Configuring vRealize Automation 6

Updated Information 7

1 External Preparations for Blueprint Provisioning 8

- Preparing Your Environment for vRealize Automation Management 8
 - Checklist for Preparing NSX Network and Security Configuration 9
 - Checklist For Providing Third-Party IPAM Provider Support 13
 - Checklist for Configuring Containers for vRealize Automation 17
 - Preparing Your vCloud Director Environment for vRealize Automation 18
 - Preparing Your vCloud Air Environment for vRealize Automation 18
 - Preparing Your Amazon AWS Environment 19
 - Preparing Red Hat OpenStack Network and Security Features 25
 - Preparing Your SCVMM Environment 26
- Configure Network-to-Azure VPC Connectivity 27
- Preparing for Machine Provisioning 28
 - Choosing a Machine Provisioning Method to Prepare 29
 - Checklist for Running Visual Basic Scripts During Provisioning 31
 - Using vRealize Automation Guest Agent in Provisioning 32
 - Checklist for Preparing to Provision by Cloning 40
 - Preparing for vCloud Air and vCloud Director Provisioning 54
 - Preparing for Linux Kickstart Provisioning 55
 - Preparing for SCCM Provisioning 58
 - Preparing for WIM Provisioning 59
 - Preparing for Virtual Machine Image Provisioning 66
 - Preparing for Amazon Machine Image Provisioning 67
 - Scenario: Prepare vSphere Resources for Machine Provisioning in Rainpole 69
- Preparing for Software Provisioning 72
 - Preparing to Provision Machines with Software 73
 - Scenario: Prepare a vSphere CentOS Template for Clone Machine and Software Component Blueprints 76
 - Scenario: Prepare for Importing the Dukes Bank for vSphere Sample Application Blueprint 80

2 Tenant and Resource Preparations for Blueprint Provisioning 85

- Configuring Tenant Settings 85
 - Choosing Directories Management Configuration Options 86
 - Upgrading External Connectors for Directories Management 145
 - Scenario: Configure an Active Directory Link for a Highly Available vRealize Automation 152

Configure External Connectors for Smart Card and Third-party Identity Provider Authentication in vRealize Automation	155
Create a Multi Domain or Multi Forest Active Directory Link	162
Configuring Groups and User Roles	164
Create Additional Tenants	168
Delete a Tenant	170
Configuring Custom Branding	171
Checklist for Configuring Notifications	173
Create a Custom RDP File to Support RDP Connections for Provisioned Machines	184
Scenario: Add Datacenter Locations for Cross Region Deployments	184
Configuring vRealize Orchestrator	186
Configuring Resources	190
Checklist for Configuring IaaS Resources	190
Configuring XaaS Resources	307
Creating and Configuring Containers	318
Installing Additional Plug-Ins on the Default vRealize Orchestrator Server	338
Working With Active Directory Policies	338
User Preferences for Notifications and Delegates	342

3 Providing Service Blueprints to Users 343

Designing Blueprints	343
Exporting and Importing Blueprints and Content	345
Scenario: Importing the Dukes Bank for vSphere Sample Application and Configuring for Your Environment	347
Scenario: Test the Dukes Bank Sample Application	350
Building Your Design Library	352
Designing Machine Blueprints	353
Designing Software Components	431
Designing XaaS Blueprints and Resource Actions	443
Publishing a Blueprint	503
Assembling Composite Blueprints	504
Understanding Nested Blueprint Behavior	506
Using Machine Components and Software Components When Assembling a Blueprint	509
Creating Property Bindings Between Blueprint Components	510
Creating Dependencies and Controlling the Order of Provisioning	511
Managing the Service Catalog	512
Checklist for Configuring the Service Catalog	513
Creating a Service	514
Working with Catalog Items and Actions	516
Creating Entitlements	519
Working with Approval Policies	526
Request Machine Provisioning By Using a Parameterized Blueprint	551

Scenario: Make the CentOS with MySQL Application Blueprint Available in the Service Catalog	552
Managing Deployed Catalog Items	556
Running Actions for Provisioned Resources	556
Specify Machine Reconfiguration Settings and Considerations for Reconfiguration	577
Reconfigure a Load Balancer in a Deployment	584

Display All NAT Rules for an Existing NSX Edge	587

Configuring vRealize Automation

Configuring vRealize Automation provides information about configuring vRealize Automation and your external environments to prepare for vRealize Automation provisioning and catalog management.

Intended Audience

This information is intended for IT professionals who are responsible for configuring vRealize Automation environment, and for infrastructure administrators who are responsible for preparing elements in their existing infrastructure for use in vRealize Automation provisioning. The information is written for experienced Windows and Linux system administrators who are familiar with virtual machine technology and datacenter operations.

VMware Technical Publications Glossary

VMware Technical Publications provides a glossary of terms that might be unfamiliar to you. For definitions of terms as they are used in VMware technical documentation, go to <http://www.vmware.com/support/pubs>.

Updated Information

The following table lists the changes to *Configuring vRealize Automation* for this product release.

Revision	Description
15 MAR 2018	<ul style="list-style-type: none">■ Updated Troubleshooting Workload Placement to include the log file name.■ Updated downloadable scripts in Prepare a Windows Reference Machine to Support Software and Prepare a Linux Reference Machine to Support Software.■ Updated Force Destroy a Deployment After a Failed Destroy Request.■ Minor updates to Configure an Active Directory over LDAP/IWA Link.
18 JAN 2018	<ul style="list-style-type: none">■ Updated Configure External Connectors for Smart Card and Third-party Identity Provider Authentication in vRealize Automation to make information more generic.
4 DEC 2017	Minor updates.
30 AUG 2017	<ul style="list-style-type: none">■ Administrator Requirements for Provisioning NSX Universal Objects■ Updated Install the Guest Agent on a Windows Reference Machine■ Updated Obtain and Import a Third-Party IPAM Provider Package in vRealize Orchestrator.■ Amazon AWS User Roles and Credentials Required for vRealize Automation
EN-002417-02	<ul style="list-style-type: none">■ Updated Install the NSX Plug-In on vRealize Orchestrator.■ Updated Configure an Active Directory over LDAP/IWA Link.
EN-002417-01	<ul style="list-style-type: none">■ Updated Configure an External vRealize Orchestrator Server.■ Updated and added KB article links in Considerations When Working With Upgraded or Migrated Endpoints.■ Updated Scenario: Import the Dukes Bank for vSphere Sample Application to resolve a case-specificity issue.■ Added a KB article link in Reconfigure a Load Balancer in a Deployment.■ Added an external reference in Creating and Using NAT Rules.■ Added an external reference in Create an NSX Endpoint and Associate to a vSphere Endpoint.■ Updated Using Container Properties and Property Groups in a Blueprint.
EN-002417-00	Initial document release.

External Preparations for Blueprint Provisioning

1

You may need to create or prepare some elements outside of vRealize Automation to support catalog item provisioning. For example, if you want to provide a catalog item for provisioning a clone machine, you need to create a template on your hypervisor to clone from.

This chapter includes the following topics:

- [Preparing Your Environment for vRealize Automation Management](#)
- [Configure Network-to-Azure VPC Connectivity](#)
- [Preparing for Machine Provisioning](#)
- [Preparing for Software Provisioning](#)

Preparing Your Environment for vRealize Automation Management

Depending on your integration platform, you might have to make some configuration changes before you can bring your environment under vRealize Automation management, or before you can leverage certain features.

Table 1-1. Preparing Your Environment for vRealize Automation Integration

Environment	Preparations
 NSX	If you want to leverage NSX to manage networking and security features of machines provisioned with vRealize Automation, prepare your NSX instance for integration. See Checklist for Preparing NSX Network and Security Configuration .
 vCloud Director	Install and configure your vCloud Director instance, set up your vSphere and cloud resources, and identify or create appropriate credentials to provide vRealize Automation with access to your vCloud Director environment. See Preparing Your vCloud Director Environment for vRealize Automation .

Table 1-1. Preparing Your Environment for vRealize Automation Integration (Continued)

Environment	Preparations
 vCloud Air	Register for your vCloud Air account, set up your vCloud Air environment, and identify or create appropriate credentials to provide vRealize Automation with access to your environment. See Preparing for vCloud Air and vCloud Director Provisioning .
 Amazon AWS	Prepare elements and user roles in your Amazon AWS environment for use in vRealize Automation, and understand how Amazon AWS features map to vRealize Automation features. See Preparing Your Amazon AWS Environment .
Microsoft Azure	Configure networking to use VPN tunneling to support Software components on Azure blueprints. See Configure Network-to-Azure VPC Connectivity .
 Red Hat OpenStack	If you want to leverage Red Hat OpenStack to manage networking and security features of machines provisioned with vRealize Automation, prepare your Red Hat OpenStack instance for integration. See Preparing Red Hat OpenStack Network and Security Features .
 SCVMM	Configure storage, networking, and understand template and hardware profile naming restrictions. See Preparing Your SCVMM Environment .
External IPAM Providers	Register an external IPAM provider package or plug-in, run the configuration workflows, and register the IPAM solution as a new vRealize Automation endpoint. See Checklist For Providing Third-Party IPAM Provider Support .
All other environments	You do not need to make changes to your environment. You can begin preparing for machine provisioning by creating templates, boot environments, or machine images. See Preparing for Machine Provisioning .

Checklist for Preparing NSX Network and Security Configuration

Before you can use NSX network and security options in vRealize Automation, you must configure the external NSX network and security environment that you intend to use.

Beginning in vRealize Automation 7.3, you no longer need to install the NSX plug-in to obtain integrated NSX functionality. All integrated NSX functionality is now sourced directly from the NSX APIs, rather than from the NSX plug-in. However, if you want to use XaaS to extend your vRealize Automation and NSX integration, you must install the NSX plug-in in vRealize Orchestrator as described here.

In preparation for using NSX network, security, and load balancing capabilities in vRealize Automation, when using NSX Manager credentials you must use the NSX Manager administrator account.

For related information about NSX, see NSX documentation at https://www.vmware.com/support/pubs/nsx_pubs.html and public blogs and articles such as [Integrating NSX with vRealize Automation](#).

Much of the vRealize Automation support for network and security configuration that you specify in blueprints and reservations is configured externally and made available to vRealize Automation after data collection is run on the compute resources.

For more information about NSX settings that you can configure for vRealize Automation blueprints, see [Configuring Network and Security Component Settings](#).

Table 1-2. Preparing NSX Networking and Security Checklist

Task	Location	Details
<input type="checkbox"/> Configure NSX network settings, including gateway and transport zone settings.	Configure network settings in NSX.	See the <i>NSX Administration Guide</i> .
<input type="checkbox"/> Create NSX security policies, tags, and groups.	Configure security settings in NSX.	See the <i>NSX Administration Guide</i> .
<input type="checkbox"/> Configure NSX load balancer settings.	Configure an NSX load balancer to work with vRealize Automation.	See the <i>NSX Administration Guide</i> . Also see Custom Properties for Networking in <i>Custom Properties Reference</i> .
<input type="checkbox"/> For cross-virtual center deployments, verify that the compute NSX manager has the primary NSX manager role.	vRealize Automation provisioning requires that the compute NSX manager for the region in which the machines reside has the primary NSX manager role.	See Administrator Requirements for Provisioning NSX Universal Objects . See the <i>NSX Installation Guide</i> and <i>NSX Administration Guide</i> for information about cross-virtual center deployment, universal objects, and the primary NSX manager role.

Install the NSX Plug-In on vRealize Orchestrator

Installing the NSX plug-in requires that you download the vRealize Orchestrator installer file, use the vRealize Orchestrator Configuration interface to upload the plug-in file, and install the plug-in on a vRealize Orchestrator server.

For general plug-in update and troubleshooting information, see vRealize Orchestrator [documentation](#).

Prerequisites

Beginning in vRealize Automation 7.3, you no longer need to install the NSX plug-in to obtain integrated NSX functionality. All integrated NSX functionality is now sourced directly from the NSX APIs, rather than from the NSX plug-in. However, if you want to use XaaS to extend your vRealize Automation and NSX integration, you must install the NSX plug-in in vRealize Orchestrator as described here.

If you are using an embedded vRealize Orchestrator that already contains an installed NSX plug-in, you can skip this procedure.

- Verify that you are running a supported vRealize Orchestrator instance.

For information about setting up vRealize Orchestrator, see *Installing and Configuring VMware vRealize Orchestrator*.

- Verify that you have credentials for an account with permission to install vRealize Orchestrator plug-ins and to authenticate through vCenter Single Sign-On.
- Verify that you installed the vRealize Orchestrator client and that you can log in with Administrator credentials.
- Confirm the correct version of the NSX plug-in in the vRealize Automation [support matrix](#).

Procedure

- 1 Download the plug-in file to a location accessible from the vRealize Orchestrator server.

The plug-in installer file name format, with appropriate version values, is o11nplugin-nsx-1.n.n.vmoapp. Plug-in installation files for the NSX networking and security product are available from the VMware product download site at <http://vmware.com/web/vmware/downloads>.

- 2 Open a browser and start the vRealize Orchestrator configuration interface.

An example of the URL format is `https://orchestrator_server.com:8283`.

- 3 Click **Plug-Ins** in the left pane and scroll down to the Install new plug-in section.
- 4 In the **Plug-In file** text box, browse to the plug-in installer file and click **Upload and install**.

The file must be in .vmoapp format.

- 5 At the prompt, accept the license agreement in the Install a plug-in pane.
- 6 In the Enabled plug-ins installation status section, confirm that the correct NSX plug-in name is specified.

See *vRealize Automation Support Matrix* for version information.

The status Plug-in will be installed at next server startup, appears.

- 7 Restart the vRealize Orchestrator server service.
- 8 Restart the vRealize Orchestrator configuration interface.
- 9 Click **Plug-Ins** and verify that the status changed to Installation OK.

- 10 Start the vRealize Orchestrator client application, log in, and use the **Workflow** tab to navigate through the library to the NSX folder.

You can browse through the workflows that the NSX plug-in provides.

What to do next

Create a vRealize Orchestrator endpoint in vRealize Automation to use for running workflows. See [Create a vRealize Orchestrator Endpoint](#).

Run a vRealize Orchestrator and NSX Security Workflow

Before you use the NSX security policy features from vRealize Automation, an administrator must run the **Enable security policy support for overlapping subnets** workflow in vRealize Orchestrator.

Security policy support for the overlapping subnets workflow is applicable to an NSX 6.1 and later endpoint. Run this workflow only once to enable this support.

Prerequisites

- Verify that a vSphere endpoint is registered with an NSX endpoint. See [Create a vSphere Endpoint](#).
- Log in to the vRealize Orchestrator client as an administrator.
- Verify that you ran the **Create NSX endpoint vRO** work flow.

Procedure

- 1 Click the **Workflow** tab and select **NSX > NSX workflows for VCAC**.
- 2 Run the **Create NSX endpoint** workflow and respond to prompts.
- 3 Run the **Enable security policy support for overlapping subnets** workflow.
- 4 Select the NSX endpoint as the input parameter for the workflow.

Use the IP address you specified when you created the vSphere endpoint to register an NSX instance.

After you run this workflow, the distributed firewall rules defined in the security policy are applied only on the vNICs of the security group members to which this security policy is applied.

What to do next

Apply the applicable security features for the blueprint.

Administrator Requirements for Provisioning NSX Universal Objects

To provision machines in a cross vCenter NSX environment when using NSX universal objects, you must provision to a vCenter in which the NSX compute manager has the primary role.

In a cross vCenter NSX environment, you can have multiple vCenter servers, each of which must be paired with its own NSX manager. One NSX manager is assigned the role of primary NSX manager, and the others are assigned the role of secondary NSX manager.

The primary NSX manager can create universal objects, such as universal logical switches. These objects are synchronized to the secondary NSX managers. You can view these objects from the secondary NSX managers, but you cannot edit them there. You must use the primary NSX manager to manage universal objects. The primary NSX manager can be used to configure any of the secondary NSX managers in the environment.

For more information about the NSX cross-vCenter environment, see *Overview of Cross-vCenter Networking and Security* in the *NSX Administration Guide* in the [NSX product documentation](#).

For a vSphere (vCenter) endpoint that is associated to the NSX endpoint of a primary NSX manager, vRealize Automation supports NSX local objects, such as local logical switches, local edge gateways, and local load balancers, security groups, and security tags. It also supports NAT one-to-one and one-to-many networks with universal transport zone, routed networks with universal transport zone and universal distributed logical routers (DLRs), and a load balancer with any type of network.

vRealize Automation does not support NSX existing and on-demand universal security groups or tags.

To provision local on-demand networks as the primary NSX manager, use a vCenter-specific local transport zone. You can configure vRealize Automation reservations to use the local transport zone and virtual wires for deployments in that local vCenter.

If you connect a vSphere (vCenter) endpoint to a corresponding secondary NSX manager endpoint, you can only provision and use local objects.

You can only associate an NSX endpoint to one vSphere endpoint. This association constraint means that you cannot provision a universal on-demand network and attach it to vSphere machines that are provisioned on different vCenters.

vRealize Automation can consume an NSX universal logical switch as an external network. If a universal switch exists, it is data-collected and then attached to or consumed by each machine in the deployment.

- Provisioning an on-demand network to a universal transport zone can create a new universal logical switch.
- Provisioning an on-demand network to a universal transport zone on the primary NSX manager creates a universal logical switch.
- Provisioning an on-demand network to a universal transport zone on a secondary NSX manager fails, as NSX cannot create a universal logical switch on a secondary NSX manager.

See the VMware Knowledge Base article *Deployment of vRealize Automation blueprints with NSX objects fail (2147240)* at <http://kb.vmware.com/kb/2147240> for more information about NSX universal objects.

Checklist For Providing Third-Party IPAM Provider Support

You can obtain IP addresses and ranges for use in network profile definition from a supported third-party IPAM provider, such as Infoblox.

Before you can create and use an external IPAM provider endpoint in a vRealize Automation network profile, you must download or otherwise obtain a vRealize Orchestrator IPAM provider plug-in or package, import the plug-in or package and run required workflows in vRealize Orchestrator, and register the IPAM solution as a vRealize Automation endpoint.

For an overview of the provisioning process for using an external IPAM provider to supply a range of possible IP addresses, see [Provisioning a vRealize Automation Deployment Using a Third-Party IPAM Provider](#).

Table 1-3. Preparing for External IPAM Provider Support Checklist

Task	Description	Details
❑ Obtain and import the supported external IPAM Provider vRealize Orchestrator plug-in.	<p>Download the IPAM provider plug-in or package, for example The Infoblox IPAM Plug-in for vRealize Orchestrator plug-in and supporting documentation, from the VMware Solution Exchange (https://solutionexchange.vmware.com/store/category_group/s/cloud-management) and import the plug-in or package to vRealize Orchestrator.</p> <p>If the VMware Solution Exchange does not contain the IPAM provider package that you need, you can create your own by using a third-party IPAM Solution Provider SDK and supporting documentation.</p> <p>A vRealize Automation version-specific third-party IPAM Solution Provider SDK, supporting documentation, and associated starter package for vRealize Orchestrator and vRealize Automation is available at https://code.vmware.com/sdks or https://code.vmware.com/samples.</p>	See Obtain and Import a Third-Party IPAM Provider Package in vRealize Orchestrator .
❑ Run the required configuration workflows and register the external IPAM solution as a vRealize Automation endpoint.	Run the vRealize Orchestrator configuration workflows and register the IPAM provider endpoint type in vRealize Orchestrator.	See Run Workflow to Register Third-Party IPAM Endpoint Type in vRealize Orchestrator .

Obtain and Import a Third-Party IPAM Provider Package in vRealize Orchestrator

To prepare to define and use an third-party IPAM provider endpoint, you must first obtain the third-party IPAM provider package and import the package in vRealize Orchestrator.

You can download and use an existing third-party IP Address Management provider plug-in, such as Infoblox IPAM. You can also create your own third-party IPAM plug-in or package by using a VMware-supplied starter package and accompanying SDK documentation for use with another third-party IPAM solution provider, such as BlueCat.

- Obtain the existing [Infoblox IPAM Plug-in for vRealize Orchestrator](#) plug-in and supporting documentation from marketplace.vmware.com. The download also contains documentation for installing and using the plug-in.

- Create your own third-party IPAM solution by obtaining and using a third-party IPAM Solution Provider SDK, supporting documentation, and an associated starter package for vRealize Orchestrator and vRealize Automation. See the [vRealize Automation Example Third-Party IPAM Package](https://code.vmware.com/web/sdk) page at code.vmware.com/web/sdk.

After you import the third-party IPAM provider plug-in or package in vRealize Orchestrator, you must run the required workflows, and register the IPAM endpoint type in vRealize Orchestrator.

For more information about importing plug-ins and packages and running vRealize Orchestrator workflows, see *Using the VMware vRealize Orchestrator Client*. For more information about extending vRealize Automation with vRealize Orchestrator plug-ins, packages, and workflows, see *Life Cycle Extensibility*.

This step sequence uses the Infoblox IPAM plug-in as an example. Your step sequence may differ depending on your vRealize Automation or plug-in version.

Prerequisites

- Download the package or plug-in from marketplace.vmware.com.
- Log in to vRealize Orchestrator with administrator privileges for importing, configuring, and registering a vRealize Orchestrator plug-in or package.

Procedure

- 1 Open the marketplace.vmware.com site.
- 2 Locate and download the plug-in or package.

For example, import the Infoblox plug-in that supports the Infoblox third-party IPAM endpoint in vRealize Orchestrator and vRealize Automation 7.1 and later.

- a In the **Publisher** category, select **Infoblox** and click **Apply**.
- b Select [The Infoblox Plug-in for vRealize Orchestrator](#).
- c Click **Tech Specs** and review the prerequisites.
- d Click **Try** for additional information and to receive an email that contains a link to the download.
- e Download the zip file as specified in the emailed instructions.

Version 4.0 and greater of the plug-in supports vRealize Automation 7.1 and greater. The zip file also contains documentation about the plug-in.

- 3 In vRealize Orchestrator, click the **Administrator** tab and click **Import package**.
- 4 Select the package to import.
- 5 Select all workflows and artifacts and click **Import selected elements**.

What to do next

[Run Workflow to Register Third-Party IPAM Endpoint Type in vRealize Orchestrator](#).

Run Workflow to Register Third-Party IPAM Endpoint Type in vRealize Orchestrator

Run the registration workflow in vRealize Orchestrator to support vRealize Automation use of the third-party IPAM provider and register the IPAM endpoint type for use in vRealize Automation.

To register IPAM endpoint types in vRealize Orchestrator, you are prompted to supply vRealize Automation vRA Administrator credentials.

For more information about importing packages and running vRealize Orchestrator workflows, see *Using the VMware vRealize Orchestrator Client*. For more information about extending vRealize Automation with vRealize Orchestrator packages and workflows, see *Life Cycle Extensibility*.

Prerequisites

- [Obtain and Import a Third-Party IPAM Provider Package in vRealize Orchestrator](#)
- Verify that you are logged in to vRealize Orchestrator with vRealize Automation with authority to run workflows.
- Be prepared to supply vRealize Automation vRealize Automation administrator credentials when prompted.

Procedure

- 1 In vRealize Orchestrator, click the **Design** tab, select **Administrator > Library**, and select **IPAM Service Package SDK**.

Each IPAM provider package is uniquely named and contains unique workflows. Each provider supplies their own registration workflow. While the workflow names might be similar between provider packages, the location of the workflows in vRealize Orchestrator can be different and is provider-specific.

- 2 For this example, run the Register IPAM Endpoint registration workflow and specify the IPAM Infoblox endpoint type.
- 3 At the prompt for vRealize Automation credentials, enter your vRealize Automation vRA administrator credentials.

The package registers Infoblox as a new IPAM endpoint type in the vRealize Automation endpoint service and makes the endpoint type available when you define endpoints in vRealize Automation.

Note If the Infoblox IPAM connection disappears from the vRealize Orchestrator **Inventory** tab after you restart the vRealize Orchestrator server in the vRealize Orchestrator Control Center. To resolve this issue, run the Create IPAM Connection workflow from the **vRO admin > Library > Infoblox > vRA > Helpers** menu sequence. You can then the vRealize Orchestrator **Inventory** tab, select **Infoblox IPAM**, and refresh the page to display the Infoblox IPAM connection.

What to do next

You can now create an IPAM Infloblox type endpoint, or an endpoint for whatever third-party package or plug-in you have just registered, in vRealize Automation. See [Create a Third-Party IPAM Provider Endpoint](#).

Checklist for Configuring Containers for vRealize Automation

To get started with Containers, you must configure the feature to support vRealize Automation user roles.

After you configure container definitions in Containers you can add and configure container components in a blueprint.

Table 1-4. Checklist for Configuring Containers for vRealize Automation

Task	Details
Assign the container administrator and container architect roles.	See Container roles information in <i>Foundations and Concepts</i> .
Display the Containers context-sensitive help system.	See Containers help information in <i>Foundations and Concepts</i> .
Define container definitions in the Containers tab in vRealize Automation.	See <i>Configuring vRealize Automation</i> .
Add container components and container networking components to blueprints in the Design tab in vRealize Automation.	See <i>Configuring vRealize Automation</i> .

Configuring Containers Using the vRealize Automation Appliance

Xenon service information is accessible in the vRealize Automation vRealize Automation appliance (**vRA Settings > Xenon**).

It contains information about the Xenon host VM, listening port, and service status. It also displays information about clustered Xenon nodes.

You can manage the Xenon Linux service with the following CLI commands in the vRealize Automation appliance.

Command	Description
<code>service xenon-service status</code>	Shows the status of the service as either running or stopped.
<code>service xenon-service start</code>	Starts the service.
<code>service xenon-service stop</code>	Stops the service.
<code>service xenon-service restart</code>	Restarts the service.
<code>service xenon-service get_host</code>	Shows the hostname on which the service is running.
<code>service xenon-service get_port</code>	Shows the service port.
<code>service xenon-service status_cluster</code>	Shows information about all clustered nodes in JSON format.
<code>service xenon-service reset</code>	Deletes the directory where Xenon keeps all configuration files and restarts the service.

Clustering Containers

You can use the Xenon service in conjunction with Containers for vRealize Automation to join nodes to a cluster. If the nodes are clustered, the Xenon service connects other nodes automatically when it starts.

You can monitor the cluster status on the **Xenon** tab in the vRealize Automation appliance or by running the following command in a CLI:

```
service xenon--service status_cluster
```

Xenon works on quorum-based clustering. The quorum is calculated by using the $(\text{number of nodes} / 2) + 1$ formula.

Preparing Your vCloud Director Environment for vRealize Automation

Before you can integrate vCloud Director with vRealize Automation, you must install and configure your vCloud Director instance, set up your vSphere and cloud resources, and identify or create appropriate credentials to provide vRealize Automation with access to your vCloud Director environment.

Configure Your Environment

Configure your vSphere resources and cloud resources, including virtual datacenters and networks. For more information, see the vCloud Director documentation.

Required Credentials for Integration

Create or identify either organization administrator or system administrator credentials that your vRealize Automation IaaS administrators can use to bring your vCloud Director environment under vRealize Automation management as an endpoint.

User Role Considerations

vCloud Director user roles in an organization do not need to correspond with roles in vRealize Automation business groups. If the user account does not exist in vCloud Director, vCloud Director performs a lookup in the associated LDAP or Active Directory and creates the user account if the user exists in the identity store. If it cannot create the user account, it logs a warning but does not fail the provisioning process. The provisioned machine is then assigned to the account that was used to configure the vCloud Director endpoint.

For related information about vCloud Director user management, see the vCloud Director documentation.

Preparing Your vCloud Air Environment for vRealize Automation

Before you integrate vCloud Air with vRealize Automation, you must register for your vCloud Air account, set up your vCloud Air environment, and identify or create appropriate credentials to provide vRealize Automation with access to your environment.

Configure Your Environment

Configure your environment as instructed in the vCloud Air documentation.

Required Credentials for Integration

Create or identify either virtual infrastructure administrator or account administrator credentials that your vRealize Automation IaaS administrators can use to bring your vCloud Air environment under vRealize Automation management as an endpoint.

User Role Considerations

vCloud Air user roles in an organization do not need to correspond with roles in vRealize Automation business groups. For related information about vCloud Air user management, see the vCloud Air documentation.

Preparing Your Amazon AWS Environment

Prepare elements and user roles in your Amazon AWS environment, prepare Amazon AWS to communicate with the guest agent and Software bootstrap agent, and understand how Amazon AWS features map to vRealize Automation features.

Amazon AWS User Roles and Credentials Required for vRealize Automation

You must configure credentials in Amazon AWS with the permissions required for vRealize Automation to manage your environment.

vRealize Automation requires access keys for endpoint credentials and does not support user names and passwords.

