vCloud Director Installation, Configuration, and Upgrade Guide

The vCloud Director Installation, Configuration, and Upgrade Guide provides information about installing and upgrading VMware vCloud Director® for Service Providers software and configuring it to work with VMware vSphere®, VMware NSX® for vSphere®, and VMware NSX-T™ Data Center.

Intended Audience

The vCloud Director Installation, Configuration, and Upgrade Guide is intended for anyone who wants to install or upgrade vCloud Director software. The information in this book is written for experienced system administrators who are familiar with Linux, Windows, IP networks, and vSphere.
# Updated Information

This *vCloud Director Installation, Configuration, and Upgrade Guide* is updated with each release of the product or when necessary.

This table provides the update history of the *vCloud Director Installation, Configuration, and Upgrade Guide*.

Overview of vCloud Director Installation, Configuration, and Upgrade

You create a vCloud Director server group by installing the vCloud Director software on one or more Linux servers, or by deploying one or more instances of the vCloud Director appliance. During the installation process, you perform the initial vCloud Director configuration, which includes establishing network and database connections.

The vCloud Director software for Linux requires an external database, whereas the vCloud Director appliance uses an embedded PostgreSQL database.

After you create the vCloud Director server group, you integrate the vCloud Director installation with your vSphere resources. For network resources, vCloud Director can use NSX Data Center for vSphere, NSX-T Data Center, or both.

When you upgrade an existing vCloud Director installation, you update the vCloud Director software and the database schema, leaving the existing relationships between servers, the database, and vSphere in place.

When you migrate an existing vCloud Director installation on Linux to the vCloud Director appliance, you update the vCloud Director software and migrate the database to the embedded database in the appliance.

This chapter includes the following topics:

- vCloud Director Architecture
- Configuration Planning

vCloud Director Architecture

A vCloud Director server group consists of one or more vCloud Director servers installed on Linux or deployments of the vCloud Director appliance. Each server in the group runs a collection of services called a vCloud Director cell. All cells share a single vCloud Director database and a transfer server storage, and connect to the vSphere and network resources.

**Important** Mixed vCloud Director installations on Linux and vCloud Director appliance deployments in one server group are unsupported.
To ensure vCloud Director high availability, you must install at least two vCloud Director cells in a server group. When you use a third-party load balancer, you can ensure an automatic failover without downtime.

You can connect a vCloud Director installation to multiple VMware vCenter Server® systems and the VMware ESXi™ hosts that they manage. For network services, vCloud Director can use NSX Data Center for vSphere associated with vCenter Server or you can register NSX-T Data Center with vCloud Director. Mixed NSX Data Center for vSphere and NSX-T Data Center are also supported.

**Figure 1-1. vCloud Director Architecture Diagram**

A vCloud Director server group installed on Linux uses an external database.

A vCloud Director server group that consists of appliance deployments uses the embedded database in the first member of the server group. You can configure a vCloud Director database high availability by deploying two instances of the appliance as standby cells in the same server group. See Appliance Deployments and Database High Availability Configuration.

**Figure 1-2. vCloud Director Appliances Comprising an Embedded Database High Availability Cluster**

The vCloud Director installation and configuration process creates the cells, connects them to the shared database and transfer server storage, and creates the system administrator account. Then the system administrator establishes connections to the vCenter Server system, the ESXi hosts, and the NSX Manager instances. For information about adding vSphere and network resources, see the vCloud Director Administrator's Guide.
Configuration Planning

vSphere provides storage, compute, and networking capacity to vCloud Director. Before you begin the installation, consider how much vSphere and vCloud Director capacity your cloud requires, and plan a configuration that can support it.

Configuration requirements depend on many factors, including the number of organizations in the cloud, the number of users in each organization, and the activity level of those users. The following guidelines can serve as a starting point for most configurations:

- Allocate one vCloud Director cell for each vCenter Server system that you want to make accessible in your cloud.
- Be sure that all target vCloud Director Linux servers meet at least the minimum requirements for memory and storage detailed in vCloud Director Release Notes.
- If you plan to install vCloud Director on Linux, configure the vCloud Director database as described in Preparing the vCloud Director Database.
vCloud Director Hardware and Software Requirements

Each server in a vCloud Director server group must meet certain hardware and software requirements. In addition, a supported database must be accessible to all members of the group. Each server group requires access to a vCenter Server system, an NSX Manager instance, and one or more ESXi hosts.

Compatibility with Other VMware Products

For the most recent information about compatibility between vCloud Director and other VMware products, see the VMware Product Interoperability Matrixes at http://partnerweb.vmware.com/comp_guide/sim/interop_matrix.php.

vSphere Configuration Requirements

vCenter Server instances and ESXi hosts intended for use with vCloud Director must meet specific configuration requirements.

- vCenter Server networks intended for use as vCloud Director external networks or network pools must be available to all hosts in any cluster intended for vCloud Director to use. Making these networks available to all hosts in a data center simplifies the task of adding new vCenter Server instances to vCloud Director.
- vSphere Distributed Switches are required for isolated networks and network pools backed by NSX Data Center for vSphere.
- vCenter Server clusters used with vCloud Director must specify a vSphere DRS automation level of Fully Automated. Storage DRS, if enabled, can be configured with any automation level.
- vCenter Server instances must trust their hosts. All hosts in all clusters managed by vCloud Director must be configured to require verified host certificates. In particular, you must determine, compare, and select matching thumbprints for all hosts. See Configure SSL Settings in the vCenter Server and Host Management documentation.

vSphere Licensing Requirements

The vCloud Director Service Provider Bundle includes the necessary vSphere licenses.
Supported Platforms, Databases, and Browsers

See the vCloud Director Release Notes for information about the server platforms, browsers, LDAP servers, and databases supported by this release of vCloud Director.

Disk Space, Memory, and CPU Requirements

Physical requirements such as disk space, memory, and CPU for vCloud Director cells are listed in the vCloud Director Release Notes.

Shared Storage

NFS or other shared storage volume for the vCloud Director transfer service. The storage volume must be expandable and accessible to all servers in the server group.

This chapter includes the following topics:

- Network Configuration Requirements for vCloud Director
- Network Security Requirements

Network Configuration Requirements for vCloud Director

Secure, reliable operation of vCloud Director depends on a secure, reliable network that supports forward and reverse lookup of host names, a network time service, and other services. Your network must meet these requirements before you begin installing vCloud Director.

The network that connects the vCloud Director servers, the database server, the vCenter Server systems, and the NSX components, must meet several requirements:

**IP addresses**
Each vCloud Director server must support two different SSL endpoints. One endpoint is for the HTTP service. The other endpoint is for the console proxy service. These endpoints can be separate IP addresses, or a single IP address with two different ports. You can use IP aliases or multiple network interfaces to create these addresses. Do not use the Linux `ip addr add` command to create the second address.

The vCloud Director appliance uses its `eth0` IP address with custom port 8443 for the console proxy service.

**Console Proxy Address**
The IP address configured as the console proxy endpoint must not be located behind an SSL-terminating load balancer or reverse proxy. All console proxy requests must be relayed directly to the console proxy IP address.
For an installation with a single IP address, you can customize the console proxy address from the vCloud Director Web Console. For example, for the vCloud Director appliance, you must customize the console proxy address to vcloud.example.com:8443.

**Network Time Service**

You must use a network time service such as NTP to synchronize the clocks of all vCloud Director servers, including the database server. The maximum allowable drift between the clocks of synchronized servers is 2 seconds.

**Server Time Zones**

All vCloud Director servers, including the database server, must be configured to be in the same time zone.

**Host Name Resolution**

All host names that you specify during installation and configuration must be resolvable by DNS using forward and reverse lookup of the fully qualified domain name or the unqualified hostname. For example, for a host named vcloud.example.com, both of the following commands must succeed on a vCloud Director host:

```
nslookup vcloud
nslookup vcloud.example.com
```

In addition, if the host vcloud.example.com has the IP address 192.168.1.1, the following command must return vcloud.example.com:

```
nslookup 192.168.1.1
```

Reverse DNS lookup of the eth0 IP address is required for the appliance. The following command must succeed in your environment:

```
host -W 15 -R 1 -T <eth0-IP-address>
```

**Network Security Requirements**

Secure operation of vCloud Director requires a secure network environment. Configure and test this network environment before you begin installing vCloud Director.
Connect all vCloud Director servers to a network that is secured and monitored. vCloud Director network connections have several additional requirements:

- Do not connect vCloud Director directly to the public Internet. Always protect vCloud Director network connections with a firewall. Only port 443 (HTTPS) must be open to incoming connections. Ports 22 (SSH) and 80 (HTTP) can also be opened for incoming connections if needed. In addition, the cell-management-tool requires access to the cell's loopback address. All other incoming traffic from a public network, including requests to JMX (port 8999) must be rejected by the firewall.

**Table 2-1. Ports That Must Allow Incoming Packets From vCloud Director Hosts**

</table>
- Route traffic between vCloud Director servers and the following servers over a dedicated private network.
  - vCloud Director database server
  - RabbitMQ
  - Cassandra
- If possible, route traffic between vCloud Director servers, vSphere, and NSX over a dedicated private network.
- Virtual switches and distributed virtual switches that support provider networks must be isolated from each other. They cannot share the same layer 2 physical network segment.
- Use NFSv4 for transfer service storage. The most common NFS version, NFSv3, does not offer on transit encryption which in some configurations might enable in-flight sniffing or tampering with data being transferred. Threats inherent in NFSv3 are described in the SANS white paper **NFS Security in Both Trusted and Untrusted Environments**. Additional information about configuring and securing the vCloud Director transfer service is available in VMware Knowledge Base article **2086127**.
Before You Install vCloud Director or Deploy the vCloud Director Appliance

Before you install vCloud Director on a Linux server or deploy the vCloud Director appliance, you must prepare your environment.

This chapter includes the following topics:

- Preparing the vCloud Director Database
- Preparing the Transfer Server Storage
- Install and Configure a RabbitMQ AMQP Broker
- Create SSL Certificates
- Download and Install the VMware Public Key
- Install and Configure NSX Data Center for vSphere for vCloud Director
- Install and Configure NSX-T Data Center for vCloud Director

Preparing the vCloud Director Database

The vCloud Director cells use a database to store shared information. Before you install vCloud Director on Linux, you must install and configure an external vCloud Director database. The vCloud Director appliance uses an embedded PostgreSQL database.

For information about the supported vCloud Director databases, see the VMware Product Interoperability Matrixes.

Regardless of the database software you decide to use, you must create a separate, dedicated database schema for vCloud Director to use. vCloud Director cannot share a database schema with any other VMware product.

**Important** vCloud Director supports SSL connections only to a PostgreSQL database. You can enable SSL on the PostgreSQL database during an unattended network and database connections configuration or after creating the vCloud Director server group. See Unattended Configuration Reference and Perform Additional Configurations on the External PostgreSQL Database.
Configure an External PostgreSQL Database for vCloud Director on Linux

PostgreSQL databases have specific configuration requirements when you use them with vCloud Director. Before you install vCloud Director on Linux, you must install and configure a database instance and create the vCloud Director database user account.

**Note** Only vCloud Director on Linux uses an external database. The vCloud Director appliance uses the embedded PostgreSQL database.

**Prerequisites**
You must be familiar with PostgreSQL commands, scripting, and operation.

**Procedure**

1. Configure the database server.
   
   A database server with 16 GB of memory, 100 GB storage, and 4 CPUs is appropriate for typical vCloud Director server groups.

2. Install a supported distribution of PostgreSQL on the database server.
   
   - The `SERVER_ENCODING` value of the database must be `UTF-8`. This value is established when you install the database and always matches the encoding used by the database server operating system.
   - Use the PostgreSQL `initdb` command to set the value of `LC_COLLATE` and `LC_CTYPE` to `en_US.UTF-8`. For example:

     ```
     initdb --locale=en_US.UTF-8
     ```

3. Create the database user.
   
   The following command creates the user `vcloud`.

   ```
   create user vcloud;
   ```

4. Create the database instance and give it an owner.
   
   Use a command like this one to specify a database user named `vcloud` as the database owner.

   ```
   create database vcloud owner vcloud;
   ```

5. Assign a database password to the database owner account.
   
   The following command assigns the password `vcloudpass` to database owner `vcloud`.

   ```
   alter user vcloud password 'vcloudpass';
   ```
6 Enable the database owner to log in to the database.

The following command assigns the login option to database owner vcloud.

```
alter role vcloud with login;
```

**What to do next**

After creating your vCloud Director server group, you can configure the PostgreSQL database to require SSL connections from the vCloud Director cells and adjust some database parameters for optimal performance. See Perform Additional Configurations on the External PostgreSQL Database.

**Configure an External Microsoft SQL Server Database for vCloud Director for Linux**

SQL Server databases have specific configuration requirements when you use them with vCloud Director. Before you install vCloud Director on Linux, you must install and configure a database instance, and create the vCloud Director database user account.

vCloud Director database performance is an important factor in overall vCloud Director performance and scalability. vCloud Director uses the SQL Server tmpdb file when storing large result sets, sorting data, and managing data that is being concurrently read and modified. This file can grow significantly when vCloud Director is experiencing heavy concurrent load. It is a good practice to create the tmpdb file on a dedicated volume that has fast read and write performance. For more information about the tmpdb file and SQL Server performance, see [http://msdn.microsoft.com/en-us/library/ms175527.aspx](http://msdn.microsoft.com/en-us/library/ms175527.aspx).

**Note** Only vCloud Director on Linux uses an external database. The vCloud Director appliance uses the embedded PostgreSQL database.

**Prerequisites**

- You must be familiar with Microsoft SQL Server commands, scripting, and operation.
- To configure Microsoft SQL Server, log on to the SQL Server host computer using administrator credentials. You can configure SQL server to run with the LOCAL_SYSTEM identity, or any identity with the privilege to run a Windows service.
- See VMware Knowledge Base article [https://kb.vmware.com/kb/2148767](https://kb.vmware.com/kb/2148767) for information about using Microsoft SQL Server Always On Availability Groups with the vCloud Director database.

**Procedure**

1 Configure the database server.

A database server configured with 16GB of memory, 100GB storage, and 4 CPUs should be adequate for most vCloud Director server groups.

2 Specify Mixed Mode authentication during SQL Server setup.

Windows Authentication is not supported when using SQL Server with vCloud Director.
3 Create the database instance.

The following script creates the database and log files, specifying the proper collation sequence.

```sql
USE [master]
GO
CREATE DATABASE [vcloud] ON PRIMARY
(NAME = N'vcloud', FILENAME = N'C:\vcloud.mdf', SIZE = 100MB, FILEGROWTH = 10%)
LOG ON
(NAME = N'vcdb_log', FILENAME = N'C:\vcloud.ldf', SIZE = 1MB, FILEGROWTH = 10%)
COLLATE Latin1_General_CS_AS
GO
```

The values shown for SIZE are suggestions. You might need to use larger values.

4 Set the transaction isolation level.

The following script sets the database isolation level to READ_COMMITTED_SNAPSHOT.

```sql
USE [vcloud]
GO
ALTER DATABASE [vcloud] SET SINGLE_USER WITH ROLLBACK IMMEDIATE;
ALTER DATABASE [vcloud] SET ALLOW_SNAPSHOT_ISOLATION ON;
ALTER DATABASE [vcloud] SET READ_COMMITTED_SNAPSHOT ON WITH NO_WAIT;
ALTER DATABASE [vcloud] SET MULTI_USER;
GO
```

For more about transaction isolation, see http://msdn.microsoft.com/en-us/library/ms173763.aspx.

5 Create the vCloud Director database user account.

The following script creates database user name vcloud with password vcloudpass.

```sql
USE [vcloud]
GO
CREATE LOGIN [vcloud] WITH PASSWORD = 'vcloudpass', DEFAULT_DATABASE = [vcloud],
    DEFAULT_LANGUAGE = [us_english], CHECK_POLICY=OFF
GO
CREATE USER [vcloud] for LOGIN [vcloud]
GO
```

6 Assign permissions to the vCloud Director database user account.

The following script assigns the db_owner role to the database user created in Step 5.

```sql
USE [vcloud]
GO
sp_addrolemember [db_owner], [vcloud]
GO
```
Preparing the Transfer Server Storage

To provide temporary storage for uploads, downloads, and catalog items that are published or subscribed externally, you must make an NFS or other shared storage volume accessible to all servers in a vCloud Director server group.

**Important** The vCloud Director appliance supports only NFS type of shared storage. The appliance deployment process involves mounting the NFS shared transfer server storage.

When NFS is used for the transfer server storage, you must configure each vCloud Director cell in the vCloud Director server group to mount and use the NFS-based transfer server storage. See [http://kb.vmware.com/kb/2086127](http://kb.vmware.com/kb/2086127).

Each member of the server group must mount this volume at the same mountpoint, typically `/opt/vmware/vcloud-director/data/transfer`. Space on this volume is consumed in two ways:

- During transfers, uploads and downloads occupy this storage. When the transfer finishes, the uploads and downloads are removed from the storage. Transfers that make no progress for 60 minutes are marked as expired and cleaned up by the system. Because transferred images can be large, it is a good practice to allocate at least several hundred gigabytes for this use.

- Catalog items in catalogs that are published externally and enable caching of the published content occupy this storage. Items from catalogs that are published externally but do not enable caching do not occupy this storage. If you enable organizations in your cloud to create catalogs that are published externally, you can assume that hundreds or even thousands of catalog items require space on this volume. The size of each catalog item is about the size of a virtual machine in a compressed OVF form.

**Note** The volume of the transfer server storage must be easily expanded.

Install and Configure a RabbitMQ AMQP Broker

AMQP, the Advanced Message Queuing Protocol, is an open standard for message queuing that supports flexible messaging for enterprise systems. vCloud Director uses the RabbitMQ AMQP broker to provide the message bus used by extension services, object extensions, and notifications.

**Procedure**

1. Download the RabbitMQ Server from [https://www.rabbitmq.com/download.html](https://www.rabbitmq.com/download.html).
   See the vCloud Director Release Notes for the list of supported RabbitMQ releases.

2. Follow the RabbitMQ installation instructions and install RabbitMQ on a supported host.
   The RabbitMQ server host must be reachable on the network by each vCloud Director cell.

3. During the RabbitMQ installation, make a note of the values that are required for configuring vCloud Director to work with this RabbitMQ installation.
   - The fully qualified domain name of the RabbitMQ server host, for example `amqp.example.com`. 
- A user name and password that are valid for authenticating with RabbitMQ.
- The port at which the broker listens for messages. The default is 5672.
- The RabbitMQ virtual host. The default is "/".

What to do next

By default, the vCloud Director AMQP service sends unencrypted messages. You can configure the AMQP service to encrypt these messages by using SSL. You can also configure the service to verify the broker certificate by using the default JCEKS trust store of the Java runtime environment on the vCloud Director cell, typically at $VCLOUD_HOME/jre/lib/security/cacerts.

To enable SSL with the vCloud Director AMQP service:

1. In the vCloud Director Web console, click the Administration tab, and click Extensibility.
2. Click Extensibility, and click the Settings tab.
3. In the AMQP Broker Settings section, select Use SSL.
4. Either select the Accept all certificates check box or provide one of the following:
   - an SSL certificate pathname
   - a JCEKS trust store pathname and password

Create SSL Certificates

vCloud Director uses SSL to secure communications between clients and servers. Before you install vCloud Director for Linux, you must create two certificates for each member of the server group and import the certificates into host keystores.

Note This procedure is required only for installing vCloud Director on Linux. The vCloud Director appliance first boot creates a self-signed SSL certificate. After the appliance deployment, you can Create and Import a Signed SSL Certificate.

Each vCloud Director server must support two different SSL endpoints. These endpoints can be separate IP addresses, or a single IP address with two different ports. Each endpoint requires its own SSL certificate. Certificates for both endpoints must include an X.500 distinguished name. Many certificate authorities recommend including an X.509 Subject Alternative Name extension in certificates they grant. vCloud Director does not require certificates to include a Subject Alternative Name.

Procedure

1. List the IP addresses for this server.
   
   Use a command like `ifconfig` to discover this server's IP addresses.

2. For each IP address, run the following command to retrieve the fully qualified domain name to which the IP address is bound.

   ```bash
   nslookup ip-address
   ```
3 Make a note of each IP address and the fully qualified domain name associated with it. Decide which IP address is for the HTTP service and which IP address is for the console proxy service. You must provide the fully qualified domain names when you create the certificates, and the IP addresses when you configure the network and database connections. If any, make a note of other fully qualified domain names that can reach the IP address, because you must provide them if you want the certificate to include a Subject Alternative Name.

