allows defragment operations on all disks of the virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Interaction.Devic e connection</td>
<td>Allows changing the connected state of a virtual machine’s disconnectable virtual devices.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Interaction.Guest operating system management by VIX API</td>
<td>Allows management of the virtual machine’s operating system through the VIX API.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Interaction.Inject USB HID scan codes</td>
<td>Allows injection of USP HID scan codes.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Interaction.Perfo rm wipe or shrink operations</td>
<td>Allows performing wipe or shrink operations on the virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Interaction.Powe r Off</td>
<td>Allows powering off a powered-on virtual machine. This operation powers down the guest operating system.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Interaction.Powe r On</td>
<td>Allows powering on a powered-off virtual machine, and resuming a suspended virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Interaction.Record session on Virtual Machine</td>
<td>Allows recording a session on a virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Interaction.Repl ay session on Virtual Machine</td>
<td>Allows replaying of a recorded session on a virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Interaction.Reset</td>
<td>Allows resetting of a virtual machine and reboots the guest operating system.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Interaction.Suspe nd</td>
<td>Allows suspending a powered-on virtual machine. This operation puts the guest in standby mode.</td>
<td>Virtual machines</td>
</tr>
</tbody>
</table>
### Table 11-29. Virtual Machine Interaction (continued)

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual machine.Interaction.Test failover</td>
<td>Allows testing of Fault Tolerance failover by making the Secondary virtual machine the Primary virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Interaction.Turn On Fault Tolerance</td>
<td>Allows turning on Fault Tolerance for a virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Interaction.VMware Tools install</td>
<td>Allows mounting and unmounting the VMware Tools CD installer as a CD-ROM for the guest operating system.</td>
<td>Virtual machines</td>
</tr>
</tbody>
</table>

### Virtual Machine Inventory

Virtual Machine Inventory privileges control adding, moving, and removing virtual machines. The table describes privileges required to add, move, and remove virtual machines in the inventory.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

### Table 11-30. Virtual Machine Inventory Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual machine.Inventory.Create from existing</td>
<td>Allows creation of a virtual machine based on an existing virtual machine or template, by cloning or deploying from a template.</td>
<td>Clusters, Hosts, Virtual machine folders</td>
</tr>
<tr>
<td>Virtual machine.Inventory.Create new</td>
<td>Allow creation of a virtual machine and allocation of resources for its execution.</td>
<td>Clusters, Hosts, Virtual machine folders</td>
</tr>
<tr>
<td>Virtual machine.Inventory.Move</td>
<td>Allows relocating a virtual machine in the hierarchy. The privilege must be present at both the source and destination.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Inventory.Register</td>
<td>Allows adding an existing virtual machine to a vCenter Server or host inventory.</td>
<td>Clusters, Hosts, Virtual machine folders</td>
</tr>
</tbody>
</table>
Table 11-30. Virtual Machine Inventory Privileges (continued)

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual machine.Inventory.Remove</td>
<td>Allows deletion of a virtual machine. Deletion removes the virtual machine’s underlying files from disk. To have permission to perform this operation, you must have this privilege assigned to both the object and its parent object.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Inventory.Unregister</td>
<td>Allows unregistering a virtual machine from a vCenter Server or host inventory. To have permission to perform this operation, you must have this privilege assigned to both the object and its parent object.</td>
<td>Virtual machines</td>
</tr>
</tbody>
</table>

**Virtual Machine Provisioning**

Virtual Machine Provisioning privileges control activities related to deploying and customizing virtual machines.

The table describes privileges required for virtual machine provisioning.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-31. Virtual Machine Provisioning Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual machine.Provisioning.Allow disk access</td>
<td>Allows opening a disk on a virtual machine for random read and write access. Used mostly for remote disk mounting.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Provisioning.Allow read-only disk access</td>
<td>Allows opening a disk on a virtual machine for random read access. Used mostly for remote disk mounting.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Provisioning.Allow virtual machine download</td>
<td>Allows read operations on files associated with a virtual machine, including vmx, disks, logs, and nvramp.</td>
<td>Root host or vCenter Server</td>
</tr>
<tr>
<td>Virtual machine.Provisioning.Allow virtual machine files upload</td>
<td>Allows write operations on files associated with a virtual machine, including vmx, disks, logs, and nvramp.</td>
<td>Root host or vCenter Server</td>
</tr>
<tr>
<td>Virtual machine.Provisioning.Clone template</td>
<td>Allows cloning of a template.</td>
<td>Templates</td>
</tr>
<tr>
<td>Virtual machine.Provisioning.Clone virtual machine</td>
<td>Allows cloning of an existing virtual machine and allocation of resources.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Provisioning.Create template from virtual machine</td>
<td>Allows creation of a new template from a virtual machine.</td>
<td>Virtual machines</td>
</tr>
</tbody>
</table>
### Table 11-31. Virtual Machine Provisioning Privileges (continued)