■ Role and Permission Authorization in Amazon Web Services

While the Power User role in AWS provides an AWS Directory Service user or group with full access to AWS services and resources, it is not required. Lower privileged user roles are also supported. The AWS security policy that meets the needs of vRealize Automation functionality is:

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [
      "ec2:DescribeInstances",
      "ec2:DescribeImages",
      "ec2:DescribeKeyPairs",
      "ec2:DescribeVpcs",
      "ec2:DescribeSubnets",
      "ec2:DescribeSecurityGroups",
      "ec2:DescribeVolumes",

      "ec2:DescribeVpcAttribute",
      "ec2:DescribeAddresses",
```

```

        "ec2:DescribeAvailabilityZones",
        "ec2:DescribeImageAttribute",
        "ec2:DescribeInstanceAttribute",
        "ec2:DescribeVolumeStatus",
        "ec2:DescribeVpnConnections",

■ Authentication Credentials in Amazon Web Services

For management of Amazon Identity and Access Management (IAM) users and groups, you must be configured with AWS Full Access Administrator credentials.

When you create an AWS endpoint in vRA, you're prompted to enter a key and secret key. To obtain the access key needed to create the Amazon endpoint, the administrator must either request a key from a user who has AWS Full Access Administrator credentials or be additionally configured with the AWS Full Access Administrator policy. See [Create an Amazon Endpoint](#).

For information about enabling policies and roles, see the *AWS Identity and Access Management (IAM)* section of Amazon Web Services product documentation.

Allow Amazon AWS to Communicate with the Software Bootstrap Agent and Guest Agent

If you intend to provision application blueprints that contain Software, or if you want the ability to further customize provisioned machines by using the guest agent, you must enable connectivity between your Amazon AWS environment, where your machines are provisioned, and your vRealize Automation environment, where the agents download packages and receive instructions.

When you use vRealize Automation to provision Amazon AWS machines with the vRealize Automation guest agent and Software bootstrap agent, you must set up network-to-Amazon VPC connectivity so your provisioned machines can communicate back to vRealize Automation to customize your machines.

For more information about Amazon AWS VPC connectivity options, see the Amazon AWS documentation.

Using Optional Amazon Features

vRealize Automation supports several Amazon features, including Amazon Virtual Private Cloud, elastic load balancers, elastic IP addresses, and elastic block storage.

Using Amazon Security Groups

Specify at least one security group when creating an Amazon reservation. Each available region requires at least one specified security group.

A security group acts as a firewall to control access to a machine. Every region includes at least the default security group. Administrators can use the Amazon Web Services Management Console to create additional security groups, configure ports for Microsoft Remote Desktop Protocol or SSH, and set up a virtual private network for an Amazon VPN.

When you create an Amazon reservation or configure a machine component in the blueprint, you can choose from the list of security groups that are available to the specified Amazon account region. Security groups are imported during data collection.

For information about creating and using security groups in Amazon Web Services, see Amazon documentation.

Understanding Amazon Web Service Regions

Each Amazon Web Services account is represented by a cloud endpoint. When you create an Amazon Elastic Cloud Computing endpoint in vRealize Automation, regions are collected as compute resources. After the IaaS administrator selects compute resources for a business group, inventory and state data collections occur automatically.

Inventory data collection, which occurs automatically once a day, collects data about what is on a compute resource, such as the following data:

- Elastic IP addresses
- Elastic load balancers
- Elastic block storage volumes

State data collection occurs automatically every 15 minutes by default. It gathers information about the state of managed instances, which are instances that vRealize Automation creates. The following are examples of state data:

- Windows passwords
- State of machines in load balancers
- Elastic IP addresses

A fabric administrator can initiate inventory and state data collection and disable or change the frequency of inventory and state data collection.

Using Amazon Virtual Private Cloud

Amazon Virtual Private Cloud allows you to provision Amazon machine instances in a private section of the Amazon Web Services cloud.

Amazon Web Services users can use Amazon VPC to design a virtual network topology according to your specifications. You can assign an Amazon VPC in vRealize Automation. However, vRealize Automation does not track the cost of using the Amazon VPC.

When you provision using Amazon VPC, vRealize Automation expects there to be a VPC subnet from which Amazon obtains a primary IP address. This address is static until the instance is terminated. You can also use the elastic IP pool to also attach an elastic IP address to an instance in vRealize Automation. That would allow the user to keep the same IP if they are continually provisioning and tearing down an instance in Amazon Web Services.

Use the AWS Management Console to create the following elements:

- An Amazon VPC, which includes Internet gateways, routing table, security groups and subnets, and available IP addresses.
- An Amazon Virtual Private Network if users need to log in to Amazon machines instances outside of the AWS Management Console.

vRealize Automation users can perform the following tasks when working with an Amazon VPC:

- A fabric administrator can assign an Amazon VPC to a cloud reservation. See [Create an Amazon EC2 Reservation](#).
- A machine owner can assign an Amazon machine instance to an Amazon VPC.

For more information about creating an Amazon VPC, see Amazon Web Services documentation.

Using Elastic Load Balancers for Amazon Web Services

Elastic load balancers distribute incoming application traffic across Amazon Web Services instances. Amazon load balancing enables improved fault tolerance and performance.

Amazon makes elastic load balancing available for machines provisioned using Amazon EC2 blueprints.

The elastic load balancer must be available in the Amazon Web Services, Amazon Virtual Private Network and at the provisioning location. For example, if a load balancer is available in us-east1c and a machine location is us-east1b, the machine cannot use the available load balancer.

vRealize Automation does not create, manage, or monitor the elastic load balancers.

For information about creating Amazon elastic load balancers by using the Amazon Web Services Management Console, see Amazon Web Services documentation.

Using Elastic IP Addresses for Amazon Web Services

Using an elastic IP address allows you to rapidly fail over to another machine in a dynamic Amazon Web Services cloud environment. In vRealize Automation, the elastic IP address is available to all business groups that have rights to the region.

An administrator can allocate elastic IP addresses to your Amazon Web Services account by using the AWS Management Console. There are two groups of elastic IP addresses in any given a region, one range is allocated for non-Amazon VPC instances and another range is for Amazon VPCs. If you allocate addresses in a non-Amazon VPC region only, the addresses are not available in an Amazon VPC. The reverse is also true. If you allocate addresses in an Amazon VPC only, the addresses are not available in a non-Amazon VPC region.

The elastic IP address is associated with your Amazon Web Services account, not a particular machine, but only one machine at a time can use the address. The address remains associated with your Amazon Web Services account until you choose to release it. You can release it to map it to a specific machine instance.

An IaaS architect can add a custom property to a blueprint to assign an elastic IP address to machines during provisioning. Machine owners and administrators can view the elastic IP addresses assigned to machines, and machine owners or administrators with rights to edit machines can assign an elastic IP addresses after provisioning. However, if the address is already associated to a machine instance, and the instance is part of the Amazon Virtual Private Cloud deployment, Amazon does not assign the address.

For more information about creating and using Amazon elastic IP addresses, see Amazon Web Services documentation.

Using Elastic Block Storage for Amazon Web Services

Amazon elastic block storage provides block level storage volumes to use with an Amazon machine instance and Amazon Virtual Private Cloud. The storage volume can persist past the life of its associated Amazon machine instance in the Amazon Web Services cloud environment.

When you use an Amazon elastic block storage volume in conjunction with vRealize Automation, the following caveats apply:

- You cannot attach an existing elastic block storage volume when you provision a machine instance. However, if you create a new volume and request more than one machine at a time, the volume is created and attached to each instance. For example, if you create one volume named `volume_1` and request three machines, a volume is created for each machine. Three volumes named `volume_1` are created and attached to each machine. Each volume has a unique volume ID. Each volume is the same size and in the same location.
- The volume must be of the same operating system and in the same location as the machine to which you attach it.
- vRealize Automation does not manage the primary volume of an elastic block storage-backed instance.

For more information about Amazon elastic block storage, and details on how to enable it by using Amazon Web Services Management Console, see Amazon Web Services documentation.

Scenario: Configure Network-to-Amazon VPC Connectivity for a Proof of Concept Environment

As the IT professional setting up a proof of concept environment to evaluate vRealize Automation, you want to temporarily configure network-to-Amazon VPC connectivity to support the vRealize Automation Software feature.

Network-to-Amazon VPC connectivity is only required if you want to use the guest agent to customize provisioned machines, or if you want to include Software components in your blueprints. For a production environment, you would configure this connectivity officially through Amazon Web Services, but because you are working in a proof of concept environment, you want to create temporary network-to-Amazon VPC connectivity. You establish the SSH tunnel and then configure an Amazon reservation in vRealize Automation to route through your tunnel.

Prerequisites

- Install and fully configure vRealize Automation. See *Installing and Configuring vRealize Automation for the Rainpole Scenario*.
- Create an Amazon AWS security group called `TunnelGroup` and configure it to allow access on port 22.
- Create or identify a CentOS machine in your Amazon AWS `TunnelGroup` security group and note the following configurations:
 - Administrative user credentials, for example `root`.
 - Public IP address.
 - Private IP address.
- Create or identify a CentOS machine on the same local network as your vRealize Automation installation.

- Install OpenSSH SSHD Server on both tunnel machines.

Procedure

- 1 Log in to your Amazon AWS tunnel machine as the root user or similar.
- 2 Disable iptables.

```
# service iptables save
# service iptables stop
# chkconfig iptables off
```

- 3 Edit `/etc/ssh/sshd_config` to enable `AllowTCPForwarding` and `GatewayPorts`.
- 4 Restart the service.

```
/etc/init.d/sshd restart
```

- 5 Log in to the CentOS machine on the same local network as your vRealize Automation installation as the root user.
- 6 Invoke the SSH Tunnel from the local network machine to the Amazon AWS tunnel machine.

```
ssh -N -v -o "ServerAliveInterval 30" -o "ServerAliveCountMax 40" -o "TCPKeepAlive yes" \
-R 1442:vRealize_automation_appliance_fqdn:5480 \
-R 1443:vRealize_automation_appliance_fqdn:443 \
-R 1444:manager_service_fqdn:443 \
User of Amazon tunnel machine@Public IP Address of Amazon tunnel machine
```

You configured port forwarding to allow your Amazon AWS tunnel machine to access vRealize Automation resources, but your SSH tunnel does not function until you configure an Amazon reservation to route through the tunnel.

What to do next

- 1 Install the software bootstrap agent and the guest agent on a Windows or Linux reference machine to create an Amazon Machine Image that your IaaS architects can use to create blueprints. See [Preparing for Software Provisioning](#).
- 2 Configure your Amazon reservation in vRealize Automation to route through your SSH tunnel. See [Scenario: Create an Amazon Reservation for a Proof of Concept Environment](#).

Preparing Red Hat OpenStack Network and Security Features

vRealize Automation supports several features in OpenStack including security groups and floating IP addresses. Understand how these features work with vRealize Automation and configure them in your environment.

Using OpenStack Security Groups

Security groups allow you to specify rules to control network traffic over specific ports.

You can specify security groups in a reservation when requesting a machine. You can also specify an existing or on-demand NSX security group in the design canvas.

Security groups are imported during data collection.

Each available region requires at least one specified security group. When you create a reservation, the available security groups that are available to you in that region are displayed. Every region includes at least the default security group.

Additional security groups must be managed in the source resource. For more information about managing security groups for the various machines, see the OpenStack documentation.

Using Floating IP Addresses with OpenStack

You can assign floating IP addresses to a running virtual instance in OpenStack.

To enable assignment of floating IP addresses, you must configure IP forwarding and create a floating IP pool in Red Hat OpenStack. For more information, see the Red Hat OpenStack documentation.

You must entitle the Associate Floating IP and Disassociate Floating IP actions to machine owners. The entitled users can then associate a floating IP address to a provisioned machine from the external networks attached to the machine by selecting an available address from the floating IP address pool. After a floating IP address has been associated with a machine, a vRealize Automation user can select a Disassociate Floating IP option to view the currently assigned floating IP addresses and disassociate an address from a machine.

Preparing Your SCVMM Environment

Before you begin creating SCVMM templates and hardware profiles for use in vRealize Automation machine provisioning, you must understand the naming restrictions on template and hardware profile names, and configure SCVMM network and storage settings.

For related information about preparing your environment, see SCVMM requirements information in *Installing vRealize Automation 7.3*.

For related information about machine provisioning, see [Create a Hyper-V \(SCVMM\) Endpoint](#).

vRealize Automation does not support a deployment environment that uses an SCVMM private cloud configuration. vRealize Automation cannot currently collect from, allocate to, or provision based on SCVMM private clouds.

Template and Hardware Profile Naming

Because of naming conventions that SCVMM and vRealize Automation use for templates and hardware profiles, do not start your template or hardware profile names with the words temporary or profile. For example, the following terms are ignored during data collection:

- TemporaryTemplate
- Temporary Template
- TemporaryProfile

- Temporary Profile
- Profile

Required Network Configuration for SCVMM Clusters

SCVMM clusters only expose virtual networks to vRealize Automation, so you must have a 1:1 relationship between your virtual and logical networks. Using the SCVMM console, map each logical network to a virtual network and configure your SCVMM cluster to access machines through the virtual network.

Required Storage Configuration for SCVMM Clusters

On SCVMM Hyper-V clusters, vRealize Automation collects data and provisions on shared volumes only. Using the SCVMM console, configure your clusters to use shared resource volumes for storage.

Required Storage Configuration for Standalone SCVMM Hosts

For standalone SCVMM hosts, vRealize Automation collects data and provisions on the default virtual machine path. Using the SCVMM console, configure default virtual machine paths for your standalone hosts.

Configure Network-to-Azure VPC Connectivity

You must configure network-to-Azure connectivity if you want to use Software components in Azure blueprints.

Prerequisites

- Install and fully configure vRealize Automation. See *Installing and Configuring vRealize Automation for the Rainpole Scenario*.
- Create an Azure security group called TunnelGroup and configure it to allow access on port 22.
- Create or identify a CentOS machine in your Azure TunnelGroup security group and note the following configurations:
 - Administrative user credentials, for example *root*.
 - Public IP address.
 - Private IP address.
- Create or identify a CentOS machine on the same local network as your vRealize Automation installation.
- Install OpenSSH SSHD Server on both tunnel machines.

Procedure

- 1 Log in to your Azure tunnel machine as the root user or similar.

2 Disable iptables.

```
# service iptables save
# service iptables stop
# chkconfig iptables off
```

3 Edit /etc/ssh/sshd_config to enable AllowTCPForwarding and GatewayPorts.

4 Restart the service.

```
/etc/init.d/sshd restart
```

5 Log in to the CentOS machine on the same local network as your vRealize Automation installation as the root user.

6 Invoke the SSH Tunnel from the local network machine to the Azure tunnel machine.

```
ssh -N -v -o "ServerAliveInterval 30" -o "ServerAliveCountMax 40" -o "TCPKeepAlive yes" \

-R 1442:vRealize_automation_appliance_fqdn:5480 \
-R 1443:vRealize_automation_appliance_fqdn:443 \
-R 1444:manager_service_fqdn:443 \
User of Azure tunnel machine@Public IP Address of Azure tunnel machine
```

You configured port forwarding to allow your Azure tunnel machine to access vRealize Automation resources, but your SSH tunnel does not function until you configure an Azure reservation to route through the tunnel.

What to do next

- 1 Install the software bootstrap agent and the guest agent on a Windows or Linux reference machine to create an Azure Machine Image that your IaaS architects can use to create blueprints. See [Preparing for Software Provisioning](#).
- 2 Configure your Azure reservation in vRealize Automation to route through your SSH tunnel. See [Create a Reservation for Microsoft Azure](#).

Preparing for Machine Provisioning

Depending on your environment and your method of machine provisioning, you might need to configure elements outside of vRealize Automation.

For example, you might need to configure machine templates or machine images. You might also need to configure NSX settings or run vRealize Orchestrator workflows.

For related information about specifying ports when preparing to provision machines, see *Secure Configuration Guide* and *Reference Architecture* at [VMware vRealize Automation Information](#).

Choosing a Machine Provisioning Method to Prepare

For most machine provisioning methods, you must prepare some elements outside of vRealize Automation.

Table 1-5. Choosing a Machine Provisioning Method to Prepare

Scenario	Supported Endpoint	Agent Support	Provisioning Method	Pre-provisioning Preparations
Configure vRealize Automation to run custom Visual Basic scripts as additional steps in the machine life cycle, either before or after machine provisioning. For example, you could use a pre-provisioning script to generate certificates or security tokens before provisioning, and then a post-provisioning script to use the certificates and tokens after machine provisioning.	You can run Visual Basic scripts with any supported endpoint except Amazon AWS.	Depends on the provisioning method you choose.	Supported as an additional step in any provisioning method, but you cannot use Visual Basic scripts with Amazon AWS machines.	Checklist for Running Visual Basic Scripts During Provisioning
Provision application blueprints that automate the installation, configuration, and life cycle management of middleware and application deployment components such as Oracle, MySQL, WAR, and database Schemas.	<ul style="list-style-type: none"> ■ vSphere ■ vCloud Air ■ vCloud Director ■ Amazon AWS 	<ul style="list-style-type: none"> ■ (Required) Guest agent ■ (Required) Software bootstrap agent and guest agent 	<ul style="list-style-type: none"> ■ Clone ■ Clone (for vCloud Air or vCloud Director) ■ Linked clone ■ Amazon Machine Image 	If you want the ability to use Software components in your blueprints, prepare a provisioning method that supports the guest agent and Software bootstrap agent. For more information about preparing for Software, see Preparing for Software Provisioning .
Further customize machines after provisioning by using the guest agent.	All virtual endpoints and Amazon AWS.	<ul style="list-style-type: none"> ■ (Required) Guest agent ■ (Optional) Software bootstrap agent and guest agent 	Supported for all provisioning methods except Virtual Machine Image.	If you want the ability to customize machines after provisioning, select a provisioning method that supports the guest agent. For more information about the guest agent, see Using vRealize Automation Guest Agent in Provisioning .
Provision machines with no guest operating system. You can install an operating system after provisioning.	All virtual machine endpoints.	Not supported	Basic	No required pre-provisioning preparations outside of vRealize Automation.

Table 1-5. Choosing a Machine Provisioning Method to Prepare (Continued)

Scenario	Supported Endpoint	Agent Support	Provisioning Method	Pre-provisioning Preparations
Provision a space-efficient copy of a virtual machine called a linked clone. Linked clones are based on a snapshot of a VM and use a chain of delta disks to track differences from a parent machine.	vSphere	<ul style="list-style-type: none"> ■ (Optional) Guest agent ■ (Optional) Software bootstrap agent and guest agent 	Linked Clone	<p>You must have an existing vSphere virtual machine.</p> <p>If you want to support Software, you must install the guest agent and software bootstrap agent on the machine you intend to clone.</p> <p>The VM snapshot identified in the blueprint should be powered off before you provision the linked clone VMs.</p>
Provision a space-efficient copy of a virtual machine by using Net App FlexClone technology.	vSphere	(Optional) Guest agent	NetApp FlexClone	Checklist for Preparing to Provision by Cloning
Provision machines by cloning from a template object created from an existing Windows or Linux machine, called the reference machine, and a customization object.	<ul style="list-style-type: none"> ■ vSphere ■ KVM (RHEV) ■ SCVMM 	<ul style="list-style-type: none"> ■ (Optional) Guest agent ■ (Optional for vSphere only) Software bootstrap agent and guest agent 	Clone	<p>See Checklist for Preparing to Provision by Cloning.</p> <p>If you want to support Software, you must install the guest agent and software bootstrap agent on the vSpheremachine you intend to clone.</p>
Provision vCloud Air or vCloud Director machines by cloning from a template and customization object.	<ul style="list-style-type: none"> ■ vCloud Air ■ vCloud Director 	<ul style="list-style-type: none"> ■ (Optional) Guest agent ■ (Optional) Software bootstrap agent and guest agent 	vCloud Air or vCloud Director Cloning	<p>See Preparing for vCloud Air and vCloud Director Provisioning.</p> <p>If you want to support Software, create a template that contains the guest agent and software bootstrap agent. For vCloud Air, configure network connectivity between your vRealize Automation environment and your vCloud Air environment.</p>
Provision a machine by booting from an ISO image, using a kickstart or autoYaSt configuration file and a Linux distribution image to install the operating system on the machine.	<ul style="list-style-type: none"> ■ All virtual endpoints ■ Red Hat OpenStack 	Guest agent is installed as part of the preparation instructions.	Linux Kickstart	Preparing for Linux Kickstart Provisioning

Table 1-5. Choosing a Machine Provisioning Method to Prepare (Continued)

Scenario	Supported Endpoint	Agent Support	Provisioning Method	Pre-provisioning Preparations
Provision a machine and pass control to an SCCM task sequence to boot from an ISO image, deploy a Windows operating system, and install the vRealize Automation guest agent.	All virtual machine endpoints.	Guest agent is installed as part of the preparation instructions.	SCCM	Preparing for SCCM Provisioning
Provision a machine by booting into a WinPE environment and installing an operating system using a Windows Imaging File Format (WIM) image of an existing Windows reference machine.	<ul style="list-style-type: none"> ■ All virtual endpoints ■ Red Hat OpenStack 	Guest agent is required. When you create the WinPE image, you must manually insert the guest agent.	WIM	Preparing for WIM Provisioning
Launch an instance from a virtual machine image.	Red Hat OpenStack	Not supported	Virtual Machine Image	See Preparing for Virtual Machine Image Provisioning .
Launch an instance from an Amazon Machine Image.	Amazon AWS	<ul style="list-style-type: none"> ■ (Optional) Guest agent ■ (Optional) Software bootstrap agent and guest agent 	Amazon Machine Image	<p>Associate Amazon machine images and instance types with your Amazon AWS account.</p> <p>If you want to support Software, create an Amazon Machine Image that contains the guest agent and software bootstrap agent, and configure network-to-VPC connectivity between your Amazon AWS and vRealize Automation environments.</p>

Checklist for Running Visual Basic Scripts During Provisioning

You can configure vRealize Automation to run your custom Visual Basic scripts as additional steps in the machine life cycle, either before or after machine provisioning. For example, you could use a pre-provisioning script to generate certificates or security tokens before provisioning, and then a post-provisioning script to use the certificates and tokens after machine provisioning. You can run Visual Basic scripts with any provisioning method, but you cannot use Visual Basic scripts with Amazon AWS machines.

Table 1-6. Running Visual Basic Scripts During Provisioning Checklist

Task	Location	Details
<input type="checkbox"/> Install and configure the EPI agent for Visual Basic scripts.	Typically the Manager Service host	See <i>Installing vRealize Automation 7.3</i> .
<input type="checkbox"/> Create your visual basic scripts.	Machine where EPI agent is installed	<p>vRealize Automation includes a sample Visual Basic script <code>PrePostProvisioningExample.vbs</code> in the <code>Scripts</code> subdirectory of the EPI agent installation directory. This script contains a header to load all arguments into a dictionary, a body in which you can include your functions, and a footer to return updated custom properties to vRealize Automation.</p> <p>When executing a Visual Basic script, the EPI agent passes all machine custom properties as arguments to the script. To return updated property values to vRealize Automation, place these properties in a dictionary and call a function provided by vRealize Automation.</p>
<input type="checkbox"/> Gather the information required to include your scripts in blueprints.	<p>Capture information and transfer to your infrastructure architects</p> <hr/> <p>Note A fabric administrator can create a property group by using the property sets <code>ExternalPreProvisioningVbScript</code> and <code>ExternalPostProvisioningVbScript</code> to provide this required information. Doing so makes it easier for blueprint architects to include this information correctly in their blueprints.</p> <hr/>	<ul style="list-style-type: none"> ■ The complete path to the Visual Basic script, including the filename and extension. For example, <code>%System Drive%\Program Files (x86)\VMware\VCAC Agents\EPI_Agents\Scripts\SendEmail.vbs</code>. ■ To run a script before provisioning, instruct infrastructure architects to enter the complete path to the script as the value of the custom property <code>ExternalPreProvisioningVbScript</code>. To run a script after provisioning, they need to use the custom property <code>ExternalPostProvisioningVbScript</code>.

Using vRealize Automation Guest Agent in Provisioning

You can install the guest agent on reference machines to further customize a machine after deployment. You can use the reserved guest agent custom properties to perform basic customizations such as adding and formatting disks, or you can create your own custom scripts for the guest agent to run within the guest operating system of a provisioned machine.

After the deployment is completed and the customization specification is run (if you provided one), the guest agent creates an XML file that contains all of the deployed machine's custom properties `c:\VRMGuestAgent\site\workitem.xml`, completes any tasks assigned to it with the guest agent custom properties, and then deletes itself from the provisioned machine.

You can write your own custom scripts for the guest agent to run on deployed machines, and use custom properties on the machine blueprint to specify the location of those scripts and the order in which to run them. You can also use custom properties on the machine blueprint to pass custom property values to your scripts as parameters.

For example, you could use the guest agent to make the following customizations on deployed machines:

- Change the IP address
- Add or format drives
- Run security scripts
- Initialize another agent, for example Puppet or Chef

You can also provide an encrypted string as a custom property in a command line argument. This allows you to store encrypted information that the guest agent can decrypt and understand as a valid command line argument.

Note The Linux guest agent assigns static IPs during the create and cloning actions for Linux Kickstart and PXE provisioning relative to vRealize Automation custom properties in work items. The guest agent is unable to accommodate the newer consistent network naming scheme, such as in Ubuntu 16.x, when it assigns static IPs.

Your custom scripts do not have to be locally installed on the machine. As long as the provisioned machine has network access to the script location, the guest agent can access and run the scripts. This lowers maintenance costs because you can update your scripts without having to rebuild all of your templates.

You can configure security settings for the virtual machines to be provisioned by specifying information in a reservation, blueprint, or guest agent script. If the machines to be provisioned requires a guest agent, you must add a security rule that contains that requirement to the reservation or the blueprint. For example, if you use a default security policy that denies communication between all machines, and rely on a separate security policy to allow communication between specific machines, the guest agent might be unable to communicate with vRealize Automation during the customization phase. To avoid this problem during machine provisioning, use a default security policy that allows communication during the customization phase.

If you choose to install the guest agent to run custom scripts on provisioned machines, your blueprints must include the appropriate guest agent custom properties. For example, if you install the guest agent on a template for cloning, create a custom script that changes the provisioned machine's IP address, and place the script in a shared location, you need to include a number of custom properties in your blueprint.

Table 1-7. Custom Properties for Changing IP Address of a Provisioned Machine with a Guest Agent

Custom Property	Description
VirtualMachine.Admin.UseGuestAgent	Set to true to initialize the guest agent when the provisioned machine is started.
VirtualMachine.Customize.WaitComplete	Set to True to prevent the provisioning workflow from sending work items to the guest agent until all customizations are complete.

Table 1-7. Custom Properties for Changing IP Address of a Provisioned Machine with a Guest Agent (Continued)

Custom Property	Description
VirtualMachine.SoftwareN.ScriptPath	<p>Specifies the full path to an application's install script. The path must be a valid absolute path as seen by the guest operating system and must include the name of the script filename.</p> <p>You can pass custom property values as parameters to the script by inserting <code>{CustomPropertyName}</code> in the path string. For example, if you have a custom property named <code>ActivationKey</code> whose value is <code>1234</code>, the script path is <code>D:\InstallApp.bat -key {ActivationKey}</code>. The guest agent runs the command <code>D:\InstallApp.bat -key 1234</code>. Your script file can then be programmed to accept and use this value.</p> <p>Insert <code>{Owner}</code> to pass the machine owner name to the script.</p> <p>You can also pass custom property values as parameters to the script by inserting <code>{YourCustomProperty}</code> in the path string. For example, entering the value <code>\\vra-scripts.mycompany.com\scripts\changeIP.bat</code> runs the <code>changeIP.bat</code> script from a shared location, but entering the value <code>\\vra-scripts.mycompany.com\scripts\changeIP.bat {VirtualMachine.Network0.Address}</code> runs the <code>changeIP</code> script but also passes the value of the <code>VirtualMachine.Network0.Address</code> property to the script as a parameter.</p>
VirtualMachine.ScriptPath.Decrypt	<p>Allows vRealize Automation to obtain an encrypted string that is passed as a properly formatted <code>VirtualMachine.SoftwareN.ScriptPath</code> custom property statement to the guest command line.</p> <p>You can provide an encrypted string, such as your password, as a custom property in a command-line argument. This allows you to store encrypted information that the guest agent can decrypt and understand as a valid command-line argument. For example, the <code>VirtualMachine.Software0.ScriptPath = c:\dosomething.bat password</code> custom property string is not secure as it contains an actual password.</p> <p>To encrypt the password, you can create a vRealize Automation custom property, for example <code>MyPassword = password</code>, and enable encryption by selecting the available check box. The guest agent decrypts the <code>[MyPassword]</code> entry to the value in the custom property <code>MyPassword</code> and runs the script as <code>c:\dosomething.bat password</code>.</p> <ul style="list-style-type: none"> ■ Create custom property <code>MyPassword = password</code> where <code>password</code> is the value of your actual password. Enable encryption by selecting the available check box. ■ Set custom property <code>VirtualMachine.ScriptPath.Decrypt as VirtualMachine.ScriptPath.Decrypt = true</code>.