4 Create the certificates.

You can use certificates signed by a trusted certification authority, or self-signed certificates.

**Note**  Signed certificates provide the highest level of trust.

### Create and Import a Signed SSL Certificate

Creating and importing signed certificates provides the highest level of trust for SSL communications and helps you secure the connections within your cloud. Creating and importing the certificates before you install and configure vCloud Director software simplifies the installation and configuration process.

Each vCloud Director server requires two SSL certificates, one for the HTTP service and one for the console proxy service, in a Java keystore file. You can use certificates signed by a trusted certification authority, or use self-signed certificates.

**Important**  These examples specify a 2048-bit key size, but you should evaluate your installation's security requirements before choosing an appropriate key size. Key sizes less than 1024 bits are no longer supported per NIST Special Publication 800-131A.

To create and import self-signed certificates, see Create a Self-Signed SSL Certificate.

**Prerequisites**

- Generate a list of fully qualified domain names and their associated IP addresses on vCloud Director server.
- Choose an address to use for the HTTP service and an address to use for the console proxy service. See Create SSL Certificates.
- Verify that you have access to a computer that has a Java version 7 runtime environment, so that you can use the keytool command to create the certificate. The vCloud Director installer places a copy of keytool in /opt/vmware/vcloud-director/jre/bin/keytool, but you can perform this procedure on any computer that has a Java version 7 runtime environment installed. Certificates created with a keytool from any other source are not supported for use with vCloud Director. These command-line examples assume that keytool is in the user's path. The keystore password is represented in these examples as passwd.
- Certificates for both endpoints must include an X.500 distinguished name. vCloud Director does not require certificates to include a Subject Alternative Name.
- Familiarize yourself with the keytool command, including its -dname and -ext options.
Gather the information required for the argument to the keytool –dname option.

Table 3-1. Information required by keytool –dname option

Procedure

1. Create an untrusted certificate for the HTTP service.

   This example command creates an untrusted certificate in a keystore file named certificates.ks. The keytool options have been placed on separate lines for clarity. The X.500 distinguished name information supplied in the argument to the –dname option uses the values shown in the prerequisites. The DNS and IP values shown in the argument to the –ext option are typical. Include all the DNS names at which this endpoint can be reached, including the one you specified for the commonName (CN) value in the –dname option argument. You can also include IP addresses, as shown here.

   keytool
   -keystore certificates.ks
   -alias http
   -storepass passwd
   -keypass passwd
   -storetype JCEKS
   -genkeypair
   -keyalg RSA
Important  The keystore file and the directory in which it is stored must be readable by the user
vcloud.vcloud. The vCloud Director installer creates this user and group.

2 Create an untrusted certificate for the console proxy service.

This command adds an untrusted certificate to the keystore file created in Step 1. The keytool
options have been placed on separate lines for clarity. The X.500 distinguished name information
supplied in the argument to the –dname option uses the values shown in the Prerequisites. The DNS
and IP values shown in the argument to the –ext option are typical. Include all the DNS names at
which this endpoint can be reached, including the one you specified for the commonName (CN) value in
the –dname option argument. You can also include IP addresses, as shown here.

```
keytool
  –keystore certificates.ks
  –alias consoleproxy
  –storepass passwd
  –keypass passwd
  –storetype JCEKS
  –genkeypair
  –keyalg RSA
  –keysize 2048
  –validity 365
  –dname "CN=vcd2.example.com, OU=Engineering, O=Example Corp, L=Palo Alto, S=California, C=US"
  –ext "san=dns:vcd2.example.com,dns:vcd2,ip:10.100.101.10"
```

3 Create a certificate signing request for the HTTP service and for the console proxy service.
   a  Create a certificate signing request in the http.csr file.

   ```
   keytool -keystore certificates.ks -storetype JCEKS -storepass passwd \
   -certreq -alias http -file http.csr -ext "san=dns:vcd2.example.com,dns:vcd2,ip:10.100.101.10"
   ```

   b  Create a certificate signing request in the consoleproxy.csr file.

   ```
   keytool -keystore certificates.ks -storetype JCEKS -storepass passwd \
   -certreq -alias consoleproxy -file consoleproxy.csr -ext "san=dns:vcd2.example.com,dns:vcd2,ip:10.100.101.10"
   ```

4 Send the certificate signing requests to your Certificate Authority.

   If your certification authority requires you to specify a Web server type, use Jakarta Tomcat.
   You obtain the CA-signed certificates.
5 If you obtained the signed certificates in PEM format, you must import them to a PKCS12 intermediate keystore.

If the certificates are not in PEM format, skip to step 6.
   a Import the PEM key and certificate for the HTTP service. Enter a password and make a note of it for later.

```bash
openssl pkcs12 -export -in path to certificate -inkey path to private key -out http.p12 -name http
```

   b Import the PEM key and certificate for the console proxy service. In many cases, this is the same key and certificate as the one for the HTTP service.

```bash
openssl pkcs12 -export -in path to certificate -inkey path to private key -out consoleproxy.p12 -name consoleproxy
```

6 Import the signed certificates into the JCEKS keystore file.
   a Import the Certificate Authority's root certificate from the root.cer file to the certificates.ks keystore file.

```bash
keytool -storetype JCEKS -storepass passwd -keystore certificates.ks -import -alias root -file root.cer
```

   b If you received intermediate certificates, import them from the intermediate.cer file to the certificates.ks keystore file.

```bash
keytool -storetype JCEKS -storepass passwd -keystore certificates.ks -import -alias intermediate -file intermediate.cer
```

   c Import the HTTP service certificate.

```bash
keytool -importkeystore -deststoretype JCEKS -deststorepass keystore password -destkeystore certificates.ks -srckeystore http.p12 -srcstoretype PKCS12 -srcstorepass keystore password
```

   d Import the console proxy service certificate.

```bash
keytool -importkeystore -deststoretype JCEKS -deststorepass keystore password -destkeystore certificates.ks -srckeystore consoleproxy.p12 -srcstoretype PKCS12 -srcstorepass keystore password
```

7 To check if the certificates are imported, run the command to list the contents of the keystore file.

```bash
keytool -storetype JCEKS -storepass passwd -keystore certificates.ks -list
```

8 Repeat this procedure on all vCloud Director servers in the server group.
What to do next

If you created the certificates.ks keystore file on a computer other than the server on which you generated the list of fully qualified domain names and their associated IP addresses, copy the keystore file to that server now. You need the keystore path name when you run the configuration script. See Configure the Network and Database Connections.

Create a Self-Signed SSL Certificate

Self-signed certificates can provide a convenient way to configure SSL for vCloud Director in environments where trust concerns are minimal.

You can generate self-signed certificates for the cell manually using this procedure, or you can use the generate-certs command of the cell management tool to generate new self-signed SSL certificates for the cell, as shown in Using the Cell Management Tool to Create Self-Signed Certificates. For more information, see "Generating Self-Signed SSL Certificates" in the vCloud Director Administrator’s Guide.

Each vCloud Director server requires two SSL certificates, one for the HTTP service and one for the console proxy service, in a Java keystore file. You can use certificates signed by a trusted certification authority, or use self-signed certificates.

Important These examples specify a 2048-bit key size, but you should evaluate your installation’s security requirements before choosing an appropriate key size. Key sizes less than 1024 bits are no longer supported per NIST Special Publication 800-131A.

To create and import signed certificates, see Create and Import a Signed SSL Certificate.

Prerequisites

You can generate self-signed certificates for the cell manually using this procedure, or you can use the generate-certs command of the cell management tool to generate new self-signed SSL certificates for the cell. For more information, see "Generating Self-Signed SSL Certificates" in the vCloud Director Administrator’s Guide.

- Generate a list of fully qualified domain names and their associated IP addresses on vCloud Director server.
- Choose an address to use for the HTTP service and an address to use for the console proxy service. See Create SSL Certificates.
- Verify that you have access to a computer that has a Java version 7 runtime environment, so that you can use the keytool command to create the certificate. The vCloud Director installer places a copy of keytool in /opt/vmware/vcloud-director/jre/bin/keytool, but you can perform this procedure on any computer that has a Java version 7 runtime environment installed. Certificates created with a keytool from any other source are not supported for use with vCloud Director. These command-line examples assume that keytool is in the user's path. The keystore password is represented in these examples as passwd.
- Certificates for both endpoints must include an X.500 distinguished name. vCloud Director does not require certificates to include a Subject Alternative Name.
Familiarize yourself with the keytool command, including its -dname and -ext options.

Gather the information required for the argument to the keytool -dname option.

**Table 3-2. Information required by keytool -dname option**

<table>
<thead>
<tr>
<th>X.500 Distinguished Name Subpart</th>
<th>Keytool key word</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>commonName</td>
<td>CN</td>
<td>The fully qualified domain name associated with the IP address of this endpoint.</td>
<td>CN=vcd1.example.com</td>
</tr>
<tr>
<td>organizationalUnit</td>
<td>OU</td>
<td>The name of an organizational unit, such as a department or division, within the organization with which this certificate is associated</td>
<td>OU=Engineering</td>
</tr>
<tr>
<td>organizationName</td>
<td>O</td>
<td>The name of the organization with which this certificate is associated</td>
<td>O=Example Corporation</td>
</tr>
<tr>
<td>localityName</td>
<td>L</td>
<td>The name of the city or town in which the organization is located.</td>
<td>L=Palo Alto</td>

<td>The name of the state or province in which the organization is located.</td>
<td>S=California</td>
</tr>
<tr>
<td>country</td>
<td>C</td>
<td>The name of the country in which the organization is located.</td>
<td>C=US</td>
</tr>
</tbody>
</table>

**Procedure**

1. Create an untrusted certificate for the HTTP service.

   This example command creates an untrusted certificate in a keystore file named certificates.ks. The keytool options have been placed on separate lines for clarity. The X.500 distinguished name information supplied in the argument to the -dname option uses the values shown in the prerequisites. The DNS and IP values shown in the argument to the -ext option are typical. Include all the DNS names at which this endpoint can be reached, including the one you specified for the commonName (CN) value in the -dname option argument. You can also include IP addresses, as shown here.

   ```
   keytool
   -keystore certificates.ks
   -alias http
   -storepass passwd
   -keypass passwd
   -storetype JCEKS
   -genkeypair
   -keyalg RSA
   ```
Important The keystore file and the directory in which it is stored must be readable by the user vcloud.vcloud. The vCloud Director installer creates this user and group.

2 Create an untrusted certificate for the console proxy service.

This command adds an untrusted certificate to the keystore file created in Step 1. The keytool options have been placed on separate lines for clarity. The X.500 distinguished name information supplied in the argument to the –dname option uses the values shown in the Prerequisites. The DNS and IP values shown in the argument to the –ext option are typical. Include all the DNS names at which this endpoint can be reached, including the one you specified for the commonName (CN) value in the –dname option argument. You can also include IP addresses, as shown here.

```
keytool
   –keystore certificates.ks
   –alias consoleproxy
   –storepass passwd
   –keypass passwd
   –storetype JCEKS
   –genkeypair
   –keyalg RSA
   –keysize 2048
   –validity 365
   –dname "CN=vcd2.example.com, OU=Engineering, O=Example Corp, L=Palo Alto, S=California, C=US"
   –ext "san=dns:vcd1.example.com,dns:vcd1,ip:10.100.101.9"
```

3 To verify that all the certificates are imported, list the contents of the keystore file.

```
keytool –storetype JCEKS –storepass passwd –keystore certificates.ks –list
```

4 Repeat this procedure on all vCloud Director servers in the server group.

**Example: Using the Cell Management Tool to Create Self-Signed Certificates**

The cell-management-tool utility is installed on the cell before the configuration agent runs. After you have run the installation file as shown in Install vCloud Director on the First Member of a Server Group, you can use the cell-management-tool to create self-signed certificates before you configure the system's network and database connections.
The command shown in this example creates or updates a keystore at /tmp/cell.ks that has the password kspw. Certificates are created using the command's default values. The issuer name is set to CN=Unknown. The certificate uses the default 2048-bit key length and expires one year after creation.

```
[root@cell1 /opt/vmware/vcloud-director/bin]# ./cell-management-tool generate-certs -j -p -o /tmp/cell.ks -w kspw
New keystore created and written to /tmp/cell.ks.
```

**Important** The keystore file and the directory in which it is stored must be readable by the user vcloud.vcloud. The vCloud Director installer creates this user and group.

**What to do next**

If you created the certificates.ks keystore file on a computer other than the server on which you generated the list of fully qualified domain names and their associated IP addresses, copy the keystore file to that server now. You need the keystore path name when you run the configuration script. See Configure the Network and Database Connections.

**Download and Install the VMware Public Key**

The installation file is digitally signed. To verify the signature, you must download and install the VMware public key.

You can use the Linux rpm tool and the VMware public key to verify the digital signature of the vCloud Director installation file, or any other signed downloaded file from vmware.com. If you install the public key on the computer where you plan to install vCloud Director, the verification happens as part of the installation or upgrade. You can also manually verify the signature before you begin the installation or upgrade procedure, then use the verified file for all installations or upgrades.

**Note** The download site also publishes a checksum value for the download. The checksum is published in two common forms. Verifying the checksum verifies that the file contents that you downloaded are the same as the contents that were posted. It does not verify the digital signature.

**Procedure**

1. Create a directory to store the VMware Packaging Public Keys.
2. Use a Web browser to download all of the VMware Public Packaging Public Keys from the http://packages.vmware.com/tools/keys directory.
3. Save the key files to the directory that you created.
4. For each key that you download, run the following command to import the key.

   ```
   # rpm --import /key_path/key_name
   ```

   *key_path* is the directory in which you saved the keys.

   *key_name* is the filename of a key.
Install and Configure NSX Data Center for vSphere for vCloud Director

If you plan your vCloud Director installation to use network resources from NSX Data Center for vSphere, you must install and configure NSX Data Center for vSphere and associate a unique NSX Manager instance with each vCenter Server instance that you plan to include in your vCloud Director installation.

NSX Manager is included in the NSX Data Center for vSphere download. For the most recent information about compatibility between vCloud Director and other VMware products, see the VMware Product Interoperability Matrices at http://partnerweb.vmware.com/comp_guide/sim/interop_matrix.php. For information about the network requirements, see Network Configuration Requirements for vCloud Director.

**Important** This procedure applies only when you are performing a new installation of vCloud Director. If you are upgrading an existing installation of vCloud Director, see Chapter 9 Upgrading vCloud Director.

**Prerequisites**
Verify that each of your vCenter Server systems meets the prerequisites for installing NSX Manager.

**Procedure**

1. Perform the installation task for the NSX Manager virtual appliance.
   See the NSX Installation Guide.

2. Log in to the NSX Manager virtual appliance that you installed and confirm the settings that you specified during installation.

3. Associate the NSX Manager virtual appliance that you installed with the vCenter Server system that you plan to add to vCloud Director in your planned vCloud Director installation.

4. Configure VXLAN support in the associated NSX Manager instances.
   vCloud Director creates VXLAN network pools to provide network resources to Provider VDCs. If VXLAN support is not configured in the associated NSX Manager, Provider VDCs show a network pool error, and you must create a different type of network pool and associate it with the Provider VDC. For details about configuring VXLAN support, see the NSX Administration Guide.

5. (Optional) If you want Edge Gateways in the system to provide distributed routing, set up an NSX Controller cluster.
   See the NSX Administration Guide.

Install and Configure NSX-T Data Center for vCloud Director

If you plan your vCloud Director installation to use network resources from NSX-T Data Center, you must install and configure NSX-T Data Center with at least one NSX-T Manager instance.
NSX-T Manager is included in the NSX-T Data Center download. For the most recent information about compatibility between vCloud Director and other VMware products, see the VMware Product Interoperability Matrices at http://partnerweb.vmware.com/comp_guide/sim/interop_matrix.php. For information about the network requirements, see Network Configuration Requirements for vCloud Director.

**Important** This procedure applies only when you are performing a new installation of vCloud Director. If you are upgrading an existing installation of vCloud Director, see Chapter 9 Upgrading vCloud Director.

**Prerequisites**

You must be familiar with NSX-T Data Center.

**Procedure**

1. Install the NSX-T Manager virtual appliance.
   
   See the NSX-T Installation Guide.

2. Prepare the ESXi hosts that you want to operate with NSX-T Data Center.
   
   See the NSX-T Installation Guide.

3. Create transport nodes and transport zones for your cloud requirements.
   
   See the NSX-T Installation Guide.

4. Configure edge nodes and clusters.
   
   See the NSX-T Installation Guide.

5. Configure tier-0 and tier-1 routers.
   
   See the NSX-T Administration Guide.

6. Configure one or more VLAN or overlay logical switches that you want to import to your vCloud Director installation.
   
   See the NSX-T Administration Guide.

**What to do next**

After you install vCloud Director, you can register the NSX-T Manager instance with your cloud. For information about registering an NSX-T Manager instance, see vCloud API Programming Guide for Service Providers.
Install vCloud Director on Linux

You can create a vCloud Director server group by installing the vCloud Director software of one or more Linux servers. Installation and configuration of the first group member creates a response file that you use to configure additional members of the group.

This procedure applies to new installations only. If you are upgrading an existing vCloud Director installation, see Chapter 9 Upgrading vCloud Director.

**Important** Mixed vCloud Director installations on Linux and vCloud Director appliance deployments in one server group are unsupported.

**Prerequisites**

- Verify that the target servers for your server group meet the Chapter 2 vCloud Director Hardware and Software Requirements.
- Verify that you created an SSL certificate for each endpoint of the target servers for your server group. All directories in the pathname to the SSL certificates must be readable by any user. Using the same keystore path on all members of a server group simplifies the installation process, for example /tmp/certificates.ks. See Create SSL Certificates.
- Verify that you prepared an NFS or other shared storage volume that is accessible to all target servers for your vCloud Director server group. See Preparing the Transfer Server Storage.
- Verify that you created a vCloud Director database that is accessible to all servers in the group. See Preparing the vCloud Director Database. Verify that the database service starts when you reboot the database server.
- Verify that all vCloud Director servers, the database server, all vCenter Server systems, and the associated NSX Manager instances can resolve each host name in the environment as described in Network Configuration Requirements for vCloud Director.
- Verify that all vCloud Director servers and the database server are synchronized to a network time server with the tolerances noted in Network Configuration Requirements for vCloud Director.
- If you plan to import users or groups from an LDAP service, verify that the service is accessible to each vCloud Director server.
Open firewall ports as shown in Network Security Requirements. Port 443 must be open between vCloud Director and vCenter Server systems.

**Procedure**

1. **Install vCloud Director on the First Member of a Server Group**
   After you prepared your environment and verified the prerequisites, you can begin creating the vCloud Director server group by running the vCloud Director installer on the first target Linux server.

2. **Configure the Network and Database Connections**
   After you install vCloud Director on the first member of the server group, you must run the configuration script that creates the network and database connections for this cell. The script creates a response file that you must use when configuring additional members of the server group.

3. **Install vCloud Director on an Additional Member of a Server Group**
   You can add servers to a vCloud Director server group at any time. Because all servers in a server group must be configured with the same database connection details, you must use the response file created when you configured the first member of the group.

4. **Set Up vCloud Director**
   After you install and configure all servers in the vCloud Director server group, you must set up your vCloud Director installation. The vCloud Director setup initializes the vCloud Director database with a license key, system administrator account, and related information.

**What to do next**

You can begin adding resources to your vCloud Director installation. To get started with vCloud Director, see vCloud Director Administrator's Guide.

**Install vCloud Director on the First Member of a Server Group**

After you prepared your environment and verified the prerequisites, you can begin creating the vCloud Director server group by running the vCloud Director installer on the first target Linux server.

vCloud Director for Linux is distributed as a digitally signed executable file with a name of the form `vmware-vcloud-director-distribution-v.v.v-nnnnnn.bin`, where `v.v.v` represents the product version and `nnnnnn` the build number. For example: `vmware-vcloud-director-distribution-8.10.0-3698331.bin`. Running this executable installs or upgrades vCloud Director.

The vCloud Director installer verifies that the target server meets all platform prerequisites and installs vCloud Director software on it.

**Prerequisites**

- Verify that you have superuser credentials for the target server.
If you want the installer to verify the digital signature of the installation file, download and install the VMware public key on the target server. If you already verified the digital signature of the installation file, you do not need to verify it again during installation. See Download and Install the VMware Public Key.