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual machine.Provisioning.Customize</td>
<td>Allows customization of a virtual machine's guest operating system without moving the virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Provisioning.Deploy template</td>
<td>Allows deployment of a virtual machine from a template.</td>
<td>Templates</td>
</tr>
<tr>
<td>Virtual machine.Provisioning.Mark as template</td>
<td>Allows marking an existing powered off virtual machine as a template.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Provisioning.Mark as virtual machine</td>
<td>Allows marking an existing template as a virtual machine.</td>
<td>Templates</td>
</tr>
<tr>
<td>Virtual machine.Provisioning.Modify customization specification</td>
<td>Allows creation, modification, or deletion of customization specifications.</td>
<td>Root vCenter Server</td>
</tr>
<tr>
<td>Virtual machine.Provisioning.Promote disks</td>
<td>Allows promote operations on a virtual machine's disks.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Provisioning.Read customization specifications</td>
<td>Allows reading a customization specification.</td>
<td>Virtual machines</td>
</tr>
</tbody>
</table>

### Virtual Machine Snapshot Management Privileges

Virtual machine snapshot management privileges control the ability to take, delete, rename, and restore snapshots.

The table describes privileges required to work with virtual machine snapshots.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

### Table 11-32. Virtual Machine State Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual machine.Snapshot management. Create snapshot</td>
<td>Allows creation of a snapshot from the virtual machine’s current state.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Snapshot management.Remove Snapshot</td>
<td>Allows removal of a snapshot from the snapshot history.</td>
<td>Virtual machines</td>
</tr>
</tbody>
</table>
Table 11-32. Virtual Machine State Privileges (continued)

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual machine.Snapshot management.Rename Snapshot</td>
<td>Allows renaming a snapshot with a new name, a new description, or both.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.Snapshot management.Revert to snapshot</td>
<td>Allows setting the virtual machine to the state it was in at a given snapshot.</td>
<td>Virtual machines</td>
</tr>
</tbody>
</table>

**Virtual Machine vSphere Replication**

Virtual Machine vSphere replication privileges control the use of replication for virtual machines. The table describes privileges used for virtual machine replication by VMware vCenter Site Recovery Manager™.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-33. Virtual Machine vSphere Replication

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual machine.vSphere Replication.Configure vSphere Replication</td>
<td>Allows configuration of replication for the virtual machine.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.vSphere Replication.Manage vSphere Replication</td>
<td>Allows triggering of full sync, online sync or offline sync on a replication.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>Virtual machine.vSphere Replication.Monitor vSphere Replication</td>
<td>Allows monitoring of replication.</td>
<td>Virtual machines</td>
</tr>
</tbody>
</table>

**dvPort Group**

Distributed virtual port group privileges control the ability to create, delete, and modify distributed virtual port groups.

The table describes the privileges required to create and configure distributed virtual port groups.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.
Table 11-34. Distributed Virtual Port Group Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>Distributed switch.Create</td>
<td>Allows creation of a distributed virtual port group.</td>
<td>Virtual port groups</td>
</tr>
<tr>
<td>Distributed switch.Delete</td>
<td>Allows deletion of distributed virtual port group. To have permission to perform this operation, you must have this privilege assigned to both the object and its parent object.</td>
<td>Virtual port groups</td>
</tr>
<tr>
<td>Distributed switch.Modify</td>
<td>Allows modification of a distributed virtual port group configuration.</td>
<td>Virtual port groups</td>
</tr>
<tr>
<td>Distributed switch.Policy operation</td>
<td>Allows setting the policy of a distributed virtual port group.</td>
<td>Virtual port groups</td>
</tr>
<tr>
<td>Distributed switch.Port configuration operation</td>
<td>Allows setting the scope of a distributed virtual port group.</td>
<td>Virtual port groups</td>
</tr>
</tbody>
</table>

vServices

vServices privileges control the ability to create, configure, and update vService dependencies for virtual machines and vApps.

The table describes privileges related to vService dependencies.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.

Table 11-35. vServices

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>vService.Create dependency</td>
<td>Allows creation of a vService dependency for a virtual machine or vApp.</td>
<td>vApps and virtual machines</td>
</tr>
<tr>
<td>vService.Destroy dependency</td>
<td>Allows removal of a vService dependency for a virtual machine or vApp.</td>
<td>vApps and virtual machines</td>
</tr>
<tr>
<td>vService.Reconfigure dependency configuration</td>
<td>Allows reconfiguration of a dependency to update the provider or binding.</td>
<td>vApps and virtual machines</td>
</tr>
<tr>
<td>vService.Update dependency</td>
<td>Allows updates of a dependence to configure the name or description.</td>
<td>vApps and virtual machines</td>
</tr>
</tbody>
</table>

VRM Policy

VRM policy privileges control the ability to query and update virtual rights management policies.

The table describes privileges related to virtual rights management.

You can set this privilege at different levels in the hierarchy. For example, if you set a privilege at the folder level, you can propagate the privilege to one or more objects within the folder. The object listed in the Required On column must have the privilege set, either directly or inherited.
Table 11-36. VRM Policy Privileges

<table>
<thead>
<tr>
<th>Privilege Name</th>
<th>Description</th>
<th>Required On</th>
</tr>
</thead>
<tbody>
<tr>
<td>VRMPolicy.Query</td>
<td>Allows querying virtual rights management policy.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>VRMPolicy</td>
<td></td>
<td></td>
</tr>
<tr>
<td>VRMPolicy.Update</td>
<td>Allows update of virtual rights management policy.</td>
<td>Virtual machines</td>
</tr>
<tr>
<td>VRMPolicy</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