Table 1-7. Custom Properties for Changing IP Address of a Provisioned Machine with a Guest Agent (Continued)

Custom Property	Description
	<ul style="list-style-type: none"> Set custom property VirtualMachine.Software0.ScriptPath as VirtualMachine.Software0.ScriptPath = c:\dosomething.bat [MyPassword]. <p>If you set VirtualMachine.ScriptPath.Decrypt to false, or do not create the VirtualMachine.ScriptPath.Decrypt custom property, then the string inside the square brackets ([and]) is not decrypted.</p>

For more information about custom properties you can use with the guest agent, see *Custom Properties Reference*.

Configuring the Guest Agent to Trust a Server

Installing the public key PEM file for the vRealize Automation Manager Service Host in the correct guest agent folder is the most secure approach to configuring the guest agent to trust a server.

Locate the guest agent folder on each template for the `cert.pem` PEM file for the Manager Service Host to trust a server:

- Windows guest agent folder on each template that uses the gagent

```
C:\VRMGuestAgent\cert.pem
```

- Linux guest agent folder on each template that uses the gagent

```
/usr/share/gagent/cert.pem
```

If you do not put the `cert.pem` file in this location, the template reference machine cannot use the guest agent. For example, if you try to collect the public key information after the VM is started for by altering scripts, you break the security condition.

Additional considerations apply, depending on your configured environment:

- For WIM installations, you must add the public key PEM file contents to the console executable and user interface. The console flag is **/cert filename**.
- For RedHat kickstart installations, you must cut and paste the public key into the sample file, otherwise the guest agent fails to execute.
- For SCCM installation, the `cert.pem` file must reside in the VRMGuestAgent folder.

- For Linux vSphere installs, the `cert.pem` file must reside in the `/usr/share/gugent` folder.

Note You can optionally install software and guest agents together by downloading the following script from <https://APPLIANCE/software/index.html>. The script allows you to handle acceptance of SSL certificate fingerprints as you create the templates.

- Linux
`prepare_vra_template.sh`
- Windows
`prepare_vra_template.ps1`

If you install the software and guest agent together, you do not need to use the instructions in [Install the Guest Agent on a Linux Reference Machine](#) or [Install the Guest Agent on a Windows Reference Machine](#).

Install the Guest Agent on a Linux Reference Machine

Install the Linux guest agent on your reference machines to further customize machines after deployment.

Prerequisites

- Identify or create the reference machine.
- The guest agent files you download contain both `tar.gz` and RPM package formats. If your operating system cannot install `tar.gz` or RPM files, use a conversion tool to convert the installation files to your preferred package format.
- Establish secure trust between the guest agent and your Manager Service machine. See [Configuring the Guest Agent to Trust a Server](#).

Procedure

- 1 Navigate to the vRealize Automation appliance management console page.
For example: `https://va-hostname.domain.com`.
- 2 Click **Guest and software agents page** in the vRealize Automation component installation section of the page.
For example: `https://va-hostname.domain.com/software/index.html`.
The **Guest and Software Agent Installers** page opens, displaying links to available downloads.
- 3 Click **Linux guest agent packages** in the guest agent installers section of the page to download and save the `LinuxGuestAgentPkgs.zip` file.
- 4 Unpack the downloaded `LinuxGuestAgentPkgs.zip` file to create the `VraLinuxGuestAgent` folder.

- 5 Install the guest agent package that corresponds to the guest operating system you are deploying during provisioning.

- Navigate to the `VraLinuxGuestAgent` subdirectory that corresponds to the guest operating system to deploy during provisioning, for example `rhel32`.
- Locate your preferred package format or convert a package to your preferred package format.
- Install the guest agent package on your reference machine.

For example, to install the files from the RPM package, run `rpm -i gagent-gagent-7.1.0-4201531.i386.rpm`.

- 6 Configure the guest agent to communicate with the Manager Service by running `installgagent.sh Manager_Service_Hostname_fqdn:portnumber ssl platform`.

The default port number for the Manager Service is 443. Accepted platform values are `ec2`, `vcd`, `vca`, and `vsphere`.

Option	Description
If you are using a load balancer	<p>Enter the fully qualified domain name and port number of your Manager Service load balancer. For example:</p> <pre>cd /usr/share/gagent ./installgagent.sh load_balancer_manager_service.mycompany.com:443 ssl ec2</pre>
With no load balancer	<p>Enter the fully qualified domain name and port number of your Manager Service machine. For example:</p> <pre>cd /usr/share/gagent ./installgagent.sh manager_service_machine.mycompany.com:443 ssl vsphere</pre>

- 7 If deployed machines are not already configured to trust the Manager Service SSL certificate, you must install the `cert.pem` file on your reference machine to establish trust.
- For the most secure approach, obtain the `cert.pem` certificate and manually install the file on the reference machine.
 - For a more convenient approach, you can connect to the manager service load balancer or manager service machine and download the `cert.pem` certificate.

Option	Description
If you are using a load balancer	<p>As the root user on the reference machine, run the following command:</p> <pre>echo openssl s_client -connect manager_service_load_balancer.mycompany.com:443 sed -ne '/-BEGIN CERTIFICATE-/,/-END CERTIFICATE-/p' > cert.pem</pre>
With no load balancer	<p>As the root user on the reference machine, run the following command:</p> <pre>echo openssl s_client -connect manager_service_machine.mycompany.com:443 sed -ne '/-BEGIN CERTIFICATE-/,/-END CERTIFICATE-/p' > cert.pem</pre>

- 8 If you are installing the guest agent on a Ubuntu operating system, create symbolic links for shared objects by running one of the following command sets.

Option	Description
64-bit systems	<pre>cd /lib/x86_64-linux-gnu sudo ln -s libssl.so.1.0.0 libssl.so.10 sudo ln -s libcrypto.so.1.0.0 libcrypto.so.10</pre>
32-bit systems	<pre>cd /lib/i386-linux-gnu sudo ln -s libssl.so.1.0.0 libssl.so.10 sudo ln -s libcrypto.so.1.0.0 libcrypto.so.10</pre>

What to do next

Convert your reference machine into a template for cloning, an Amazon Machine Image, or a snapshot that your IaaS architects can use when creating blueprints.

Install the Guest Agent on a Windows Reference Machine

Install the vRealize Automation Windows guest agent on a Windows reference machine to run as a Windows service and enable further customization of machines.

Prerequisites

- Identify or create the reference machine.
- Establish secure trust between the guest agent and your Manager Service machine. See [Configuring the Guest Agent to Trust a Server](#).

Procedure

- 1 Navigate to the vRealize Automation appliance **Guest and Software Agent Installers** page:
<https://vrealize-automation-appliance-FQDN/software>
- 2 Under **Guest Agent Installers**, download and save the 32-bit or 64-bit executable to the root of the C: drive.

Note There is a command-line alternative to this procedure for guest agent installation. Instead of downloading the executables, you may go to **Windows Software Installers** on the Guest and Software Agent Installers page. There, you can download and run the `prepare_vra_template.ps1` PowerShell script:

```
PowerShell -NoProfile -ExecutionPolicy Bypass -Command prepare_vra_template.ps1
```

- 3 Extract the Windows guest agent files by running the executable.
Extraction creates C:\VRMGuestAgent and adds the files.
Do not rename C:\VRMGuestAgent.

4 Configure the guest agent to communicate with the Manager Service.

- a Open an elevated command prompt.
- b Navigate to `C:\VRMGuestAgent`.
- c Put the trusted Manager Service PEM file in the `C:\VRMGuestAgent\` directory to configure the guest agent to trust your Manager Service machine.
- d Run `win service -i -h Manager_Service_Hostname_fdqn:portnumber -p ssl`.

The default port number for the Manager Service is 443.

Option	Description
If you are using a load balancer	Enter the fully qualified domain name and port number of your Manager Service load balancer. For example, <code>win service -i -h load_balancer_manager_service.mycompany.com:443 -p ssl</code> .
With no load balancer	Enter the fully qualified domain name and port number of your Manager Service machine. For example, <code>win service -i -h manager_service_machine.mycompany.com:443 -p ssl</code> .
If you are preparing an Amazon machine image	You need to specify that you are using Amazon. For example, <code>win service -i -h manager_service_machine.mycompany.com:443:443 -p ssl -c ec2</code> .

The name of the Windows service is `VCACGuestAgentService`. You can find the installation log `VCAC-GuestAgentService.log` in `C:\VRMGuestAgent`.

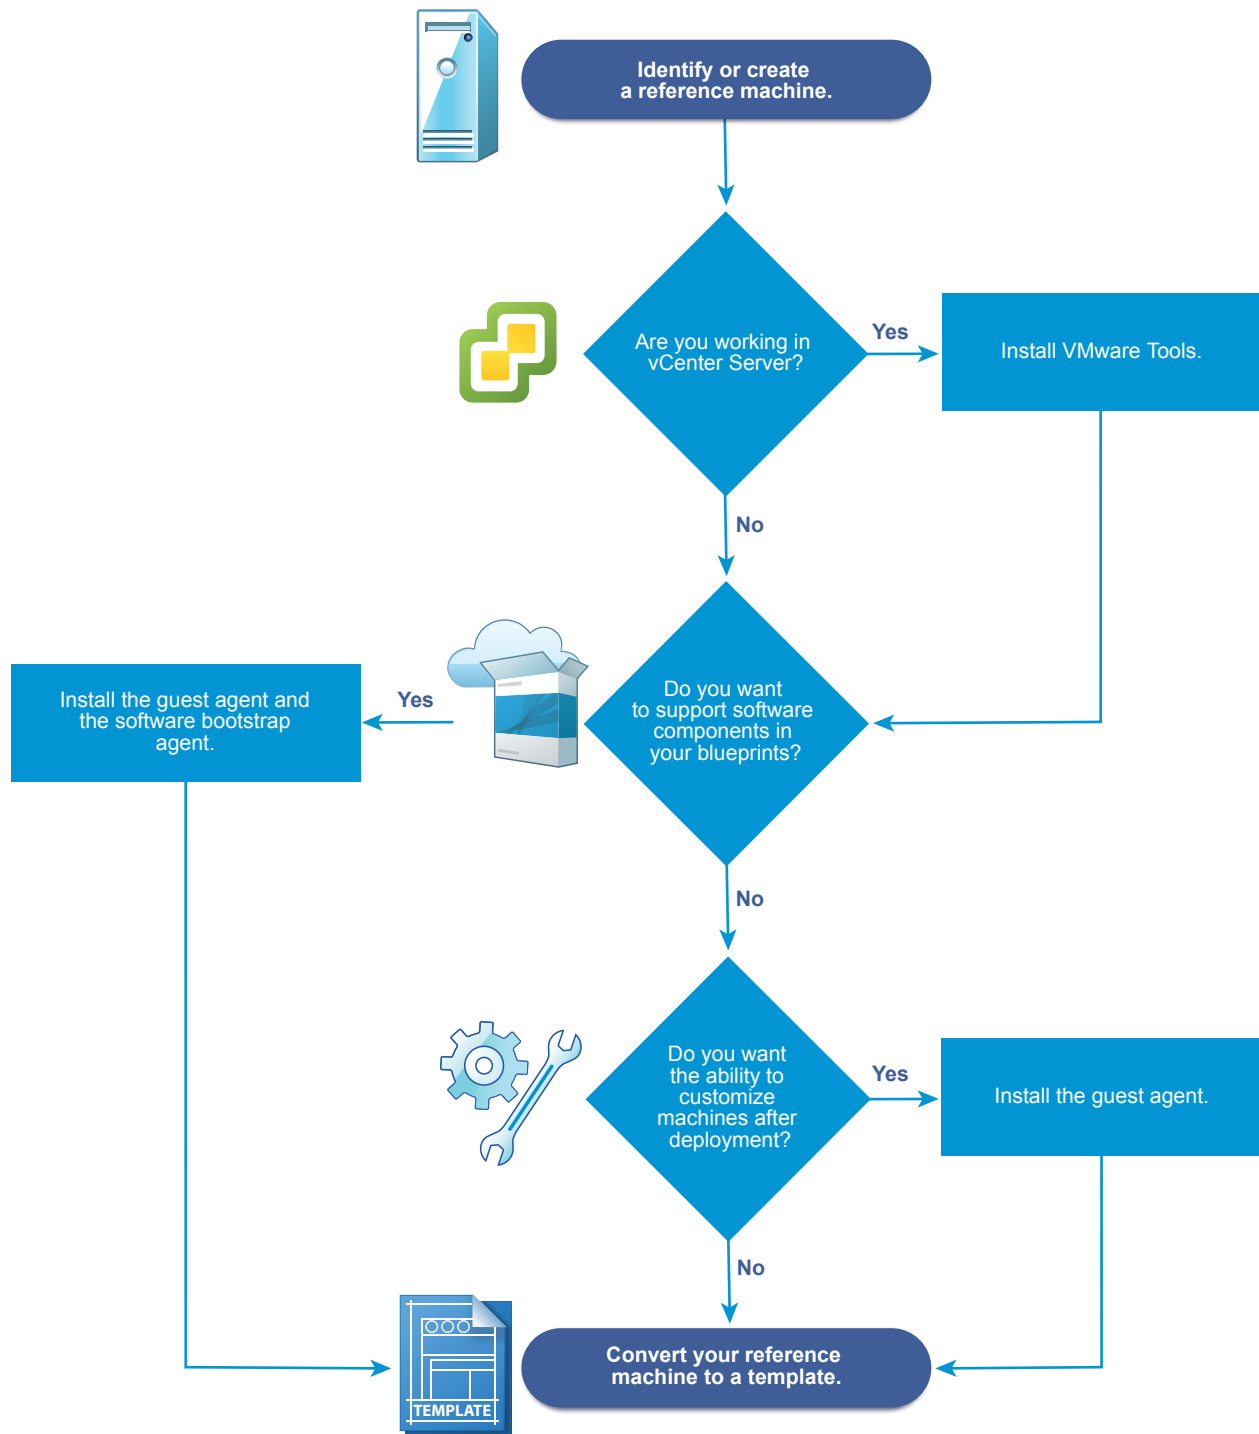

What to do next

Convert your reference machine into a template for cloning, an Amazon machine image, or a snapshot so your IaaS architects can use your template when creating blueprints.

Checklist for Preparing to Provision by Cloning

You must perform some preparation outside of vRealize Automation to create the template and the customization objects used to clone Linux and Windows virtual machines.

Cloning requires a template to clone from, created from a reference machine.

If you are provisioning a Windows machine by cloning, the only way to join the provisioned machine to an Active Directory domain is by using the customization specification from vCenter Server or by including a guest operating system profile with your SCVMM template. Machines provisioned by cloning cannot be placed in an Active Directory container during provisioning. You must do this manually after provisioning.

Table 1-8. Checklist for Preparing to Provision by Cloning

Task	Location	Details
<input type="checkbox"/> Identify or create the reference machine.	Hypervisor	See the documentation provided by your hypervisor.
<input type="checkbox"/> (Optional) If you want your clone template to support Software components, install the vRealize Automation guest agent and software bootstrap agent on your reference machine.	Reference machine	For Windows reference machines, see Prepare a Windows Reference Machine to Support Software . For Linux reference machines, see Prepare a Linux Reference Machine to Support Software .
<input type="checkbox"/> (Optional) If you do not need your clone template to support Software components, but you do want the ability to customize deployed machines, install the vRealize Automation guest agent on your reference machine.	Reference machine	See Using vRealize Automation Guest Agent in Provisioning .
<input type="checkbox"/> If you are working in a vCenter Server environment, install VMware Tools on the reference machine.	vCenter Server	See the VMware Tools documentation.
<input type="checkbox"/> Use the reference machine to create a template for cloning.	Hypervisor	The reference machine may be powered on or off. If you are cloning in vCenter Server, you can use a reference machine directly without creating a template. See the documentation provided by your hypervisor.
<input type="checkbox"/> Create the customization object to configure cloned machines by applying System Preparation Utility information or a Linux customization.	Hypervisor	If you are cloning for Linux you can install the Linux guest agent and provide external customization scripts instead of creating a customization object. If you are cloning with vCenter Server, you must provide the customization specification as the customization object. See the documentation provided by your hypervisor.
<input type="checkbox"/> Gather the information required to create blueprints that clone your template.	Capture information and transfer to your IaaS architects.	See Worksheet for Virtual Provisioning by Cloning .

Worksheet for Virtual Provisioning by Cloning

Complete the knowledge transfer worksheet to capture information about the template, customizations, and custom properties required to create clone blueprints for the templates you prepared in your environment. Not all of this information is required for every implementation. Use this worksheet as a guide, or copy and paste the worksheet tables into a word processing tool for editing.

Required Template and Reservation Information

Table 1-9. Template and Reservation Information Worksheet

Required Information	My Value	Details
Template name		
Reservations on which the template is available, or reservation policy to apply		To avoid errors during provisioning, ensure that the template is available on all reservations or create reservation policies that architects can use to restrict the blueprint to reservations where the template is available.
(vSphere only) Type of cloning requested for this template		<ul style="list-style-type: none"> ■ Clone ■ Linked Clone ■ NetApp FlexClone
Customization specification name (Required for cloning with static IP addresses)		You cannot perform customizations of Windows machines without a customization specification object.
(SCVMM only) ISO name		
(SCVMM only) Virtual hard disk		
(SCVMM only) Hardware profile to attach to provisioned machines		

Required Property Groups

You can complete the custom property information sections of the worksheet, or you can create property groups and ask architects to add your property groups to their blueprints instead of numerous individual custom properties.

Required vCenter Server Operating System

You must supply the guest operating system custom property for vCenter Server provisioning.

Table 1-10. vCenter Server Operating System

Custom Property	My Value	Description
VMware.VirtualCenter.OperatingSystem		Specifies the vCenter Server guest operating system version (VirtualMachineGuestOsIdentifier) with which vCenter Server creates the machine. This operating system version must match the operating system version to be installed on the provisioned machine. Administrators can create property groups using one of several property sets, for example, VMware[OS_Version]Properties, that are predefined to include the correct VMware.VirtualCenter.OperatingSystem values. This property is for virtual provisioning.

Visual Basic Script Information

If you configured vRealize Automation to run your custom Visual Basic scripts as additional steps in the machine life cycle, you must include information about the scripts in the blueprint.

Note A fabric administrator can create a property group by using the property sets ExternalPreProvisioningVbScript and ExternalPostProvisioningVbScript to provide this required information. Doing so makes it easier for blueprint architects to include this information correctly in their blueprints.

Table 1-11. Visual Basic Script Information

Custom Property	My Value	Description
ExternalPreProvisioningVbScript		Run a script before provisioning. Enter the complete path to the script including the filename and extension. <i>%System Drive%Program Files (x86)\VMware\VCAC Agents\EPI_Agents\Scripts\SendEmail.vbs.</i>
ExternalPostProvisioningVbScript		Run a script after provisioning. Enter the complete path to the script including the filename and extension. <i>%System Drive%Program Files (x86)\VMware\VCAC Agents\EPI_Agents\Scripts\SendEmail.vbs</i>

Linux Guest Agent Customization Script Information

If you configured your Linux template to use the guest agent for running customization scripts, you must include information about the scripts in the blueprint.

Table 1-12. Linux Guest Agent Customization Script Information Worksheet

Custom Property	My Value	Description
Linux.ExternalScript.Name		Specifies the name of an optional customization script, for example <code>config.sh</code> , that the Linux guest agent runs after the operating system is installed. This property is available for Linux machines cloned from templates on which the Linux agent is installed. If you specify an external script, you must also define its location by using the <code>Linux.ExternalScript.LocationType</code> and <code>Linux.ExternalScript.Path</code> properties.
Linux.ExternalScript.LocationType		Specifies the location type of the customization script named in the <code>Linux.ExternalScript.Name</code> property. This can be either <code>local</code> or <code>nfs</code> . You must also specify the script location using the <code>Linux.ExternalScript.Path</code> property. If the location type is <code>nfs</code> , also use the <code>Linux.ExternalScript.Server</code> property.
Linux.ExternalScript.Server		Specifies the name of the NFS server, for example <code>lab-ad.lab.local</code> , on which the Linux external customization script named in <code>Linux.ExternalScript.Name</code> is located.
Linux.ExternalScript.Path		Specifies the local path to the Linux customization script or the export path to the Linux customization on the NFS server. The value must begin with a forward slash and not include the file name, for example <code>/scripts/linux/config.sh</code> .

Other Guest Agent Custom Properties

If you installed the guest agent on your reference machine, you can use custom properties to further customize machines after deployment.

Table 1-13. Custom Properties for Customizing Cloned Machines with a Guest Agent Worksheet

Custom Property	My Value	Description
VirtualMachine.Admin.AddOwnerToAdmins		Set to True (default) to add the machine's owner, as specified by the VirtualMachine.Admin.Owner property, to the local administrators group on the machine.
VirtualMachine.Admin.AllowLogin		Set to True (default) to add the machine owner to the local remote desktop users group, as specified by the VirtualMachine.Admin.Owner property.
VirtualMachine.Admin.UseGuestAgent		If the guest agent is installed as a service on a template for cloning, set to True on the machine blueprint to enable the guest agent service on machines cloned from that template. When the machine is started, the guest agent service is started. Set to False to disable the guest agent. If set to False, the enhanced clone workflow will not use the guest agent for guest operating system tasks, reducing its functionality to VMwareCloneWorkflow. If not specified or set to anything other than False, the enhanced clone workflow sends work items to the guest agent.
VirtualMachine.DiskN.Active		Set to True (default) to specify that the machine's disk <i>N</i> is active. Set to False to specify that the machine's disk <i>N</i> is not active.

Table 1-13. Custom Properties for Customizing Cloned Machines with a Guest Agent Worksheet (Continued)

Custom Property	My Value	Description
<code>VirtualMachine.DiskN.Size</code>		<p>Defines the size in GB of disk <i>N</i>. For example, to give a size of 150 GB to a disk G, define the custom property <code>VirtualMachine.Disk0.Size</code> and enter a value of 150. Disk numbering must be sequential. By default a machine has one disk referred to by <code>VirtualMachine.Disk0.Size</code>, where size is specified by the storage value on the blueprint from which the machine is provisioned. The storage value on the blueprint user interface overwrites the value in the <code>VirtualMachine.Disk0.Size</code> property. The <code>VirtualMachine.Disk0.Size</code> property is not available as a custom property because of its relationship with the storage option on the blueprint. More disks can be added by specifying <code>VirtualMachine.Disk1.Size</code>, <code>VirtualMachine.Disk2.Size</code> and so on. <code>VirtualMachine.Admin.TotalDiskUsage</code> always represents the total of the <code>.DiskN.Size</code> properties plus the <code>VMware.Memory.Reservation</code> size allocation.</p>
<code>VirtualMachine.DiskN.Label</code>		<p>Specifies the label for a machine's disk <i>N</i>. The disk label maximum is 32 characters. Disk numbering must be sequential. When used with a guest agent, specifies the label of a machine's disk <i>N</i> inside the guest operating system.</p>
<code>VirtualMachine.DiskN.Letter</code>		<p>Specifies the drive letter or mount point of a machine's disk <i>N</i>. The default is C. For example, to specify the letter D for Disk 1, define the custom property as <code>VirtualMachine.Disk1.Letter</code> and enter the value D. Disk numbering must be sequential. When used in conjunction with a guest agent, this value specifies the drive letter or mount point under which an additional disk <i>N</i> is mounted by the guest agent in the guest operating system.</p>

Table 1-13. Custom Properties for Customizing Cloned Machines with a Guest Agent Worksheet (Continued)

Custom Property	My Value	Description
VirtualMachine.Admin.CustomizeGuestOSDelay		Specifies the time to wait after customization is complete and before starting the guest operating system customization. The value must be in HH:MM:SS format. If the value is not set, the default value is one minute (00:01:00). If you choose not to include this custom property, provisioning can fail if the virtual machine reboots before guest agent work items are completed, causing provisioning to fail.
VirtualMachine.Customize.WaitComplete		Set to True to prevent the provisioning workflow from sending work items to the guest agent until all customizations are complete.
VirtualMachine.SoftwareN.Name		Specifies the descriptive name of a software application <i>N</i> or script to install or run during provisioning. This is an optional and information-only property. It serves no real function for the enhanced clone workflow or the guest agent but it is useful for a custom software selection in a user interface or for software use reporting.
VirtualMachine.SoftwareN.ScriptPath		<p>Specifies the full path to an application's install script. The path must be a valid absolute path as seen by the guest operating system and must include the name of the script filename.</p> <p>You can pass custom property values as parameters to the script by inserting <i>{CustomPropertyName}</i> in the path string. For example, if you have a custom property named <i>ActivationKey</i> whose value is 1234, the script path is <code>D:\InstallApp.bat -key {ActivationKey}</code>. The guest agent runs the command <code>D:\InstallApp.bat -key 1234</code>. Your script file can then be programmed to accept and use this value.</p>

Table 1-13. Custom Properties for Customizing Cloned Machines with a Guest Agent Worksheet (Continued)

Custom Property	My Value	Description
VirtualMachine.SoftwareN.ISOName		Specifies the path and filename of the ISO file relative to the datastore root. The format is <code>/folder_name/subfolder_name/file_name.iso</code> . If a value is not specified, the ISO is not mounted.
VirtualMachine.SoftwareN.ISOLocation		Specifies the storage path that contains the ISO image file to be used by the application or script. Format the path as it appears on the host reservation, for example <code>netapp-1:it_nfs_1</code> . If a value is not specified, the ISO is not mounted.

Networking Custom Properties

You can specify configuration for specific network devices on a machine by using custom properties.

Common networking-related custom properties are listed in the following table. For additional and related custom properties, see *Custom Properties for Clone Blueprints* and *Custom Properties for Networking* in *Custom Properties Reference*.