Procedure

1. Log in to the target server as root.

2. Download the installation file to the target server.
   If you purchased the software on media, copy the installation file to a location that is accessible to the target server.

3. Verify that the checksum of the download matches the checksum posted on the download page.
   Values for MD5 and SHA1 checksums are posted on the download page. Use the appropriate tool to verify that the checksum of the downloaded installation file matches the checksum shown on the download page. A Linux command of the following form displays the checksum for installation-file.

   
   ```bash
   [root@cell1 /tmp]# md5sum installation-file
   
   The command returns the installation file checksum that must match the MD5 checksum from the download page.
   ```

4. Ensure that the installation file is executable.
   The installation file requires execute permission. To be sure that it has this permission, open a console, shell, or terminal window and run the following Linux command, where installation-file is the full pathname to the vCloud Director installation file.

   
   ```bash
   [root@cell1 /tmp]# chmod u+x installation-file
   ```

5. Run the installation file.
   To run the installation file, enter the full pathname, for example:

   
   ```bash
   [root@cell1 /tmp]# ./installation-file
   ```

   The file includes an installation script and an embedded RPM package.

   **Note** You cannot run the installation file from a directory whose pathname includes any embedded space characters.

   If you did not install the VMware public key on the target server, the installer prints a warning of the following form:

   ```bash
   warning:installation-file.rpm: Header V3 RSA/SHA1 signature: NOKEY, key ID 66fd4949
   ```

   The installer performs the following actions.

   a. Verifies that the host meets all requirements.
b Verifies the digital signature on the installation file.
c Creates the vcloud user and group.
d Unpacks the vCloud Director RPM package.
e Installs the software.

When the installation finishes, the installer prompts you to run the configuration script, which configures the network and database connections.

6 Select whether to run the configuration script.

a To run the configuration script in an interactive mode, enter y and press Enter.
b To run the configuration script later in an interactive or unattended mode, enter n and press Enter.

Configure the Network and Database Connections

After you install vCloud Director on the first member of the server group, you must run the configuration script that creates the network and database connections for this cell. The script creates a response file that you must use when configuring additional members of the server group.

All members of the vCloud Director server group share database connection and other configuration details. When you run the configuration script on the first member of the vCloud Director server group, the script creates a response file that preserves database connections information for use in subsequent server installations.

You can run the configuration script in either an interactive mode or an unattended mode. For an interactive configuration, you run the command without options and the script prompts you for the required setup information. For an unattended configuration, you provide the setup information by using the command options.

If you want to use a single IP address with two different ports for the HTTP service and the console proxy service, you must run the configuration script in an unattended mode.

**Note**  The cell management tool includes subcommands that you can use to change the network and database connection details that you initially configured. Changes you make using these subcommands are written to the global configuration file and the response file. For information about using the cell management tool, see the *vCloud Director Administrator's Guide*.

**Prerequisites**

- For an interactive configuration, review *Interactive Configuration Reference*.
- For an unattended configuration, review *Unattended Configuration Reference*.
- For an unattended configuration, verify that the value of the environment variable V CLOUD_HOME is set to the full pathname of the directory in which vCloud Director is installed. This value is typically /opt/vmware/vcloud-director.
Procedure

1. Log in to the vCloud Director server as root.
2. Run the `configure` command:
   - For an interactive mode, run the command and, on the prompts, provide the required information.
     ```bash
     /opt/vmware/vcloud-director/bin/configure
     ```
   - For an unattended mode, run the command with appropriate options and arguments.
     ```bash
     /opt/vmware/vcloud-director/bin/configure options --unattended
     ```

   The script validates the information, then:
   a. Initializes the database and connects the server to it.
   b. Displays a URL at which you can connect to the VMware vCloud Director Setup wizard after the vCloud Director service starts.
   c. Offers to start the vCloud Director cell.
3. (Optional) Take a note of the VMware vCloud Director Setup wizard URL and enter `y` to start the vCloud Director service.
   You can decide to start the service later by running the `service vmware-vcd start` command.

Database connection information and other reusable information that you supplied during the configuration are preserved in the response file at `/opt/vmware/vcloud-director/etc/responses.properties` on this server. This file contains sensitive information that you must reuse when you add servers to a server group.

What to do next

Save a copy of the response file at a secure location. Restrict access to it, and make sure it is backed up to a secure location. When you back up the file, avoid sending clear texts across a public network.

If you plan to add servers to the server group, mount the shared transfer storage at `/opt/vmware/vcloud-director/data/transfer`.

Interactive Configuration Reference

When you run the `configure` script in an interactive mode, the script prompts you for the following information.

To accept a default value, press Enter.
Table 4-1. Required Information During an Interactive Network and Database Configuration

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>

</tbody>
</table>

**Example: Unattended Configuration with Two IP Addresses**

The following example command runs an unattended configuration of a vCloud Director server with two different IP addresses for the HTTP service and console proxy service.

```
[root@cell1 /opt/vmware/vcloud-director/bin]# ./configure --ip 10.17.118.159 --cons 10.17.118.158 --dbtype sqlserver --dbhost 10.150.10.78 --dbname mssql-db --dbuser vcloud --enable-ceip true --dbpassword P@55word -k /opt/keystore/certificates.ks -w $3Cret --loghost 10.150.10.10 --unattended
```
Example: Unattended Configuration with a Single IP Address

The following example command runs an unattended configuration of a vCloud Director server with a single IP address with two different ports for the HTTP service and console proxy service.

```
[root@cell1 /opt/vmware/vcloud-director/bin]# ./configure -ip 10.17.118.159 --primary-port-https 9000 -cons 10.17.118.159 --console-proxy-port-https 9010 -dbtype sqlserver -dbhost 10.150.10.78 -dbname mssql-db -dbuser vcloud -dbpassword P@55word -k /opt/keystore/certificates.ks -w $3Cret -loghost 10.150.10.10 --enable-ceip true -unattended
```

Install vCloud Director on an Additional Member of a Server Group

You can add servers to a vCloud Director server group at any time. Because all servers in a server group must be configured with the same database connection details, you must use the response file created when you configured the first member of the group.

**Important** Mixed vCloud Director installations on Linux and vCloud Director appliance deployments in one server group are unsupported.

**Prerequisites**

- Verify that you can access the response file that was created when you configured the first member of this server group. See Configure the Network and Database Connections.

- Verify that you mounted the shared transfer storage on the first member of the vCloud Director server group at /opt/vmware/vcloud-director/data/transfer.

**Procedure**

1. Log in to the target server as **root**.
2. Download the installation file to the target server.
   
   If you purchased the software on media, copy the installation file to a location that is accessible to the target server.

3. Ensure that the installation file is executable.
   
   The installation file requires execute permission. To be sure that it has this permission, open a console, shell, or terminal window and run the following Linux command, where **installation-file** is the full pathname to the vCloud Director installation file.

   ```
   [root@cell1 /tmp]# chmod u+x installation-file
   ```

4. Run the installation file.
   
   To run the installation file, enter the full pathname, for example:

   ```
   [root@cell1 /tmp]# ./installation-file
   ```
The file includes an installation script and an embedded RPM package.

**Note** You cannot run the installation file from a directory whose pathname includes any embedded space characters.

If you did not install the VMware public key on the target server, the installer prints a warning of the following form:

```
warning:installation-file.rpm: Header V3 RSA/SHA1 signature: NOKEY, key ID 66fd4949
```

The installer performs the following actions.

a  Verifies that the host meets all requirements.
b  Verifies the digital signature on the installation file.
c  Creates the vcloud user and group.
d  Unpacks the vCloud Director RPM package.
e  Installs the software.

When the installation finishes, the installer prompts you to run the configuration script, which configures the network and database connections.

5  Enter n and press Enter to reject running the configuration script.

You run the configuration script later by providing the response file as input.

6  Mount the shared transfer storage at `/opt/vmware/vcloud-director/data/transfer`.

All vCloud Director servers in the server group must mount this volume at the same mountpoint.

7  Copy the response file to a location accessible to this server.

All directories in the pathname to the response file must be readable by root.

8  Run the configuration script.

a  Run the `configure` command by providing the response file pathname.

```
/opt/vmware/vcloud-director/bin/configure -r /responses.properties
```

The script copies the response file to a location readable by `vcloud.vcloud` and runs the configuration script using the response file as input.

b  On the prompts, provide the IP addresses for the HTTP and the console proxy services.

c  If the configuration script does not find valid certificates in the pathname saved in the response file, when prompted, provide the pathname to the certificates and the passwords.

The script validates the information, connects the server to the database, and offers to start the vCloud Director cell.

9  (Optional) Enter y to start the vCloud Director service.

You can decide to start the service later by running the `service vmware-vcd start` command.
What to do next

Repeat this procedure to add more servers to this server group.

When the vCloud Director services are running on all servers, you must initialize the vCloud Director database with a license key, system administrator account, and related information. You can initialize the database in one of the following ways:

- Using a Web browser, open the setup wizard at the URL displayed when the configuration script finished. See Set Up vCloud Director.
- Use the cell management tool with the `system-setup` subcommand. For information about using the cell management tool, see vCloud Director Administrator's Guide.

Set Up vCloud Director

After you install and configure all servers in the vCloud Director server group, you must set up your vCloud Director installation. The vCloud Director setup initializes the vCloud Director database with a license key, system administrator account, and related information.

Before you can start the vCloud Director Web Console, you run the VMware vCloud Director Setup wizard, which gathers the information that the Web Console requires to start.

As an alternative to using the VMware vCloud Director Setup wizard, to configure the vCloud Director installation, you can use the `system-setup` subcommand of the cell management tool. For information about the cell management tool, see the vCloud Director Administrator's Guide.

Prerequisites

- Verify that the vCloud Director services are started on all servers.
- Obtain a vCloud Director product serial number from the VMware License Portal.

Procedure

Procedure

1 Open a Web browser and go to the URL that the configuration script displayed.

   To discover the URL of the VMware vCloud Director Setup wizard, you can also look up the fully qualified domain name associated with the IP address that you specified for the HTTP service during the installation of the first server. To connect to the wizard, go to https://fully-qualified-domain-name, for example, https://mycloud.example.com.

   **Note** Starting the wizard might take a few minutes.

2 Review the Welcome page and click Next.

3 Read and accept the licence agreement, and click Next.

   If you reject the license agreement, you cannot proceed with the vCloud Director configuration.

4 Enter your vCloud Director product serial number and click Next.
5 Enter a user name, password, and contact information for the vCloud Director system administrator, and click Next.

The vCloud Director system administrator has superuser privileges throughout the cloud. This system administrator can create additional system administrator accounts.

6 Configure the system settings that control how vCloud Director interacts with vSphere and NSX Manager, and click Next.

   a In the System name text box, enter a name for the vCenter Server folder to use for this vCloud Director installation.

   b In the Installation ID text box, set the ID for this vCloud Director installation to use when you create MAC addresses for virtual NICs.

       If you plan to create stretched networks across vCloud Director installations in multisite deployments, consider setting a unique installation ID for each vCloud Director installation.

7 On the Ready to Log In page, review the settings, and click Finish.

When the configuration process finishes, you are redirected to the vCloud Director Web Console login page.

What to do next

Log in to the vCloud Director Web Console with the system administrator user name and password and begin provisioning your cloud. For information about adding resources to vCloud Director, see the vCloud Director Administrator's Guide.
Deploying the vCloud Director Appliance

You can create a vCloud Director server group by deploying one or more instances of the vCloud Director appliance. You deploy the vCloud Director appliance by using the vSphere Client (HTLM5), the vSphere Web Client (Flex), or VMware OVF Tool.

**Important** Mixed vCloud Director installations on Linux and vCloud Director appliance deployments in one server group are unsupported.

The vCloud Director appliance is a preconfigured virtual machine that is optimized for running the vCloud Director services.

The appliance is distributed with a name of the form VMware vCloud Director-\*v.v.v-\*nnnnnn_OVF10.ova, where v.v.v represents the product version and nnnnnn the build number. For example: VMware vCloud Director-9.7.0.0-9229800_OVA10.ova.

The vCloud Director appliance package contains the following software:

- VMware Photon™ OS
- The vCloud Director group of services
- PostgreSQL 10

The large vCloud Director primary appliance size is suitable for production systems, while the small is suitable for lab or test systems. After the deployment, you can reconfigure the size of the appliance.

**Important** Installing any third-party component on the vCloud Director appliance is unsupported. You can install only supported VMware components according to VMware Product Interoperability Matrices. For example, you can install a supported version of a VMware vRealize® Operations Manager™ or VMware vRealize® Log Insight™ monitoring agent.

Appliance Database Configuration

Starting with version 9.7, the vCloud Director appliance includes an embedded PostgreSQL database with a high availability (HA) function. To create an appliance deployment with a database HA cluster, you must deploy one instance of the vCloud Director appliance as a primary cell, and two instances as standby cells. You can deploy additional instances of the vCloud Director appliance in the server group as vCD application cells, which run only the vCloud Director group of services without the embedded database. vCD application cells connect to the database in the primary cell. See Appliance Deployments and Database High Availability Configuration.
By default, the vCloud Director appliance uses TLS, in place of the deprecated SSL, for database connections, including replication. This feature is active immediately after deployment, using a self-signed PostgreSQL certificate. To use a signed certificate from a certificate authority (CA), see Replace a Self-Signed Embedded PostgreSQL and vCloud Director Appliance Management UI Certificate.

**Note**  The vCloud Director appliance does not support external databases.

### Appliance Network Configuration

Starting with version 9.7, the vCloud Director appliance is deployed with two networks, eth0 and eth1, so that you can isolate the HTTP traffic from the database traffic. Different services listen on one or both of the corresponding network interfaces.

<table>
<thead>
<tr>

The vCloud Director appliance supports user customization of firewall rules by using iptables. To add custom iptables rules, you can add your own configuration data to the end of the `/etc/systemd/scripts/iptables` file.

This chapter includes the following topics:

- Appliance Deployments and Database High Availability Configuration
- Prerequisites for Deploying the vCloud Director Appliance
- Deploy the vCloud Director Appliance By Using the vSphere Web Client or the vSphere Client
- Deploying the vCloud Director Appliance by Using VMware OVF Tool

### Appliance Deployments and Database High Availability Configuration

The vCloud Director appliance includes an embedded PostgreSQL database. The embedded PostgreSQL database includes the Replication Manager (repmgr) tool suite, which provides a high availability (HA) function to a cluster of PostgreSQL servers. You can create an appliance deployment with a database HA cluster that provides failover capabilities to your vCloud Director database.
You can deploy the vCloud Director appliance as a primary cell, standby cell, or vCD application cell. See *Deploy the vCloud Director Appliance By Using the vSphere Web Client or the vSphere Client* or *Deploying the vCloud Director Appliance by Using VMware OVF Tool*.

To configure HA for your vCloud Director database, when you create your server group, you can configure a database HA cluster by deploying one primary and two standby instances of the vCloud Director appliance.

**Figure 5-1. A vCloud Director Appliance Database HA Cluster**

Creating a vCloud Director Appliance Deployment with Database HA

To create a vCloud Director server group with a database HA configuration, follow this workflow:

1. Deploy the vCloud Director appliance as a primary cell.

   The primary cell is the first member in the vCloud Director server group. The embedded database is configured as the vCloud Director database. The database name is `vcloud`, and the database user is `vcloud`.

2. Verify that the primary cell is up and running.
   a. To verify the vCloud Director service health, log in with the *system administrator* credentials to the vCloud Director Web Console at `https://primary_eth0_ip_address/cloud`.
   b. To verify the PostgreSQL database health, log in as `root` to the appliance management user interface at `https://primary_eth1_ip_address:5480`.

   The primary node must be in a running status.

3. Deploy two instances of the vCloud Director appliance as standby cells.
The embedded databases are configured in a replication mode with the primary database.

**Note** After the initial standby appliance deployment, the replication manager begins synchronizing its database with the primary appliance database. During this time, the vCloud Director database and therefore the vCloud Director UI are unavailable.

4 Verify that all cells in the HA cluster are running.

See View the Status of the Cells in a Database High Availability Cluster.

5 (Optional) Deploy one or more instances of the vCloud Director appliance as vCD Application cells.

The embedded databases are not used. The vCD Application cell connects to the primary database.

---

Creating a vCloud Director Appliance Deployment Without Database HA

To create a vCloud Director server without a database HA configuration, follow this workflow:

1 Deploy the vCloud Director appliance as a primary cell.

   The primary cell is the first member in the vCloud Director server group. The embedded database is configured as the vCloud Director database. The database name is `vcloud`, and the database user is `vcloud`.

2 Verify that the primary cell is up and running.
   a To verify the vCloud Director service health, log in with the **system administrator** credentials to the vCloud Director Web Console at `https://primary_eth0_ip_address/cloud`.
   b To verify the PostgreSQL database health, log in as **root** to the appliance management user interface at `https://primary_eth1_ip_address:5480`.

---

VMware, Inc. 48
The primary node must be in a running status.

3. (Optional) Deploy one or more instances of the vCloud Director appliance as vCD Application cells.

The embedded database is not used. The vCD Application cell connects to the primary database.

Prerequisites for Deploying the vCloud Director Appliance

To ensure a successful deployment of the vCloud Director appliance, you must perform some tasks and pre-checks before starting the deployment.

- Verify that you have access to the vCloud Director .ova file.
- Before you deploy the primary appliance, prepare an NFS shared transfer service storage. See Preparing the Transfer Server Storage.

  Note  The shared transfer service storage must contain neither a responses.properties file nor an appliance-nodes directory.

- Install and Configure a RabbitMQ AMQP Broker.

Deploy the vCloud Director Appliance By Using the vSphere Web Client or the vSphere Client

You can deploy the vCloud Director appliance as an OVF template by using the vSphere Web Client (Flex) or the vSphere Client (HTML5).

You must deploy the first member of a vCloud Director server group as a primary cell. You can deploy a subsequent member of a vCloud Director server group as a standby or vCD application cell. See Appliance Deployments and Database High Availability Configuration.

Important  Mixed vCloud Director installations on Linux and vCloud Director appliance deployments in one server group are unsupported.

For information about deploying OVF templates in vSphere, see vSphere Virtual Machine Administration.

As an alternative, you can deploy the appliance by using VMware OVF Tool. See Deploying the vCloud Director Appliance by Using VMware OVF Tool.

Note  Deploying the vCloud Director appliance in vCloud Director is unsupported.
Prerequisites

See Prerequisites for Deploying the vCloud Director Appliance.

Procedure

1. **Start the vCloud Director Appliance Deployment**
   
   To start the appliance deployment, you open the deployment wizard in the vSphere Web Client (Flex) or the vSphere Client (HTML5).

2. **Customize the vCloud Director Appliance and Finish the Deployment**
   
   To configure the vCloud Director details, you customize the appliance template.

What to do next

- Configure the public console proxy address, because the vCloud Director appliance uses its eth0 NIC with custom port 8443 for the console proxy service. See Customize Public Endpoints.
- To add members to the vCloud Director server group, repeat the procedure.
- To enter the license key, log in to the vCloud Director Web Console.
- To replace the self-signed certificate that is created during the appliance first boot, you can Create and Import a Signed SSL Certificate.

Start the vCloud Director Appliance Deployment

To start the appliance deployment, you open the deployment wizard in the vSphere Web Client (Flex) or the vSphere Client (HTML5).

Procedure

1. In the vSphere Web Client or the vSphere Client, right-click any inventory object and click Deploy OVF Template.

2. Enter the path to the vCloud Director .ova file and click Next.

3. Enter a name for the virtual machine and browse the vCenter Server repository to select a data center or folder on which to deploy the appliance, and click Next.

4. Select an ESXi host or cluster on which to deploy the appliance and click Next.

5. Review the template details and click Next.

6. Read and accept the license agreements, and click Next.
Select the deployment type and size, and click **Next**.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Primary-small</strong></td>
<td>Deploys the appliance with 12 GB of RAM and 2 vCPUs as the first member in a vCloud Director server group. The embedded database in the primary cell is configured as the vCloud Director database. The database name is <code>vcloud</code>, and the database user is <code>vcloud</code>.</td>
</tr>
<tr>
<td><strong>Primary-large</strong></td>
<td>Deploys the appliance with 24 GB of RAM and 4 vCPUs as the first member in a vCloud Director server group. The embedded database in the primary cell is configured as the vCloud Director database. The database name is <code>vcloud</code>, and the database user is <code>vcloud</code>.</td>
</tr>
<tr>
<td><strong>Standby-small</strong></td>
<td>Used to join a primary-small cell in a database HA cluster. Deploys the appliance with 12 GB of RAM and 2 vCPUs as the second or the third member in a vCloud Director server group with a database high availability configuration. The embedded database in a standby cell is configured in a replication mode with the primary database.</td>
</tr>
<tr>
<td><strong>Standby-large</strong></td>
<td>Used to join a primary-large cell in a database HA cluster. Deploys the appliance with 24 GB of RAM and 4 vCPUs as the second or the third member in a vCloud Director server group with a database high availability configuration. The embedded database in a standby appliance is configured in a replication mode with the primary database.</td>
</tr>
<tr>
<td><strong>vCD Cell Application</strong></td>
<td>Deploys the appliance with 8 GB of RAM and 2 vCPUs as a subsequent member in a vCloud Director server group. The embedded database in a vCD application cell is not used. The vCD application cell connects to the primary database.</td>
</tr>
</tbody>
</table>

**Important**  The primary and the standby cells in a vCloud Director server group must be of the same size. A database HA cluster can consist of one primary-small and two standby-small cells, or consist of one primary-large and two standby-large cells.

After the deployment, you can reconfigure the size of the appliance.

8. Select the disk format and the datastore for the virtual machine configuration files and virtual disks, and click **Next**.

Thick formats improve performance, and thin formats save storage space.

9. From the drop-down menus in the **Destination Network** cells, select the target networks for the `eth1` and `eth0` NICs of the appliance.

**Important**  The two destination networks must be different.

10. From the **IP allocation Settings** drop-down menus, select **Static-Manual** IP allocation, and select **IPv4** protocol.

11. Click **Next**.

You are redirected to the **Customize template** page to configure the vCloud Director details.
Customize the vCloud Director Appliance and Finish the Deployment

To configure the vCloud Director details, you customize the appliance template. When you customize the vCloud Director appliance, you configure the appliance settings, the database, and the network properties. You configure the initial system settings only when deploying a primary appliance, which is the first member of a server group.

**Procedure**

1. In section **VCD Appliance Settings**, configure the appliance details.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NTP Server</td>
<td>The host name or IP address of the NTP server to use.</td>
</tr>
<tr>
<td>Initial root password</td>
<td>The initial root password for the appliance. Must contain at least eight characters, one uppercase character, one lowercase character, one numeric digit, and one special character.</td>
</tr>
<tr>
<td></td>
<td><strong>Important</strong> The initial root password becomes the keystore password. The cluster deployment requires all the cells to have the same root password during the initial deployment. After the boot process finishes, you can change the root password on any desired cell.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> The OVF deployment wizard does not validate the initial root password against password criteria.</td>
</tr>
<tr>
<td>Expire Root Password Upon First Login</td>
<td>If you want to continue using the initial password after the first login, you must verify that the initial password meets root password criteria. To continue using the initial root password after the first login, deselect this option.</td>
</tr>
<tr>
<td>Enable SSH</td>
<td>Disabled by default.</td>
</tr>
<tr>
<td>NFS mount for transfer file location</td>
<td>See Preparing the Transfer Server Storage.</td>
</tr>
</tbody>
</table>

**Note** For information about changing the date, time, or time zone of the appliance, see [https://kb.vmware.com/kb/59674](https://kb.vmware.com/kb/59674).

2. If you are deploying the first member of a server group, in section **VCD Configure - Required only for "primary" appliances**, enter the database details, create the **system administrator** account, and configure the system settings.

   The database name is **vcloud**, and the database user is **vcloud**.

<table>
<thead>
<tr>

</tr>
<tr>
<td>Admin User Name</td>
<td>The user name for the system administrator account. Defaults to administrator.</td>
</tr>
<tr>
<td>Admin Full Name</td>
<td>The full name of the system administrator. Defaults to vCD Admin.</td>
</tr>
<tr>
<td>Admin user password</td>
<td>The password for the system administrator account.</td>
</tr>
<tr>
<td>Admin email</td>
<td>The email address of the system administrator.</td>
</tr>
</tbody>
</table>
3 (Optional) In section **Additional Networking Properties**, if your network topology requires it, enter the static routes for the eth0 and eth1 network interfaces, and click **Next**.

You might need to provide static routes if you want to reach hosts over a non-default gateway route. For example, management infrastructure is accessible only via eth1 interface, while the default gateway is on eth0. In most cases, this setting can remain empty.

The static routes must be in a comma-separated list of route specifications. A route specification must consist of the IP address of the target gateway and, optionally, a Classless Inter-Domain Routing (CIDR) network specification. For example, 172.16.100.253 172.16.100.0/19, 172.16.200.253.

4 In section **Networking Properties**, enter the network details for the eth0 and eth1 NICs, and click **Next**.

**Note** All settings are required.

5 On the **Ready to Complete** page, review the configuration settings for the vCloud Director appliance, and click **Finish** to start the deployment.

**What to do next**

Power on the newly created virtual machine.
Deploying the vCloud Director Appliance by Using VMware OVF Tool

You can deploy the vCloud Director appliance as an OVF template by using the VMware OVF Tool.

You must deploy the first member of a vCloud Director server group as a primary cell. You can deploy a subsequent member of a vCloud Director server group as a standby or vCD application cell. See Appliance Deployments and Database High Availability Configuration.

For information about installing OVF Tool, see the VMware OVF Tool Release Notes document.

For information about using OVF Tool, see the OVF Tool User's Guide.

Before running the deployment command, see Prerequisites for Deploying the vCloud Director Appliance.

After you deploy the appliance, view the firstboot log file for warning error messages. See Examine the Log Files in the vCloud Director Appliance.

**ovftool Command Options and Properties for Deploying the vCloud Director Appliance**

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--noSSLVerify</td>
<td>n/a</td>
<td>Skips SSL verification for vSphere connections.</td>
</tr>
<tr>
<td>--acceptAllEulas</td>
<td>n/a</td>
<td>Accepts all end-user licenses agreements (EULAs).</td>
</tr>
<tr>
<td>--datastore</td>
<td>target_vc_datastore</td>
<td>The target datastore name on which to store the virtual machine configuration files and virtual disks.</td>
</tr>
<tr>
<td>--allowAllExtraConfig</td>
<td>n/a</td>
<td>Converts all extra config options to the VMX format.</td>
</tr>
<tr>

<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>--deploymentOption</code></td>
<td>primary-small, primary-large, standby-small, standby-large, or cell</td>
<td>The appliance type and size that you want to deploy.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- primary-small deploys the appliance with 12 GB of RAM and 2 vCPUs as the first member in a vCloud Director server group. The embedded database in the primary cell is configured as the vCloud Director database. The database name is vcloud, and the database user is vcloud.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- primary-large deploys the appliance with 24 GB of RAM and 4 vCPUs as the first member in a vCloud Director server group. The embedded database in the primary cell is configured as the vCloud Director database. The database name is vcloud, and the database user is vcloud.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- standby-small deploys the appliance with 12 GB of RAM and 2 vCPUs as the second or the third member in a vCloud Director server group with a database high availability configuration. The embedded database in a standby cell is configured in a replication mode with the primary database.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- standby-large deploys the appliance with 24 GB of RAM and 4 vCPUs as the second or the third member in a vCloud Director server group with a database high availability configuration. The embedded database in a standby cell is configured in a replication mode with the primary database.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cell deploys the appliance with 8 GB of RAM and 2 vCPUs as a subsequent member in a vCloud Director server group. The embedded database in a vCD application cell is not used. The vCD application cell connects to the primary database.</td>
</tr>
</tbody>
</table>

**Important** The primary and the standby cells in a vCloud Director server group must be of the same size. A database HA cluster can consist of one primary-small and two standby-small cells, or consist of one primary-large and two standby-large cells.

After the deployment, you can reconfigure the size of the appliance.
An Example Command for Deploying the Primary vCloud Director Appliance

```
ovftool \
  --noSSLVerify \ 
  --acceptAllEulas \ 
  --datastore='datastore6' \ 
  --allowAllExtraConfig \ 
  --net:"eth0 Network"="My_UI_API_Network" \ 
  --net:"eth1 Network"="My_Internal_DB_Services_Network" \ 
  --name=MyAppliance \ 
  --diskMode=thin \ 
  --prop:"vami.ip0.VMware_vCloud_Director"="10.0.0.142" \ 
  --prop:"vami.ip1.VMware_vCloud_Director"="172.18.41.24" \ 
  --prop:"vami.DNS.VMware_vCloud_Director"="10.0.0.2" \ 
  --prop:"vami.domain.VMware_vCloud_Director"="mycompany.com" \ 
  --prop:"vami.gateway.VMware_vCloud_Director"="10.0.0.1" \ 
  --prop:"vami.netmask0.VMware_vCloud_Director"="255.255.0.0" \ 
  --prop:"vami.netmask1.VMware_vCloud_Director"="255.255.224.0" \ 
  --prop:"vami.searchpath.VMware_vCloud_Director"="eng.mycompany.com" \ 
  --prop:"vcloudapp.enable_ssh.VMware_vCloud_Director"="False" \ 
  --prop:"vcloudapp.expire_root_password.VMware_vCloud_Director"="True" \ 
  --prop:"vcloudapp.nfs_mount.VMware_vCloud_Director"="10.0.0.96:/data/transfer" \ 
  --prop:"vcloudapp.ntp-server.VMware_vCloud_Director"="time.mycompany.com" \ 
  --prop:"vcloudconf.db_pwd.VMware_vCloud_Director"="XjO52mXAP7n#" \

  --powerOn /"MyPath/VMware_vCloud_Director-version_number_OVF10.ova" \ 
vi://vc_user_name:vc_password@vc_hostname_or_ip_address/vc_datacenter_name/host/vc_cluster_name
```

An Example Command for Deploying a Standby vCloud Director Appliance

```
ovftool \
  --noSSLVerify \ 
  --acceptAllEulas \ 
  --datastore='datastore6' \ 
  --allowAllExtraConfig \ 
  --net:"eth0 Network"="My_UI_API_Network" \ 
  --net:"eth1 Network"="My_Internal_DB_Services_Network" \ 
  --name=MySecondAppliance \ 
  --diskMode=thin \ 
  --prop:"vami.ip0.VMware_vCloud_Director"="10.0.0.143" \ 
  --prop:"vami.ip1.VMware_vCloud_Director"="172.18.41.25" \ 
  --prop:"vami.DNS.VMware_vCloud_Director"="10.0.0.2" \ 
  --prop:"vami.domain.VMware_vCloud_Director"="mycompany.com" \ 
  --prop:"vami.gateway.VMware_vCloud_Director"="10.0.0.1" 
```
You can view the status of the cells in a database HA cluster, you can back up and restore the embedded database, you can reconfigure the appliance settings.

After you deploy the vCloud Director appliance, you cannot change the eth0 and eth1 network IP addresses. If you want the vCloud Director appliance to have different addresses, you must deploy a new appliance.

This chapter includes the following topics:

- View the Status of the Cells in a Database High Availability Cluster
- Recover from a Primary Database Failure in a High Availability Cluster
- Embedded Database Backup and Restore of vCloud Director Appliance
- Configure External Access to the vCloud Director Database
- Enable or Disable SSH Access to the vCloud Director Appliance
- Edit the DNS Settings of the vCloud Director Appliance
- Configuration Scripts in the vCloud Director Appliance
- Renew the vCloud Director Appliance Certificates
- Replace a Self-Signed Embedded PostgreSQL and vCloud Director Appliance Management UI Certificate

**View the Status of the Cells in a Database High Availability Cluster**

To view the status of the primary and the standby cells in an appliance database high availability (HA) cluster, you can log in to the appliance management user interface of any cell from the database HA cluster.

The vCloud Director appliance database HA cluster consists of one primary and two standby cells. See Appliance Deployments and Database High Availability Configuration.

**Procedure**

1. In a Web browser, go to the appliance management user interface at https://vcd_ip_address:5480.
2. Log in as root.
3 To view the details about the cells in the database HA cluster, click **vCD Database Availability**.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The DNS name of the cell.</td>
</tr>
<tr>
<td>Role</td>
<td>Can be either primary or standby. An appliance database HA cluster consists of one primary and two standby cells.</td>
</tr>
<tr>
<td>Status</td>
<td>Can be running, unreachable, or failed. An asterisk (*) indicates the status of the primary cell.</td>
</tr>
<tr>
<td>Following</td>
<td>The name of the primary cell with which the standby cell replicates.</td>
</tr>
</tbody>
</table>

**What to do next**

If a standby cell is not in a running state, deploy a new standby cell.

If the primary cell is not in a running state, **Recover from a Primary Database Failure in a High Availability Cluster**.

**Recover from a Primary Database Failure in a High Availability Cluster**

If the primary cell is not running properly, to recover the vCloud Director database, you can promote one of the standby cells to become the new primary cell. After that, you must deploy a new standby cell.

**Prerequisites**

- The primary cell is in the not reachable or failed state.
- The two standby cells are in the running state.

See **View the Status of the Cells in a Database High Availability Cluster**.

**Procedure**

1. Log in as **root** to the appliance management user interface of a running standby cell, `https://standby_ip_address:5480`.

2. In the **Role** column for the standby cell that you want to become the new primary cell, click **Promote**.

   The cell becomes the new primary cell in running state. The other standby cell is following the newly promoted primary cell.

3. Deploy a new standby appliance.

**What to do next**

1. Remove the failed primary appliance from both the vCloud Director server group and the repmgr high availability cluster. See **Delete a Cloud Cell** and **Unregister a Failed Primary Cell in a Database High Availability Cluster**.
2 If necessary, delete the failed primary appliance.

### Embedded Database Backup and Restore of vCloud Director Appliance

You can back up the vCloud Director appliance embedded PostgreSQL database, which can help you to restore your vCloud Director environment after a failure.

#### Back up the vCloud Director Appliance Embedded Database

If your environment consists vCloud Director appliance deployments with embedded PostgreSQL databases, you can back up the vCloud Director database from the primary cell. The resulting .tgz file is stored on the NFS shared transfer service storage location.

**Procedure**

1. Log in directly or SSH to the primary cell as root.
2. Navigate to /opt/vmware/appliance/bin.
3. Run the create-db-backup command.

On the NFS shared transfer service storage, in the vcloudapp.nfs_mount.VMware_vCloud_Director/pgdb-backup/ directory, you can see the newly created db-backup-date_time_format.tgz file. The .tgz file contains the database dump file, the global.properties, responses.properties, certificates, and proxycertificates files of the primary cell.

#### Restoring a vCloud Director Appliance Environment from an Embedded Database Backup

If you backed up the embedded PostgreSQL database, you can restore your vCloud Director appliance environment after a failure.

The restore workflow includes two major stages.

- Copying the embedded database backup .tar file from the transfer service NFS shared storage
- Restoring the database to the embedded database of the primary cell.

**Prerequisites**

You have a backup .tar file of the embedded PostgreSQL database. See Back up the vCloud Director Appliance Embedded Database.

**Procedure**

1. Log in as root to the console of each cell, and run the command to stop the vCloud Director service.

   ```
   service vmware-vcd stop
   ```

2. Copy the backup .tar file to the /tmp folder on the primary cell.
If there is not enough free space on the /tmp folder, use another location to store the .tar file.

3 Untar the backup file at /tmp.

    tar -zxvf db-backup-date_time_format.tgz

In the /tmp folder, you can see the extracted global.properties, responses.properties, certificates, proxycertificates, and the database dump file named vcloud_date_time_format.

4 Log in as root to the console of the primary cell, and copy the database backup.
   a Switch the user to postgres, connect to the psql database terminal, and run the statement to drop the vcloud database.

       sudo -i -u postgres /opt/vmware/vpostgres/current/bin/psql -c 'DROP DATABASE vcloud;'

   b Run the pg_restore command.

       sudo -u postgres /opt/vmware/vpostgres/current/bin/pg_restore -C -d postgres /tmp/vcloud_date_time_name

5 On each cell, back up and replace the configuration data, and reconfigure and start the vCloud Director service.
   a Back up the properties and the certificates files, and copy and replace these files from the backup files that you extracted at Step 3.

       The global.properties, responses.properties, certificates, and proxycertificates files are at /opt/vmware/vcloud-director/etc/.

   b Back up the keystore file that is at /opt/vmware/vcloud-director/certificates.ks file.

   c Run the command to reconfigure the vCloud Director service.

       /opt/vmware/vcloud-director/bin/configure --unattended-installation --database-type postgres --database-user vcloud --database-password db_password_new_primary --database-host eth1_ip_new_primary --database-port 5432 --database-name vcloud --database-ssl true --uuid --keystore /opt/vmware/vcloud-director/certificates.ks --keystore-password ks_password --primary-ip appliance_eth0_ip --console-proxy-ip appliance_eth0_ip --console-proxy-port-https 8443

Where:
- The --keystore-password option matches the keystore password for the certificates on the appliance.
- The --database-password option matches the database password that you set during the appliance deployment.
- The --database-host option matches the eth1 network IP address of the primary appliance.
The --primary-ip value matches the eth0 network IP address of the appliance.

The --console-proxy-ip option matches the eth0 network IP address of the appliance.

For troubleshooting information, see Reconfiguring the vCloud Director Service Fails When Migrating or Restoring to vCloud Director Appliance.

d Run the command to start the vCloud Director service.

```
service vmware-vcd start
```

You can monitor the progress of the cell startup at /opt/vmware/vcloud-director/logs/cell.log.

6 After all cells of the server group finish the startup process, verify that the restore of your vCloud Director environment is successful.

a Open the vCloud Director Web Console by using the eth0 network IP address of any cell from the new server group, https://eth0_IP_new_cell/cloud.

b Log in to the vCloud Director Web Console with your existing system administrator credentials.

c Validate that your vSphere and cloud resources are available in the new environment.

7 After the successful verification of the database restore, use the vCloud Director Web Console to delete the disconnected cells that belong to the old vCloud Director environment.

a From the Manage & Monitor tab, click Cloud Cells.

b Right-click a cell name and select Delete.

### Configure External Access to the vCloud Director Database

You can enable access from particular external IP addresses to the vCloud Director database that is embedded in the primary appliance.

During a migration to the vCloud Director appliance, or if you plan to use a third party database backup solution, you might want to enable external access to the embedded vCloud Director database.

**Procedure**

1 Log in directly or SSH to the primary cell as root.

2 Navigate to the database directory, /opt/vmware/appliance/etc/pg_hba.d/.

3 Create a text file containing entries for the target external IP addresses similar to:

```
#TYPE  DATABASE  USER    ADDRESS        METHOD
host   vcloud    vcloud  CIDR_notation  md5
```
For example:

<table>
<thead>
<tr>
<th>TYPE</th>
<th>DATABASE</th>
<th>USER</th>
<th>ADDRESS</th>
<th>METHOD</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>vcloud</td>
<td>vcloud</td>
<td>172.168.100.5/32</td>
<td>md5</td>
</tr>
<tr>
<td>host</td>
<td>vcloud</td>
<td>vcloud</td>
<td>172.168.20.5/32</td>
<td>md5</td>
</tr>
</tbody>
</table>

Your entries are appended to the dynamically updated `pg_hba.conf` file, which controls the access to the primary database in the HA cluster.

Enable or Disable SSH Access to the vCloud Director Appliance

During the appliance deployment, you can leave disabled or you can enable the SSH access to the appliance. After the deployment, you can switch the SSH access setting.

The SSH daemon runs in the appliance for use by the database HA function and for remote root logins. You can disable the SSH access for the root user. The SSH access for the database HA function remains unchanged.

**Procedure**

1. Log in directly or SSH to the vCloud Director appliance console as root.
2. Run the script for enabling or disabling the SSH root access.
   - To enable the SSH root access, run the `enable_root_login.sh` script.
   - To disable the SSH root access, run the `disable_root_login.sh` script.

Edit the DNS Settings of the vCloud Director Appliance

After the deployment, you can change the DNS settings of the vCloud Director appliance, for example, you can change the DNS timeout and retry values. The `/etc/resolv.conf` file in the vCloud Director appliance stores the current DNS settings.

**Procedure**

1. Log in directly or SSH to the vCloud Director appliance console as root.
2. (Optional) Verify the current DNS configuration by running the following command:
   
   `ovfenv --key vami.DNS.VMware_vCloud_Director`

3. Run the command to change the DNS value.
   
   `ovfenv --key vami.DNS.VMware_vCloud_Director --value DNS_server_IP`

4. Reboot the virtual machine.
Configuration Scripts in the vCloud Director Appliance

The vCloud Director appliance contains specific configuration scripts.