Table 1-14. Custom Properties for Networking Configuration

Custom Property	My Value	Description
VirtualMachine.NetworkN.Addresses		Specifies the IP address of network device <i>N</i> in a machine provisioned with a static IP address.
VirtualMachine.NetworkN.MacAddressType		<p>Indicates whether the MAC address of network device <i>N</i> is generated or user-defined (static). This property is available for cloning.</p> <p>The default value is generated. If the value is static, you must also use <code>VirtualMachine.NetworkN.MacAddress</code> to specify the MAC address.</p> <p><code>VirtualMachine.NetworkN</code> custom properties are specific to individual blueprints and machines. When a machine is requested, network and IP address allocation is performed before the machine is assigned to a reservation. Because blueprints are not guaranteed to be allocated to a specific reservation, do not use this property on a reservation. This property is not supported for on-demand NAT or on-demand routed networks.</p>

Table 1-14. Custom Properties for Networking Configuration (Continued)

Custom Property	My Value	Description
VirtualMachine.NetworkN.MacAddress		<p>Specifies the MAC address of a network device <i>N</i>. This property is available for cloning.</p> <p>If the value of <code>VirtualMachine.NetworkN.MacAddressType</code> is generated, this property contains the generated address.</p> <p>If the value of <code>VirtualMachine.NetworkN.MacAddressType</code> is static, this property specifies the MAC address. For virtual machines provisioned on ESX server hosts, the address must be in the range specified by VMware. For details, see vSphere documentation.</p> <p><code>VirtualMachine.NetworkN</code> custom properties are specific to individual blueprints and machines. When a machine is requested, network and IP address allocation is performed before the machine is assigned to a reservation. Because blueprints are not guaranteed to be allocated to a specific reservation, do not use this property on a reservation. This property is not supported for on-demand NAT or on-demand routed networks.</p>

Table 1-14. Custom Properties for Networking Configuration (Continued)

Custom Property	My Value	Description
VirtualMachine.NetworkN.Name		<p>Specifies the name of the network to connect to, for example the network device <i>N</i> to which a machine is attached. This is equivalent to a network interface card (NIC).</p> <p>By default, a network is assigned from the network paths available on the reservation on which the machine is provisioned. Also see <code>VirtualMachine.NetworkN.AddressType</code> and <code>VirtualMachine.NetworkN.ProfileName</code>.</p> <p>You can ensure that a network device is connected to a specific network by setting the value of this property to the name of a network on an available reservation. For example, if you give properties for $N=0$ and 1, you get 2 NICs and their assigned value, provided the network is selected in the associated reservation.</p> <p><code>VirtualMachine.NetworkN</code> custom properties are specific to blueprints and machines. When a machine is requested, network and IP address allocation is performed before the machine is assigned to a reservation. Because blueprints are not guaranteed to be allocated to a specific reservation, do not use this property on a reservation. This property is not supported for on-demand NAT or on-demand routed networks.</p> <p>For an example of how to use this custom property to dynamically set <code>VirtualMachine.Network0.Name</code> based on a consumer's selection from a list of predefined available networks, see the Adding a Network Selection Drop-Down in vRA 7 blog post.</p>

Table 1-14. Custom Properties for Networking Configuration (Continued)

Custom Property	My Value	Description
VirtualMachine.NetworkN.PortID		<p>Specifies the port ID to use for network device <i>N</i> when using a dvPort group with a vSphere distributed switch.</p> <p>VirtualMachine.NetworkN custom properties are specific to individual blueprints and machines. When a machine is requested, network and IP address allocation is performed before the machine is assigned to a reservation. Because blueprints are not guaranteed to be allocated to a specific reservation, do not use this property on a reservation. This property is not supported for on-demand NAT or on-demand routed networks.</p>
VirtualMachine.NetworkN.ProfileName and VirtualMachine.NetworkN.NetworkProfileName		<p>Specifies the name of a network profile from which to assign a static IP address to network device <i>N</i> or from which to obtain the range of static IP addresses that can be assigned to network device <i>N</i> of a cloned machine, where <i>N</i>=0 for the first device, 1 for the second, and so on.</p> <ul style="list-style-type: none"> ■ Use VirtualMachine.NetworkN.ProfileName to select any network from the reservation regardless of whether it has a corresponding network profile. ■ Use VirtualMachine.NetworkN.NetworkProfileName to only select networks that have a corresponding network profile with the same name. <p>The network profile that the property points to is used to allocate an IP address. However, the provisioned machine is attached to any network that is selected in the reservation using a round-robin fashion model.</p>

Table 1-14. Custom Properties for Networking Configuration (Continued)

Custom Property	My Value	Description
<ul style="list-style-type: none"> VirtualMachine.NetworkN.SubnetMask VirtualMachine.NetworkN.Gateway VirtualMachine.NetworkN.PrimaryDns VirtualMachine.NetworkN.SecondaryDns VirtualMachine.NetworkN.PrimaryWins VirtualMachine.NetworkN.SecondaryWins VirtualMachine.NetworkN.DnsSuffix VirtualMachine.NetworkN.DnsSearchSuffixes 		<p>Appending a name allows you to create multiple versions of a custom property. For example, the following properties might list load balancing pools set up for general use and machines with high, moderate, and low performance requirements:</p> <ul style="list-style-type: none"> VCNS.LoadBalancerEdgePool.Names VCNS.LoadBalancerEdgePool.Names.moderate VCNS.LoadBalancerEdgePool.Names.high VCNS.LoadBalancerEdgePool.Names.low <p>Configures attributes of the network profile specified in VirtualMachine.NetworkN.ProfileName.</p>
VCNS.LoadBalancerEdgePool.Names.name		<p>Specifies the NSX load balancing pools to which the virtual machine is assigned during provisioning. The virtual machine is assigned to all service ports of all specified pools. The value is an <i>edge/pool</i> name or a list of <i>edge/pool</i> names separated by commas. Names are case-sensitive.</p> <p>Appending a name allows you to create multiple versions of a custom property. For example, the following properties might list load balancing pools set up for general use and machines with high, moderate, and low performance requirements:</p> <ul style="list-style-type: none"> VCNS.LoadBalancerEdgePool.Names VCNS.LoadBalancerEdgePool.Names.moderate VCNS.LoadBalancerEdgePool.Names.high VCNS.LoadBalancerEdgePool.Names.low

Table 1-14. Custom Properties for Networking Configuration (Continued)

Custom Property	My Value	Description
VCNS.SecurityGroup.Names. <i>name</i>		<p>Specifies the NSX security group or groups to which the virtual machine is assigned during provisioning. The value is a security group name or a list of names separated by commas. Names are case-sensitive.</p> <p>Appending a name allows you to create multiple versions of the property, which can be used separately or in combination. For example, the following properties can list security groups intended for general use, for the sales force, and for support:</p> <ul style="list-style-type: none"> ■ VCNS.SecurityGroup.Names ■ VCNS.SecurityGroup.Names.sale s ■ VCNS.SecurityGroup.Names.supp ort
VCNS.SecurityTag.Names. <i>name</i>		<p>Specifies the NSX security tag or tags to which the virtual machine is associated during provisioning. The value is a security tag name or a list of names separated by commas. Names are case-sensitive.</p> <p>Appending a name allows you to create multiple versions of the property, which can be used separately or in combination. For example, the following properties can list security tags intended for general use, for the sales force, and for support:</p> <ul style="list-style-type: none"> ■ VCNS.SecurityTag.Names ■ VCNS.SecurityTag.Names.sales ■ VCNS.SecurityTag.Names.supp ort

Preparing for vCloud Air and vCloud Director Provisioning

To prepare for provisioning vCloud Air and vCloud Director machines by using vRealize Automation, you must configure the organization virtual data center with templates and customization objects.

To provision vCloud Air and vCloud Director resources using vRealize Automation, the organization requires a template to clone from that consists of one or more machine resources.

Templates that are to be shared across organizations must be public. Only reserved templates are available to vRealize Automation as a cloning source.

Note When you create a blueprint by cloning from a template, that template's unique identifier becomes associated with the blueprint. When the blueprint is published to the vRealize Automation catalog and used in the provisioning and data collection processes, the associated template is recognized. If you delete the template in vCloud Air or vCloud Director, subsequent vRealize Automation provisioning and data collection fails because the associated template no longer exists. Instead of deleting and recreating a template, for example to upload an updated version, replace the template using the vCloud Air vCloud Director template replacement process. Using vCloud Air or vCloud Director to replace the template, rather than deleting and recreating the template, keeps the template's unique ID intact and allows provisioning and data collection to continue functioning.

The following overview illustrates the steps you need to perform before you use vRealize Automation to create endpoints and define reservations and blueprints. For more information about these administrative tasks, see vCloud Air and vCloud Director product documentation.

- 1 In vCloud Air or vCloud Director, create a template for cloning and add it to the organization catalog.
- 2 In vCloud Air or vCloud Director, use the template to specify custom settings such as passwords, domain, and scripts for the guest operating system on each machine.

You can use vRealize Automation to override some of these settings.

Customization can vary depending on the guest operating system of the resource.

- 3 In vCloud Air or vCloud Director, configure the catalog to be shared with everyone in the organization.
In vCloud Air or vCloud Director, configure account administrator access to applicable organizations to allow all users and groups in the organization to have access to the catalog. Without this sharing designation, the catalog templates are not be visible to endpoint or blueprint architects in vRealize Automation.
- 4 Gather the following information so that you can include it in blueprints:
 - Name of the vCloud Air or vCloud Director template.
 - Amount of total storage specified for the template.

Preparing for Linux Kickstart Provisioning

Linux Kickstart provisioning uses a configuration file to automate a Linux installation on a newly provisioned machine. To prepare for provisioning you must create a bootable ISO image and a Kickstart or autoYaST configuration file.

The following is a high-level overview of the steps required to prepare for Linux Kickstart provisioning:

- 1 Verify that a DHCP server is available on the network. vRealize Automation cannot provision machines by using Linux Kickstart provisioning unless DHCP is available.
- 2 Prepare the configuration file. In the configuration file, you must specify the locations of the vRealize Automation server and the Linux agent installation package. See [Prepare the Linux Kickstart Configuration Sample File](#).

- 3 Edit the `isolinux/isolinux.cfg` or `loader/isolinux.cfg` to specify the name and location of the configuration file and the appropriate Linux distribution source.
- 4 Create the boot ISO image and save it to the location required by your virtualization platform. See the documentation provided by your hypervisor for information about the required location.
- 5 (Optional) Add customization scripts.
 - a To specify post-installation customization scripts in the configuration file, see [Specify Custom Scripts in a kickstart/autoYaST Configuration File](#).
 - b To call Visual Basic scripts in blueprint, see [Checklist for Running Visual Basic Scripts During Provisioning](#).
- 6 Gather the following information so that blueprint architects can include it in their blueprints:
 - a The name and location of the ISO image.
 - b For vCenter Server integrations, the vCenter Server guest operating system version with which vCenter Server is to create the machine.

Note You can create a property group with the property set `BootIsoProperties` to include the required ISO information. This makes it easier to include this information correctly on blueprints.

Prepare the Linux Kickstart Configuration Sample File

vRealize Automation provides sample configuration files that you can modify and edit to suit your needs. There are several changes required to make the files usable.

Procedure

- 1 Navigate to the vRealize Automation appliance management console page.
For example: `https://va-hostname.domain.com`.
- 2 Click **Guest and software agents page** in the vRealize Automation component installation section of the page.
For example: `https://va-hostname.domain.com/software/index.html`.
The **Guest and Software Agent Installers** page opens, displaying links to available downloads.
- 3 Click **Linux guest agent packages** in the guest agent installers section of the page to download and save the `LinuxGuestAgentPkgs.zip` file.
- 4 Unpack the downloaded `LinuxGuestAgentPkgs.zip` file to create the `VraLinuxGuestAgent` folder.
- 5 Navigate to the `VraLinuxGuestAgent` subdirectory that corresponds to the guest operating system to deploy during provisioning.
For example: `rhel32`.
- 6 Open a file in the `samples` subdirectory that corresponds to your target system.
For example, `samples/sample-https-rhel6-x86.cfg`.

- 7 Replace all instances of the string `host=dcac.example.net` with the IP address or fully qualified domain name and port number for the Manager Service or the load balancer for the Manager Service.

Platform	Required Format
vSphere ESXi	IP Address, for example: <code>--host=172.20.9.59</code>
vSphere ESX	IP Address, for example: <code>--host=172.20.9.58</code>
SUSE 10	IP Address, for example: <code>--host=172.20.9.57</code>
All others	FQDN, for example: <code>--host=mycompany-host1.mycompany.local:443</code>

- 8 Locate each instance of `gugent.rpm` or `gugent.tar.gz` and replace the URL `rpm.example.net` with the location of the guest agent package.

For example:

```
rpm -i nfs:172.20.9.59/suseagent/gugent.rpm
```

- 9 Save the file to a location accessible to newly provisioned machines.

Specify Custom Scripts in a kickstart/autoYaST Configuration File

You can modify the configuration file to copy or install custom scripts onto newly provisioned machines. The Linux agent runs the scripts at the specified point in the workflow.

Your script can reference any of the `./properties.xml` files in the `/usr/share/gugent/site/workitem` directories.

Prerequisites

- Prepare a kickstart or autoYaST configuration file. See [Prepare the Linux Kickstart Configuration Sample File](#).
- Your script must return a non-zero value on failure to prevent machine provisioning failure.

Procedure

- 1 Create or identify the script you want to use.
- 2 Save the script as *NN_scriptname*.

NN is a two digit number. Scripts are executed in order from lowest to highest. If two scripts have the same number, the order is alphabetical based on *scriptname*.

- 3 Make your script executable.
- 4 Locate the post-installation section of your kickstart or autoYaST configuration file.

In kickstart, this is indicated by `%post`. In autoYaST, this is indicated by `post-scripts`.

- 5 Modify the post-installation section of the configuration file to copy or install your script into the `/usr/share/gugent/site/workitem` directory of your choice.

Custom scripts are most commonly run for virtual kickstart/autoYaST with the work items SetupOS (for create provisioning) and CustomizeOS (for clone provisioning), but you can run scripts at any point in the workflow.

For example, you can modify the configuration file to copy the script `11_addusers.sh` to the `/usr/share/gugent/site/SetupOS` directory on a newly provisioned machine by using the following command:

```
cp nfs:172.20.9.59/linuxscripts/11_addusers.sh /usr/share/gugent/site/SetupOS
```

The Linux agent runs the script in the order specified by the work item directory and the script file name.

Preparing for SCCM Provisioning

vRealize Automation boots a newly provisioned machine from an ISO image, and then passes control to the specified SCCM task sequence.

SCCM provisioning is supported for the deployment of Windows operating systems. Linux is not supported. Software distribution and updates are not supported.

The following is a high-level overview of the steps required to prepare for SCCM provisioning:

- 1 Consult with your network administrator to ensure that the following network requirements are met:
 - Communication with SCCM requires the NetBios name of the SCCM server. At least one Distributed Execution Manager (DEM) must be able to resolve the fully qualified name of the SCCM server to its NetBios name.
 - The SCCM server and the vRealize Automation server must be on the same network and available to each other.
- 2 Create a software package that includes the vRealize Automation guest agent. See [Create a Software Package for SCCM Provisioning](#).
- 3 In SCCM, create the desired task sequence for provisioning the machine. The final step must be to install the software package you created that contains the vRealize Automation guest agent. For information about creating task sequences and installing software packages, see SCCM documentation.
- 4 Create a zero touch boot ISO image for the task sequence. By default, SCCM creates a light touch boot ISO image. For information about configuring SCCM for zero touch ISO images, see SCCM documentation.
- 5 Copy the ISO image to the location required by your virtualization platform. If you do not know the appropriate location, refer to the documentation provided by your hypervisor.
- 6 Gather the following information so that blueprint architects can include it on blueprints:
 - a The name of the collection containing the task sequence.

- b The fully qualified domain name of the SCCM server on which the collection containing the sequence resides.
- c The site code of the SCCM server.
- d Administrator-level credentials for the SCCM server.
- e (Optional) For SCVMM integrations, the ISO, virtual hard disk, or hardware profile to attach to provisioned machines.

Create a Software Package for SCCM Provisioning

The final step in your SCCM task sequence must be to install a software package that includes the vRealize Automation guest agent.

Procedure

- 1 Navigate to the vRealize Automation appliance management console page.
For example: `https://va-hostname.domain.com`.
- 2 Click **Guest and software agents page** in the vRealize Automation component installation section of the page.
For example: `https://va-hostname.domain.com/software/index.html`.
The **Guest and Software Agent Installers** page opens, displaying links to available downloads.
- 3 Click Windows guest agent files (**32-bit**) or (**64-bit**) in the component installation section of the page to download and save the `GuestAgentInstaller.exe` or `GuestAgentInstaller_x64.exe` file.
- 4 Extract the Windows guest agent files to a location available to SCCM.
This produces the directory `C:\VRMGuestAgent`. Do not rename this directory.
- 5 Create a software package from the definition file `SCCMPackageDefinitionFile.sms`.
- 6 Make the software package available to your distribution point.
- 7 Select the contents of the extracted Windows guest agent files as your source files.

Preparing for WIM Provisioning

Provision a machine by booting into a WinPE environment and then install an operating system using a Windows Imaging File Format (WIM) image of an existing Windows reference machine.

The following is a high-level overview of the steps required to prepare for WIM provisioning:

- 1 Identify or create the staging area. The staging area should be a network directory that can be specified as a UNC path or mounted as a network drive by
 - The reference machine.
 - The system where you build the WinPE image.
 - The virtualization host where you provision the machines.

- 2 Ensure that the network has a DHCP server. vRealize Automation cannot provision machines with a WIM image unless DHCP is available.
- 3 Identify or create the reference machine in the virtualization platform you intend to use for provisioning. For vRealize Automation requirements, see [Reference Machine Requirements for WIM Provisioning](#). For information about creating a reference machine, see the documentation provided by your hypervisor.
- 4 Using the System Preparation Utility for Windows, prepare the reference machine's operating system for deployment. See [SysPrep Requirements for the Reference Machine](#).
- 5 Create the WIM image of the reference machine. Do not include any spaces in the WIM image file name or provisioning fails.
- 6 Create a WinPE image that contains the vRealize Automation guest agent.
 - (Optional) Create any custom scripts you want to use to customize provisioned machines and place them in the appropriate work item directory.
 - If you are using VirtIO for network or storage interfaces, you must ensure that the necessary drivers are included in your WinPE image and WIM image. See [Preparing for WIM Provisioning with VirtIO Drivers](#).

When you create the WinPE image, you must manually insert the vRealize Automation guest agent. See [Manually Insert the Guest Agent into a WinPE Image](#).

- 7 Place the WinPE image in the location required by your virtualization platform. If you do not know the location, see your hypervisor documentation.
- 8 Gather the following information to include in the blueprint:
 - a The name and location of the WinPE ISO image.
 - b The name of the WIM file, the UNC path to the WIM file, and the index used to extract the desired image from the WIM file.
 - c The user name and password under which to map the WIM image path to a network drive on the provisioned machine.
 - d (Optional) If you do not want to accept the default, K, the drive letter to which the WIM image path is mapped on the provisioned machine.
 - e For vCenter Server integrations, the vCenter Server guest operating system version with which vCenter Server is to create the machine.
 - f (Optional) For SCVMM integrations, the ISO, virtual hard disk, or hardware profile to attach to provisioned machines.

Note You can create a property group to include all of this required information. Using a property group makes it easier to include all the information correctly in blueprints.

1 [Reference Machine Requirements for WIM Provisioning](#)

WIM provisioning involves creating a WIM image from a reference machine. The reference machine must meet basic requirements for the WIM image to work for provisioning in vRealize Automation.

2 SysPrep Requirements for the Reference Machine

A SysPrep answer file contains several required settings that are used for WIM provisioning.

3 Preparing for WIM Provisioning with VirtIO Drivers

If you are using VirtIO for network or storage interfaces, you must ensure that the necessary drivers are included in your WinPE image and WIM image. VirtIO generally offers better performance when provisioning with KVM (RHEV).

4 Manually Insert the Guest Agent into a WinPE Image

You must manually insert the vRealize Automation guest agent into your WinPE image.

Reference Machine Requirements for WIM Provisioning

WIM provisioning involves creating a WIM image from a reference machine. The reference machine must meet basic requirements for the WIM image to work for provisioning in vRealize Automation.

The following is a high-level overview of the steps to prepare a reference machine:

- 1 If the operating system on your reference machine is Windows Server 2008 R2, Windows Server 2012, Windows 7, or Windows 8, the default installation creates a small partition on the system's hard disk in addition to the main partition. vRealize Automation does not support the use of WIM images created on such multi-partitioned reference machines. You must delete this partition during the installation process.
- 2 Install NET 4.5 and Windows Automated Installation Kit (AIK) for Windows 7 (including WinPE 3.0) on the reference machine.
- 3 If the reference machine operating system is Windows Server 2003 or Windows XP, reset the administrator password to be blank. (There is no password.)
- 4 (Optional) If you want to enable XenDesktop integration, install and configure a Citrix Virtual Desktop Agent.
- 5 (Optional) A Windows Management Instrumentation (WMI) agent is required to collect certain data from a Windows machine managed by vRealize Automation, for example the Active Directory status of a machine's owner. To ensure successful management of Windows machines, you must install a WMI agent (typically on the Manager Service host) and enable the agent to collect data from Windows machines. See *Installing vRealize Automation 7.3*.

SysPrep Requirements for the Reference Machine

A SysPrep answer file contains several required settings that are used for WIM provisioning.

Table 1-15. Windows Server or Windows XP reference machine SysPrep required settings

GuiUnattended Settings	Value
AutoLogon	Yes
AutoLogonCount	1

Table 1-15. Windows Server or Windows XP reference machine SysPrep required settings (Continued)

GuiUnattended Settings	Value
AutoLogonUsername	<i>username</i> (<i>username</i> and <i>password</i> are the credentials used for auto logon when the newly provisioned machine boots into the guest operating system. Administrator is typically used.)
AutoLogonPassword	<i>password</i> corresponding to the AutoLogonUsername.

Table 1-16. Required SysPrep Settings for reference machine that are not using Windows Server 2003 or Windows XP:

AutoLogon Settings	Value
Enabled	Yes
LogonCount	1
Username	<i>username</i> (<i>username</i> and <i>password</i> are the credentials used for auto logon when the newly provisioned machine boots into the guest operating system. Administrator is typically used.)
Password	<i>password</i> (<i>username</i> and <i>password</i> are the credentials used for auto logon when the newly provisioned machine boots into the guest operating system. Administrator is typically used.)

Note For reference machines that use a Windows platform newer than Windows Server 2003/Windows XP, you must set the autologon password by using the custom property Sysprep.GuiUnattended.AdminPassword. A convenient way to ensure this is done is to create a property group that includes this custom property so that tenant administrators and business group managers can include this information correctly in their blueprints.

Preparing for WIM Provisioning with VirtIO Drivers

If you are using VirtIO for network or storage interfaces, you must ensure that the necessary drivers are included in your WinPE image and WIM image. VirtIO generally offers better performance when provisioning with KVM (RHEV).

Windows drivers for VirtIO are included as part of the Red Hat Enterprise Virtualization and are located in the `/usr/share/virtio-win` directory on the file system of the Red Hat Enterprise Virtualization Manager. The drivers are also included in the Red Hat Enterprise Virtualization Guest Tools located `/usr/share/rhev-guest-tools-iso/rhev-tools-setup.iso`.

The high-level process for enabling WIM-based provisioning with VirtIO drivers is as follows:

- 1 Create a WIM image from a Windows reference machine with the VirtIO drivers installed or insert the drivers into an existing WIM image.
- 2 Copy the VirtIO driver files and insert the drivers into a WinPE image.

- 3 Upload the WinPE image ISO to the Red Hat Enterprise Virtualization ISO storage domains using the `rhevms-isouploader` command. For more information about managing ISO images in RHEV refer to the Red Hat documentation.
- 4 Create a KVM (RHEV) blueprint for WIM provisioning and select the WinPE ISO option. The custom property `VirtualMachine.Admin.DiskInterfaceType` must be included with the value **VirtIO**. A fabric administrator can include this information in a property group for inclusion on blueprints.

The custom properties `Image.ISO.Location` and `Image.ISO.Name` are not used for KVM (RHEV) blueprints.

Manually Insert the Guest Agent into a WinPE Image

You must manually insert the vRealize Automation guest agent into your WinPE image.

Prerequisites

- Select a Windows system from which the staging area you prepared is accessible and on which .NET 4.5 and Windows Automated Installation Kit (AIK) for Windows 7 (including WinPE 3.0) are installed.
- Create a WinPE.

Procedure

1 [Install the Guest Agent in a WinPE](#)

You must manually copy the guest agent files to your WinPE image.

2 [Configure the doagent.bat File](#)

You must manually configure the `doagent.bat` file.

3 [Configure the doagentc.bat File](#)

You must manually configure the `doagentc.bat` file.

4 [Configure the Guest Agent Properties Files](#)

You must manually configure the guest agent properties files.

Procedure

1 [Install the Guest Agent in a WinPE.](#)

2 [Configure the doagent.bat File.](#)

3 [Configure the doagentc.bat File.](#)

4 [Configure the Guest Agent Properties Files.](#)

Install the Guest Agent in a WinPE

You must manually copy the guest agent files to your WinPE image.

Prerequisites

- Select a Windows system from which the staging area you prepared is accessible and on which .NET 4.5 and Windows Automated Installation Kit (AIK) for Windows 7 (including WinPE 3.0) are installed.

- Create a WinPE.

Procedure

- ◆ Download and install the vRealize Automation guest agent from https://vRealize_VA_Hostname_fqdn/software/index.html.
 - a Download `GugentZip_version` to the C drive on the reference machine.

Select either `GuestAgentInstaller.exe` (32-bit) or `GuestAgentInstaller_x64.exe` (64-bit) depending on which is appropriate for your operating system.
 - b Right-click the file and select **Properties**.
 - c Click **General**.
 - d Click **Unblock**.
 - e Extract the files to `C:\`.

This produces the directory `C:\VRMGuestAgent`. Do not rename this directory.

What to do next

[Configure the doagent.bat File.](#)

Configure the doagent.bat File

You must manually configure the `doagent.bat` file.

Prerequisites

[Install the Guest Agent in a WinPE.](#)

Procedure

- 1 Navigate to the `VRMGuestAgent` directory within your WinPE Image.

For example: `C:\Program Files (x86)\VMware\Plugins\VRM Agent\VRMGuestAgent`.
- 2 Make a copy of the file `doagent-template.bat` and name it `doagent.bat`.
- 3 Open `doagent.bat` in a text editor.
- 4 Replace all instances of the string `#Dcac Hostname#` with the fully qualified domain name and port number of the IaaS Manager Service host.

Option	Description
If you are using a load balancer	Enter the fully qualified domain name and port of the load balancer for the IaaS Manager Service. For example, <pre>manager_service_LB.mycompany.com:443</pre>
With no load balancer	Enter the fully qualified domain name and port of the machine on which the IaaS Manager Service is installed. For example, <pre>manager_service.mycompany.com:443</pre>

- 5 Replace all instances of the string `#Protocol#` with the string `/ssl`.
- 6 Replace all instances of the string `#Comment#` with `REM` (`REM` must be followed by a trailing space).
- 7 (Optional) If you are using self-signed certificates, uncomment the `openssl` command.

```
echo QUIT | c:\VRMGuestAgent\bin\openssl s_client -connect
```

- 8 Save and close the file.
- 9 Edit the `Startnet.cmd` script for your WinPE to include the `doagentc.bat` as a custom script.

What to do next

[Configure the doagentc.bat File.](#)

Configure the doagentc.bat File

You must manually configure the `doagentc.bat` file.

Prerequisites

[Configure the doagentc.bat File.](#)

Procedure

- 1 Navigate to the `VRMGuestAgent` directory within your WinPE Image.
For example: `C:\Program Files (x86)\VMware\Plugins\VRM Agent\VRMGuestAgent`.
- 2 Make a copy of the file `doagentsvc-template.bat` and name it `doagentc.bat`.
- 3 Open `doagentc.bat` in a text editor.
- 4 Remove all instance of the string `#Comment#`.
- 5 Replace all instances of the string `#Dcac Hostname#` with the fully qualified domain name and port number of the Manager Service host.

The default port for the Manager Service is 443.

Option	Description
If you are using a load balancer	Enter the fully qualified domain name and port of the load balancer for the Manager Service. For example, <code>load_balancer_manager_service.mycompany.com:443</code>
With no load balancer	Enter the fully qualified domain name and port of the Manager Service. For example, <code>manager_service.mycompany.com:443</code>

- 6 Replace all instances of the string `#errorlevel#` with the character `1`.
- 7 Replace all instances of the string `#Protocol#` with the string `/ssl`.
- 8 Save and close the file.

What to do next

[Configure the Guest Agent Properties Files.](#)

Configure the Guest Agent Properties Files

You must manually configure the guest agent properties files.

Prerequisites

[Configure the doagentc.bat File.](#)

Procedure

- 1 Navigate to the VRMGuestAgent directory within your WinPE Image.
For example: C:\Program Files (x86)\VMware\Plugins\VRM Agent\VRMGuestAgent.
- 2 Make a copy of the file gument.properties and name it gument.properties.template.
- 3 Make a copy of the file gument.properties.template and name it gumentc.properties.
- 4 Open gument.properties in a text editor.
- 5 Replace all instances of the string GuestAgent.log the string
X:/VRMGuestAgent/GuestAgent.log.
- 6 Save and close the file.
- 7 Open gumentc.properties in a text editor.
- 8 Replace all instances of the string GuestAgent.log the string
C:/VRMGuestAgent/GuestAgent.log.
- 9 Save and close the file.

Preparing for Virtual Machine Image Provisioning

Before you provision instances with OpenStack, you must have virtual machine images and flavors configured in the OpenStack provider.

Virtual Machine Images

You can select an virtual machine image from a list of available images when creating blueprints for OpenStack resources.

A virtual machine image is a template that contains a software configuration, including an operating system. Virtual machine images are managed by the OpenStack provider and are imported during data collection.

If an image that is used in a blueprint is later deleted from the OpenStack provider, it is also removed from the blueprint. If all the images have been removed from a blueprint, the blueprint is disabled and cannot be used for machine requests until it is edited to add at least one image.

OpenStack Flavors

You can select one or more flavors when creating OpenStack blueprints.

OpenStack flavors are virtual hardware templates that define the machine resource specifications for instances provisioned in OpenStack. Flavors are managed by the OpenStack provider and are imported during data collection.

vRealize Automation supports several flavors of OpenStack. For the most current information about OpenStack flavor support, see the *vRealize Automation Support Matrix* at <https://www.vmware.com/support/pubs/vcac-pubs.html>.

Preparing for Amazon Machine Image Provisioning

Prepare your Amazon Machine Images and instance types for provisioning in vRealize Automation.

Understanding Amazon Machine Images

You can select an Amazon machine image from a list of available images when creating Amazon machine blueprints.

An Amazon machine image is a template that contains a software configuration, including an operating system. They are managed by Amazon Web Services accounts. vRealize Automation manages the instance types that are available for provisioning.

The Amazon machine image and instance type must be available in an Amazon region. Not all instance types are available in all regions.

You can select an Amazon machine image provided by Amazon Web Services, a user community, or the AWS Marketplace site. You can also create and optionally share your own Amazon machine images. A single Amazon machine image can be used to launch one or many instances.

The following considerations apply to Amazon machine images in the Amazon Web Services accounts from which you provision cloud machines:

- Each blueprint must specify an Amazon machine image.
A private Amazon machine image is available to a specific account and all its regions. A public Amazon machine image is available to all accounts, but only to a specific region in each account.
- When the blueprint is created, the specified Amazon machine image is selected from regions that have been data-collected. If multiple Amazon Web Services accounts are available, the business group manager must have rights to any private Amazon machine images. The Amazon machine image region and the specified user location restrict provisioning request to reservations that match the corresponding region and location.
- Use reservations and policies to distribute Amazon machine images in your Amazon Web Services accounts. Use policies to restrict provisioning from a blueprint to a particular set of reservations.

- vRealize Automation cannot create user accounts on a cloud machine. The first time a machine owner connects to a cloud machine, she must log in as an administrator and add her vRealize Automation user credentials or an administrator must do that for her. She can then log in using her vRealize Automation user credentials.

If the Amazon machine image generates the administrator password on every boot, the Edit Machine Record page displays the password. If it does not, you can find the password in the Amazon Web Services account. You can configure all Amazon machine images to generate the administrator password on every boot. You can also provide administrator password information to support users who provision machines for other users.

- To allow remote Microsoft Windows Management Instrumentation (WMI) requests on cloud machines provisioned in Amazon Web Services accounts, enable a Microsoft Windows Remote Management (WinRM) agent to collect data from Windows machines managed by vRealize Automation. See *Installing vRealize Automation 7.3*.
- A private Amazon machine image can be seen across tenants.

For related information, see *Amazon Machine Images (AMI)* topics in Amazon documentation.

Understanding Amazon Instance Types

An IaaS architect selects one or more Amazon instance types when creating Amazon EC2 blueprints. An IaaS administrator can add or remove instance types to control the choices available to the architects.

An Amazon EC2 instance is a virtual server that can run applications in Amazon Web Services. Instances are created from an Amazon machine image and by choosing an appropriate instance type.

To provision a machine in an Amazon Web Services account, an instance type is applied to the specified Amazon machine image. The available instance types are listed when architects create the Amazon EC2 blueprint. Architects select one or more instance types, and those instance types become choices available to the user when they request to provision a machine. The instance types must be supported in the designated region.

For related information, see *Selecting Instance Types* and *Amazon EC2 Instance Details* topics in Amazon documentation.

Add an Amazon Instance Type

Several instance types are supplied with vRealize Automation for use with Amazon blueprints. An administrator can add and remove instance types.

The machine instance types managed by IaaS administrators are available to blueprint architects when they create or edit an Amazon blueprint. Amazon machine images and instance types are made available through the Amazon Web Services product.

Prerequisites

Log in to the vRealize Automation console as an **IaaS administrator**.

Procedure

1 Click **Infrastructure > Administration > Instance Types**.

2 Click **New**.

3 Add a new instance type, specifying the following parameters.

Information about the available Amazon instances types and the setting values that you can specify for these parameters is available from Amazon Web Services documentation in *EC2 Instance Types - Amazon Web Services (AWS)* at aws.amazon.com/ec2 and *Instance Types* at docs.aws.amazon.com.

- Name
- API name
- Type Name
- IO Performance Name
- CPUs
- Memory (GB)
- Storage (GB)
- Compute Units

4 Click the **Save** icon (✓).

When IaaS architects create Amazon Web Services blueprints, they can use your custom instance types.

What to do next

Add the compute resources from your endpoint to a fabric group. See [Create a Fabric Group](#).

Scenario: Prepare vSphere Resources for Machine Provisioning in Rainpole

As the vSphere administrator creating templates for vRealize Automation, you want to use the vSphere Web Client to prepare for cloning CentOS machines in vRealize Automation.

You want to convert an existing CentOS reference machine into a vSphere template so you and your Rainpole architects can create blueprints for cloning CentOS machines in vRealize Automation. To prevent any conflicts that might arise from deploying multiple virtual machines with identical settings, you also want to create a general customization specification that you and your architects can use to create clone blueprints for Linux templates.

Procedure

1 Scenario: Convert Your CentOS Reference Machine into a Template for Rainpole

Using the vSphere Client, you convert your existing CentOS reference machine into a vSphere template for your vRealize Automation IaaS architects to reference as the base for their clone blueprints.

2 Scenario: Create a Customization Specification for Cloning Linux Machines in Rainpole

Using the vSphere Client, you create a standard customization specification for your vRealize Automation IaaS architects to use when they create clone blueprints for Linux machines.

Scenario: Convert Your CentOS Reference Machine into a Template for Rainpole

Using the vSphere Client, you convert your existing CentOS reference machine into a vSphere template for your vRealize Automation IaaS architects to reference as the base for their clone blueprints.

Procedure

1 Log in to your reference machine as the root user and prepare the machine for conversion.

a Remove udev persistence rules.

```
/bin/rm -f /etc/udev/rules.d/70*
```

b Enable machines cloned from this template to have their own unique identifiers.

```
/bin/sed -i '/^\(HWADDR\|UUID\)=/d'
/etc/sysconfig/network-scripts/ifcfg-eth0
```

c Power down the machine.

```
shutdown -h now
```

2 Log in to the vSphere Web Client as an administrator.

3 Click the **VM Options** tab.

4 Right-click your reference machine and select **Edit Settings**.

5 Enter **Rainpole_centos_63_x86** in the **VM Name** text box.

6 Even though your reference machine has a CentOS guest operating system, select **Red Hat Enterprise Linux 6 (64-bit)** from the **Guest OS Version** drop-down menu.

If you select CentOS, your template and customization specification might not work as expected.

- 7 Right-click your **Rainpole_centos_63_x86** reference machine in the vSphere Web Client and select **Template > Convert to Template**.

vCenter Server marks your Rainpole_centos_63_x86 reference machine as a template and displays the task in the Recent Tasks pane.

What to do next

To prevent any conflicts that might arise from deploying multiple virtual machines with identical settings, you create a general customization specification that you and your Rainpole architects can use to create clone blueprints for Linux templates.

Scenario: Create a Customization Specification for Cloning Linux Machines in Rainpole

Using the vSphere Client, you create a standard customization specification for your vRealize Automation IaaS architects to use when they create clone blueprints for Linux machines.

Procedure

- 1 On the home page, click **Customization Specification Manager** to open the wizard.
- 2 Click the **New** icon.
- 3 Specify properties.
 - a Select **Linux** from the **Target VM Operating System** drop-down menu.
 - b Enter **Linux** in the **Customization Spec Name** text box.
 - c Enter **Rainpole Linux cloning with vRealize Automation** in the **Description** text box.
 - d Click **Next**.
- 4 Set computer name.
 - a Select **Use the virtual machine name**.
 - b Enter the domain on which cloned machines are going to be provisioned in the **Domain name** text box.

For example, **rainpole.local**.
 - c Click **Next**.
- 5 Configure time zone settings.
- 6 Click **Next**.
- 7 Select **Use standard network settings for the guest operating system, including enabling DHCP on all network interfaces**.
- 8 Follow the prompts to enter the remaining required information.
- 9 On the **Ready to complete** page, review your selections and click **Finish**.

You have a general customization specification that you can use to create blueprints for cloning Linux machines.

What to do next

Log in to the vRealize Automation console as the configuration administrator you created during the installation and request the catalog items that quickly set up your proof of concept.

Preparing for Software Provisioning

Use Software to deploy applications and middleware as part of the vRealize Automation provisioning process for vSphere, vCloud Director, vCloud Air, and Amazon AWS machines.

You can deploy Software on machines if your blueprint supports Software and if you install the guest agent and software bootstrap agent on your reference machines before you convert them into templates, snapshots, or Amazon Machine Images.

For related information about specifying ports when preparing for provisioning, see *Secure Configuration Guide* and *Reference Architecture* at [VMware vRealize Automation Information](#).

Table 1-17. Provisioning Methods that Support Software

Machine Type	Provisioning Method	Required Preparation
vSphere	Clone	A clone blueprint provisions a complete and independent virtual machine based on a vCenter Server virtual machine template. If you want your templates for cloning to support Software components, install the guest agent and software bootstrap agent on your reference machine as you prepare a template for cloning. See Checklist for Preparing to Provision by Cloning .
vSphere	Linked Clone	A linked clone blueprint provisions a space-efficient copy of a vSphere machine based on a snapshot, using a chain of delta disks to track differences from the parent machine. If you want your linked clone blueprints to support Software components, install the guest agent and software bootstrap agent on the machine before you take the snapshot. If your snapshot machine was cloned from a template that supports Software, the required agents are already installed.
vCloud Director	Clone	A clone blueprint provisions a complete and independent virtual machine based on a vCenter Server virtual machine template. If you want your templates for cloning to support Software components, install the guest agent and software bootstrap agent on your reference machine as you prepare a template for cloning. See Checklist for Preparing to Provision by Cloning .

Table 1-17. Provisioning Methods that Support Software (Continued)

Machine Type	Provisioning Method	Required Preparation
vCloud Air	Clone	A clone blueprint provisions a complete and independent virtual machine based on a vCenter Server virtual machine template. If you want your templates for cloning to support Software components, install the guest agent and software bootstrap agent on your reference machine as you prepare a template for cloning. See Checklist for Preparing to Provision by Cloning .
Amazon AWS	Amazon Machine Image	An Amazon machine image is a template that contains a software configuration, including an operating system. If you want to create an Amazon machine image that supports Software, connect to a running Amazon AWS instance that uses an EBS volume for the root device. Install the guest agent and software bootstrap agent on the reference machine, then create an Amazon Machine Image from your instance. For instruction on creating Amazon EBS-backed AMIs, see the Amazon AWS documentation. For the guest agent and Software bootstrap agent to function on provisioned machines, you must configure network-to-VPC connectivity.

Preparing to Provision Machines with Software

To support Software components, you must install the guest agent and Software bootstrap agent on your reference machine before you convert to a template for cloning, create an Amazon machine image, or take a snapshot.

Prepare a Windows Reference Machine to Support Software

You use a single script to install the Java Runtime Environment, guest agent, and Software bootstrap agent on a Windows reference machine. From the reference machine, you can create a template for cloning, a snapshot, or an Amazon machine image that supports Software components.

Software supports scripting with Windows CMD and PowerShell 2.0.

Important The startup process must not be interrupted. Configure the virtual machine so that nothing pauses the virtual machine startup process before reaching the login prompt. For example, verify that no processes or scripts prompt for user interaction while the virtual machine starts.

Prerequisites

- Identify or create a Windows reference machine.
- Establish secure trust between the reference machine and your IaaS Manager Service host. See [Configuring the Guest Agent to Trust a Server](#).
- On the reference machine, verify that the Darwin user has Log on as a service access.
- If you plan to remotely access the machine for troubleshooting or other reasons, install Remote Desktop Services (RDS).
- Remove network configuration artifacts from the network configuration files.

Procedure

- 1 Log in to the Windows reference server as an administrator.
- 2 Open a browser to the software download page on the vRealize Automation appliance.
`https://vrealize-automation-appliance-FQDN/software`
- 3 Save the template ZIP to the Windows server.
`prepare_vra_template_windows.zip`
- 4 Extract the ZIP contents to a folder, and run the batch file.
`.\prepare_vra_template.bat`
- 5 Follow the prompts.
- 6 When finished, shut down the Windows virtual machine.

The script removes any previous guest or Software bootstrap agents, and installs the supported versions of the Java Runtime Environment, the guest agent, and the Software bootstrap agent.

What to do next

Convert the reference machine into a template for cloning, a snapshot, or an Amazon machine image. Each supports Software components, and infrastructure architects can use them when creating blueprints.

Prepare a Linux Reference Machine to Support Software

You use a single script to install the Java Runtime Environment, guest agent, and Software bootstrap agent on your Linux reference machine. From the reference machine, you can create a template for cloning, a snapshot, or an Amazon machine image that supports Software components.

Software supports scripting with Bash.

Important The boot process must not be interrupted. Configure the virtual machine so that nothing pauses the virtual machine boot process before reaching the login prompt. For example, verify that no processes or scripts prompt for user interaction while the virtual machine starts.

Prerequisites

- Identify or create a Linux reference machine.
- Verify that the following commands are available, depending on your Linux system:
 - `yum` or `apt-get`
 - `wget` or `curl`
 - `python`
 - `dmidecode` as required by cloud providers

- Common requirements such as `sed`, `awk`, `perl`, `chkconfig`, `unzip`, and `grep` depending on your Linux distribution

You might also use an editor to inspect the downloaded `prepare_vra_template.sh` script, which exposes the commands that it uses.

- If you plan to remotely access the machine for troubleshooting or other reasons, install OpenSSH.
- Remove network configuration artifacts from the network configuration files.

Procedure

- 1 Log in to your reference machine as root.

- 2 Download the template tar.gz package from the vRealize Automation appliance.

```
wget https://vrealize-automation-appliance-  
FQDN/software/download/prepare_vra_template.tar.gz
```

If your environment is using self-signed certificates, you might need the `--no-check-certificate` option.

```
wget --no-check-certificate https://vrealize-automation-appliance-  
FQDN/software/download/prepare_vra_template.tar.gz
```

- 3 Untar the package.

```
tar -xvf prepare_vra_template.tar.gz
```

- 4 In the untar output, find the installer script, and make it executable.

```
chmod +x prepare_vra_template.sh
```

- 5 Run the installer script.

```
./prepare_vra_template.sh
```

If you need information about non-interactive options and expected values, see the script help.

```
./prepare_vra_template.sh --help
```

- 6 Follow the prompts.

A confirmation appears when installation succeeds. If errors and logs appear, resolve the errors and rerun the script.

- 7 When finished, shut down the Linux virtual machine.

The script removes any previous guest or Software bootstrap agents, and installs the supported versions of the Java Runtime Environment, the guest agent, and the Software bootstrap agent.

What to do next

On your hypervisor or cloud provider, turn the reference machine into a template for cloning, a snapshot, or an Amazon machine image. Each supports Software components, and infrastructure architects can use them when creating blueprints.

Updating Existing Virtual Machine Templates in vRealize Automation

If you are updating your templates, Amazon Machine Images, or snapshots for the latest version of the Windows Software bootstrap agent, or if you are manually updating to the latest Linux Software bootstrap agent instead of using the `prepare_vra_template.sh` script, you need to remove any existing versions and delete any logs.

Linux

For Linux reference machines, running the `prepare_vra_template.sh` script resets the agent and removes any logs for you before reinstalling. However, if you intend to manually install, you need to log in to the reference machine as the root user and run the command to reset and remove the artifacts.

```
/opt/vmware-appdirector/agent-bootstrap/agent_reset.sh
```

Windows

For Windows reference machines, you remove the existing Software agent bootstrap and vRealize Automation 6.0 or later guest agent, and delete any existing runtime log files. In a PowerShell command window, run the commands to remove the agent and artifacts.

```
c:\opt\vmware-appdirector\agent-bootstrap\agent_bootstrap_removal.bat  
c:\opt\vmware-appdirector\agent-bootstrap\agent_reset.bat
```

Scenario: Prepare a vSphere CentOS Template for Clone Machine and Software Component Blueprints

As a vCenter Server administrator, you want to prepare a vSphere template that your vRealize Automation architects can use to clone Linux CentOS machines. You want to ensure that your template supports blueprints with software components, so you install the guest agent and the software bootstrap agent before you turn your reference machine into a template.

Prerequisites

- Identify or create a Linux CentOS reference machine with VMware Tools installed. Include at least one Network Adapter to provide internet connectivity in case blueprint architects do not add this functionality at the blueprint level. For information about creating virtual machines, see the vSphere documentation.
- You must be connected to a vCenter Server to convert a virtual machine to a template. You cannot create templates if you connect the vSphere Client directly to an vSphere ESXi host.

Procedure

1 Scenario: Prepare Your Reference Machine for Guest Agent Customizations and Software Components

So that your template can support software components, you install the software bootstrap agent and its prerequisite, the guest agent, on your reference machine. The agents ensure that vRealize Automation architects who use your template can include software components in their blueprints.

2 Scenario: Convert Your CentOS Reference Machine into a Template

After you install the guest agent and software bootstrap agent onto your reference machine, you turn your reference machine into a template that vRealize Automation architects can use to create clone machine blueprints.

3 Scenario: Create a Customization Specification for vSphere Cloning

Create a customization specification for your blueprint architects to use with your `cpb_centos_63_x84` template.

You created a template and customization specification from your reference machine that blueprint architects can use to create vRealize Automation blueprints that clone Linux CentOS machines. Because you installed the Software bootstrap agent and the guest agent on your reference machine, architects can use your template to create elaborate catalog item blueprints that include Software components or other guest agent customizations such as running scripts or formatting disks. Because you installed VMware Tools, architects and catalog administrators can allow users to perform actions against machines, such as reconfigure, snapshot, and reboot.

What to do next

After you configure vRealize Automation users, groups, and resources, you can use your template and customization specification to create a machine blueprint for cloning. See *Installing and Configuring vRealize Automation for the Rainpole Scenario*.

Scenario: Prepare Your Reference Machine for Guest Agent Customizations and Software Components

So that your template can support software components, you install the software bootstrap agent and its prerequisite, the guest agent, on your reference machine. The agents ensure that vRealize Automation architects who use your template can include software components in their blueprints.

To simplify the process, you download and run a vRealize Automation script that installs both agents, instead of downloading and installing separate packages.

The script also connects to the Manager Service instance and downloads the SSL certificate, which establishes trust between the Manager Service and machines deployed from the template. Note that having the script download the certificate is less secure than manually obtaining the Manager Service SSL certificate and installing it on your reference machine in `/usr/share/gugent/cert.pem`.

Procedure

- 1 In your Web browser, open the following URL.
`https://vrealize-automation-appliance-FQDN/software/index.html`
- 2 Save the `prepare_vra_template.sh` script to your reference machine.
- 3 On the reference machine, make `prepare_vra_template.sh` executable.

```
chmod +x prepare_vra_template.sh
```

- 4 Run `prepare_vra_template.sh`.

```
./prepare_vra_template.sh
```

- 5 Follow the prompts.

If you need non-interactive information about options and values,
enter `./prepare_vra_template.sh --help`.

A confirmation message appears when installation finishes. If error messages and logs appear, correct the issues and rerun the script.

Scenario: Convert Your CentOS Reference Machine into a Template

After you install the guest agent and software bootstrap agent onto your reference machine, you turn your reference machine into a template that vRealize Automation architects can use to create clone machine blueprints.

After you convert your reference machine to a template, you cannot edit or power on the template unless you convert it back to a virtual machine.

Procedure

- 1 Log in to your reference machine as the root user and prepare the machine for conversion.
 - a Remove udev persistence rules.

```
/bin/rm -f /etc/udev/rules.d/70*
```

- b Enable machines cloned from this template to have their own unique identifiers.

```
/bin/sed -i '/^\(HWADDR\|UUID\)=/d'  
/etc/sysconfig/network-scripts/ifcfg-eth0
```

- c If you rebooted or reconfigured the reference machine after installing the software bootstrap agent, reset the agent.

```
/opt/vmware-appdirector/agent-bootstrap/agent_reset.sh
```

- d Power down the machine.

```
shutdown -h now
```

- 2 Log in to the vSphere Web Client as an administrator.
- 3 Right-click your reference machine and select **Edit Settings**.
- 4 Enter **cpb_centos_63_x84** in the **VM Name** text box.
- 5 Even though your reference machine has a CentOS guest operating system, select **Red Hat Enterprise Linux 6 (64-bit)** from the **Guest OS Version** drop-down menu.
If you select CentOS, your template and customization specification might not work as expected.
- 6 Right-click your reference machine in the vSphere Web Client and select **Template > Convert to Template**.

vCenter Server marks your **cpb_centos_63_x84** reference machine as a template and displays the task in the Recent Tasks pane. If you have already brought your vSphere environment under vRealize Automation management, your template is discovered during the next automated data collection. If you have not configured your vRealize Automation yet, the template is collected during that process.

Scenario: Create a Customization Specification for vSphere Cloning

Create a customization specification for your blueprint architects to use with your **cpb_centos_63_x84** template.

Procedure

- 1 Log in to the vSphere Web Client as an administrator.
- 2 On the home page, click **Customization Specification Manager** to open the wizard.
- 3 Click the **New** icon.
- 4 Click the **New** icon.
- 5 Specify properties.
 - a Select **Linux** from the **Target VM Operating System** drop-down menu.
 - b Enter **Customspecs** in the **Customization Spec Name** text box.
 - c Enter **cpb_centos_63_x84 cloning with vRealize Automation** in the **Description** text box.
 - d Click **Next**.

- 6 Set computer name.
 - a Select **Use the virtual machine name**.
 - b Enter the domain on which cloned machines are going to be provisioned in the **Domain name** text box.
 - c Click **Next**.
- 7 Configure time zone settings.
- 8 Click **Next**.
- 9 Select **Use standard network settings for the guest operating system, including enabling DHCP on all network interfaces**.

Fabric administrators and infrastructure architects handle network settings for provisioned machine by creating and using Network profiles in vRealize Automation.
- 10 Follow the prompts to enter the remaining required information.
- 11 On the **Ready to complete** page, review your selections and click **Finish**.

Scenario: Prepare for Importing the Dukes Bank for vSphere Sample Application Blueprint

As a vCenter Server administrator, you want to prepare a vSphere CentOS 6.x Linux template and customization specification that you can use to provision the vRealize Automation Dukes Bank sample application.

You want to ensure that your template supports the sample application software components, so you install the guest agent and the software bootstrap agent onto your Linux reference machine before you convert it to a template and create a customization specification. You disable SELinux on your reference machine to ensure your template supports the specific implementation of MySQL used in the Dukes Bank sample application.

Prerequisites

- Install and fully configure vRealize Automation. See *Installing and Configuring vRealize Automation for the Rainpole Scenario*.
- Identify or create a CentOS 6.x Linux reference machine with VMware Tools installed. For information about creating virtual machines, see the vSphere documentation.
- You must be connected to a vCenter Server to convert a virtual machine to a template. You cannot create templates if you connect the vSphere Client directly to an vSphere ESXi host.

Procedure

1 Scenario: Prepare Your Reference Machine for the Dukes Bank vSphere Sample Application

You want your template to support the Dukes Bank sample application, so you must install both the guest agent and the software bootstrap agent on your reference machine so vRealize Automation can provision the software components. To simplify the process, you download and run a vRealize Automation script that installs both the guest agent and the software bootstrap agent instead of downloading and installing the packages separately.

2 Scenario: Convert Your Reference Machine into a Template for the Dukes Bank vSphere Application

After you install the guest agent and software bootstrap agent on your reference machine, you disable SELinux to ensure your template supports the specific implementation of MySQL used in the Dukes Bank sample application. You turn your reference machine into a template that you can use to provision the Dukes Bank vSphere sample application.

3 Scenario: Create a Customization Specification for Cloning the Dukes Bank vSphere Sample Application Machines

You create a customization specification to use with your Dukes Bank machine template.

You created a template and customization specification from your reference machine that supports the vRealize Automation Dukes Bank sample application.

Scenario: Prepare Your Reference Machine for the Dukes Bank vSphere Sample Application

You want your template to support the Dukes Bank sample application, so you must install both the guest agent and the software bootstrap agent on your reference machine so vRealize Automation can provision the software components. To simplify the process, you download and run a vRealize Automation script that installs both the guest agent and the software bootstrap agent instead of downloading and installing the packages separately.

Procedure

- 1 Log in to your reference machine as the root user.
- 2 Download the installation script from your vRealize Automation appliance.

```
wget https://vRealize_VA_Hostname_fqdn/software/download/prepare_vra_template.sh
```

If your environment is using self-signed certificates, you might have to use the wget option `--no-check-certificate` option. For example:

```
wget --no-check-certificate  
https://vRealize_VA_Hostname_fqdn/software/download/prepare_vra_template.sh
```

- 3 Make the `prepare_vra_template.sh` script executable.

```
chmod +x prepare_vra_template.sh
```

4 Run the `prepare_vra_template.sh` installer script.

```
./prepare_vra_template.sh
```

You can run the help command `./prepare_vra_template.sh --help` for information about non-interactive options and expected values.

5 Follow the prompts to complete the installation.

You see a confirmation message when the installation is successfully completed. If you see an error message and logs in the console, resolve the errors and run the installer script again.

You installed both the software bootstrap agent and its prerequisite, the guest agent, to ensure the Dukes Bank sample application successfully provisions software components. The script also connected to your Manager Service instance and downloaded the SSL certificate to establish trust between the Manager Service and machines deployed from your template. This is a less secure approach than obtaining the Manager Service SSL certificate and manually installing it on your reference machine in `/usr/share/gugent/cert.pem`, and you can manually replace this certificate now if security is a high priority.

Scenario: Convert Your Reference Machine into a Template for the Dukes Bank vSphere Application

After you install the guest agent and software bootstrap agent on your reference machine, you disable SELinux to ensure your template supports the specific implementation of MySQL used in the Dukes Bank sample application. You turn your reference machine into a template that you can use to provision the Dukes Bank vSphere sample application.

After you convert your reference machine to a template, you cannot edit or power on the template unless you convert it back to a virtual machine.

Procedure

1 Log in to your reference machine as the root user.

- a Edit your `/etc/selinux/config` file to disable SELinux.

```
SELINUX=disabled
```

If you do not disable SELinux, the MySQL software component of the Duke's Bank Sample application might not work as expected.

- b Remove udev persistence rules.

```
/bin/rm -f /etc/udev/rules.d/70*
```

- c Enable machines cloned from this template to have their own unique identifiers.

```
/bin/sed -i '/^\(HWADDR\|UUID\)=/d'
/etc/sysconfig/network-scripts/ifcfg-eth0
```

- d If you rebooted or reconfigured the reference machine after installing the software bootstrap agent, reset the agent.

```
/opt/vmware-appdirector/agent-bootstrap/agent_reset.sh
```

- e Power down the machine.

```
shutdown -h now
```

- 2 Log in to the vSphere Web Client as an administrator.
- 3 Right-click your reference machine and select **Edit Settings**.
- 4 Enter **dukes_bank_template** in the **VM Name** text box.
- 5 If your reference machine has a CentOS guest operating system, select **Red Hat Enterprise Linux 6 (64-bit)** from the **Guest OS Version** drop-down menu.
If you select CentOS, your template and customization specification might not work as expected.
- 6 Click **OK**.
- 7 Right-click your reference machine in the vSphere Web Client and select **Template > Convert to Template**.

vCenter Server marks your dukes_bank_template reference machine as a template and displays the task in the Recent Tasks pane. If you have already brought your vSphere environment under vRealize Automation management, your template is discovered during the next automated data collection. If you have not configured your vRealize Automation yet, the template is collected during that process.

Scenario: Create a Customization Specification for Cloning the Dukes Bank vSphere Sample Application Machines

You create a customization specification to use with your Dukes Bank machine template.

Procedure

- 1 Log in to the vSphere Web Client as an administrator.
- 2 On the home page, click **Customization Specification Manager** to open the wizard.
- 3 Click the **New** icon.
- 4 Specify properties.
 - a Select **Linux** from the **Target VM Operating System** drop-down menu.
 - b Enter **Customspecs_sample** in the **Customization Spec Name** text box.
 - c Enter **Dukes Bank customization spec** in the **Description** text box.
 - d Click **Next**.

- 5 Set computer name.
 - a Select **Use the virtual machine name**.
 - b Enter the domain on which you want to provision the Dukes Bank sample application in the **Domain name** text box.
 - c Click **Next**.
- 6 Configure time zone settings.
- 7 Click **Next**.
- 8 Select **Use standard network settings for the guest operating system, including enabling DHCP on all network interfaces**.

Fabric administrators and infrastructure architects handle network settings for provisioned machine by creating and using Network profiles in vRealize Automation.
- 9 Follow the prompts to enter the remaining required information.
- 10 On the **Ready to complete** page, review your selections and click **Finish**.

You created a template and customization specification that you can use to provision the Dukes Bank sample application.

What to do next

- 1 Create an external network profile to provide a gateway and a range of IP addresses. See [Create an External Network Profile by Using A Third-Party IPAM Provider](#).
- 2 Map your external network profile to your vSphere reservation. See [Create a Reservation for Hyper-V, KVM, SCVMM, vSphere, or XenServer](#). The sample application cannot provision successfully without an external network profile.
- 3 Import the Duke's Bank sample application into your environment. See [Scenario: Importing the Dukes Bank for vSphere Sample Application and Configuring for Your Environment](#).

Tenant and Resource Preparations for Blueprint Provisioning

2

You can configure multiple tenant environments, each with their own groups of users and unique access to resources that you bring under vRealize Automation management.

This chapter includes the following topics:

- [Configuring Tenant Settings](#)
- [Configuring Resources](#)
- [User Preferences for Notifications and Delegates](#)

Configuring Tenant Settings

Tenant administrators configure tenant settings such as user authentication, and manage user roles and business groups. System administrators and tenant administrators configure options such as email servers to handle notifications, and branding for the vRealize Automation console.

You can use the Configuring Tenant Settings Checklist to see a high-level overview of the sequence of steps required to configure tenant settings.