<table>
<thead>
<tr>
<th>Directory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/opt/vmware/appliance/bin/</td>
<td>The appliance configuration scripts.</td>
</tr>
<tr>
<td>/opt/vmware/appliance/etc/</td>
<td>The appliance configuration files.</td>
</tr>
<tr>
<td>/opt/vmware/appliance/etc/pg_hba.d/</td>
<td>The directory where you can add custom entries to the pg_hba.conf file. See Configure External Access to the vCloud Director Database.</td>
</tr>
</tbody>
</table>

Renew the vCloud Director Appliance Certificates

When you deploy the vCloud Director appliance, it generates self-signed certificates with a validity period of 365 days. If there are expiring or expired certificates in your environment, you can generate new self-signed certificates. You must renew the certificates for each vCloud Director cell individually.

The vCloud Director appliance uses two sets of SSL certificates. The vCloud Director service uses one set of certificates for HTTPS and console proxy communications. The embedded PostgreSQL database and the vCloud Director appliance management user interface share the other set of SSL certificates.

Prerequisites

If you are renewing the certificate for the primary node in a database high availability cluster, place all other nodes in maintenance mode to prevent data loss. See Managing a Cell.

Procedure

1. SSH or log in as root to the OS of the vCloud Director appliance.
2. Run the command to stop the vCloud Director services.
   ```
   /opt/vmware/vcloud-director/bin/cell-management-tool -u administrator cell --shutdown
   ```
3. Run the command to generate new certificates.
   ```
   /opt/vmware/appliance/bin/generate-certificates.sh root password
   ```
   This command restarts the PostgreSQL and the Nginx servers.
4. Run the command to import the new certificates to vCloud Director.
   ```
   /opt/vmware/vcloud-director/bin/cell-management-tool certificates -j -p --keystore /opt/vmware/vcloud-director/certificates.ks --keystore-password root password
   ```
5. Run the command to restart the vCloud Director service.
   ```
   service vmware-vcd start
   ```

The renewed self-signed certificates are visible in the vCloud Director user interface.
The new PostgreSQL certificate is imported to the vCloud Director truststore on other vCloud Director cells the next time the appliance-sync function runs. The operation might take up to 60 seconds.

What to do next

If necessary, a self-signed certificate can be replaced with a certificate signed by an external or internal certificate authority.

Replace a Self-Signed Embedded PostgreSQL and vCloud Director Appliance Management UI Certificate

By default, the embedded PostgreSQL database and the vCloud Director appliance management user interface share a set of self-signed SSL certificates. For increased security, you can replace the default self-signed certificates with certificate authority (CA) signed certificates.

When you deploy the vCloud Director appliance, it generates self-signed certificates with a validity period of 365 days. The vCloud Director appliance uses two sets of SSL certificates. The vCloud Director service uses one set of certificates for HTTPS and the console proxy communications. The embedded PostgreSQL database and the vCloud Director appliance management user interface share the other set of SSL certificates.

Procedure

1. Send the certificate signing request located at /opt/vmware/appliance/etc/ssl/vcd_ova.csr to the CA for signing.
2. If you are replacing the certificate for the primary database, place all other nodes into maintenance mode to prevent the possibility of data loss.
3. Replace the existing PEM-format certificate at /opt/vmware/appliance/etc/ssl/vcd_ova.crt with the signed certificate, obtained from your CA in Step 1.
4. To pick up the new certificate, restart the vpostgres and vcd_ova_ui services.
5. If you are replacing the certificate for the primary database, take all other nodes out of maintenance mode.

The new certificate is imported to the vCloud Director truststore on other vCloud Director cells the next time the appliance-sync function runs. The operation might take up to 60 seconds.
Using the Replication Manager Tool Suite in a High Availability Cluster Configuration

The repmgr open-source tool suite is part of the embedded PostgreSQL database of the vCloud Director appliance. You can use repmgr to configure, monitor, and control PostgreSQL replication and database failover in your vCloud Director database high availability cluster.

You can use the repmgr command-line interface to check the status and events of a node or a cluster, to register or unregister a node, to promote a standby node, to swap the roles of a primary and a standby, or to follow a new primary node.

To learn more about vCloud Director database high availability configuration, see Appliance Deployments and Database High Availability Configuration.

To learn more about repmgr, visit repmgr.org.

This chapter includes the following topics:

- Check the Connectivity Status of a Database High Availability Cluster
- Check the Replication Status of a Node in a Database High Availability Cluster
- Check the Status of a Database High Availability Cluster
- Detecting a Former Primary Node That Comes Back Online in a High Availability Cluster
- Switch the Roles of the Primary and a Standby Cell in a Database High Availability Cluster
- Unregister a Failed or Unreachable Standby Node in a Database High Availability Cluster
- Unregister a Failed Primary Cell in a Database High Availability Cluster
- Unregister a Running Standby Cell in a Database High Availability Cluster

Check the Connectivity Status of a Database High Availability Cluster

You can use the replication manager tool suite to check the connectivity between the nodes in your database high availability cluster.

Procedure

1. Log in or SSH as root to the OS of any of the running cells in the cluster.
2. Change the user to `postgres`.

```
sudo -i -u postgres
```

3. Check the connectivity of the cluster.
   - The `repmgr cluster matrix` command runs the `repmgr cluster show` command on each node of the cluster and presents the result as a matrix.

```
/opt/vmware/vpostgres/current/bin/repmgr -f /opt/vmware/vpostgres/current/etc/repmgr.conf
cluster matrix
```

In the following example, node 1 and node 2 are up, and node 3 is down. Each row corresponds to one server and represents the result of testing an outbound connection from that server.

The three entries in the third row are marked with a `?` symbol because node 3 is down and there is no information on its outbound connections.

<table>
<thead>
<tr>
<th>Name</th>
<th>Id</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>node 1</td>
<td>1</td>
<td>*</td>
<td>*</td>
<td>x</td>
</tr>
<tr>
<td>node 2</td>
<td>2</td>
<td>*</td>
<td>*</td>
<td>x</td>
</tr>
<tr>
<td>node 3</td>
<td>3</td>
<td>?</td>
<td>?</td>
<td>?</td>
</tr>
</tbody>
</table>

- The `repmgr cluster crosscheck` command crosschecks the connections between each combination of nodes and might provide a better overview of the cluster connectivity.

```
/opt/vmware/vpostgres/current/bin/repmgr -f /opt/vmware/vpostgres/current/etc/repmgr.conf
cluster crosscheck
```

In the following example, the node from which you run the `repmgr cluster crosscheck` command merges its cluster matrix system output with the output from the other nodes and does a crosscheck between the nodes. In this case, all nodes are up, but the firewall drops packets originating from node 1 and directed at node 3. This is an example of an asymmetric network partition, where node 1 cannot send packets to node 3.

<table>
<thead>
<tr>
<th>Name</th>
<th>Id</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>node 1</td>
<td>1</td>
<td>*</td>
<td>*</td>
<td>x</td>
</tr>
<tr>
<td>node 2</td>
<td>2</td>
<td>*</td>
<td>*</td>
<td>*</td>
</tr>
<tr>
<td>node 3</td>
<td>3</td>
<td>*</td>
<td>*</td>
<td>*</td>
</tr>
</tbody>
</table>

**What to do next**

To determine the overall connectivity status in your database high availability cluster, run these commands on each node and compare the results.
Check the Replication Status of a Node in a Database High Availability Cluster

You can use the replication manager tool suite and the PostgreSQL interactive terminal to check the replication status of individual nodes in a database high availability cluster.

Procedure

1. Log in or SSH as root to the OS of any of the running nodes in the cluster.
2. Change the user to postgres.

   ```bash
   sudo -i -u postgres
   ```
3. Check the replication status of the node.

   ```bash
   /opt/vmware/vpostgres/current/bin/repmgr -f /opt/vmware/vpostgres/current/etc/repmgr.conf node status
   ```

   The system output provides information on the node, PostgreSQL version, and replication details.
4. (Optional) For more detailed information, use the PostgreSQL interactive terminal to check the replication status of the nodes.

   The PostgreSQL interactive terminal can provide information regarding whether any of the received log records of the standby nodes are lagging behind the logs sent by the primary.
   a. Connect to the psql terminal

      ```bash
      /opt/vmware/vpostgres/current/bin/psql
      ```
   b. To expand the display and make query results easier to read, run the set \x command.
   c. Run a replication status query depending on the role of the node.

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run a query on the primary node.</td>
<td>/opt/vmware/vpostgres/current/bin/psql</td>
</tr>
<tr>
<td>Run a query on a standby node.</td>
<td><code>select * from pg_stat_wal_receiver;</code></td>
</tr>
</tbody>
</table>

Check the Status of a Database High Availability Cluster

To troubleshoot problems in your database high availability cluster, you must monitor the status of the nodes and the events in the cluster.

Procedure

1. Log in or SSH as root to the OS of any of the running cells in the cluster.
2 Change the user to **postgres**.

```bash
sudo -i -u postgres
```

3 Check the status of the cluster.

```bash
/opt/vmware/vpostgres/current/bin/repmgr cluster show
```

The console output displays the cluster information. In the following example, the primary node in the cluster, node 3, is unreachable.

<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>Role</th>
<th>Status</th>
<th>Upstream</th>
<th>Location</th>
<th>Connection string</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Node 1</td>
<td>standby</td>
<td>running</td>
<td>Node 3 name</td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
<tr>
<td></td>
<td>Node 2</td>
<td>standby</td>
<td>running</td>
<td>Node 3 name</td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
<tr>
<td></td>
<td>Node 3</td>
<td>primary</td>
<td>? unreachable</td>
<td></td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
</tbody>
</table>

In the following system output example, node 3 is the primary node in a healthy running cluster.

<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>Role</th>
<th>Status</th>
<th>Upstream</th>
<th>Location</th>
<th>Connection string</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Node 1</td>
<td>standby</td>
<td>running</td>
<td>Node 3 name</td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
<tr>
<td></td>
<td>Node 2</td>
<td>standby</td>
<td>running</td>
<td>Node 3 name</td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
<tr>
<td></td>
<td>Node 3</td>
<td>primary</td>
<td>*running</td>
<td></td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
</tbody>
</table>

4 Check the cluster events log.

```bash
/opt/vmware/vpostgres/current/bin/repmgr -f /opt/vmware/vpostgres/current/etc/repmgr.conf cluster event
```

The system output shows creation, cloning, and registration events in the cluster.

**What to do next**

If the status of the primary node is unreachable or failed, you must promote a standby node.

If the status of a standby node is unreachable or failed, repair the node and start the PostgreSQL service if it is not running.
Detecting a Former Primary Node That Comes Back Online in a High Availability Cluster

If a primary node in your cluster fails and then it comes back online when you promote a standby node to be the new primary, this causes inaccuracies in the repmgr data. You can detect irregularities with the repmgr cluster show command.

**Example: Running repmgr cluster show on the Former Primary Node**

In the following example, running the repmgr cluster show command on a former primary node that comes back online, results in the following system output.

<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>Role</th>
<th>Status</th>
<th>Upstream</th>
<th>Location</th>
<th>Connection string</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Node 1</td>
<td>standby</td>
<td>!running as primary</td>
<td>Node 3 name</td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
<tr>
<td></td>
<td>Node 2</td>
<td>standby</td>
<td>running</td>
<td>Node 3 name</td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
<tr>
<td></td>
<td>Node 3</td>
<td>primary</td>
<td>* running</td>
<td></td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
</tbody>
</table>

WARNING: following issues were detected
- node 1(ID: Node 1) is registered as standby but running as primary

In the example, node 1 is the current primary node in the cluster.

When you run the repmgr cluster show command, getting !running as primary status for a standby node indicates that a former primary node is running in the cluster. In this case, you must shut down and unregister the former primary node.

**Example: Running repmgr cluster show on the New Primary**

In the following example, running the repmgr cluster show command on the new primary node results in the following system output.

<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>Role</th>
<th>Status</th>
<th>Upstream</th>
<th>Location</th>
<th>Connection string</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Node 1</td>
<td>primary</td>
<td>* running</td>
<td></td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
<tr>
<td></td>
<td>Node 2</td>
<td>standby</td>
<td>running</td>
<td>Node 1 name</td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
<tr>
<td></td>
<td>Node 3</td>
<td>primary</td>
<td>! running</td>
<td></td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
</tbody>
</table>

WARNING: following issues were detected
- node 3(ID: Node 3) is running but the repmgr node record is inactive

In this case, the repmgr data is correct. It accurately indicates that node 1 is running and that it is the current primary node. The warning message about node 3, the former primary, indicates that the repmgr data on that node is not accurate.
Example: Running `repmgr cluster show` After Promoting a Standby Node, Without Running `standby follow` on the Remaining Standby Nodes

In the following example, you can see the repmgr data on each node in a cluster in which the primary node failed. A standby was promoted manually using the `repmgr standby promote` command, but without running `repmgr standby follow` on the remaining standby nodes.

When you run `repmgr cluster show` on the new primary, the system output represents correct repmgr data, but the new primary node, node 2, is not followed by any standby nodes.

<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>Role</th>
<th>Status</th>
<th>Upstream</th>
<th>Location</th>
<th>Connection string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node 1</td>
<td>Node1 name</td>
<td>primary</td>
<td>* running</td>
<td></td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
<tr>
<td>Node 2</td>
<td>Node2 name</td>
<td>primary</td>
<td>! running</td>
<td></td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
<tr>
<td>Node 3</td>
<td>Node3 name</td>
<td>standby</td>
<td>running</td>
<td>Node 1 name</td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
</tbody>
</table>

WARNING: following issues were detected
- node 1(ID: Node 1) is running but the repmgr node record is inactive

Both node 1, which is the former primary, and node 3, which is the standby that follows the former primary, provide inaccurate repmgr data.

<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>Role</th>
<th>Status</th>
<th>Upstream</th>
<th>Location</th>
<th>Connection string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node 1</td>
<td>Node1 name</td>
<td>primary</td>
<td>* running</td>
<td></td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
<tr>
<td>Node 2</td>
<td>Node2 name</td>
<td>standby</td>
<td>! running as primary</td>
<td>Node1 name</td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
<tr>
<td>Node 3</td>
<td>Node3 name</td>
<td>standby</td>
<td>running</td>
<td>Node1 name</td>
<td>default</td>
<td>host=host IP address user=repmgr dbname=repmgr</td>
</tr>
</tbody>
</table>

WARNING: following issues were detected
- node 2(ID: Node 2) is registered as standby but running as primary

Example: Running `repmgr cluster show` on a Standby Node

Running the command on a standby node that is following the current primary, results in a system output with accurate repmgr data that is identical to the data on the current primary.

Running the command on a standby node that is following the former primary, results in a system output with inaccurate repmgr data that is identical to the data on the former primary.
Log Entries

If a former primary that failed comes back online after you promote a standby node to be the new primary, the following entries appear in the `update-repmgr-data.log` file on all nodes with inaccurate repmgr data.

```
ERROR: An old primary is running in the repmgr cluster.
ERROR: Manual intervention is required to repair the repmgr cluster.
ERROR: The first step should be to shutdown and unregister the old primary.
```

Switch the Roles of the Primary and a Standby Cell in a Database High Availability Cluster

You can use a repmgr command to switch the roles of the primary and one of the standby nodes in your database high availability cluster during a planned maintenance.

Prerequisites

- Put all vCloud Director cells that are part of the high availability cluster into maintenance mode.
- Verify that all the nodes in the cluster are healthy and online.

Procedure

1. Log in or SSH as `root` to the OS of the standby node that you want to promote.
2. Change the user to `postgres`.
   ```bash
   sudo -i -u postgres
   ```
3. (Optional) Verify that the prerequisites for the switchover are met by running the command with the `--dry-run` option.
   ```bash
   /opt/vmware/vpostgres/current/bin/repmgr standby switchover -f /opt/vmware/vpostgres/current/etc/repmgr.conf --siblings-follow --dry-run
   ```
4. Switch the roles of the primary and the standby cell.
   ```bash
   /opt/vmware/vpostgres/current/bin/repmgr standby switchover -f /opt/vmware/vpostgres/current/etc/repmgr.conf --siblings-follow
   ```

The last line of the console output indicates that the standby switchover has completed successfully.

What to do next

1. Run the `reconfigure-database` command to update the database IP address on all vCloud Director cells. See Update the Database IP Addresses on vCloud Director Cells.
2. When you reconfigure the vCloud Director cells in the server group to point to the new primary database, take out of maintenance mode all vCloud Director cells that are part of the high availability cluster.
Unregister a Failed or Unreachable Standby Node in a Database High Availability Cluster

You can use repmgr on a running node on your cluster to unregister a failed or unreachable standby node.

**Note** For the primary node to function normally, at least one standby node must always be running.

**Prerequisites**

To unregister a standby node that is not running, you must provide the node ID. To find the IP address, check the status of the cluster and locate the node. On that row, use the host value from the Connection string column to identify the IP address of the node. See [Check the Status of a Database High Availability Cluster](#).

**Procedure**

1. Log in or SSH as `root` to the OS of any of the running nodes of the cluster.
2. Change the user to `postgres`.
   ```bash
   sudo -i -u postgres
   ```
3. Unregister the failed or unreachable node.
   ```bash
   /opt/vmware/vpostgres/current/bin/repmgr standby unregister -f /opt/vmware/vpostgres/current/etc/repmgr.conf --node-id=ID
   ```

Unregistering the node removes the node information from the repmgr metadata.

Unregister a Failed Primary Cell in a Database High Availability Cluster

If the primary node in your database high availability cluster fails and you promote a new primary, you must unregister the failed primary node to remove it from the cluster and avoid inconsistent cluster status data.

**Prerequisites**

- To unregister a primary node that is not running, you must provide the node ID. To find the IP address, check the status of the cluster and locate the node. On that row, use the host value from the Connection string column to identify the IP address of the node. See [Check the Status of a Database High Availability Cluster](#).
- Verify that the failed primary is inactive and without any following standby nodes, and promote a new primary.

**Procedure**

1. Log in or SSH as `root` to the OS of any of the running nodes in the cluster.
2  Change the user to `postgres`.

```
sudo -i -u postgres
```

3  (Optional) To verify that the prerequisites for unregistering the node are met, run the command with the `--dry-run` option.

```
/opt/vmware/vpostgres/current/bin/repmgr primary unregister --node-id=node ID --dry-run
```

4  Unregister the node.

```
/opt/vmware/vpostgres/current/bin/repmgr primary unregister --node-id=node ID
```

The operation removes the node from the repmgr metadata.

### Unregister a Running Standby Cell in a Database High Availability Cluster

If you want to use a node in another role, or if you want to remove it from the high availability cluster, you must unregister it.

You can run this command during the normal system operation.

**Note**  For the primary node to function normally, at least one standby node must always be running.

### Prerequisites

To unregister a standby node, you must provide the node ID. To find the IP address, check the status of the cluster and locate the node. On that row, use the host value from the Connection string column to identify the IP address of the node. See Check the Status of a Database High Availability Cluster.

### Procedure

1  Log in or SSH as `root` to the OS of any of the running nodes in the cluster.

2  Change the user to `postgres`.

```
sudo -i -u postgres
```

3  Unregister the node.

```
/opt/vmware/vpostgres/current/bin/repmgr standby unregister --node-id=node ID -f /opt/vmware/vpostgres/current/etc/repmgr.conf
```

Unregistering the node removes the record of the standby from the internal metadata table of the repmgr tool suite.
After you Install vCloud Director or Deploy the vCloud Director Appliance

After you create the vCloud Director server group, you can install Microsoft Sysprep files and Cassandra database. If you are using a PostreSQL database, you can configure SSL and adjust some parameters on the database.

This chapter includes the following topics:

- Install Microsoft Sysprep Files on the Servers
- Customize Public Endpoints
- Install and Configure a Cassandra Database for Storing Historic Metric Data
- Perform Additional Configurations on the External PostgreSQL Database

Install Microsoft Sysprep Files on the Servers

If your cloud requires guest customization support for certain older Microsoft operating systems, you must install the appropriate Microsoft Sysprep files on each member of the server group.

Sysprep files are required only for some older Microsoft operating systems. If your cloud does not need to support guest customization for those operating systems, you do not need to install Sysprep files.

To install the Sysprep binary files, you copy them to a specific location on the server. You must copy the files to each member of the server group.

Prerequisites

Verify that you have access to the 32- and 64-bit Sysprep binary files for Windows 2003 and Windows XP.

Procedure

1. Log in to the target server as root.
2. Change directory to $V CLOUD_HOME/guestcustomization/default/windows.
   ```
   [root@cell1 /]# cd /opt/vmware/vcloud-director/guestcustomization/default/windows
   ```
3. Create a directory named sysprep.
   ```
   [root@cell1 /opt/vmware/vcloud-director/guestcustomization/default/windows]# mkdir sysprep
   ```
For each guest operating system that requires Sysprep binary files, create a subdirectory of $VCLoud_HOME/guestcustomization/default/windows/sysprep.

Subdirectory names are specific to a guest operating system.

Table 8-1. Subdirectory Assignments for Sysprep Files

<table>
<thead>
<tr>
<th>Guest OS</th>
<th>Subdirectory to Create Under $VCLoud_HOME/guestcustomization/default/windows/sysprep</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows 2003 (32-bit)</td>
<td>svr2003</td>
</tr>
<tr>
<td>Windows 2003 (64-bit)</td>
<td>svr2003-64</td>
</tr>
<tr>
<td>Windows XP (32-bit)</td>
<td>xp</td>
</tr>
<tr>
<td>Windows XP (64-bit)</td>
<td>xp-64</td>
</tr>
</tbody>
</table>

For example, to create a subdirectory to hold Sysprep binary files for Windows XP, use the following Linux command.

```
[root@cell1 /opt/vmware/vcloud-director/guestcustomization/default/windows]# mkdir sysprep/xp
```

5 Copy the Sysprep binary files to the appropriate location on each vCloud Director server in the server group.

6 Ensure that the Sysprep files are readable by the user vcloud.vcloud.

Use the Linux chown command to do this.

```
[root@cell1 /]# chown -R vcloud:vcloud $VCLoud_HOME/guestcustomization
```

When the Sysprep files are copied to all members of the server group, you can perform guest customization on virtual machines in your cloud. You do not need to restart vCloud Director after the Sysprep files are copied.

Customize Public Endpoints

To fulfill load balancer or proxy requirements, you can change the default endpoint Web addresses for the vCloud Director Web Console, vCloud API, Tenant Portal, and console proxy.

If you deployed the vCloud Director appliance, you must configure the vCloud Director public console proxy address, because the appliance uses a single IP address with custom port 8443 for the console proxy service. See Step 5.

Prerequisites

Only the system administrator can customize public endpoints.

Procedure

1 Click the Administration tab and, in the left pane, click Public Addresses.
2 Select **Customize Public Endpoints**.

Deselecting this check box reverts all endpoints to their default values, which are not shown on the page.

3 To customize the vCloud REST API and OpenAPI URLs, edit the **API** endpoints.

   a Enter a custom HTTP base URL.

   For example, if you set the HTTP base URL to **http://vcloud.example.com**, you can access the vCloud API at **http://vcloud.example.com/api**, and you can access the vCloud OpenAPI at **http://vcloud.example.com/cloudapi**.

   b Enter a custom HTTPS REST API base URL and click **Browse** to upload the certificates that establish the trust chain for that endpoint.

   For example, if you set the HTTPS REST API base URL to **https://vcloud.example.com**, you can access the vCloud API at **https://vcloud.example.com/api**, and you can access the vCloud OpenAPI at **https://vcloud.example.com/cloudapi**.

   The certificate chain must match the certificate used by the service endpoint, which is either the certificate uploaded to each vCloud Director cell keystore with alias *http* or the load balancer VIP certificate if an SSL termination is used. The certificate chain must include an endpoint certificate, intermediate certificates, and a root certificate in **PEM** format without a private key.

4 To customize the vCloud Director Tenant Portal URLs, edit the **Tenant Portal** endpoints.

   - To configure the vCloud Director Tenant Portal to use the same endpoints and certificate chain that you specified in **Step 3**, select **Copy API URL Settings**.

   - To configure the vCloud Director Tenant Portal to use different endpoints and certificate chain, perform the following steps.

     a Deselect **Copy API URL Settings**.

     b Enter a custom HTTP base URL.

     For example, if you set the HTTP base URL to **http://vcloud.example.com**, you can access the Tenant Portal at **http://vcloud.example.com/tenant/org_name**.

     c Enter a custom HTTPS REST API base URL and click **Browse** to upload the certificates that establish the trust chain for that endpoint.

     For example, if you set the HTTPS REST API base URL to **https://vcloud.example.com**, you can access the Tenant Portal at **https://vcloud.example.com/tenant/org_name**.

     The certificate chain must match the certificate used by the service endpoint, which is either the certificate uploaded to each vCloud Director cell keystore with alias *http* or the load balancer VIP certificate if an SSL termination is used. The certificate chain must include an endpoint certificate, intermediate certificates, and a root certificate in **PEM** format without a private key.
To customize the vCloud Director Web Console URLs and the console proxy address, edit the Web Console endpoints.

a. Enter a custom vCloud Director public URL for HTTP connections.
   The URL must include /cloud.
   For example, if you set the vCloud Director public URL to http://vcloud.example.com/cloud, you can access the vCloud Director Web Console at http://vcloud.example.com/cloud.

b. Enter a custom REST API URL for HTTPS connections and click Browse to upload the certificates that establish the trust chain for that endpoint.
   The URL must include /cloud.
   For example, if you set the base URL to https://vcloud.example.com, you can access the vCloud Director Web Console at https://vcloud.example.com/cloud.
   The certificate chain must match the certificate used by the service endpoint, which is the certificate uploaded to each vCloud Director cell keystore with alias consoleproxy. SSL termination of console proxy connections at a load balancer is not supported. The certificate chain must include an endpoint certificate, intermediate certificates, and a root certificate in PEM format without a private key.

c. Enter a custom vCloud Director public console proxy address.
   This address is the fully qualified domain name (FQDN) of the vCloud Director server or load-balancer with the port number. The default port is 443.
   Important The vCloud Director appliance uses its eth0 NIC with custom port 8443 for the console proxy service.
   For example, for a vCloud Director appliance instance with FQDN vcloud.example.com, enter vcloud.example.com:8443.
   The vCloud Director Web Console uses the console proxy address when opening a remote console window on a VM.

To save your changes, click Apply.

Install and Configure a Cassandra Database for Storing Historic Metric Data

vCloud Director can collect metrics that provide current and historic information about virtual machine performance and resource consumption for the virtual machines that are in your cloud. Data for historic metrics is stored in a Cassandra cluster.

Cassandra is an open-source database that you can use to provide the backing store for a scalable, high-performance solution for collecting time series data like virtual machine metrics. If you want vCloud Director to support retrieval of historic metrics from virtual machines, you must install and configure a Cassandra cluster, and use the cell-management-tool to connect the cluster to vCloud Director. Retrieval of current metrics does not require optional database software.
Prerequisites

- Verify that vCloud Director is installed and running before you configure the optional database software.
- If you are not already familiar with Cassandra, review the material at http://cassandra.apache.org/.
- See the vCloud Director Release Notes for a list of Cassandra releases supported for use as a metrics database. You can download Cassandra from http://cassandra.apache.org/download/.
- Install and configure the Cassandra cluster:
  - The Cassandra cluster must include least four virtual machines deployed on two or more hosts.
  - Two Cassandra seed nodes are required.
  - Enable Java Native Access (JNA) version 3.2.7 or later on each Cassandra cluster.
  - Cassandra node-to-node encryption is optional.
  - Use of SSL with Cassandra is optional. If you decide not to enable SSL for Cassandra, you must set the configuration parameter cassandra.use.ssl to 0 in the global.properties file on each cell ($V CLOUD_HOME/etc/global.properties).

Procedure

1. Use the cell-management-tool utility to configure a connection between vCloud Director and the nodes in the Cassandra cluster.

   In the following example command, node1-ip, node2-ip, node3-ip, and node4-ip are the IP address of the members of the Cassandra cluster. The default port (9042) is used. Metrics data is retained for 15 days.

   ```
   [root@cell1 /opt/vmware/vcloud-director/bin]# ./cell-management-tool cassandra --configure --create-schema --cluster-nodes node1-ip,node2-ip,node3-ip, node4-ip --username admin --password 'P@55w0rd' --ttl 15
   ```

   For information about using the cell management tool, see the vCloud Director Administrator's Guide.

2. (Optional) If you are upgrading vCloud Director from version 9.1, use the cell-management-tool to configure the metrics database to store rolled-up metrics.

   Run a command similar to the following example:

   ```
   [root@cell1 /opt/vmware/vcloud-director/bin]# ./cell-management-tool cassandra --add-rollup --username admin --password 'P@55w0rd'
   ```

3. Restart each vCloud Director cell.
Perform Additional Configurations on the External PostgreSQL Database

After creating your vCloud Director server group, you can configure the external PostgreSQL database to require SSL connections from the vCloud Director cells and adjust some database parameters for optimal performance.

The most secure connections require a well-signed SSL certificate, which includes a complete trust chain rooted in a well-known public certificate authority. Alternatively, you can use a self-signed SSL certificate or an SSL certificate that is signed by a private certificate authority, but you must import that certificate to the vCloud Director truststore.

To obtain optimal performance for your system specification and requirements, you can adjust the database configurations and autovacuum parameters in the database configuration file.

Procedure

1. Configure SSL connections between vCloud Director and the PostgreSQL database.
   a. If you used a self-signed or private certificate for the external PostgreSQL database, from each vCloud Director cell, run the command to import the database certificate to the vCloud Director truststore.

   
   ```
   [root@cell1 /opt/vmware/vcloud-director/bin]# cell-management-tool import-trusted-certificates --source path_to_self-signed_or_private_cert
   ```

   b. Run the command to enable SSL connections between vCloud Director and PostgreSQL.

   
   ```
   [root@cell1 /opt/vmware/vcloud-director/bin]# cell-management-tool reconfigure-database --database-ssl true
   ```

   You can run the command against all cells in the server group by using the --private-key-path option.

   ```
   [root@cell1 /opt/vmware/vcloud-director/bin]# cell-management-tool reconfigure-database --database-ssl true --private-key-path path_to_private_key
   ```

   For more information about using the cell management tool, see the vCloud Director Administrator’s Guide.

2. Edit the database configurations in the `postgresql.conf` file for your system specification.

   For example, for a system with 16 GB of memory, you can use the following fragment.

   ```
   max_connections = 500
   # Set effective cache size to 50% of total memory.
   effective_cache_size = 8GB
   # Set shared buffers to 25% of total memory
   shared_buffers = 4GB
   ```
3 Edit the autovacuum parameters in the `postgresql.conf` file for your requirements.

For typical vCloud Director workloads, you can use the following fragment.

```sql
autovacuum = on
track_counts = on
autovacuum_max_workers = 3
autovacuum_naptime = 1min
autovacuum_vacuum_cost_limit = 2400
```

The system sets a custom `autovacuum_vacuum_scale_factor` value for the activity and the `activity_parameters` tables.

**What to do next**

If you edited the `postgresql.conf` file, you must restart the database.
Upgrading vCloud Director

To upgrade vCloud Director to a new version, you shut down the vCloud Director services on all cells in the server group, install the new version on each server, upgrade the vCloud Director database, and restart the vCloud Director cells.

If your existing vCloud Director server group consists of vCloud Director installations on Linux, you can use the vCloud Director installer for Linux to upgrade your environment. As an alternative, you can migrate your environment to vCloud Director 9.7 appliance. See Chapter 10 Migrating to vCloud Director Appliance.

If your existing vCloud Director server group consists of vCloud Director 9.5 appliance deployments, you can only migrate your environment to vCloud Director 9.7 appliance. You use the vCloud Director installer for Linux to upgrade the existing environment only as part of the migration workflow. See Chapter 10 Migrating to vCloud Director Appliance.

You can either Perform an Orchestrated Upgrade of a vCloud Director Installation or Manually Upgrade a vCloud Director Installation. With the orchestrated upgrade, you run a single command which upgrades all cells in the server group and the database. With the manual upgrade, you upgrade each cell and the database in a sequence.

Starting with vCloud Director 9.5:

- Oracle databases are unsupported. If your existing vCloud Director installation uses an Oracle database, see the Workflow for Upgrading a vCloud Director Installation with an Oracle Database.
- Enabling and disabling ESXi hosts is unsupported. Before starting the upgrade, you must enable all ESXi hosts. You can put ESXi hosts in maintenance mode by using the vSphere Web Client.
- vCloud Director uses Java with an improved LDAP support. If you are using an LDAPS server, to avoid LDAP login failures, you must verify that you have a properly constructed certificate. For information, see the Java 8 Release Changes at https://www.java.com.

When you are upgrading vCloud Director, the new version must be compatible with the following components of your existing installation:

- The database software you are currently using for the vCloud Director database.
  
  If your existing vCloud Director installation uses an Oracle database, see the Workflow for Upgrading a vCloud Director Installation with an Oracle Database.
- The VMware vSphere ® release you are currently using.
- The VMware NSX® release that you are currently using.
For information about upgrade paths and compatibility of vCloud Director with other VMware products and with third-party databases, refer to the *VMware Product Interoperability Matrices* at [http://partnerweb.vmware.com/comp_guide/sim/interop_matrix.php](http://partnerweb.vmware.com/comp_guide/sim/interop_matrix.php). If you plan to upgrade vSphere or NSX components as part of the vCloud Director upgrade, you must upgrade them Chapter 12 After you Upgrade or Migrate vCloud Director.

After you upgrade at least one vCloud Director server, you can upgrade the vCloud Director database. The database stores information about the runtime state of the server, including the state of all vCloud Director tasks it is running. To ensure that no invalid task information remains in the database after an upgrade, you must verify that no tasks are active on any server before you begin the upgrade.

The upgrade also preserves the following artifacts, which are not stored in the vCloud Director database:

- Local and global properties files are copied to the new installation.
- Microsoft Sysprep files used for guest customization support are copied to the new installation.

The upgrade requires sufficient vCloud Director downtime to upgrade all servers in the server group and the database. If you are using a load balancer, you can configure it to return a message, for example, *The system is offline for upgrade.*

### Workflow for Upgrading a vCloud Director Installation with an Oracle Database

Before upgrading a vCloud Director installation that uses an Oracle database, you must migrate the database to PostgreSQL from vCloud Director version 9.1.

1. If your current vCloud Director version is earlier than 9.1, upgrade to version 9.1.
   
   For information about upgrading vCloud Director to version 9.1, see the *vCloud Director Installation, Configuration, and Upgrade Guide* 9.1.

2. When your vCloud Director installation is of version 9.1, migrate the Oracle database to a PostgreSQL database.
   
   For information about migrating to a PostgreSQL database, see the cell management tool reference in the *vCloud Director Administrator's Guide* documentation.

3. Upgrade your vCloud Director installation from version 9.1. You can either Perform an Orchestrated Upgrade of a vCloud Director Installation or Manually Upgrade a vCloud Director Installation.

This chapter includes the following topics:

- Perform an Orchestrated Upgrade of a vCloud Director Installation
- Manually Upgrade a vCloud Director Installation
- Database Upgrade Utility Reference
Perform an Orchestrated Upgrade of a vCloud Director Installation

You can upgrade all cells in the server group together with the shared database by running the vCloud Director installer with the --private-key-path option.

You can use the vCloud Director installer for Linux to upgrade a vCloud Director server group that consists of vCloud Director installations on a supported Linux OS. If your vCloud Director server group consists of vCloud Director 9.5 appliances deployments, you use the vCloud Director installer for Linux to upgrade your existing environment only as part of the migration workflow. See Chapter 10 Migrating to vCloud Director Appliance.

vCloud Director for Linux is distributed as a digitally signed executable file with a name of the form vmware-vcloud-director-distribution-v.v.v-nnnnnn.bin, where v.v.v represents the product version and nnnnnn the build number. For example: vmware-vcloud-director-distribution-8.10.0-3698331.bin. Running this executable installs or upgrades vCloud Director.

When you run the vCloud Director installer with the --private-key-path option, you can add other command options of the upgrade utility, for example, --maintenance-cell. For information about the database upgrade utility options, see Database Upgrade Utility Reference.

Prerequisites

- Verify that your vCloud Director database, the vSphere components, and the NSX components are compatible with the new version of vCloud Director.

  Important If your existing vCloud Director installation uses an Oracle database, verify that you migrated to a PostgreSQL database from vCloud Director version 9.1. See the Workflow for Upgrading a vCloud Director Installation with an Oracle Database.

- Verify that you have superuser credentials for the target server.

- If you want the installer to verify the digital signature of the installation file, download and install the VMware public key on the target server. If you already verified the digital signature of the installation file, you do not need to verify it again during installation. See Download and Install the VMware Public Key.

- Verify that you have a valid license key to use the version of the vCloud Director software to which you are upgrading.

- Verify that all cells permit SSH connections from the superuser without a password. To perform a verification, you can run the following Linux command:

  ```bash
  sudo -u vcloud ssh -i private-key-path root@cell-ip
  ```
This example sets your identity to vcloud, then makes an SSH connection to the cell at cell-ip as root but does not supply the root password. If the private key in private-key-path on the local cell is readable by user vcloud.vcloud and the corresponding public key is present in the authorized-keys file for the root user at cell-ip the command succeeds.

**Note** The vcloud user, vcloud group, and vcloud.vcloud account are created by the vCloud Director installer for use as an identity with which vCloud Director processes run. The vcloud user has no password.

- Verify that you all ESXi hosts are enabled. Starting with vCloud Director 9.5, disabled ESXi hosts are unsupported.
- Verify that all servers in the server group can access the shared transfer server storage. See Preparing the Transfer Server Storage.
- If your vCloud Director installation uses an LDAPS server, to avoid LDAP login failures after the upgrade, verify that you have a properly constructed certificate for Java 8 Update 181. For information, see the Java 8 Release Changes at https://www.java.com.
- Shut down the vCloud Director services on each cell in the server group. You can use the cell subcommand of the cell management tool

  ```bash
  [root@cell1 /opt/vmware/vcloud-director/bin]# ./cell-management-tool -u administrator cell --shutdown
  ```

  For more information about managing a cell, see the cell management reference in the vCloud Director Administrator's Guide.

**Procedure**

1. Log in to the target server as root.
2. Download the installation file to the target server.
   - If you purchased the software on media, copy the installation file to a location that is accessible to the target server.
3. Verify that the checksum of the download matches the checksum posted on the download page.
   - Values for MD5 and SHA1 checksums are posted on the download page. Use the appropriate tool to verify that the checksum of the downloaded installation file matches the checksum shown on the download page. A Linux command of the following form displays the checksum for installation-file.

   ```bash
   [root@cell1 /tmp]# md5sum installation-file
   ```

   The command returns the installation file checksum that must match the MD5 checksum from the download page.
4 Ensure that the installation file is executable.

The installation file requires execute permission. To be sure that it has this permission, open a console, shell, or terminal window and run the following Linux command, where **installation-file** is the full pathname to the vCloud Director installation file.

```
[root@cell1 /tmp]# chmod u+x installation-file
```

5 In a console, shell, or terminal window, run the installation file with the **--private-key-path** option and the pathname to the private key of the target cell.

You can add other command options of the database upgrade utility.

```
./installation-file --private-key-path /vcloud/.ssh/id_rsa
```

**Note** You cannot run the installation file from a directory whose pathname includes any embedded space characters.

The installer detects an earlier version of vCloud Director and prompts you to confirm the upgrade.

If the installer detects a version of vCloud Director that is equal to or later than the version in the installation file, it displays an error message and exits.

6 Enter **y** and press Enter to confirm the upgrade.

The installer initiates the following multi-cell upgrade workflow.

1 Verifies that the current cell host meets all requirements.
2 Unpacks the vCloud Director RPM package.
3 Upgrades vCloud Director software on the current cell.
4 Upgrades the vCloud Director database.
5 Upgrades vCloud Director software on each of the remaining cells, then restarts vCloud Director services on the cell.
6 Restarts vCloud Director services on the current cell.

**What to do next**

Start the vCloud Director services on all cells in the server group.

You can now Upgrade Each NSX Manager That Is Associated with an Attached vCenter Server System, then Upgrade vCenter Server Systems, ESXi Hosts, and NSX Edges.

**Manually Upgrade a vCloud Director Installation**

You can upgrade a single cell by running the vCloud Director installer without command options. Before you restart an upgraded cell, you must upgrade the database schema. You upgrade the database schema after upgrading at least one cell in the server group.
You can use the vCloud Director installer for Linux to upgrade a vCloud Director server group that consists of vCloud Director installations on a supported Linux OS. If your vCloud Director server group consists of vCloud Director 9.5 appliances deployments, you use the vCloud Director installer for Linux to upgrade your existing environment only as part of the migration workflow. See Chapter 10 Migrating to vCloud Director Appliance.