Table 2-1. Checklist for Configuring Tenant Settings

Task	vRealize Automation Role	Details
<input type="checkbox"/> Create local user accounts and assign a tenant administrator.	System administrator	For an example of creating local user accounts, see <i>Installing and Configuring vRealize Automation for the Rainpole Scenario</i> .
<input type="checkbox"/> Configure Directories Management to set up tenant identity management and access control settings.	Tenant administrator	Choosing Directories Management Configuration Options
<input type="checkbox"/> Create business groups and custom groups, and grant user access rights to the vRealize Automation console.	Tenant administrator	Configuring Groups and User Roles
<input type="checkbox"/> (Optional) Create additional tenants so users can access the appropriate applications and resources they need to complete their work assignments.	System administrator	Create Additional Tenants
<input type="checkbox"/> (Optional) Configure custom branding on the tenant login and application pages of the vRealize Automation console.	<ul style="list-style-type: none">■ System administrator■ Tenant administrator	Configuring Custom Branding

Table 2-1. Checklist for Configuring Tenant Settings (Continued)

Task	vRealize Automation Role	Details
❑ (Optional) Configure vRealize Automation to send users notifications when specific events occur.	<ul style="list-style-type: none"> ■ System administrator ■ Tenant administrator 	Checklist for Configuring Notifications
❑ (Optional) Configure vRealize Orchestrator to support XaaS and other extensibility.	<ul style="list-style-type: none"> ■ System administrator ■ Tenant administrator 	Configuring vRealize Orchestrator
❑ (Optional) Create a custom remote desktop protocol file that IaaS architects use in blueprints to configure RDP settings.	System administrator	Create a Custom RDP File to Support RDP Connections for Provisioned Machines
❑ (Optional) Define datacenter locations that your fabric administrators and IaaS architects can leverage to allow users to select an appropriate location for provisioning when they request machines.	System administrator	For an example of adding datacenter locations, see Scenario: Add Datacenter Locations for Cross Region Deployments .

Choosing Directories Management Configuration Options

You can use vRealize Automation Directories Management features to configure an Active Directory link in accordance with your user authentication requirements.

Directories Management provides many options to support a highly customized user authentication.

Table 2-2. Choosing Directories Management Configuration Options

Configuration Option	Procedure
Configure a link to your Active Directory.	<ol style="list-style-type: none"> 1 Configure a link to your Active Directory. See Configure an Active Directory over LDAP/IWA Link. 2 If you configured vRealize Automation for high availability, see Configure Directories Management for High Availability.
(Optional) Enhance security of a user ID and password based directory link by configuring bi-directional integration with Active Directory Federated Services.	Configure a Bi Directional Trust Relationship Between vRealize Automation and Active Directory
(Optional) Add users and groups to an existing Active Directory Link .	Add Users or Groups to an Active Directory Connection.
(Optional) Edit the default policy to apply custom rules for an Active Directory link.	Manage the User Access Policy.
(Optional) Configure network ranges to restrict the IP addresses through which users can log in to the system, manage login restrictions (timeout, number of login attempts before lock-out).	Add or Edit a Network Range.

Directories Management Overview

Tenant administrators can configure tenant identity management and access control settings using the Directories Management options on the vRealize Automation application console.

You can manage the following settings from the **Administration > Directories Management** tab.

Table 2-3. Directories Management Settings

Setting	Description
Directories	<p>The Directories page enables you to create and manage Active Directory links to support vRealize Automation tenant user authentication and authorization. You create one or more directories and then sync those directories with your Active Directory deployment. This page displays the number of groups and users that are synced to the directory and the last sync time. You can click Sync Now, to manually start the directory sync.</p> <p>See Using Directories Management to Create an Active Directory Link.</p> <p>When you click on a directory and then click the Sync Settings button, you can edit the sync settings, navigate the Identity Providers page, and view the sync log.</p> <p>From the directories sync settings page you can schedule the sync frequency, see the list of domains associated with this directory, change the mapped attributes list, update the user and groups list that syncs, and set the safeguard targets.</p>
Connectors	<p>The Connectors page lists deployed connectors for your enterprise network. A connector syncs user and group data between Active Directory and the Directories Management service, and when it is used as the identity provider, authenticates users to the service. Each vRealize Automation appliance contains a connector by default. See Managing Connectors and Connector Clusters.</p>
User Attributes	<p>The User Attributes page lists the default user attributes that sync in the directory and you can add other attributes that you can map to Active Directory attributes. See Select Attributes to Sync with Directory.</p>
Network Ranges	<p>This page lists the network ranges that are configured for your system. You configure a network range to allow users access through those IP addresses. You can add additional network ranges and you can edit existing ranges. See Add or Edit a Network Range.</p>
Identity Providers	<p>The Identity Providers page lists identity providers that are available on your system. vRealize Automation systems contain a connector that serves as the default identity provider and that suffices for many user needs. You can add third-party identity provider instances or have a combination of both.</p> <p>See Configure a Third Party Identity Provider Connection.</p>
Policies	<p>The Policies page lists the default access policy and any other web application access policies you created. Policies are a set of rules that specify criteria that must be met for users to access their application portals or to launch Web applications that are enabled for them. The default policy should be suitable for most vRealize Automation deployments, but you can edit it if needed. See Manage the User Access Policy.</p>

Important Concepts Related to Active Directory

Several concepts related to Active Directory are integral to understanding how Directories Management integrates with your Active Directory environments.

Connector

The connector, a component of the service, performs the following functions.

- Syncs user and group data between Active Directory and the service.
- When being used as an identity provider, authenticates users to the service.

The connector is the default identity provider. For the authentication methods the connector supports, see *VMware Identity Manager Administration*. You can also use third-party identity providers that support the SAML 2.0 protocol. Use a third-party identity provider for an authentication type the connector does not support or for an authentication type the connector does support, if the third-party identity provider is preferable based on your enterprise security policy.

Note Even if you use third-party identity providers, you must configure the connector to sync user and group data.

Directory

The Directories Management service has its own concept of a directory, which uses Active Directory attributes and parameters to define users and groups. You create one or more directories and then sync those directories with your Active Directory deployment. You can create the following directory types in the service.

- Active Directory over LDAP. Create this directory type if you plan to connect to a single Active Directory domain environment. For the Active Directory over LDAP directory type, the connector binds to Active Directory using simple bind authentication.
- Active Directory, Integrated Windows Authentication. Create this directory type if you plan to connect to a multi-domain or multi-forest Active Directory environment. The connector binds to Active Directory using Integrated Windows Authentication.

The type and number of directories that you create varies depending on your Active Directory environment, such as single domain or multi-domain, and on the type of trust used between domains. In most environments, you create one directory.

The service does not have direct access to Active Directory. Only the connector has direct access to Active Directory. Therefore, you associate each directory created in the service with a connector instance.

Worker

When you associate a directory with a connector instance, the connector creates a partition for the associated directory called a worker. A connector instance can have multiple workers associated with it. Each worker acts as an identity provider. You define and configure authentication methods per worker.

The connector syncs user and group data between Active Directory and the service through one or more workers.

You cannot have two workers of the Integrated Windows Authentication type on the same connector instance.

Active Directory Environments

You can integrate the service with an Active Directory environment that consists of a single Active Directory domain, multiple domains in a single Active Directory forest, or multiple domains across multiple Active Directory forests.

Single Active Directory Domain Environment

A single Active Directory deployment allows you to sync users and groups from a single Active Directory domain.

See [Configure an Active Directory over LDAP/IWA Link](#). For this environment, when you add a directory to the service, select the Active Directory over LDAP option.

Multi-Domain, Single Forest Active Directory Environment

A multi-domain, single forest Active Directory deployment allows you to sync users and groups from multiple Active Directory domains within a single forest.

You can configure the service for this Active Directory environment as a single Active Directory, Integrated Windows Authentication directory type or, alternatively, as an Active Directory over LDAP directory type configured with the global catalog option.

- The recommended option is to create a single Active Directory, Integrated Windows Authentication directory type.

See [Configure an Active Directory over LDAP/IWA Link](#). When you add a directory for this environment, select the Active Directory (Integrated Windows Authentication) option.

Multi-Forest Active Directory Environment with Trust Relationships

A multi-forest Active Directory deployment with trust relationships allows you to sync users and groups from multiple Active Directory domains across forests where two-way trust exists between the domains.

See [Configure an Active Directory over LDAP/IWA Link](#). When you add a directory for this environment, select the Active Directory (Integrated Windows Authentication) option.

Multi-Forest Active Directory Environment Without Trust Relationships

A multi-forest Active Directory deployment without trust relationships allows you to sync users and groups from multiple Active Directory domains across forests without a trust relationship between the domains. In this environment, you create multiple directories in the service, one directory for each forest.

See [Configure an Active Directory over LDAP/IWA Link](#). The type of directories you create in the service depends on the forest. For forests with multiple domains, select the Active Directory (Integrated Windows Authentication) option. For a forest with a single domain, select the Active Directory over LDAP option.

Using Directories Management to Create an Active Directory Link

After you create vRealize Automation tenants, you must log in to the system console as a tenant administrator and create an Active Directory link to support user authentication.

There are three Active Directory communication protocol options when configuring an Active Directory connection using Directories Management.

- Active Directory over LDAP - An Active Directory over LDAP protocol supports DNS Service Location lookup by default.
- Active Directory (Integrated Windows Authentication) - With Active Directory (Integrated Windows Authentication), you configure the domain to join. Active Directory over LDAP is appropriate for single domain deployments. Use Active Directory (Integrated Windows Authentication) for all multi-domain and multi-forest deployments.
- OpenLDAP - You can use the open source version of LDAP to support Directories Management user authentication.

After you select a communication protocol and configure an Active Directory link, you can specify the domains to use with the Active Directory configuration and then select the users and groups to sync with the specified configuration.

Configure an Active Directory over LDAP/IWA Link

You can configure an Active Directory over LDAP/IWA link to support user authentication using the Directories Management feature to configure a link to Active Directory to support user authentication for all tenants and select users and groups to sync with the Directories Management directory.

For information and instructions about using OpenLDAP with Directories Management, see [Configure an OpenLDAP Directory Connection](#).

For Active Directory (Integrated Windows Authentication), when you have multi-forest Active Directory configured and the Domain Local group contains members from domains in different forests, make sure that the Bind user is added to the Administrators group of the domain in which the Domain Local group resides. If you fail to do this, these members will be missing from the Domain Local group.

Prerequisites

- Select the required default attributes and add additional attributes on the User Attributes page. See [Select Attributes to Sync with Directory](#).
- List of the Active Directory groups and users to sync from Active Directory.
- If your Active Directory requires access over SSL or STARTTLS, the Root CA certificate of the Active Directory domain controller is required.
- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Directories Management > Directories**.
- 2 Click **Add Directory** and select **Add Active Directory over LDAP/IWA**.
- 3 On the Add Directory page, specify the IP address for the Active Directory server in the **Directory Name** text box.

- 4 Select the appropriate Active Directory communication protocol using the radio buttons under the **Directory Name** text box.

Option	Description
Windows Authentication	Select Active Directory (Integrated Windows Authentication) . For Active Directory Integrated Windows Authentication, required information includes the domain's Bind user UPN address and password.
LDAP	Select Active Directory over LDAP . For Active Directory over LDAP, information required includes the Base DN, Bind DN, and Bind DN password.

- 5 Configure the connector that synchronizes users from the Active Directory to the VMware Directories Management directory in the Directory Sync and Authentication section.

Option	Description
Sync Connector	Select the appropriate connector to use for your system. Each vRealize Automation appliance contains a default connector. Consult your system administrator if you need help in choosing the appropriate connector.
Authentication	<p>Click the appropriate radio button to indicate whether the selected connector also performs authentication.</p> <p>If you are using Active Directory (Integrated Windows Authentication), with a third party identity provider to authenticate users, click No. After you configure the Active Directory connection to sync users and groups use the Identity Providers page to add the third-party identity provider for authentication.</p> <p>For information about using authentication adapters such as PasswordIpddAdapter, SecurIDAdapter, and RadiusAuthAdapter, see the <i>VMware Identity Manager Administration Guide</i>.</p>
Directory Search Attribute	<p>Select the appropriate account attribute that contains the user name. VMware recommends using the sAMAccount attribute rather than userPrincipalName. If you use userPrincipalName for sync operations, integration with second and third party software that requires a user name may not function correctly.</p> <p>Note If you select sAMAccountName when using a global catalog, indicated by selecting the This Directory has a Global Catalog check box in the Server Location area, users will be unable to log in.</p>

- 6 Enter the appropriate information in the Server Location text box if you selected Active Directory over LDAP, or enter information in the Join Domain Details text boxes if you selected Active Directory (Integrated Windows Authentication).

Option	Description
Server Location - Displayed when Active Directory over LDAP is selected	<ul style="list-style-type: none"> ■ If you want to use DNS Service Location to locate Active Directory domains, leave the This Directory supports DNS Service Location check box selected. <p>Note You cannot change the port assignment to 636 if you select this option.</p> <p>A <code>domain_krb.properties</code> file, auto-populated with a list of domain controllers, is created along with the directory. See About Domain Controller Selection.</p> <p>If the Active Directory requires STARTTLS encryption, select the This Directory requires all connections to use STARTTLS check box in the Certificates section and copy and paste the Active Directory Root CA certificate in the SSL Certificate field.</p> <ul style="list-style-type: none"> ■ If the specified Active Directory does not use DNS Service Location lookup, deselect the check box beside This Directory supports DNS Service Location in the Server Location fields and enter the Active Directory server host name and port number in the appropriate text boxes. <p>Select the This Directory has a Global Catalog check box if the associated Active Directory uses a global catalog. A global catalog contains a representation of all objects in every domain in a multi-domain Active Directory forest.</p> <p>To configure the directory as a global catalog, see the Multi-Domain Single Forest Active Directory Environment section in Active Directory Environments.</p> <p>If Active Directory requires access over SSL, select the This Directory requires all connections to use SSL check box under the Certificates heading and provide the Active Directory SSL certificate.</p> <p>When you select this option, port 636 is used automatically and cannot be changed.</p> <p>Ensure that the certificate is in PEM format and includes the BEGIN CERTIFICATE and END CERTIFICATE lines.</p>
Join Domain Details - Displayed when Active Directory (Integrated Windows Authentication) is selected	<p>Enter the appropriate credentials in the Domain Name, Domain Admin User Name, and Domain Admin Password text boxes.</p> <p>If the Active Directory requires STARTTLS encryption, select the This Directory requires all connections to use STARTTLS check box in the Certificates section and copy and paste the Active Directory Root CA certificate in the SSL Certificate field.</p> <p>Ensure that the certificate is in PEM format and includes the BEGIN CERTIFICATE and END CERTIFICATE lines.</p> <p>If the directory uses multiple domains, add the Root CA certificates for all domains, one at a time.</p> <p>Note If the Active Directory requires STARTTLS and you do not provide the certificate, you cannot create the directory.</p>

- 7 In the Bind User Details section, enter the appropriate credentials to facilitate directory synchronization.

For Active Directory over LDAP:

Option	Description
Base DN	Enter the search base distinguished name. For example, cn=users,dc=corp,dc=local .
Bind DN	Enter the bind distinguished name. For example, cn=fritz infra,cn=users,dc=corp,dc=local

For Active Directory (Integrated Windows Authentication):

Option	Description
Bind User UPN	Enter the User Principal Name of the user who can authenticate with the domain. For example, UserName@example.com .
Bind DN Password	Enter the Bind User password.

- 8 Click **Test Connection** to test the connection to the configured directory.

This button does not appear if you selected Active Directory (Integrated Windows Authentication).

- 9 Click **Save & Next**.

The Select the Domains page appears with the list of domains.

- 10 Review and update the domains listed for the Active Directory connection.

- For Active Directory (Integrated Windows Authentication), select the domains that should be associated with this Active Directory connection.
- For Active Directory over LDAP, the available domain is listed with a checkmark.

Note If you add a trusting domain after the directory is created, the service does not automatically detect the newly trusting domain. To enable the service to detect the domain, the connector must leave and then rejoin the domain. When the connector rejoins the domain, the trusting domain appears in the list.

- 11 Click **Next**.

- 12 Verify that the Directories Management directory attribute names are mapped to the correct Active Directory attributes.

If the directory attribute names are not mapped correctly, select the correct Active Directory attribute from the drop-down menu.

- 13 Click **Next**.

- 14 Click  to select the groups you want to sync from Active Directory to the directory.

When you add a group from Active Directory, if members of that group are not in the Users list, they are added. When you sync a group, any users that lack Domain Users as their primary group in Active Directory are not synced.

Note The Directories Management user authentication system imports data from Active Directory when adding groups and users, and the speed of the system is limited by Active Directory capabilities. As a result, import operations may require significant time depending on the number of groups and users being added. To minimize the potential for delays or problems, limit the number of groups and users to only those required for vRealize Automation operation.

If your system performance degrades or if errors occur, close any unneeded applications and ensure that your system has appropriate memory allocated to Active Directory. If problems persist, increase the Active Directory memory allocation as needed. For systems with a large number of users and groups, you may need to increase the Active Directory memory allocation to as much as 24 GB.

- 15 Click **Next**.

- 16 Click  to add additional users.

The appropriate values are as follows:

- Single user: **CN=*username*,CN=Users,OU=Users,DC=myCorp,DC=com**
- Multiple users: **OU=Users,OU=myUnit,DC=myCorp,DC=com**

To exclude users, click  to create a filter to exclude some types of users. You select the user attribute to filter by, the query rule, and the value.

- 17 Click **Next**.

- 18 Review the page to see how many users and groups are syncing to the directory.

If you want to make changes to users and groups, click the Edit links.

Note Ensure that you specify user DNs that are under the Base DN specified previously. If the user DN is outside of the Base DN, users from that DN are synced but will be unable to log in.

- 19 Click **Push to Workspace** to start the synchronization to the directory.

The connection to the Active Directory is complete and the selected users and groups are added to the directory. You can now assign user and groups to the appropriate vRealize Automation roles by selecting **Administration > Users and Groups > Directory Users and Groups**. See [Assign Roles to Directory Users or Groups](#) for more information.

What to do next

If your vRealize Automation environment is configured for high availability, you must specifically configure Directories Management for high availability. See [Configure Directories Management for High Availability](#).

- Set up authentication methods. After users and groups sync to the directory, if the connector is also used for authentication, you can set up additional authentication methods on the connector. If a third party is the authentication identity provider, configure that identity provider in the connector.
- Review the default access policy. The default access policy is configured to allow all appliances in all network ranges to access the Web browser, with a session time out set to eight hours or to access a client app with a session time out of 2160 hours (90 days). You can change the default access policy and when you add Web applications to the catalog, you can create new ones.
- Apply custom branding to the administration console, user portal pages and the sign-in screen.

Configure an OpenLDAP Directory Connection

You can configure an OpenLDAP Directory connection with Directories Management.

Though there are several different LDAP protocols, OpenLDAP is the only protocol that is tested and approved for use with vRealize Automation Directories Management.

To integrate your LDAP directory, you create a corresponding Directories Management directory and sync users and groups from your LDAP directory to the Directories Management directory. You can set up a regular sync schedule for subsequent updates.

You also select the LDAP attributes that you want to sync for users and map them to Directories Management attributes.

Your LDAP directory configuration may be based on default schemas or you may have created custom schemas. You may also have defined custom attributes. For Directories Management to be able to query your LDAP directory to obtain user or group objects, you need to provide the LDAP search filters and attribute names that are applicable to your LDAP directory.

Specifically, you need to provide the following information.

- LDAP search filters for obtaining groups, users, and the bind user
- LDAP attribute names for group membership, UUID, and distinguished name

Prerequisites

- Review the configuration on the User Attributes page and add any other attributes that you want to sync. You will map the Directories Management attributes to your LDAP directory attributes when you create the directory. These attributes will be synced for the users in the directory.

Note When you make changes to user attributes, consider the effect on other directories in the service. If you plan to add both Active Directory and LDAP directories, ensure that you do not mark any attributes as required except for **userName**. The settings on the User Attributes page apply to all directories in the service. If an attribute is marked required, users without that attribute are not synced to the Directories Management service.

- A Bind DN user account. Using a Bind DN user account with a non-expiring password is recommended.
- In your LDAP directory, the UUID of users and groups must be in plain text format.
- In your LDAP directory, a domain attribute must exist for all users and groups.

You map this attribute to the Directories Management **domain** attribute when you create the Directories Management directory.

- User names must not contain spaces. If a user name contains a space, the user is synced but entitlements are not available to the user.
- If you use certificate authentication, users must have values for userPrincipalName and email address attributes.

Procedure

- 1 Select **Administration > Directories Management > Directories**.
- 2 Click **Add Directory** and select **Add LDAP Directory**.
- 3 Enter the required information in the Add LDAP Directory page.

Option	Description
Directory Name	Enter a name for the Directories Management directory.
Directory Sync and Authentication	<p>a In the Sync Connector field, select the connector you want to use to sync users and groups from your LDAP directory to the Directories Management directory.</p> <p>A connector component is always available with the Directories Management service by default. This connector appears in the drop-down list. If you install multiple Directories Management appliances for high availability, the connector component of each appears in the list.</p> <p>You do not need a separate connector for an LDAP directory. A connector can support multiple directories, regardless of whether they are Active Directory or LDAP directories.</p> <p>b In the Authentication field, if you want to use this LDAP directory to authenticate users, select Yes.</p> <p>If you want to use a third-party identity provider to authenticate users, select No. After you add the directory connection to sync users and groups, go to the Administration > Directories Management > Identity Providers page to add the third-party identity provider for authentication.</p> <p>c For most configurations, leave the Custom default selected in the Directory Search Attribute text box. In the Custom Directory Search Attribute field, specify the LDAP directory attribute to be used for user and group names. This attribute uniquely identifies entities, such as users and groups, from the LDAP server. For example, cn.</p>
Server Location	<p>Enter the LDAP Directory server host and port number. For the server host, you can specify either the fully-qualified domain name or the IP address. For example, myLDAPserver.example.com or 100.00.00.0.</p> <p>If you have a cluster of servers behind a load balancer, enter the load balancer information instead.</p>

Option	Description
LDAP Configuration	<p>Specify the LDAP search filters and attributes that Directories Management can use to query your LDAP directory. Default values are provided based on the core LDAP schema.</p> <p>Filter Queries</p> <ul style="list-style-type: none"> ■ Groups: The search filter for obtaining group objects. For example: (objectClass=group) ■ Bind user: The search filter for obtaining the bind user object, that is, the user that can bind to the directory. For example: (objectClass=person) ■ Users: The search filter for obtaining users to sync. For example: (&(objectClass=user)(objectCategory=person)) <p>Attributes</p> <ul style="list-style-type: none"> ■ Membership: The attribute that is used in your LDAP directory to define the members of a group. For example: member ■ Object UUID: The attribute that is used in your LDAP directory to define the UUID of a user or group. For example: entryUUID ■ Distinguished Name: The attribute that is used in your LDAP directory for the distinguished name of a user or group. For example: entryDN
Certificates	<p>If your LDAP directory requires access over SSL, select the This Directory requires all connections to use SSL check box. Then copy and paste the LDAP directory server's root CA SSL certificate into the SSL Certificate text box. Ensure the certificate is in PEM format and include the "BEGIN CERTIFICATE" and "END CERTIFICATE" lines.</p> <p>Finally, ensure that the correct port number is specified in the Server Port field in the Server Location section of the page.</p>
Bind User Details	<p>Base DN: Enter the DN from which to start searches. For example, cn=users,dc=example,dc=com</p> <p>All applicable users must reside under the Base DN. If a particular user is not located under the Base DN, that user will be unable to log in even if he is a member of a group that is under the Base DN.</p> <p>Bind DN: Enter the DN to use to bind to the LDAP directory. You can also enter user names, but a DN is more appropriate for most deployments.</p> <p>Note Using a Bind DN user account with a non-expiring password is recommended.</p> <p>Bind DN Password: Enter the password for the Bind DN user.</p>

- 4 To test the connection to the LDAP directory server, click **Test Connection**.

If the connection is not successful, check the information you entered and make the appropriate changes.

- 5 Click **Save & Next**.

- 6 Verify the correct domain is selected on the Select the Domains page, and then click **Next**.

- 7 In the Map Attributes page, verify that the Directories Management attributes are mapped to the correct LDAP attributes.

These attributes will be synced for users.

Important You must specify a mapping for the **domain** attribute.

You can add attributes to the list from the User Attributes page.

- 8 Click **Next**.
- 9 Click **+** to select the groups you want to sync from the LDAP directory to the Directories Management directory on Select the groups (users) you want to sync page.

If you have multiple groups with the same name in your LDAP directory, you must specify unique names for them in the groups page.

When you add a group from Active Directory, if members of that group are not in the Users list, they are added. When you sync a group, any users that lack Domain Users as their primary group in Active Directory are not synced.

The **Sync nested group members** option is enabled by default. When this option is enabled, all the users that belong directly to the group you select as well as all the users that belong to nested groups under it are synced. Note that the nested groups are not synced; only the users that belong to the nested groups are synced. In the Directories Management directory, these users will appear as members of the top-level group that you selected for sync. In effect, the hierarchy under a selected group is flattened and users from all levels appear in Directories Management as members of the selected group.

If this option is disabled, when you specify a group to sync, all the users that belong directly to that group are synced. Users that belong to nested groups under it are not synced. Disabling this option is useful for large directory configurations where traversing a group tree is resource and time intensive. If you disable this option, ensure that you select all the groups whose users you want to sync.

Note The Directories Management user authentication system imports data from Active Directory when adding groups and users, and the speed of the system is limited by Active Directory capabilities. As a result, import operations may require a significant amount of time depending on the number of groups and users being added. To minimize the potential for delays or problems, limit the number of groups and users to only those required for vRealize Automation operation.

If your system performance degrades or if errors occur, close any unneeded applications and ensure that your system has appropriate memory allocated to Directories Management. If problems persist, increase the Directories Management memory allocation as needed. For systems with large numbers of users and groups, you may need to increase the Directories Management memory allocation to as much as 24 GB.

- 10 Click **Next**.

- 11 Click **+** to add additional users. For example, enter
CN=username,CN=Users,OU=myUnit,DC=myCorp,DC=com.

You can add organizational units as well as individual users here.

You can create a filter to exclude some types of users. Select the user attribute to filter by, the query rule, and the value.

- 12 Click **Next**.

- 13 Review the page to see how many users and groups will sync to the directory and to view the default sync schedule.

To make changes to users and groups, or to the sync frequency, click the **Edit** links.

- 14 Click **Sync Directory** to start the directory sync.

The connection to the LDAP directory is established and users and groups are synced from the LDAP directory to the Directories Management directory.

You can now assign user and groups to the appropriate vRealize Automation roles by selecting **Administration > Users and Groups > Directory Users and Groups**. See [Assign Roles to Directory Users or Groups](#) for more information.

Limitations of LDAP Directory Integration

There are several important limitations related to LDAP Directory integration in Directories Management.

- You can only integrate a single-domain LDAP directory environment.
 To integrate multiple domains from an LDAP directory, you need to create additional Directories Management directories, one for each domain.
- The following authentication methods are not supported for Directories Management directories of type LDAP directory.
 - Kerberos authentication
 - RSA Adaptive Authentication
 - ADFS as a third-party identity provider
 - SecurID
 - Radius authentication with Vasco and SMS Passcode server
- You cannot join an LDAP domain.
- Integration with View or Citrix-published resources is not supported for Directories Management directories of type LDAP directory.
- User names must not contain spaces. If a user name contains a space, the user is synced but entitlements are not available to the user.

- If you plan to add both Active Directory and LDAP directories, ensure that you do not mark any attributes required in the User Attributes page, except for `userName`, which can be marked required. The settings in the User Attributes page apply to all directories in the service. If an attribute is marked required, users without that attribute are not synced to the Directories Management service.
- If you have multiple groups with the same name in your LDAP directory, you must specify unique names for them in the Directories Management service. You can specify the names when you select the groups to sync.
- The option to allow users to reset expired passwords is not available.
- The `domain_krb.properties` file is not supported.

Configure Directories Management for High Availability

You can use Directories Management to configure a high availability Active Directory connection in vRealize Automation.

Each vRealize Automation appliance includes a connector that supports user authentication, although only one connector is typically configured to perform directory synchronization. It does not matter which connector you choose to serve as the sync connector. To support Directories Management high availability, you must configure a second connector that corresponds to your second vRealize Automation appliance, which connects to your Identity Provider and points to the same Active Directory. With this configuration, if one appliance fails, the other takes over management of user authentication.

In a high availability environment, all nodes must serve the same set of Active Directories, users, authentication methods, etc. The most direct method to accomplish this is to promote the Identity Provider to the cluster by setting the load balancer host as the Identity Provider host. With this configuration, all authentication requests are directed to the load balancer, which forwards the request to either connector as appropriate.

Prerequisites

- Configure your vRealize Automation deployment with at least two instance of the vRealize Automation appliance.
- Install vRealize Automation in Enterprise mode operating in a single domain with two instances of the vRealize Automation appliance.
- Install and configure an appropriate load balancer to work with your vRealize Automation deployment.
- Configure tenants and Directories Management using one of the connectors supplied with the installed instances of the vRealize Automation appliance. For information about tenant configuration, see [Configuring Tenant Settings](#).