For a multi-cell vCloud Director installation, instead of manually upgrading each cell and the database in a sequence, you can Perform an Orchestrated Upgrade of a vCloud Director Installation.

Prerequisites

- Verify that your vCloud Director database, the vSphere components, and the NSX components are compatible with the new version of vCloud Director.

  Important If your existing vCloud Director installation uses an Oracle database, verify that you migrated to a PostgreSQL database from vCloud Director version 9.1. See the Workflow for Upgrading a vCloud Director Installation with an Oracle Database.

- Verify that you have superuser credentials for the servers in your vCloud Director server group.

- If you want the installer to verify the digital signature of the installation file, download and install the VMware public key on the target server. If you already verified the digital signature of the installation file, you do not need to verify it again during installation. See Download and Install the VMware Public Key.

- Verify that you have a valid license key to use the version of the vCloud Director software to which you are upgrading.

- Verify that you all ESXi hosts are enabled. Starting with vCloud Director 9.5, disabled ESXi hosts are unsupported.

- Shut down the vCloud Director services on each cell in the server group. You can use the cell subcommand of the cell management tool:

  ```bash
  [root@cell1 /opt/vmware/vcloud-director/bin]# ./cell-management-tool -u administrator cell --shutdown
  ```

  For more information about managing a cell, see the cell management reference in the vCloud Director Administrator's Guide.

Procedure

1 Upgrade a vCloud Director Cell
   The vCloud Director installer verifies that the target server meets all upgrade prerequisites and upgrades the vCloud Director software on the server.

2 Upgrade the vCloud Director Database
   From an upgraded vCloud Director server, you run a tool that upgrades the vCloud Director database. You must not restart any upgraded vCloud Director server before upgrading the shared database.
What to do next

After you upgraded all vCloud Director servers in the server group and the database, you can start the vCloud Director services on all cells.

You can Upgrade Each NSX Manager That Is Associated with an Attached vCenter Server System, after which you can Upgrade vCenter Server Systems, ESXi Hosts, and NSX Edges.

Upgrade a vCloud Director Cell

The vCloud Director installer verifies that the target server meets all upgrade prerequisites and upgrades the vCloud Director software on the server.

vCloud Director for Linux is distributed as a digitally signed executable file with a name of the form vmware-vcloud-director-distribution-v.v.v-nnnnnn.bin, where v.v.v represents the product version and nnnnnn the build number. For example: vmware-vcloud-director-distribution-8.10.0-3698331.bin. Running this executable installs or upgrades vCloud Director.

For a multi-cell vCloud Director installation, you must run the vCloud Director installer on each member of the vCloud Director server group.

Procedure

1. Log in to the target server as root.

2. Download the installation file to the target server.
   If you purchased the software on media, copy the installation file to a location that is accessible to the target server.

3. Verify that the checksum of the download matches the checksum posted on the download page.
   Values for MD5 and SHA1 checksums are posted on the download page. Use the appropriate tool to verify that the checksum of the downloaded installation file matches the checksum shown on the download page. A Linux command of the following form displays the checksum for installation-file.

   ```bash
   [root@cell1 /tmp]# md5sum installation-file
   ```
   The command returns the installation file checksum that must match the MD5 checksum from the download page.

4. Ensure that the installation file is executable.
   The installation file requires execute permission. To be sure that it has this permission, open a console, shell, or terminal window and run the following Linux command, where installation-file is the full pathname to the vCloud Director installation file.

   ```bash
   [root@cell1 /tmp]# chmod u+x installation-file
   ```
5 Run the installation file.

To run the installation file, enter the full pathname, for example:

```
[root@cell1 /tmp]# ./installation-file
```

The file includes an installation script and an embedded RPM package.

**Note** You cannot run the installation file from a directory whose pathname includes any embedded space characters.

If the installer detects a version of vCloud Director that is equal to or later than the version in the installation file, it displays an error message and exits.

If the installer detects an earlier version of vCloud Director, it prompts you to confirm the upgrade.

6 Enter `y` and press Enter to confirm the upgrade.

The installer initiates the following upgrade workflow.

a Verifies that the host meets all requirements.

b Unpacks the vCloud Director RPM package.

c After all active vCloud Director jobs on the cell finish, stops vCloud Director services on the server and upgrades the installed vCloud Director software.

If you did not install the VMware public key on the target server, the installer displays a warning of the following form:

```
warning:installation-file.rpm: Header V3 RSA/SHA1 signature: NOKEY, key ID 66fd4949
```

When changing the existing `global.properties` file on the target server, the installer displays a warning of the following form:

```
warning: /opt/vmware/vcloud-director/etc/global.properties created as /opt/vmware/vcloud-director/etc/global.properties.rpmnew
```

**Note** If you previously updated the existing `global.properties` file, you can retrieve the changes from `global.properties.rpmnew`.

7 (Optional) Update logging properties.

After an upgrade, new logging properties are written to the file `/opt/vmware/vcloud-director/etc/log4j.properties.rpmnew`.

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you did not change existing logging properties</td>
<td>Copy this file to <code>/opt/vmware/vcloud-director/etc/log4j.properties</code>.</td>
</tr>
<tr>
<td>If you changed logging properties</td>
<td>To preserve your changes, merge <code>/opt/vmware/vcloud-director/etc/log4j.properties.rpmnew</code> with the existing <code>/opt/vmware/vcloud-director/etc/log4j.properties</code> file.</td>
</tr>
</tbody>
</table>
When the vCloud Director upgrade finishes, the installer displays a message with information about the location of the old configuration files. Then the installer prompts you to run the database upgrade tool.

**What to do next**

If not upgraded yet, you can upgrade the vCloud Director database.

Repeat this procedure on each vCloud Director cell in the server group.

**Important** Do not start the vCloud Director services until you upgrade all cells in the server group and the database.

### Upgrade the vCloud Director Database

From an upgraded vCloud Director server, you run a tool that upgrades the vCloud Director database. You must not restart any upgraded vCloud Director server before upgrading the shared database.

Information about all running and recently completed tasks is stored in the vCloud Director database. Because a database upgrade invalidates this task information, the database upgrade utility verifies that no tasks are running when the upgrade process begins.

All cells in a vCloud Director server group share the same database. Regardless of how many cells you are upgrading, you upgrade the database only once. After the database is upgraded, vCloud Director cells that are not upgraded cannot connect to the database. You must upgrade all cells so that they connect to the upgraded database.

**Prerequisites**

- Back up your existing database. Use the procedures that your database software vendor recommends.

- Verify that all vCloud Director cells in the server group are stopped. The upgraded cells are stopped during the upgrade process. If there are vCloud Director servers that are not yet upgraded, you can use the cell management tool to quiesce and shut down their services. For information about how to manage a cell by using the cell management tool, see *vCloud Director Administrator's Guide*.

- If your vCloud Director installation uses an Oracle database, migrate to a PostgreSQL database. For information about migrating to a PostgreSQL database, see the cell management tool reference in *vCloud Director Administrator's Guide*.

- Review the *Database Upgrade Utility Reference*. The options and arguments are not mandatory.

**Procedure**

1. Run the database upgrade utility with or without options.

   ```bash
   /opt/vmware/vcloud-director/bin/upgrade
   ```

   If the database upgrade utility detects an incompatible version of NSX Manager, it displays a warning message and cancels the upgrade.

2. On the prompt, enter `y` and press Enter to confirm the database upgrade.
3 On the prompt, enter `y` and press Enter to confirm that you backed up the database.

If you used the `--backup-completed` option, the utility skips this prompt.

4 If the utility detects an active cell, on the prompt to continue, enter `n` to exit the shell, then verify that no cells are running and retry the upgrade from Step Step 1.

The database upgrade tool runs and displays progress messages. When the upgrade finishes, you are prompted to start the vCloud Director service on the current server.

What to do next

Enter `y` and press Enter or start the service at a later time by running the `service vmware-vcd start` command.

You can start the services of the upgraded vCloud Director servers.

You can upgrade the rest vCloud Director members of the server group and start their services. See Upgrade a vCloud Director Cell.

Database Upgrade Utility Reference

When you run the upgrade utility, you provide the setup information at the command line as options and arguments.

Table 9-1. Database Upgrade Utility Options and Arguments

<table>
<thead>
<tr>
<th>Option</th>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--backup-completed</code></td>
<td>None</td>
<td>Specifies that you have completed a backup of the vCloud Director. When you include this option, the upgrade utility does not prompt you to back up the database.</td>
</tr>
<tr>
<td><code>--ceip-user</code></td>
<td>The username for the CEIP service account.</td>
<td>Upgrade will fail if a user with this username already exists in the System organization. Default: phone-home-system-account.</td>

<td>This account is used by the vCloud Director Multi-Site feature. Upgrade will fail if a user with this username already exists in the System organization. Default: multisite-system-account.</td>
</tr>
<tr>
<td>--private-key-path</td>
<td>pathname</td>
<td>The full pathname to the cell's private key. When you use this option, all cells in the server group will be gracefully shut down, upgraded, and re-started after the database has been upgraded. See Perform an Orchestrated Upgrade of a vCloud Director Installation for more information about this upgrade workflow.</td>
</tr>
<tr>
<td>--unattended-upgrade</td>
<td>None</td>
<td>Specifies unattended upgrade</td>
</tr>
</tbody>
</table>

If you use the `--private-key-path` option, all cells must be configured to permit SSH connections from the superuser without a password. You can use a Linux command line like the one shown here to verify this. This example sets your identity to `vcloud`, then makes an SSH connection to the cell at `cell-ip` as `root` but does not supply the root password.

```
sudo -u vcloud ssh -i private-key-path root@cell-ip
```

If the private key in `private-key-path` on the local cell is readable by user `vcloud.vcloud` and the corresponding public key has been added to the `authorized-keys` file for the root user at `cell-ip` the command succeeds.

**Note** The `vcloud` user, `vcloud` group, and `vcloud.vcloud` account are created by the vCloud Director installer for use as an identity with which vCloud Director processes run. The `vcloud` user has no password.
Migrating to vCloud Director Appliance

Starting with version 9.7, the vCloud Director appliance includes an embedded PostgreSQL database with a high availability function. You can migrate your existing vCloud Director environment of an earlier version to a vCloud Director environment that consists of vCloud Director 9.7 appliance deployments.

You can migrate a vCloud Director environment that consists of vCloud Director installations on Linux or vCloud Director appliance deployments. You can migrate a vCloud Director environment that uses an external Microsoft SQL database or an external PostgreSQL database.

If your vCloud Director environment uses an external Oracle database, before migrating to vCloud Director appliance, you must migrate the database to PostgreSQL from vCloud Director version 9.1. For information about the workflow for upgrading a vCloud Director installation with an Oracle Database, see Chapter 9 Upgrading vCloud Director.

This chapter includes the following topics:

- Migrating vCloud Director with an External Microsoft SQL Database to vCloud Director Appliance
- Migrating vCloud Director with an External PostgreSQL Database to vCloud Director Appliance

Migrating vCloud Director with an External Microsoft SQL Database to vCloud Director Appliance

If your current vCloud Director environment of an earlier version uses an external Microsoft SQL database, you can migrate to a new vCloud Director environment that consists of vCloud Director 9.7 appliance deployments. Your current vCloud Director environment can consist of vCloud Director installations on Linux or vCloud Director appliance deployments. The new vCloud Director environment can use the appliance embedded PostgreSQL databases in a high availability mode.

The migration workflow includes four major stages.

- Creating the new vCloud Director server group by deploying one or more instances of the vCloud Director 9.7 appliance
- Upgrading the existing vCloud Director environment
- Migrating the external to the embedded database
- Copying the shared transfer service data and the certificates data.
Procedure

1. Upgrade your current vCloud Director environment to version 9.7, and upgrade the source database schema.

   See Chapter 9 Upgrading vCloud Director.

2. Verify that the migration source vCloud Director restart is successful.

3. If you want the new vCloud Director environment to use the IP addresses of the existing environment, change the IP addresses of the existing cells to temporary IP addresses.

4. If you want the new vCloud Director environment to use the NFS server of the existing environment, create and export a new directory on this NFS server as the new shared NFS mountpoint.

5. Create the new server group by deploying one or more instances of the vCloud Director 9.7 appliance.
   - If you want to use the database high availability function, deploy one primary and two standby cells, and, optionally, one or more vCD application cells.
   - If you changed the IP addresses of the existing cells to temporary IP addresses, you can use the original IP addresses for the new cells.
   - If you exported a new path on the existing NFS server, you can use this new shared mountpoint for the new environment.

   See Chapter 5 Deploying the vCloud Director Appliance.

6. On each existing cell and on each newly deployed cell, run the command to stop the vCloud Director service.

   ```
   /opt/vmware/vcloud-director/bin/cell-management-tool -u <admin username> cell --shutdown
   ```

7. Choose one of the existing cells to serve as a migration source.

   The migration source must have access to the eth1 network IP address of the newly deployed primary cell.

8. On the new primary cell, enable access to the embedded database from the migration source.

   See Configure External Access to the vCloud Director Database.

9. On the migration source, run the cell management tool to migrate the external database to the database that is embedded in the new primary cell.

   The embedded database uses the eth1 network IP address of the appliance.

   ```
   /opt/vmware/vcloud-director/bin/cell-management-tool dbmigrate --dbhost eth1_IP_new_primary --dbport 5432 --dbuser vcloud --dbname vcloud --dbpassword database_password_new_primary
   ```

   For information about using the cell management tool, see the vCloud Director Administrator's Guide.
10 On each newly deployed cell, back up and replace the configuration data, and reconfigure and start the vCloud Director service.

   a Back up the properties and the certificates files, and copy and replace these files from the migration source.

   The global.properties, responses.properties, certificates, and proxycertificates files are at /opt/vmware/vcloud-director/etc/.

   Important If you are migrating to vCloud Director version 9.7.0.1 or later, you must also back up, copy, and replace the truststore file from the migration source, along with the other files.

   b Back up the keystore file that is at /opt/vmware/vcloud-director/certificates.ks file.

   c Run the command to reconfigure the vCloud Director service.

   ```bash
   /opt/vmware/vcloud-director/bin/configure --unattended-installation --database-type postgres
   --database-user vcloud
   --database-password db_password_new_primary --database-host eth1_ip_new_primary --database-port 5432
   --database-name vcloud --database-ssl true --uuid --keystore /opt/vmware/vcloud-director/certificates.ks
   --keystore-password root_password_new_primary --primary-ip appliance_eth0_ip
   --console-proxy-ip appliance_eth0_ip --console-proxy-port-https 8443
   ```

   Where:

   - The --keystore-password value matches the initial root password of this appliance.
   - The --database-password value matches the database password that you set during the appliance deployment.
   - The --database-host value matches the eth1 network IP address of the primary appliance.
   - The --primary-ip value matches the eth0 network IP address of the appliance.
   - The --console-proxy-ip value matches the eth0 network IP address of the appliance.

   For troubleshooting information, see Reconfiguring the vCloud Director Service Fails When Migrating or Restoring to vCloud Director Appliance.

   d Run the command to start the vCloud Director service.

   ```bash
   service vmware-vcd start
   ```

   You can monitor the progress of the cell startup at /opt/vmware/vcloud-director/logs/cell.log.

11 After all cells of the new server group finish the startup process, verify that the migration of your vCloud Director environment is successful.

   a Open the vCloud Director Web Console by using the eth0 network IP address of any cell from the new server group, https://et0_IP_new_cell/cloud.

   b Log in to the vCloud Director Web Console with your existing system administrator credentials.
c Validate that your vSphere and cloud resources are available in the new environment.

12 After the successful verification of the vCloud Director migration, use the vCloud Director Web Console to delete the disconnected cells that belong to the old vCloud Director environment.

a From the Manage & Monitor tab, click Cloud Cells.

b Right-click a cell name and select Delete.

You can deploy the vCloud Director appliance to add members to the server group of the migrated environment.

What to do next

The new migrated vCloud Director appliance environment uses self-signed certificates. To use the well-signed certificates from the old environment, on each cell of the new environment, follow these steps:

1 Copy and replace the keystore file from the old cell that is at /opt/vmware/vcloud-director/data/transfer/certificates.ks.

2 Run the cell management tool command to replace the certificates.

Ensure that vcloud.vcloud is the owner of this file.

```
/opt/vmware/vcloud-director/bin/cell-management-tool certificates -j -p --keystore /opt/vmware/vcloud-director/data/transfer/certificates.ks \
--keystore-password ks_password_old_vCD
```

3 Restart the vCloud Director service.

```
service vmware-vcd restart
```

If you add new members to this server group, the new appliance cells are deployed with these well-signed certificates.

Migrating vCloud Director with an External PostgreSQL Database to vCloud Director Appliance

If your current vCloud Director environment of an earlier version uses an external PostgreSQL database, you can migrate to a new vCloud Director environment that consists of vCloud Director 9.7 appliance deployments. Your current vCloud Director environment can consist of vCloud Director installations on Linux or vCloud Director appliance deployments. The new vCloud Director environment can use the appliance embedded PostgreSQL databases in a high availability mode.

The migration workflow includes four major stages.

- Upgrading the existing vCloud Director environment
- Creating the new vCloud Director server group by deploying one or more instances of the vCloud Director 9.7 appliance
- Migrating the external to the embedded database
Copying the shared transfer service data and the certificates data.

**Procedure**

1. If your current external PostgreSQL database is of version 9.x, upgrade the external PostgreSQL database to version 10.

2. Upgrade your current vCloud Director environment to version 9.7.
   
   See Chapter 9 Upgrading vCloud Director.

3. Verify that the migration source vCloud Director restart is successful.

4. On each cell of the upgraded vCloud Director environment, run the command to stop the vCloud Director service.
   
   ```
   /opt/vmware/vcloud-director/bin/cell-management-tool -u <admin username> cell --shutdown
   ```

5. On the external PostgreSQL database, back up the current database.

   ```
   sudo -u postgres path_to_pg_dump -Fc db_name > /tmp/db_dump_name
   ```

   If there is not enough free space on the /tmp folder, use another location to store the dump file.

6. If the database owner and database name are different from vcloud, make a note of the user name and database name.

   You must create this user in the new environment and rename the database at Step 13.

7. If you want the new vCloud Director environment to use the IP addresses of the existing environment, you must copy the properties and the certificates files to a location on the external PostgreSQL database and power off the cells.
   
   a. Copy the `global.properties`, `responses.properties`, `certificates`, and `proxycertificates` files located at `/opt/vmware/vcloud-director/etc/` to the /tmp or any preferred location on the external PostgreSQL database.
   
   b. Power off the cells in the existing environment.

8. If you want the new vCloud Director environment to use the NFS server of the existing environment, create and export a new directory on this NFS server as the new shared NFS mountpoint.

9. Create the new server group by deploying one or more instances of the vCloud Director 9.7 appliance.

   a. If you want to use the database high availability function, deploy one primary and two standby cells, and, optionally, one or more vCD application cells.
   
   b. If you powered off the cells in the existing environment, you can use the original IP addresses for the new cells.
   
   c. If you exported a new path on the existing NFS server, you can use this new shared mountpoint for the new environment.

   See Chapter 5 Deploying the vCloud Director Appliance.
10 On each newly deployed cell, run the command to stop the vCloud Director service.

```
service vmware-vcd stop
```

11 Copy the dump file from the /tmp folder on the external PostgreSQL database to the /tmp folder on the primary cell of the new environment.

See Step 5.

12 Change the permissions on the dump file.

```
chmod a+r /tmp/db_dump_name
```

13 Log in as root to the console of the newly deployed primary cell, and transfer the vCloud Director database from the external to the embedded database.

a Switch the user to postgres, connect to the psql database terminal, and run the statement to drop the vcloud database.

```
sudo -i -u postgres /opt/vmware/vpostgres/current/bin/psql -c 'DROP DATABASE vcloud;'
```

b If the database owner of the existing external database is different from vcloud, create a user with the name that you noted at Step 6.

```
sudo -i -u postgres /opt/vmware/vpostgres/current/bin/psql -c 'CREATE USER <db_owner_external_pg>;'  
```

c Run the pg_restore command.

```
sudo -u postgres /opt/vmware/vpostgres/current/bin/pg_restore -C -d postgres /tmp/db_dump_name
```

d If the database name of the existing external database is different from vcloud, change the database name to vcloud by using the name that you noted at Step 6.

```
sudo -i -u postgres /opt/vmware/vpostgres/current/bin/psql -c 'ALTER DATABASE <db_name_external_pg> RENAME TO vcloud;'
```

e If the database owner of the existing vCloud Director environment is different from vcloud, change the database owner to vcloud, and reassign the tables to vcloud.

```
sudo -i -u postgres /opt/vmware/vpostgres/current/bin/psql -c 'ALTER DATABASE vcloud OWNER TO vcloud;'
```

```
sudo -i -u postgres /opt/vmware/vpostgres/current/bin/psql -d vcloud -c 'REASSIGN OWNED BY <db_owner_external_pg> TO vcloud;'
```
On each newly deployed cell, back up and replace the configuration data, and reconfigure and start the vCloud Director service.

a. Back up the properties and the certificates files, and copy and replace these files from the location on the external PostgreSQL database of the migration source, to which you copied the files in step 7a.