Procedure

- 1 Log in to the load balancer for your vRealize Automation deployment as a tenant administrator.
The load balancer URL is `<load balancer address>/vcac/org/tenant_name`.
- 2 Select **Administration > Directories Management > Identity Providers**.

- 3 Click the Identity Provider that is currently in use for your system.

The existing directory and connector that provide basic identity management for your system appears.

- 4 On the Identity Provider properties page, click the **Add a Connector** drop-down list, and select the connector that corresponds to your secondary vRealize Automation appliance.
- 5 Enter the appropriate password in the **Bind DN Password** text box that appears when you select the connector.
- 6 Click **Add Connector**.
- 7 The main connector appears in the **IdP Hostname** text box by default. Change the host name to point to the load balancer.

Configure a Bi Directional Trust Relationship Between vRealize Automation and Active Directory

You can enhance system security of a basic vRealize Automation Active Directory connection by configuring a bi directional trust relationship between your identity provider and Active Directory Federated Services.

To configure a bi-directional trust relationship between vRealize Automation and Active Directory, you must create a custom identity provider and add Active Directory metadata to this provider. Also, you must modify the default policy used by your vRealize Automation deployment. Finally, you must configure Active Directory to recognize your identity provider.

Prerequisites

- Verify that you have configured tenants for your vRealize Automation deployment set up an appropriate Active Directory link to support basic Active Directory user ID and password authentication.
- Active Directory is installed and configured for use on your network.
- Obtain the appropriate Active Directory Federated Services (ADFS) metadata.
- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Obtain the Federation Metadata file.

You can download this file from

<https://servername.domain/FederationMetadata/2007-06/FederationMetadata.xml>

- 2 Search for the word `logout`, and edit the location of each instance to point to `https://servername.domain/adfs/ls/logout.aspx`

For example, the following:

```
SingleLogoutService
  Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"
  Location="https://servername.domain/adfs/ls/ "/>
```

Should be changed to:

```
SingleLogoutService
  Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"
  Location="https://servername.domain/adfs/ls/logout.aspx"/>
```

- 3 Create a new Identity Provider for you deployment.
 - a Select **Administration > Directories Management > Identity Providers**.
 - b Click **Add Identity Provider** and complete the fields as appropriate.

Option	Description
Identity Provider Name	Enter a name for the new identity provider
Identity Provider Metadata (URI or XML)	Paste the contents of your Active Directory Federated Services metadata file here.
Name ID Policy in SAML Request (Optional)	If appropriate, enter a name for the identity policy SAML request.
Users	Select the domains to which you want users to have access privileges.
Process IDP Metadata	Click to process the metadata file that you added.
Network	Select the network ranges to which you want users to have access.
Authentication Methods	Enter a name for the authentication method used by this identity provider.
SAML Context	Select the appropriate context for your system.
SAML Signing Certificate	Click the link beside the SAML Metadata heading to download the Directories Management metadata.

- c Save the Directories Management metadata file as `sp.xml`.
 - d Click **Add**.
- 4 Add a rule to the default policy.
 - a Select **Administration > Directories Management > Policies**.
 - b Click the default policy name.

- c Click the + icon under the **Policy Rules** heading to add a new rule.

Use the fields on the Add a Policy Rule page to create a rule that specifies the appropriate primary and secondary authentication methods to use for a specific network range and device.

For example, if your network range is **My Machine**, and you need to access content from **All Device Types** then, for a typical deployment, you must authenticate by using the following method: **ADFS Username and Password**.

- d Click **Save** to save your policy updates.
- e On the Default Policy page, drag the new rule to the top of the table so that it takes precedence over existing rules.

- 5 Using the Active Directory Federated Services management console, or another appropriate tool, set up a relying party trust relationship with the vRealize Automation identity provider.

To set up this trust, you must import the Directories Management metadata that you previously downloaded. See the Microsoft Active Directory documentation for more information about configuring Active Directory Federated Services for bi-directional trust relationships. As part of this process, you must do the following:

- Set up a Relying Party Trust. When you set up this trust, you must import the VMware Identity Provider service provider metadata XML file that you copied and saved
- Create a claim rule that transforms the attributes retrieved from LDAP in the Get Attributes rule into the desired SAML format. After you create the rule, edit the rule by adding the following text:

```
c:[Type == "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/emailaddress"]
=> issue(Type = "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/nameidentifier", Issuer
= c.Issuer, OriginalIssuer = c.OriginalIssuer, Value = c.Value, ValueType = c.ValueType,
Properties["http://schemas.xmlsoap.org/ws/2005/05/identity/claimproperties/format"] =
"urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress",
Properties["http://schemas.xmlsoap.org/ws/2005/05/identity/claimproperties/spnamequalifier"] =
"vmwareidentity.domain.com");
```

Configure SAML Federation Between Directories Management and SSO2

You can establish SAML federation between vRealize Automation Directories Management and systems that use SSO2 to support single sign on.

Establish federation between Directories Management and SSO2 by creating a SAML connection between the two parties. Currently, the only supported end-to-end flow is where SSO2 acts as the Identity Provider (IdP) and Directories Management acts as the service provider (SP).

For SSO2 user authentication, the same account must exist in both Directories Management and SSO2. Minimally, the UserPrincipalName (UPN) of the user has to match on both ends. Other attributes can differ as they are required to identify the SAML subject.

For local users in SSO2, such as `admin@vsphere.local`, corresponding accounts must also exist in Directories Management, where at least the UPN of the user matches. Create these accounts manually or with a script using the Directories Management local user creation APIs.

Setting up SAML between SSO2 and Directories Management involves configuration on the Directories Management and SSO components.

Table 2-4. SAML Federation Component Configuration

Component	Configuration
Directories Management	Configure SSO2 as a third-party Identity Provider on Directories Management and update the default authentication policy. You can create an automated script to set up Directories Management.
SSO2 component	Configure Directories Management as a service provider by importing the Directories Management <code>sp.xml</code> file. This file enables you to configure SSO2 to use Directories Management as the Service Provider (SP).

Prerequisites

- Configure tenants for your vRealize Automation deployment. See [Create Additional Tenants](#).
- Set up an appropriate Active Directory link to support basic Active Directory user ID and password authentication.
- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Download SSO2 Identity Provider metadata through the SSO2 user interface.
 - a Log in to vCenter as an administrator at `https://<cloudvm-hostname>/`.
 - b Click the **Log in to vSphere Web Client** link.
 - c On the left navigation pane, select **Administration > Single Sign On > Configuration**.
 - d Click **Download** adjacent to the Metadata for your SAML service provider heading.
The `vsphere.local.xml` file should begin downloading.
 - e Copy the contents of the `vsphere.local.xml` file.
- 2 On the vRealize Automation Directories Management Identity Providers page, create a new Identity Provider.
 - a Log in to vRealize Automation as a **tenant administrator**.
 - b Select **Administration > Directories Management > Identity Providers**.

- c Click **Add Identity Provider** and provide the configuration information.

Option	Action
Identity Provider Name	Enter a name for the new Identity Provider.
Identity Provider Metadata (URI or XML) text box	Paste the contents of your SSO2 idp.xml metadata file in the text box and click Process IDP Metadata .
Name ID Policy in SAML Request (Optional)	Enter http://schemas.xmlsoap.org/claims/UPN.
Users	Select the domains to which you want users to have access privileges.
Network	Select the network ranges from which you want users to have access privileges. If you want to authenticate users from an IP addresses, select All Ranges .
Authentication Methods	Enter a name for the authentication method. Then, use the SAML Context drop down menu to the right to map the authentication method to urn:oasis:names:tc:SAML:2.0:ac:classes:Password.
SAML Signing Certificate	Click the link beside the SAML Metadata heading to download the Directories Management metadata.

- d Save the Directories Management metadata file as sp.xml.
- e Click **Add**.
- 3 Update the relevant authentication policy using the Directories Management Policies page to redirect authentication to the third party SSO2 identity provider.
- a Select **Administration > Directories Management > Policies**.
- b Click the default policy name.
- c Click the authentication method under the **Policy Rules** heading to edit the existing authentication rule.
- d On the Edit a Policy Rule page, change the authentication method from password to the appropriate method.
In this case, the method should be SSO2.
- e Click **Save** to save your policy updates.
- 4 On the left navigation pane, select **Administration > Single Sign On > Configuration**, and click **Update** to upload the sp.xml file to vSphere.

Add Users or Groups to an Active Directory Connection

You can add users or groups to an existing Active Directory connection.

The Directories Management user authentication system imports data from Active Directory when adding groups and users. The speed of the data transport is limited by Active Directory capabilities. As a result, actions can take a long time depending on the number of groups and users that are added. To minimize problems, limit the groups and users to only the groups and users required for a vRealize Automation

action. If problems occur, close unneeded applications and verify that your deployment has appropriate memory allocated to Active Directory. If problems continue, increase the Active Directory memory allocation. For deployments with large numbers of users and groups, you might need to increase the Active Directory memory allocation to as much as 24 GB.

When you sync a vRealize Automation deployment with a many users and groups, there might be a delay before the Log details are available. The time stamp on the log file can differ from the completed time displayed on the console.

If members of a group are not in the Users list, when you add the group from Active Directory, the members are added to the list. When you sync a group, any users that do not have Domain Users as their primary group in Active Directory are not synced.

Note You cannot cancel a synchronize action after you start the action.

Prerequisites

- Connector installed and the activation code activated. Select the required default attributes and add additional attributes on the User Attributes page.

See *Select Attributes to Sync with Directory* in *Configuring vRealize Automation*.

- List of the Active Directory groups and users to sync from Active Directory.
- For Active Directory over LDAP, information required includes the Base DN, Bind DN, and Bind DN password.
- For Active Directory Integrated Windows Authentication, the information required includes the domain's Bind user UPN address and password.
- If Active Directory is accessed over SSL, a copy of the SSL certificate is required.
- If you have a multi-forest Active Directory integrated with Windows Authentication and the Domain Local group contains members from different forests, do the following. Add the Bind user to the Administrators group of the Domain Local group. If the Bind user is not added, these members are missing from the Domain Local group.
- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Directories Management > Directories**.
- 2 Click the desired directory name.
- 3 Click **Sync Settings** to open a dialog box with synchronization options.
- 4 Click the appropriate icon depending on whether you want to change the user or group configuration.

To edit the group configuration:

- To add groups, click the **+** icon to add a line for group DN definitions and enter the appropriate group DN.
- If you want to delete a group DN definition, click the **x** icon for the desired group DN.

To edit the user configuration:

- ◆ To add users, click the **+** icon to add a line for a user DN definition and enter the appropriate user DN.

If you want to delete a user DN definition, click the **x** icon for the desired user DN.

- 5 Click **Save** to save your changes without synchronizing your updates immediately. Click **Save & Sync** to save your changes and synchronize your updates immediately.

Select Attributes to Sync with Directory

When you set up the Directories Management directory to sync with Active Directory, you specify the user attributes that sync to the directory. Before you set up the directory, you can specify on the User Attributes page which default attributes are required and, if you want, add additional attributes that you want to map to Active Directory attributes.

When you configure the User Attributes page before the directory is created, you can change default attributes from required to not required, mark attributes as required, and add custom attributes.

For a list of the default mapped attributes, see [Managing User Attributes that Sync from Active Directory](#).

After the directory is created, you can change a required attribute to not be required, and you can delete custom attributes. You cannot change an attribute to be a required attribute.

When you add other attributes to sync to the directory, after the directory is created, go to the directory's Mapped Attributes page to map these attributes to Active Directory Attributes.

Procedure

- 1 Log in to vRealize Automation as a system or tenant administrator.
- 2 Click the Administration tab.
- 3 Select **Directories Management > User Attributes**
- 4 In the Default Attributes section, review the required attribute list and make appropriate changes to reflect what attributes should be required.
- 5 In the Attributes section, add the Directories Management directory attribute name to the list.
- 6 Click **Save**.

The default attribute status is updated and attributes you added are added on the directory's Mapped Attributes list.

- 7 After the directory is created, go to the Identity Stores page and select the directory.
- 8 Click **Sync Settings > Mapped Attributes**.
- 9 In the drop-down menu for the attributes that you added, select the Active Directory attribute to map to.
- 10 Click **Save**.

The directory is updated the next time the directory syncs to the Active Directory.

Add Memory to Directories Management

You may need to allocate additional memory to Directories Management if you have Active Directory connections that contain a large number of users or groups.

By default, 4 GB of memory is allocated to the Directories Management service. This is sufficient for many small to medium sized deployments. If you have an Active Directory connection that uses a large number of users or groups, you may need to increase this memory allocation. Increased memory allocation is appropriate for systems with more than 100,000 users, each in 30 groups and 750 groups overall. For these system, VMware recommends increasing the Directories Management memory allocation to 6 GB.

Directories Management memory is calculated based on the total memory allocated to the vRealize Automation appliance. The following table shows memory allocations for relevant components.

Table 2-5. vRealize Automation Appliance Memory Allocation

Virtual Appliance memory	vRA service memory	VIDM service memory
18 GB	3.3 GB	4 GB
24 GB	4.9 GB	6 GB
30 GB	7.4 GB	9.1 GB

Note These allocations assume that all default services are enabled and running on the virtual appliance. They may change if some services are stopped.

Prerequisites

- An appropriate Active Directory connection is configured and functioning on your vRealize Automation deployment.

Procedure

- 1 Stop each machine on which a vRealize Automation appliance is running.
- 2 Increase the virtual appliance memory allocation on each machine.

If you are using the default memory allocation of 18 GB, VMware recommends increasing the memory allocation to 24 GB.

- 3 Restart the vRealize Automation appliance machines.

Create a Domain Host Lookup File to Override DNS Service Location (SRV) Lookup

When you enable Integrated Windows Authentication, the Directory configuration is changed to enable the DNS Service Location field. The connector service location lookup is not site aware. If you want to override the random DC selection, you can create a file called `domain_krb.properties` and add the domain to host values that take precedence over SRV lookup.

Procedure

- 1 From the appliance-va command line, log in as the user with root privileges.

- 2 Change directories to `/usr/local/horizon/conf` and create a file called `domain_krb.properties`.
- 3 Edit the `domain_krb.properties` file to add the list of the domain to host values. Add the information as `<AD Domain>=<host:port>, <host2:port2>, <host2:port2>`.

For example, enter the list as `example.com=examplehost.com:636, examplehost2.example.com:389`
- 4 Change the owner of the `domain_krb.properties` file to `horizon` and group to `www`. Enter **`chown horizon:www /usr/local/horizon/conf/domain_krb.properties`**.
- 5 Restart the service. Enter **`service horizon-workspace restart`**.

Managing User Attributes that Sync from Active Directory

The Directories Management User Attributes page lists the user attributes that sync to your Active Directory connection.

Changes that you make and save in the User Attributes page are added to the Mapped Attributes page in the Directories Management directory. The attributes changes are updated to the directory with the next sync to Active Directory.

The User Attributes page lists the default directory attributes that you can map to Active Directory attributes. You select the attributes that are required, and you can add other Active Directory attributes to sync to the directory.

Table 2-6. Default Active Directory Attributes to Sync to Directory

Directory Attribute Name	Default Mapping to Active Directory Attribute
<code>userPrincipalName</code>	<code>userPrincipalName</code>
<code>distinguishedName</code>	<code>distinguishedName</code>
<code>employeeId</code>	<code>employeeID</code>
<code>domain</code>	<code>canonicalName</code> . Adds the fully qualified domain name of the object.
<code>disabled (external user disabled)</code>	<code>userAccountControl</code> . Flagged with <code>UF_Account_Disable</code> . When an account is disabled, users cannot log in to access their applications and resources. The resources that users were entitled to are not removed from the account so that when the flag is removed from the account users can log in and access their entitled resources.
<code>phone</code>	<code>telephoneNumber</code>
<code>lastName</code>	<code>sn</code>
<code>firstName</code>	<code>givenName</code>
<code>email</code>	<code>mail</code>
<code>userName</code>	<code>sAMAccountName</code>

The User Attributes page lists the default directory attributes that you can map to Active Directory attributes. You select the attributes that are required, and you can add other Active Directory attributes to sync to the directory.

Table 2-7. Default Active Directory Attributes to Sync to Directory

Directory Attribute Name	Default Mapping to Active Directory Attribute
userPrincipalName	userPrincipalName
distinguishedName	distinguishedName
employeeId	employeeID
domain	canonicalName. Adds the fully qualified domain name of the object.
disabled (external user disabled)	userAccountControl. Flagged with UF_Account_Disable. When an account is disabled, users cannot log in to access their applications and resources. The resources that users were entitled to are not removed from the account so that when the flag is removed from the account users can log in and access their entitled resources.
phone	telephoneNumber
lastName	sn
firstName	givenName
email	mail
userName	sAMAccountName

Managing Connectors and Connector Clusters

The Connectors page lists deployed connectors for your enterprise network. A connector syncs user and group data between Active Directory and the Directories Management service, and when it is used as the identity provider, authenticates users to the service.

In vRealize Automation, each vRealize Automation appliance contains its own connector, and these connectors are suitable for most deployments.

When you associate a directory with a connector instance, the connector creates a partition for the associated directory called a worker. A connector instance can have multiple associated workers. Each worker acts as an identity provider. The connector syncs user and group data between Active Directory and the service through one or more workers. You define and configure authentication methods on a per worker basis.

You can manage various aspects of an Active Directory link from the Connectors page. This page contains a table and several buttons that enable you to complete various management tasks.

- In the Worker column, select a worker to view the connector details and navigate to the Auth Adapters page to see the status of the available authentication methods. For information about authentication, see [Integrating Alternative User Authentication Products with Directories Management](#).

- In the Identity Provider column, select the IdP to view, edit or disable. See [Configure a Third Party Identity Provider Connection](#).
- In the Associated Directory column, access the directory associated with this worker.
- Click **Join Domain** to join the connector to a specific Active Directory domain. For example when you configure Kerberos authentication, you must join the Active Directory domain either containing users or having trust relationship with the domains containing users.
- When you configure a directory with an Integrated Windows Authentication Active Directory, the connector joins the domain according to the configuration details.

Connectors in a Clustered Environment

In a distributed, vRealize Automation deployment, all available connectors perform any required user authorization, while a single designated connector handles all configuration synchronization. Typically, synchronization would include additions, deletions, or changes to the user configuration, and synchronization occurs automatically as long as all connectors are available. There are some specific situations in which automatic synchronization may not occur.

For changes related to directory configuration, such as base dn, vRealize Automation attempts to automatically push updates to all connectors in a cluster. If a connector is inoperable or unreachable for some reason, that connector will not receive the update, even when it resumes online operation. To implement configuration changes to connectors that may not have received them automatically, system administrators must manually save the changes to all applicable connectors.

For directory sync profile related changes, vRealize Automation attempts to automatically push updates to all connectors as well. If the sync connector is operational, the update is saved and pushed to all available authorization connectors. If one or more connectors is unreachable, the system admin receives a warning indicating that not all connectors were updated. If the sync connector is inoperable, the update fails and an error occurs. If the system admin changes the connector designated as the sync connector, the new sync connector receives the latest available profile information, and this information is pushed to all applicable, and available, connectors.

Join a Connector Machine to a Domain

In some cases, you may need to join a machine containing a Directories Management connector to a domain.

For Active Directory over LDAP directories, you can join a domain after creating the directory. For Active Directory (Integrated Windows Authentication) directories, the connector is joined to the domain automatically when you create the directory. In both cases, you must supply the appropriate credentials.

To join a domain, you need Active Directory credentials that have the privilege to "join computer to AD domain". This is configured in Active Directory with the following rights:

- Create Computer Objects
- Delete Computer Objects

When you join a domain, a computer object is created in the default location in Active Directory.

If you do not have the rights to join a domain, or if your company policy requires a custom location for the computer object, you must ask your administrator to create the object and then join the connector machine to the domain.

Procedure

- 1 Ask your Active Directory administrator to create the computer object in Active Directory in a location determined by your company policy. You must provide the host name of the connector. Ensure that you provide the fully-qualified domain name, for example `server.example.com`.

You can find the host name in the Host Name column on the Connectors page in the administrative console. Select **Administration > Directories Management > Connectors**.

- 2 After the computer object is created, click **Join Domain** on the Connectors page to join the domain using any domain user account available in Directories Management.

About Domain Controller Selection

The `domain_krb.properties` file determines which domain controllers are used for directories that have DNS Service Location (SRV records) lookup enabled. It contains a list of domain controllers for each domain. The connector creates the file initially, and you must maintain it subsequently. The file overrides DNS Service Location (SRV) lookup.

The following types of directories have DNS Service Location lookup enabled.

- Active Directory over LDAP with the **This Directory supports DNS Service Location** option selected
- Active Directory (Integrated Windows Authentication), which always has DNS Service Location lookup enabled

When you first create a directory that has DNS Service Location lookup enabled, a `domain_krb.properties` file is created automatically in the `/usr/local/horizon/conf` directory of the virtual machine and is auto-populated with domain controllers for each domain. To populate the file, the connector attempts to find domain controllers that are at the same site as the connector and selects two that are reachable and that respond the fastest.

When you create additional directories that have DNS Service Location enabled, or add new domains to an Integrated Windows Authentication directory, the new domains, and a list of domain controllers for them, are added to the file.

You can override the default selection at any time by editing the `domain_krb.properties` file. As a best practice, after you create a directory, view the `domain_krb.properties` file and verify that the domain controllers listed are the optimal ones for your configuration. For a global Active Directory deployment that has multiple domain controllers across different geographical locations, using a domain controller that is in close proximity to the connector ensures faster communication with Active Directory.

You must also update the file manually for any other changes. The following rules apply.

- The `domain_krb.properties` file is created in the virtual machine that contains the connector. In a typical deployment, with no additional connectors deployed, the file is created in the Directories Management service virtual machine. If you are using an additional connector for the directory, the file is created in the connector virtual machine. A virtual machine can only have one `domain_krb.properties` file.
- The file is created, and auto-populated with domain controllers for each domain, when you first create a directory that has DNS Service Location lookup enabled.
- Domain controllers for each domain are listed in order of priority. To connect to Active Directory, the connector tries the first domain controller in the list. If it is not reachable, it tries the second one in the list, and so on.
- The file is updated only when you create a new directory that has DNS Service Location lookup enabled or when you add a domain to an Integrated Windows Authentication directory. The new domain and a list of domain controllers for it are added to the file.

Note that if an entry for a domain already exists in the file, it is not updated. For example, if you created a directory, then deleted it, the original domain entry remains in the file and is not updated.

- The file is not updated automatically in any other scenario. For example, if you delete a directory, the domain entry is not deleted from the file.
- If a domain controller listed in the file is not reachable, edit the file and remove it.
- If you add or edit a domain entry manually, your changes will not be overwritten.

How Domain Controllers are Selected to Auto-Populate the `domain_krb.properties` File

To auto-populate the `domain_krb.properties` file, domain controllers are selected by first determining the subnet on which the connector resides (based on the IP address and netmask), then using the Active Directory configuration to identify the site of that subnet, getting the list of domain controllers for that site, filtering the list for the appropriate domain, and picking the two domain controllers that respond the fastest.

To detect the domain controllers that are the closest, VMware Identity Manager has the following requirements.

- The subnet of the connector must be present in the Active Directory configuration, or a subnet must be specified in the `runtime-config.properties` file.

The subnet is used to determine the site.

- The Active Directory configuration must be site aware.

If the subnet cannot be determined or if your Active Directory configuration is not site aware, DNS Service Location lookup is used to find domain controllers, and the file is populated with a few domain controllers that are reachable. Note that these domain controllers may not be at the same geographical location as the connector, which can result in delays or timeouts while communicating with Active Directory. In this case, edit the `domain_krb.properties` file manually and specify the correct domain controllers to use for each domain.

Sample domain_krb.properties File

```
example.com=host1.example.com:389,host2.example.com:389
```

■ [Override the Default Subnet Selection](#)

To auto-populate the `domain_krb.properties` file, the connector attempts to find domain controllers that are at the same site so there is minimal latency between the connector and Active Directory.

■ [Edit the domain_krb.properties file](#)

The `/usr/local/horizon/conf/domain_krb.properties` file determines the domain controllers to use for directories that have DNS Service Location lookup enabled. You can edit the file at any time to modify the list of domain controllers for a domain, or to add or delete domain entries. Your changes will not be overridden.

■ [Troubleshooting domain_krb.properties](#)

Use this information to troubleshoot the `domain_krb.properties` file.

Override the Default Subnet Selection

To auto-populate the `domain_krb.properties` file, the connector attempts to find domain controllers that are at the same site so there is minimal latency between the connector and Active Directory.

To find the site, the connector determines the subnet on which it resides, based on its IP address and netmask, then uses the Active Directory configuration to identify the site for that subnet. If the subnet of the virtual machine is not in Active Directory, or if you want to override the automatic subnet selection, you can specify a subnet in the `runtime-config.properties` file.

Procedure

- 1 Log in to the Directories Management virtual machine as the root user.

Note If you are using an additional connector for the directory, log in to the connector virtual machine.

- 2 Edit the `/usr/local/horizon/conf/runtime-config.properties` file and add the following attribute.

siteaware.subnet.override=*subnet*

where *subnet* is a subnet for the site whose domain controllers you want to use. For example:

siteaware.subnet.override=10.100.0.0/20

- 3 Save and close the file.

- 4 Restart the service.

```
service horizon-workspace restart
```

Edit the domain_krb.properties file

The `/usr/local/horizon/conf/domain_krb.properties` file determines the domain controllers to use for directories that have DNS Service Location lookup enabled. You can edit the file at any time to modify the list of domain controllers for a domain, or to add or delete domain entries. Your changes will not be overridden.

The file is initially created and auto-populated by the connector. You need to update it manually in some scenarios.

- If the domain controllers selected by default are not the optimal ones for your configuration, edit the file and specify the domain controllers to use.
- If you delete a directory, delete the corresponding domain entry from the file.
- If any domain controllers in the file are not reachable, remove them from the file.

See also [About Domain Controller Selection](#).

Procedure

- 1 Log in to the Directories Management virtual machine as the root user.

Note If you are using an additional connector for the directory, log in to the connector virtual machine.

- 2 Change directories to `/usr/local/horizon/conf`.
- 3 Edit the `domain_krb.properties` file to add or edit the list of domain to host values.

Use the following format:

domain=host:port,host2:port,host3:port

For example:

`example.com=examplehost1.example.com:389,examplehost2.example.com:389`

List the domain controllers in order of priority. To connect to Active Directory, the connector tries the first domain controller in the list. If it is not reachable, it tries the second one in the list, and so on.

Important Domain names must be in lowercase.

- 4 Change the owner of the `domain_krb.properties` file to `horizon` and group to `www` using the following command:

`chown horizon:www /usr/local/horizon/conf/domain_krb.properties`

- 5 Restart the service.

`service horizon-workspace restart`

Troubleshooting domain_krb.properties

Use this information to troubleshoot the `domain_krb.properties` file.

"Error resolving domain" error

If the `domain_krb.properties` file already includes an entry for a domain, and you try to create a new directory of a different type for the same domain, an "Error resolving domain" error occurs. You must edit the `domain_krb.properties` file and manually remove the domain entry before creating the new directory.

Domain controllers are unreachable

Once a domain entry is added to the `domain_krb.properties` file, it is not updated automatically. If any domain controllers listed in the file become unreachable, edit the file manually and remove them.

Managing Access Policies

The Directories Management policies are a set of rules that specify criteria that must be met for users to access their app portal or to launch specified Web applications.

You create the rule as part of a policy. Each rule in a policy can specify the following information.

- The network range, where users are allowed to log in from, such as inside or outside the enterprise network.
- The device type that can access through this policy.
- The order that the enabled authentication methods are applied.
- The number of hours the authentication is valid.
- Custom access denied message.

Note The policies do not control the length of time that a Web application session lasts. They control the amount of time that users have to launch a Web application.

The Directories Management service includes a default policy that you can edit. This policy controls access to the service as a whole. See [Applying the Default Access Policy](#). To control access to specific Web applications, you can create additional policies. If you do not apply a policy to a Web application, the default policy applies.

Configuring Access Policy Settings

A policy contains one or more access rules. Each rule consists of settings that you can configure to manage user access to their application portals as a whole or to specified Web applications.

Network Range

For each rule, you determine the user base by specifying a network range. A network range consists of one or more IP ranges. You create network ranges from the Identity & Access Management tab, Setup > Network Ranges page prior to configuring access policy sets.

Device Type

Select the type of device that the rule manages. The client types are Web Browser, Identity Manager Client App, iOS, Android, and All device types.

Authentication Methods

Set the priority of the authentication methods for the policy rule. The authentication methods are applied in the order they are listed. The first identity provider instances that meets the authentication method and network range configuration in the policy is selected, and the user authentication request is forwarded to the identity provider instance for authentication. If authentication fails, the next authentication method in the list is selected. If Certificate authentication is used, this method must be the first authentication method in the list.