The global.properties, responses.properties, certificates, and proxycertificates files are at /opt/vmware/vcloud-director/etc/.

**Important** If you are migrating to vCloud Director version 9.7.0.1 or later, you must also back up, copy, and replace the truststore file from the migration source, along with the other files.

b. Back up the keystore file that is at /opt/vmware/vcloud-director/certificates.ks file.

c. Run the command to reconfigure the vCloud Director service.

```
/opt/vmware/vcloud-director/bin/configure --unattended-installation --database-type postgres 
--database-user vcloud 
--database-password db_password_new_primary --database-host eth1_ip_new_primary --database-port 5432 
--database-name vcloud --database-ssl true --uuid --keystore /opt/vmware/vcloud-director/ 
certificates.ks 
--keystore-password root_password_new_primary --primary-ip appliance_eth0_ip 
--console-proxy-ip appliance_eth0_ip --console-proxy-port-https 8443
```

Where:
- The `--keystore-password` value matches the initial root password of this appliance.
- The `--database-password` value matches the database password that you set during the appliance deployment.
- The `--database-host` value matches the eth1 network IP address of the primary appliance.
- The `--primary-ip` value matches the eth0 network IP address of the appliance.
- The `--console-proxy-ip` value matches the eth0 network IP address of the appliance.
- The `--console-proxy-port` value matches the appliance console proxy port 8443.

For troubleshooting information, see Reconfiguring the vCloud Director Service Fails When Migrating or Restoring to vCloud Director Appliance.

d. Run the command to start the vCloud Director service.

```
service vmware-vcd start
```

You can monitor the progress of the cell startup at /opt/vmware/vcloud-director/logs/cell.log.
15 After all cells of the new server group finish the startup process, verify that the migration of your vCloud Director environment is successful.
   a. Open the vCloud Director Web Console by using the eth0 network IP address of any cell from the new server group, https://et0_IP_new_cell/cloud.
   b. Log in to the vCloud Director Web Console with your existing system administrator credentials.
   c. Validate that your vSphere and cloud resources are available in the new environment.

16 After the successful verification of the vCloud Director migration, use the vCloud Director Web Console to delete the disconnected cells that belong to the old vCloud Director environment.
   a. From the Manage & Monitor tab, click Cloud Cells.
   b. Right-click a cell name and select Delete.

You can deploy the vCloud Director appliance to add members to the server group of the migrated environment.

**What to do next**

The new migrated vCloud Director appliance environment uses self-signed certificates. To use the well-signed certificates from the old environment, on each cell of the new environment, follow these steps:

1. Copy and replace the keystore file from the old cell that is at /opt/vmware/vcloud-director/data/transfer/certificates.ks.

2. Run the cell management tool command to replace the certificates.

   Ensure that vcloud.vcloud is the owner of this file.

   ```bash
   /opt/vmware/vcloud-director/bin/cell-management-tool certificates -j -p --keystore /opt/vmware/vcloud-director/data/transfer/certificates.ks \
   --keystore-password ks_password_old_vCD
   ```

3. Restart the vCloud Director service.

   ```bash
   service vmware-vcd restart
   ```

If you add new members to this server group, the new appliance cells are deployed with these well-signed certificates.
Patching and Updating the vCloud Director Appliance Deployments

You can apply patches to the vCloud Director appliance deployments or update the base packages of the Photon OS of a vCloud Director appliance.

This chapter includes the following topics:

- Patch the vCloud Director Appliance Deployment
- Apply All Updates to the Photon OS of the vCloud Director Appliance
- Apply Security Updates to the Photon OS of vCloud Director

Patch the vCloud Director Appliance Deployment

You can update the vCloud Director appliance with patches that might be related to product functionality and security improvements.

During the patch of the vCloud Director appliance deployment, the vCloud Director service stops working and some downtime can be expected. The downtime depends on the time you need to patch each vCloud Director appliance and to run the vCloud Director database upgrade script. The number of working cells in the vCloud Director server group reduces until you stop the vCloud Director service on the last vCloud Director appliance. A properly configured load balancer in front of the vCloud Director HTTP endpoints should stop routing traffic to the cells that are stopped.

After you apply the patch to every vCloud Director appliance and the database upgrade is complete, you must restart the vCloud Director services across the server group to bring it online again.

Procedure

1. In a Web browser, log in to the appliance management user interface of a vCloud Director appliance instance to identify the primary appliance, `https://appliance_ip_address:5480`.

   Make a note of the primary appliance name. You must use the primary appliance name when upgrading the database.

2. Download the update package to an appliance.

   vCloud Director is distributed as an executable file with a name of the form `VMware_vCloud_Director_v.v.v.v-nnnnnnnn_update.tar.gz`, where `v.v.v.v` represents the product version and `nnnnnnnn` the build number. For example, `VMware_vCloud_Director_9.7.0.4248-13560441_update.tar.gz`. 
3 Create the local-update-package directory in which to extract the update package.
```bash
mkdir /tmp/local-update-package
```

4 Extract the update package in the newly created directory.
```bash
tar -zxf VMware_vCloud_Director_v.v.v-nnnnnnnn_update.tar.gz \
   -C /tmp/local-update-package
```

5 Set the local-update-package directory as the update repository.
```bash
vamicli update --repo file:///tmp/local-update-package
```

6 Check for updates to verify that you established correctly the repository.
```bash
vamicli update --check
```

The patch release appears as an Available Update.

7 Shut down vCloud Director by running the following command:
```bash
/opt/vmware/vcloud-director/bin/cell-management-tool -u <admin username> cell --shutdown
```

8 Apply the available patch.
```bash
vamicli update --install latest
```

9 Repeat Step 2 to Step 8 on each appliance.

10 From the primary appliance, back up the vCloud Director appliance embedded database.
```bash
/opt/vmware/appliance/bin/create-db-backup
```

11 From any appliance, run the vCloud Director database upgrade script.
```bash
/opt/vmware/vcloud-director/bin/upgrade
```

12 Start the vCloud Director services on each appliance.
```bash
service vmware-vcd start
```

### Apply All Updates to the Photon OS of the vCloud Director Appliance

You can use a YUM-compatible package manager to update the base Photon OS packages, which might include security patches.

If your environment consists of a vCloud Director appliance, you can update the base Photon OS packages by using directly the YUM-compatible package manager tdnf.

Applying updates to the Photon OS does not update the vCloud Director build.
Procedure

1. Update the Photon OS packages.
   
   ```
   tdnf upgrade
   ```

2. Restart the appliance.

3. Repeat the procedure for each vCloud Director appliance.

Apply Security Updates to the Photon OS of vCloud Director

You can update only the Photon OS packages that have published security advisories, and ignore the packages with non-security updates.

If your environment consists of a vCloud Director appliance, you can apply security patches to the Photon OS by using directly the YUM-compatible package manager tdnf.

Applying updates to the Photon OS does not update the vCloud Director build.

Procedure

1. Verify that there are security updates for the installed packages.
   
   ```
   tdnf updateinfo list
   ```

2. (Optional) To see more details about all published security advisories, run the following command:
   
   ```
   tdnf updateinfo info
   ```

3. Update the packages with security advisories.
   
   ```
   tdnf upgrade --security
   ```

4. Restart the appliance.

5. Repeat the procedure for each vCloud Director appliance.
After you Upgrade or Migrate vCloud Director

After you upgraded or migrated all vCloud Director servers and the shared database, you can upgrade the NSX Manager instances that provide network services to your cloud. After that, you can upgrade the ESXi hosts and the vCenter Server instances that are registered to your vCloud Director installation.

**Important** Starting with version 9.7, vCloud Director supports only advanced edge gateways. You must convert any legacy non-advanced edge gateway to an advanced gateway. See https://kb.vmware.com/kb/66767.

This chapter includes the following topics:

- Upgrade Each NSX Manager That Is Associated with an Attached vCenter Server System
- Upgrade vCenter Server Systems, ESXi Hosts, and NSX Edges
- New Rights in This Release

**Upgrade Each NSX Manager That Is Associated with an Attached vCenter Server System**

Before you upgrade a vCenter Server and ESXi hosts registered to vCloud Director, you must upgrade each NSX Manager associated with that vCenter Server.

Upgrading NSX Manager interrupts access to NSX administrative functions but does not interrupt network services. You can upgrade NSX Manager before or after you upgrade vCloud Director, whether or not any vCloud Director cells are running.

For information about upgrading NSX, see the NSX for vSphere documentation at https://docs.vmware.com.

**Procedure**

1. Upgrade the NSX Manager associated with each vCenter Server registered to your vCloud Director installation.
2. After you have upgraded all your NSX Managers, you can upgrade your registered vCenter Server systems and ESXi hosts.
Upgrade vCenter Server Systems, ESXi Hosts, and NSX Edges

After you upgrade vCloud Director and NSX Manager, you must upgrade the vCenter Server systems and ESXi hosts that are registered to vCloud Director. After you upgrade all attached vCenter Server systems and ESXi hosts, you can upgrade the NSX Edges.

Prerequisites

Verify that you have already upgraded each NSX Manager that is associated with the vCenter Server systems that are attached to your cloud. See Upgrade Each NSX Manager That Is Associated with an Attached vCenter Server System.

Procedure

1. Disable the vCenter Server instance.
   a. In the vCloud Director Web Console, click the Manage and Monitor tab, and, in the left pane, click vCenters.
   b. Right-click the target vCenter Server name and click Disable.
   c. Click Yes.

2. Upgrade the vCenter Server system.
   For information, see vCenter Server Upgrade.

3. Verify all vCloud Director public URLs and certificate chains.
   a. In the vCloud Director Web Console, click the Administration tab, and, in the left pane, click Public Addresses.
   b. Verify all public addresses.

4. Refresh the vCenter Server registration with vCloud Director.
   a. In the vCloud Director Web Console, click the Manage and Monitor tab, and, in the left pane, click vCenters.
   b. Right-click the target vCenter Server name and click Refresh.
   c. Click Yes.
5 Upgrade each ESXi host that the upgraded vCenter Server system supports.

   See the VMware ESXi Upgrade.

   **Important** To ensure that you have enough upgraded host capacity to support the virtual machines in your cloud, upgrade hosts in small batches. When you do this, host agent upgrades can complete in time to allow virtual machines to migrate back to the upgraded host.

   a Use the vCenter Server system to put the host into maintenance mode and allow all the virtual machines on that host to migrate to another host.
   
   b Upgrade the host.
   
   c Use the vCenter Server system to reconnect the host.
   
   d Use the vCenter Server system to take the host out of maintenance mode.

6 (Optional) Upgrade NSX Edges managed by the NSX Manager associated with the upgraded vCenter Server system.

Upgraded NSX Edges deliver improvements in performance and integration. You can use either NSX Manager or vCloud Director upgrade NSX Edges.

- For information about using NSX Manager to upgrade NSX Edges, see the NSX for vSphere documentation at https://docs.vmware.com.
- To use vCloud Director to upgrade an NSX Edges, you must operate on the vCloud Director network object that the Edge supports:
  - An appropriate upgrade of an Edge Gateway occurs automatically when you use either the vCloud Director Web console or vCloud API to reset a network that the Edge Gateway serves.
  - Redeploying an Edge Gateway upgrades the associated NSX Edge appliance.
  - Resetting a vApp network from within the context of the vApp upgrades the NSX Edge appliance associated with that network. To use vCloud Director Web console to reset a vApp network from within the context of a vApp, navigate to the Networking tab for the vApp, display its networking details, right-click the vApp network, and select Reset Network.

For more information on how to redeploy Edge Gateways and reset vApp networks, see the vCloud Director Web console online help or the vCloud API Programming Guide.

**What to do next**

Repeat this procedure for the other vCenter Server systems registered to your vCloud Director installation.

**New Rights in This Release**

vCloud Director 9.7 introduces new rights, which you might want to add to any existing global roles that you published to your tenants.
<table>
<thead>
<tr>
<th>Right</th>
<th>Description</th>
<th>Default Role</th>
</tr>
</thead>
<tbody>
<tr>
<td>SDDC: View SDDC</td>
<td>Allows you to view all SDDCs that are published to your organization. The <strong>system administrator</strong> can view all SDDCs.</td>
<td>System Administrator and <strong>Organization Administrator</strong></td>
</tr>
<tr>
<td>SDDC: Manage SDDC</td>
<td>Allows you to add, remove, and edit SDDCs.</td>
<td><strong>System Administrator</strong></td>
</tr>
<tr>
<td>SDDC: Manage SDDC Proxy</td>
<td>Allows you to add, remove, enable, and disable SDDC proxies.</td>
<td><strong>System Administrator</strong></td>
</tr>
<tr>
<td>Service Applications: View</td>
<td>Allows you to see the list of registered service applications. Used for VMC</td>
<td><strong>System Administrator</strong></td>
</tr>
<tr>
<td>Service Applications</td>
<td>accounts.</td>
<td></td>
</tr>
<tr>
<td>Service Applications: Register</td>
<td>Allows you to create, view, edit, and remove service applications. Used for VMC accounts.</td>
<td><strong>System Administrator</strong></td>
</tr>
<tr>
<td>VMC SDDC</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Service Applications: Manage</td>
<td>Allows you to register service applications. Used for VMC accounts.</td>
<td><strong>System Administrator</strong></td>
</tr>
<tr>
<td>Service Applications</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Edge Cluster: View Edge Cluster</td>
<td>Allows you to see a list of edge cluster, and to retrieve an individual edge cluster.</td>
<td>**System Administrator and <strong>Organization Administrator</strong></td>
</tr>
<tr>
<td>Edge Cluster: Manage Edge Cluster</td>
<td>Allows you to create, edit, and remove edge clusters.</td>
<td>**System Administrator and <strong>Organization Administrator</strong></td>
</tr>
<tr>
<td>vApp: Edit VM Compute Policy</td>
<td>Allows users to change the compute policy of a virtual machine.</td>
<td><strong>system administrator, organization administrator, Catalog Author, and vApp Author</strong></td>
</tr>
<tr>
<td>Gateway: Import Edge Gateway</td>
<td>Allows you to import a Tier-1 router as an edge gateway.</td>
<td>**System Administrator and <strong>Organization Administrator</strong></td>
</tr>
</tbody>
</table>

For information about managing rights and roles, see the *vCloud Director Service Provider Admin Portal Guide*. 

---

**VMware, Inc.**

110
Troubleshooting the vCloud Director Appliance

If the vCloud Director appliance deployment fails or if the appliance is not operating properly, you can examine the appliance log files to determine the cause of the problem.

This chapter includes the following topics:

- Examine the Log Files in the vCloud Director Appliance
- The vCloud Director Cell Fails to Start After the Appliance Deployment
- Reconfiguring the vCloud Director Service Fails When Migrating or Restoring to vCloud Director Appliance
- Using the Log Files to Troubleshoot vCloud Director Updates and Patches
- Checking for vCloud Director Updates Fails
- Installing the Latest Update of vCloud Director Fails

Examine the Log Files in the vCloud Director Appliance

After you deploy the vCloud Director appliance, you can examine the firstboot and database logs for errors and warnings.

Procedure

1. Log in directly or SSH to the vCloud Director appliance console as root.
2. Navigate to /opt/vmware/var/log.
3. Examine the log files.
   - The firstboot file contains logging information related to the first boot of the appliance.
   - The /opt/vmware/var/log/vcd/ directory contains logs related to the Replication Manager (repmgr) tool suite setup and reconfiguration and appliance synchronization.
   - The /opt/vmware/var/log/vcd/pg/ directory contains logs related to the backup of the embedded appliance database.
   - The /opt/vmware/etc/vami/ovfEnv.xml file contains the deployment OVF parameters.
The vCloud Director Cell Fails to Start After the Appliance Deployment

You deployed the vCloud Director appliance successfully, but the vCloud Director services might fail to start.

**Problem**

The `vmware-vcd` service is inactive after the appliance deployment.

**Cause**

If you deployed a primary cell, the vCloud Director services might fail to start due to a pre-populated NFS shared transfer service storage. Before you deploy the primary appliance, the shared transfer service storage must not contain a `responses.properties` file or an `appliance-nodes` directory.

If you deployed a standby or vCD application cell, the vCloud Director services might fail to start due to a missing `responses.properties` file in the NFS shared transfer storage. Before you deploy a standby or vCD application appliance, the shared transfer service storage must contain the `responses.properties` file.

**Solution**

1. Log in directly or SSH to the vCloud Director appliance console as `root`.
2. Examine the `/opt/vmware/var/log/vcd/setupvcd.log` for error messages regarding the NFS storage.
3. Prepare the NFS storage for the appliance type.
4. Redeploy the cell.

Reconfiguring the vCloud Director Service Fails When Migrating or Restoring to vCloud Director Appliance

When you are migrating or restoring to vCloud Director appliance, running the `configure` command might fail.

**Problem**

During the procedure for migrating or restoring vCloud Director to a new vCloud Director appliance environment, you run the `configure` command to reconfigure the vCloud Director service in each new cell. The `configure` command might fail with the error message `sun.security.validator.ValidatorException: PKIX path validation failed: java.security.cert.CertPathValidatorException: signature check failed`. 
Solution

1. On the target cell, run the command.

   ```bash
   sed -i '/vcd_ova.crt/ s/$/ --force /' /opt/vmware/appliance/bin/appliance-sync.sh
   ```

2. Wait 1 minute, and rerun the configure command.

Using the Log Files to Troubleshoot vCloud Director Updates and Patches

You can examine the log files for errors and warnings when you apply patches to the vCloud Director appliance.

Problem

If the `vamicli` command returns an error, you can use the log files to troubleshoot.

Solution

1. Log in directly or SSH to the vCloud Director appliance console as `root`.

2. Navigate to the appropriate log file.

   - If the `vamicli update --check` fails, navigate to `/opt/vmware/var/log/vami/vami.log`.
   - If the `vamicli update --install latest` fails, navigate to `/opt/vmware/var/log/vami/updatecli.log`.

3. Examine the log file.

Checking for vCloud Director Updates Fails

When you are checking for updates to the vCloud Director appliance, running the `vamicli update --check` command might fail.

Problem

During the procedure of applying a patch to the vCloud Director appliance, you run the `vamicli update --check` command to check for available updates. The `vamicli update --check` command might fail with `Failure: Error downloading manifest. Please contact your vendor.`

Cause

The path to the update repository directory is incorrect.

Solution

1. Run the `vamicli` command with the correct path.

   ```bash
   vamicli update --repo file:/root/local-update-repo
   ```
2 Run again the command to check for updates.

   vamicli update --check

Installing the Latest Update of vCloud Director Fails

When you are installing the latest updates to the vCloud Director appliance, running the `vamicli update --install latest` command might fail.

Problem

During the procedure of applying a patch to the vCloud Director appliance, you run the `vamicli update --install latest` command to apply the latest available patch. The `vamicli update --install latest` command might fail with Failure: Error while running package installation.

Cause

The error occurs when the NFS server is inaccessible.

Solution

1 Verify that the NFS server mounted at `/opt/vmware/vcloud-director/data/transfer` is accessible.

2 Run again the command to apply the available patch.

   vamicli update --install latest
Uninstall vCloud Director Software

Use the Linux `rpm` command to uninstall vCloud Director software from an individual server.

**Procedure**

1. Log in to the target server as **root**.
2. Unmount the transfer service storage, typically mounted at `/opt/vmware/vcloud-director/data/transfer`.
3. Open a console, shell, or terminal window and run the Linux `rpm` command.

```
rpm -e vmware-phonehome vmware-vcloud-director vmware-vcloud-director-rhel
```

If other installed packages depend on the `vmware-vcloud-director` package, the system prompts you to uninstall those packages before you uninstall vCloud Director.