You can configure access policy rules to require users to pass credentials through two authentication methods before they can sign in. If one or both authentication method fails and fallback methods are also configured, users are prompted to enter their credentials for the next authentication methods that are configured. The following two scenarios describe how authentication chaining can work.

- In the first scenario, the access policy rule is configured to require users to authenticate with their password and with their Kerberos credential. Fallback authentication is set up to require the password and the RADIUS credential for authentication. A user enters the password correctly, but fails to enter the correct Kerberos authentication credential. Since the user entered the correct password, the fallback authentication request is only for the RADIUS credential. The user does not need to re-enter the password.
- In the second scenario, the access policy rule is configured to require users to authenticate with their password and their Kerberos credential. Fallback authentication is set up to require RSA SecurID and a RADIUS for authentication. A user enters the password correctly but fails to enter the correct Kerberos authentication credential. The fallback authentication request is for both the RSA SecurID credential and the RADIUS credential for authentication.

Authentication Session Length

For each rule, you set the length that this authentication is valid. The value determines the maximum amount of time users have since their last authentication event to access their portal or to launch a specific Web application. For example, a value of 4 in a Web application rule gives users four hours to launch the web application unless they initiate another authentication event that extends the time.

Custom Access Denied Error Message

When users attempt to sign in and fail because of invalid credentials, incorrect configuration, or system error, an access denied message is displayed. The default message is

```
Access denied as no valid authentication methods were found.
```

You can create a custom error message for each access policy rule that overrides the default message. The custom message can include text and a link for a call to action message. For example, in a policy rules for mobile devices that you want to manage, if a user tries to sign in from an unenrolled device, the follow custom error message could appear:

```
Please enroll your device to access corporate resources by clicking the link at the end of this message. If your device is already enrolled, contact support for help.
```

Example Default Policy

The following policy serves as an example of how you can configure the default policy to control access to the apps portal. See [Manage the User Access Policy](#).

The policy rules are evaluated in the order listed. You can change the order of the policy by dragging and dropping the rule in the Policy Rules section.

In the following use case, this policy example applies to all applications.

The screenshot shows the configuration for a policy named 'default_access_policy_set'. The description is 'Default access policy set'. It applies to 'All Applications'. The policy rules section contains two rules:

Network Range	Device type	Authentication Method	Re-authenticate (Hours)	
Internal Network	Web Browser	First, try: Kerberos and 1 more...	8	✗ +
ALL RANGES	Web Browser	Securid	4	✗ +

- For the internal network (Internal Network Range), two authentication methods are configured for the rule, Kerberos and password authentication as the fallback method. To access the apps portal from an internal network, the service attempts to authenticate users with Kerberos authentication first, as it is the first authentication method listed in the rule. If that fails, users are prompted to enter their Active Directory password. Users log in using a browser and now have access to their user portals for an eight-hour session.
 - For access from the external network (All Ranges), only one authentication method is configured, RSA SecurID. To access the apps portal from an external network, users are required to log in with SecurID. Users log in using a browser and now have access to their apps portals for a four-hour session.
- When a user attempts to access a resource, except for Web applications covered by a Web-application-specific policy, the default portal access policy applies.

For example, the re-authentication time for such resources matches the re-authentication time of the default access policy rule. If the time for a user who logs in to the apps portal is eight hours according to the default access policy rule, when the user attempts to launch a resource during the session, the application launches without requiring the user to re-authenticate.

Managing Web-Application-Specific Policies

When you add Web applications to the catalog, you can create Web-application-specific access policies. For example, you can create an policy with rules for a Web application that specifies which IP addresses have access to the application, using which authentication methods, and for how long until reauthentication is required.

The following Web-application-specific policy provides an example of a policy you can create to control access to specified Web applications.

Example 1 Strict Web-Application-Specific Policy

In this example, a new policy is created and applied to a sensitive Web application.

The screenshot shows the configuration page for a policy named "Sensitive Web Applications". The description is "To be applied to Web applications that should have limited access." Under the "Applies To" section, "AirWatch Content Locker" is selected. The "Policy Rules" table is as follows:

Network Range	Device type	Authentication Method	Re-authenticate (Hours)	
Internal Network	Web Browser	First, try: Kerberos and 1 more...	8	✗ +
ALL RANGES	Web Browser	Securid	4	✗ +

- 1 To access the service from outside the enterprise network, the user is required to log in with RSA SecurID. The user logs in using a browser and now has access to the apps portal for a four hour session as provided by the default access rule.
- 2 After four hours, the user tries to launch a Web application with the Sensitive Web Applications policy set applied.
- 3 The service checks the rules in the policy and applies the policy with the ALL RANGES network range since the user request is coming from a Web browser and from the ALL RANGES network range.

The user logs in using the RSA SecurID authentication method, but the session just expired. The user is redirected for reauthentication. The reauthentication provides the user with another four hour session and the ability to launch the application. For the next four hours, the user can continue to launch the application without having to reauthenticate.

Example 2 Stricter Web-Application-Specific Policy

For a stricter rule to apply to extra sensitive Web applications, you could require re-authentication With Secureid on any device after 1 hour. The following is an example of how this type of policy access rule is implemented.

- 1 User logs in from an inside the enterprise network using the password authentication method.

Now, the user has access to the apps portal for eight hours, as set up in Example 1.

- 2 The user immediately tries to launch a Web application with the Example 2 policy rule applied, which requires RSA SecurID authentication.
- 3 The user is redirected to an identity provider that provides RSA SecurID authentication.
- 4 After the user successfully logs in, the service launches the application and saves the authentication event.

The user can continue to launch this application for up to one hour but is asked to reauthenticate after an hour, as dictated by the policy rule.

Manage the User Access Policy

vRealize Automation is supplied with a default user access policy that you can use as is or edit as needed to manage tenant access to applications.

vRealize Automation is supplied with a default user access policy, and you cannot add new policies. You can edit the existing policy to add rules.

Prerequisites

- Select or configure the appropriate identity providers for your deployment. See [Configure a Third Party Identity Provider Connection](#).
- Configure the appropriate network ranges for your deployment. See [Add or Edit a Network Range](#).
- Configure the appropriate authentication methods for your deployment. See [Integrating Alternative User Authentication Products with Directories Management](#).
- If you plan to edit the default policy (to control user access to the service as a whole), configure it before creating Web-application-specific policy.
- Add Web applications to the Catalog. The Web applications must be listed in the Catalog page before you can add a policy.
- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Directories Management > Policies**.
- 2 Click **Edit Policy** to add a new policy.
- 3 Add a policy name and description in the respective text boxes.
- 4 In the Applies To section, click **Select** and in the page that appears, select the Web applications that are associated with this policy.
- 5 In the Policy Rules section, click **+** to add a rule.

The Add a Policy Rule page appears.

- a Select the network range to apply to this rule.
- b Select the type of device that can access the web applications for this rule.
- c Select the authentication methods to use in the order the method should be applied.

- d Specify the number of hours a Web application session open.
 - e Click **Save**.
- 6 Configure additional rules as appropriate.
- 7 Click **Save**.

Configuring Additional Identity Provider Connections

You can configure additional identity provider connections as needed to support different identity management scenarios, including additional built-in identity providers and third-party identity providers.

You can create three types of identity provider connections using Directories Management.

- **Create Third-Party IDP** - Use this item to create a connection to an external third-party identity provider. Ensure that you have following before adding a third-party identity provider instance.
 - Verify that the third-party instances are SAML 2.0 compliant and that the service can reach the third-party instance.
 - Obtain the appropriate third-party metadata information to add when you configure the identity provider in the administration console. The metadata information you obtain from the third-party instance is either the URL to the metadata or the actual metadata.
- **Create Workspace IDP** - When you enable a connector to authenticate users during Directories Management configuration, a Workspace IDP is created as the identity provider and password authentication is enabled. You can configure additional workspace identity providers behind different load balancers.
- **Create Built-in IDP** - Built in Identity Providers use the internal Directories Management mechanisms to support authentication. You can configure built-in identity providers to use authentication methods that do not require the use of an on premises connector. When you configure the built-in provider, you associate the authentication methods to use with the provider.
- [Configure a Third Party Identity Provider Connection](#)
vRealize Automation is supplied with a default identity provider connection instance. Users may want to create additional identity provider connections to support just-in-time user provisioning or other custom configurations.
- [Configure Additional Workspace Identity Providers](#)
When you configure a Directories Management connector to authenticate users, a Workspace IDP is created and password authentication is enabled.
- [Configure a Built-in Identity Provider Connection](#)
You can configure multiple built-in identity providers and associate authentication methods with them.

Configure a Third Party Identity Provider Connection

vRealize Automation is supplied with a default identity provider connection instance. Users may want to create additional identity provider connections to support just-in-time user provisioning or other custom configurations.

vRealize Automation is supplied with an default identity provider. In most cases, the default provider is sufficient for customer needs. If you use an existing enterprise identity management solution, you can set up a custom identity provider to redirect users to your existing identity solution.

When using a custom identity provider, Directories Management uses SAML metadata from that provider to establish a trust relationship with the provider. After this relationship is established, Directories Management maps the users from the SAML assertion to the list of internal vRealize Automation users based the subject name ID.

Prerequisites

- Configure the network ranges that you want to direct to this identity provider instance for authentication. See [Add or Edit a Network Range](#).
- Access to the third-party metadata document. This can be either the URL to the metadata or the actual metadata.
- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Directories Management > Identity Providers**.

This page displays all configured Identity Providers.

- 2 Click **Add Identity Provider**.

A menu appears with Identity Provider options.

- 3 Select **Create Third Party IDP**.

- 4 Enter the appropriate information to configure the identity provider.

Option	Description
Identity Provider Name	Enter a name for this identity provider instance.
SAML Metadata	<p>Add the third party IdPs XML-based metadata document to establish trust with the identity provider.</p> <ol style="list-style-type: none"> 1 Enter the SAML metadata URL or the xml content into the text box. 2 Click Process IdP Metadata. The NameID formats supported by the IdP are extracted from the metadata and added to the Name ID Format table. 3 In the Name ID value column, select the user attribute in the service to map to the ID formats displayed. You can add custom third-party name ID formats and map them to the user attribute values in the service. 4 (Optional) Select the NameIDPolicy response identifier string format.
Users	Select the Directories Management directories of the users that can authenticate using this identity provider.
Just-in-Time User Provisioning	<p>Select the appropriate options to support just-in-time provisioning using an appropriate third party identity provider.</p> <p>Enter the Directory Name to use for just-in-time provisioning.</p> <p>Enter one or more Domains that exist within the external identity provider that you will use for just-in-time provisioning.</p>

Option	Description
Network	The existing network ranges configured in the service are listed. Select the network ranges for the users, based on their IP addresses, that you want to direct to this identity provider instance for authentication.
Authentication Methods	Add the authentication methods supported by the third-party identity provider. Select the SAML authentication context class that supports the authentication method.
SAML Signing Certificate	Click Service Provider (SP) Metadata to see URL to Directories Management SAML service provider metadata URL . Copy and save the URL. This URL is configured when you edit the SAML assertion in the third-party identity provider to map Directories Management users.
Hostname	If the Hostname field displays, enter the hostname where the identity provider is redirected to for authentication. If you are using a non-standard port other than 443, you can set this as Hostname:Port. For example, myco.example.com:8443.

5 Click **Add**.

What to do next

- Copy and save the Directories Management service provider metadata that is required to configure the third-party identity provider instance. This metadata is available either in the SAML Signing Certificate section of the Identity Provider page.
- Add the authentication method of the identity provider to the services default policy.

See the *Setting Up Resources in Directories Management* guide for information about adding and customizing resources that you add to the catalog.

Configure Additional Workspace Identity Providers

When you configure a Directories Management connector to authenticate users, a Workspace IDP is created and password authentication is enabled.

You can configure additional connectors to operate behind multiple load balancers. When your deployment includes more than one load balancer, you can configure additional Workspace identity providers for authentication in each load balancer configuration.

Procedure

- 1 Select **Administration > Directories Management > Identity Providers**.

This page displays all configured Identity Providers.

- 2 Click **Add Identity Provider**.

A menu appears with Identity Provider options.

- 3 Select **Create Workspace IDP**.

- 4 Enter the appropriate information to configure the identity provider.

Option	Description
Identity Provider Name	Enter the name for this built-in identity provider instance.
Users	Select the users to authenticate. The configured directories are listed.

Option	Description
Users	Select the group of users who can authenticate using this Workspace identity provider.
Network	The existing network ranges configured in the service are listed. Select the network range for the users based on the IP addresses that you want to direct to this identity provider instance for authentication.
Authentication Methods	Authentication methods that are configured for the service are displayed. Select the check box for the authentication methods to associate with this identity provider. For device compliance and Password, with AirWatch and AirWatch Connector, ensure that the option is enabled on the AirWatch configuration page.

5 Click **Add**.

Configure a Built-in Identity Provider Connection

You can configure multiple built-in identity providers and associate authentication methods with them.

Prerequisites

If you are using Built-in Keberos authentication, download the KDC issuer certificate to use in the AirWatch configuration of the iOS device management profile.

Procedure

1 Select **Administration > Directories Management > Identity Providers**.

This page displays all configured Identity Providers.

2 Click **Add Identity Provider**.

A menu appears with Identity Provider options.

3 Select **Create Built-in IDP**.

4 Enter the appropriate information to configure the identity provider.

Option	Description
Identity Provider Name	Enter the name for this built-in identity provider instance.
Users	Select the users to authenticate. The configured directories are listed.
Network	The existing network ranges configured in the service are listed. Select the network range for the users based on the IP addresses that you want to direct to this identity provider instance for authentication.
Authentication Methods	The authentication methods that are configured for the service are displayed. Select the check box for the authentication methods to associate with this identity provider. For device compliance and Password, with AirWatch and AirWatch Connector, ensure that the appropriate option is enabled on the AirWatch configuration page.

5 Click **Add**.

Integrating Alternative User Authentication Products with Directories Management

Typically, when you initially configure Directories Management, you use the connectors supplied with your existing vRealize Automation infrastructure to create an Active Directory connection for user ID and password based authentication and management. Alternatively, you can integrate Directories Management with other authentication solutions such as Kerberos or RSA SecurID.

The identity provider instance can be the Directories Management connector instance, third-party identity provider instances, or a combination of both.

The identity provider instance that you use with the Directories Management service creates an in-network federation authority that communicates with the service using SAML 2.0 assertions.

When you initially deploy the Directories Management service, the connector is the initial identity provider for the service. Your existing Active Directory infrastructure is used for user authentication and management.

The following authentication methods are supported. You configure these authentication methods from the administration console.

Table 2-8. User Authentication Types Supported by Directories Management

Authentication Types	Description
Password (on-premise deployment)	Without any configuration after Active Directory is configured, Directories Management supports Active Directory password authentication. This method authenticates users directly against Active Directory.
Kerberos for desktops	Kerberos authentication provides domain users with single sign-in access to their apps portal. Users do not need to sign in again after they sign in to the network.
Certificate (on-premise deployment)	<p>Certificate-based authentication can be configured to allow clients to authenticate with certificates on their desktop and mobile devices or to use a smart card adapter for authentication.</p> <p>Certificate-based authentication is based on what the user has and what the person knows. An X.509 certificate uses the public key infrastructure standard to verify that a public key contained within the certificate belongs to the user.</p>
RSA SecurID (on-premise deployment)	When RSA SecurID authentication is configured, Directories Management is configured as the authentication agent in the RSA SecurID server. RSA SecurID authentication requires users to use a token-based authentication system. RSA SecurID is an authentication method for users accessing Directories Management from outside the enterprise network.
RADIUS (on-premise deployment)	RADIUS authentication provides two-factor authentication options. You set up the RADIUS server that is accessible to the Directories Management service. When users sign in with their user name and passcode, an access request is submitted to the RADIUS server for authentication.
RSA Adaptive Authentication (on-premise deployment)	RSA authentication provides a stronger multi-factor authentication than only user name and password authentication against Active Directory. When RSA Adaptive Authentication is enabled, the risk indicators specified in the risk policy set up in the RSA Policy Management application. The Directories Management service configuration of adaptive authentication is used to determine the required authentication prompts.

Table 2-8. User Authentication Types Supported by Directories Management (Continued)

Authentication Types	Description
Mobile SSO (for iOS)	Mobile SSO for iOS authentication is used for single sign-on authentication for AirWatch-managed iOS devices. Mobile SSO (for iOS) authentication uses a Key Distribution Center (KDC) that is part of the Directories Management service. You must initiate the KDC service in the VMware Identity Manager service before you enable this authentication method.
Mobile SSO (for Android)	Mobile SSO for Android authentication is used for single sign-on authentication for AirWatch-managed Android devices. A proxy service is set up between the Directories Management service and AirWatch to retrieve the certificate from AirWatch for authentication.
Password (AirWatch Connector)	The AirWatch Cloud Connector can be integrated with the Directories Management service for user password authentication. You configure the Directories Management service to sync users from the AirWatch directory.

Users are authenticated based on the authentication methods, the default access policy rules, network ranges, and the identity provider instance you configure. After the authentication methods are configured, you create access policy rules that specify the authentication methods to be used by device type.

Configuring SecurID for Directories Management

When you configure RSA SecurID server, you must add the Directories Management service information as the authentication agent on the RSA SecurID server and configure the RSA SecurID server information on the Directories Management service.

When you configure SecurID to provide additional security, you must ensure that your network is properly configured for your Directories Management deployment. For SecurID specifically, you must ensure that the appropriate port is open to enable SecurID to authenticate users outside your network.

After you run the Directories Management Setup wizard and configured your Active Directory connection, you have the information necessary to prepare the RSA SecurID server. After you prepare the RSA SecurID server for Directories Management, you enable SecurID in the administration console.

- **Prepare the RSA SecurID Server**

The RSA SecurID server must be configured with information about the Directories Management appliance as the authentication agent. The information required is the host name and the IP addresses for network interfaces.

- **Configure RSA SecurID Authentication**

After Directories Management is configured as the authentication agent in the RSA SecurID server, you must add the RSA SecurID configuration information to the connector.

Prepare the RSA SecurID Server

The RSA SecurID server must be configured with information about the Directories Management appliance as the authentication agent. The information required is the host name and the IP addresses for network interfaces.

Prerequisites

- Verify that one of the following RSA Authentication Manager versions is installed and functioning on the enterprise network: RSA AM 6.1.2, 7.1 SP2 and later, and 8.0 and later. The Directories Management server uses AuthSDK_Java_v8.1.1.312.06_03_11_03_16_51 (Agent API 8.1 SP1), which only supports the preceding versions of RSA Authentication Manager (the RSA SecurID server). For information about installing and configuring RSA Authentication Manager (RSA SecurID server), see RSA documentation.

Procedure

- 1 On a supported version of the RSA SecurID server, add the Directories Management connector as an authentication agent. Enter the following information.

Option	Description
Hostname	The host name of Directories Management.
IP address	The IP address of Directories Management.
Alternate IP address	If traffic from the connector passes through a network address translation (NAT) device to reach the RSA SecurID server, enter the private IP address of the appliance.

- 2 Download the compressed configuration file and extract the `sdconf.rec` file.

Be prepared to upload this file later when you configure RSA SecurID in Directories Management.

What to do next

Go to the administration console and in the Identity & Access Management tab Setup pages, select the connector and in the AuthAdapters page configure SecurID.

Configure RSA SecurID Authentication

After Directories Management is configured as the authentication agent in the RSA SecurID server, you must add the RSA SecurID configuration information to the connector.

Prerequisites

- Verify that RSA Authentication Manager (the RSA SecurID server) is installed and properly configured.
- Download the compressed file from the RSA SecurID server and extract the server configuration file.

Procedure

- 1 As a tenant administrator, navigate to **Administration > Directories Management > Connectors**
- 2 On the Connectors page, select the Worker link for the connector that is being configured with RSA SecurID.
- 3 Click **Auth Adapters** and then click **SecurIDIdpAdapter**.

You are redirected to the identity manager sign in page.

- 4 In the Authentication Adapters page SecurIDdpAdapter row, click **Edit**.
- 5 Configure the SecurID Authentication Adapter page.

Information used and files generated on the RSA SecurID server are required when you configure the SecurID page.

Option	Action
Name	A name is required. The default name is SecurIDdpAdapter. You can change this.
Enable SecurID	Select this box to enable SecurID authentication.
Number of authentication attempts allowed	Enter the maximum number of failed login attempts when using the RSA SecurID token. The default is five attempts.
Connector Address	Enter the IP address of the connector instance. The value you enter must match the value you used when you added the connector appliance as an authentication agent to the RSA SecurID server. If your RSA SecurID server has a value assigned to the Alternate IP address prompt, enter that value as the connector IP address. If no alternate IP address is assigned, enter the value assigned to the IP address prompt.
Agent IP Address	Enter the value assigned to the IP address prompt in the RSA SecurID server.
Server Configuration	Upload the RSA SecurID server configuration file. First, you must download the compressed file from the RSA SecurID server and extract the server configuration file, which by default is named <code>sdconf.rec</code> .
Node Secret	Leaving the node secret field blank allows the node secret to auto generate. It is recommended that you clear the node secret file on the RSA SecurID server and intentionally do not upload the node secret file. Ensure that the node secret file on the RSA SecurID server and on the server connector instance always match. If you change the node secret at one location, change it at the other location.

- 6 Click **Save**.

What to do next

Add the authentication method to the default access policy. Navigate to **Administration > Directories Management > Policies** and click **Edit Default Policy** to edit the default policy rules to add the SecurID authentication method to the rule in the correct authentication order.

Configuring RADIUS for Directories Management

You can configure Directories Management so that users are required to use RADIUS (Remote Authentication Dial-In User Service) authentication. You configure the RADIUS server information on the Directories Management service.

RADIUS support offers a wide range of alternative two-factor token-based authentication options. Because two-factor authentication solutions, such as RADIUS, work with authentication managers installed on separate servers, you must have the RADIUS server configured and accessible to the identity manager service.

When users sign in to their My Apps portal and RADIUS authentication is enabled, a special login dialog box appears in the browser. Users enter their RADIUS authentication user name and passcode in the login dialog box. If the RADIUS server issues an access challenge, the identity manager service displays a dialog box prompting for a second passcode. Currently support for RADIUS challenges is limited to prompting for text input.

After a user enters credentials in the dialog box, the RADIUS server can send an SMS text message or email, or text using some other out-of-band mechanism to the user's cell phone with a code. The user can enter this text and code into the login dialog box to complete the authentication.

If the RADIUS server provides the ability to import users from Active Directory, end users might first be prompted to supply Active Directory credentials before being prompted for a RADIUS authentication username and passcode.

Prepare the RADIUS Server

Set up the RADIUS server and then configure it to accept RADIUS requests from the Directories Management service.

Refer to your RADIUS vendor's setup guides for information about setting up the RADIUS server. Note your RADIUS configuration information as you use this information when you configure RADIUS in the service. To view the type of RADIUS information required to configure Directories Management see [Configure RADIUS Authentication in Directories Management](#).

You can set up a secondary Radius authentication server to be used for high availability. If the primary RADIUS server does not respond within the server timeout configured for RADIUS authentication, the request is routed to the secondary server. When the primary server does not respond, the secondary server receives all future authentication requests.

Configure RADIUS Authentication in Directories Management

You enable RADIUS software on an authentication manager server. For RADIUS authentication, follow the vendor's configuration documentation.

Prerequisites

Install and configure the RADIUS software on an authentication manager server. For RADIUS authentication, follow the vendor's configuration documentation.

You need to know the following RADIUS server information to configure RADIUS on the service.

- IP address or DNS name of the RADIUS server.
- Authentication port numbers. Authentication port is usually 1812.
- Authentication type. The authentication types include PAP (Password Authentication Protocol), CHAP (Challenge Handshake Authentication Protocol), MSCHAP1, MSCHAP2 (Microsoft Challenge Handshake Authentication Protocol, versions 1 and 2).
- RADIUS shared secret that is used for encryption and decryption in RADIUS protocol messages.
- Specific timeout and retry values needed for RADIUS authentication.
- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Directories Management > Connectors**.
- 2 On the Connectors page, select the Worker link for the connector that is being configured for RADIUS authentication.
- 3 Click **Auth Adapters** and then click **RadiusAuthAdapter**.
You are redirected to the identity manager sign-in page.
- 4 Click **Edit** to configure these fields on the Authentication Adapter page.

Option	Action
Name	A name is required. The default name is RadiusAuthAdapter. You can change this.
Enable Radius Adapter	Select this box to enable RADIUS authentication.
Number of authentication attempts allowed	Enter the maximum number of failed login attempts when using RADIUS to log in. The default is five attempts.
Number of attempts to Radius server	Specify the total number of retry attempts. If the primary server does not respond, the service waits for the configured time before retrying again.
Radius server hostname/address	Enter the host name or the IP address of the RADIUS server.
Authentication port	Enter the Radius authentication port number. This is usually 1812.
Accounting port	Enter 0 for the port number. The accounting port is not used at this time.
Authentication type	Enter the authentication protocol that is supported by the RADIUS server. Either PAP, CHAP, MSCHAP1, OR MSCHAP2.
Shared secret	Enter the shared secret that is used between the RADIUS server and the VMware Identity Manager service.
Server timeout in seconds	Enter the RADIUS server timeout in seconds, after which a retry is sent if the RADIUS server does not respond.
Realm Prefix	(Optional) The user account location is called the realm. If you specify a realm prefix string, the string is placed at the beginning of the user name when the name is sent to the RADIUS server. For example, if the user name is entered as jdoe and the realm prefix DOMAIN-A\ is specified, the user name DOMAIN-A\jdoe is sent to the RADIUS server. If you do not configure these fields, only the user name that is entered is sent.

Option	Action
Realm Suffix	(Optional) If you specify a realm suffix, the string is placed at end of the user name. For example, if the suffix is @myco.com, the username jdoe@myco.com is sent to the RADIUS server.
Login page passphrase hint	Enter the text string to display in the message on the user login page to direct users to enter the correct Radius passcode. For example, if this field is configured with AD password first and then SMS passcode , the login page message would read Enter your AD password first and then SMS passcode . The default text string is RADIUS Passcode .

- 5 You can enable a secondary RADIUS server for high availability.

Configure the secondary server as described in step 4.

- 6 Click **Save**.

What to do next

Add the RADIUS authentication method to the default access policy. Select **Administration > Directories Management > Policies** and click **Edit Default Policy** to edit the default policy rules to add the RADIUS authentication method to the rule in the correct authentication order.

Configuring a Certificate or Smart Card Adapter for Use with Directories Management

You can configure x509 certificate authentication to allow clients to authenticate with certificates on their desktop and mobile devices or to use a smart card adapter for authentication. Certificate-based authentication is based on what the user has (the private key or smart card), and what the person knows (the password to the private key or the smart-card PIN.) An X.509 certificate uses the public key infrastructure (PKI) standard to verify that a public key contained within the certificate belongs to the user. With smart card authentication, users connect the smart card with the computer and enter a PIN.

The smart card certificates are copied to the local certificate store on the user's computer. The certificates in the local certificate store are available to all the browsers running on this user's computer, with some exceptions, and therefore, are available to a Directories Management instance in the browser.

- [Using User Principal Name for Certificate Authentication](#)

You can use certificate mapping in Active Directory. Certificate and smart card logins uses the user principal name (UPN) from Active Directory to validate user accounts. The Active Directory accounts of users attempting to authenticate in the Directories Management service must have a valid UPN that corresponds to the UPN in the certificate.

- [Certificate Authority Required for Authentication](#)

To enable logging in using certificate authentication, root certificates and intermediate certificates must be uploaded to the Directories Management.

- [Using Certificate Revocation Checking](#)

You can configure certificate revocation checking to prevent users who have their user certificates revoked from authenticating. Certificates are often revoked when a user leaves an organization, loses a smart card, or moves from one department to another.

■ [Configure Certificate Authentication for Directories Management](#)

You enable and configure certificate authentication from the vRealize Automation administration console Directories Management feature.

Using User Principal Name for Certificate Authentication

You can use certificate mapping in Active Directory. Certificate and smart card logins uses the user principal name (UPN) from Active Directory to validate user accounts. The Active Directory accounts of users attempting to authenticate in the Directories Management service must have a valid UPN that corresponds to the UPN in the certificate.

You can configure the Directories Management to use an email address to validate the user account if the UPN does not exist in the certificate.

You can also enable an alternate UPN type to be used.

Certificate Authority Required for Authentication

To enable logging in using certificate authentication, root certificates and intermediate certificates must be uploaded to the Directories Management.

The certificates are copied to the local certificate store on the user's computer. The certificates in the local certificate store are available to all the browsers running on this user's computer, with some exceptions, and therefore, are available to a Directories Management instance in the browser.

For smart-card authentication, when a user initiates a connection to a the Directories Management instance, the Directories Management service sends a list of trusted certificate authorities (CA) to the browser. The browser checks the list of trusted CAs against the available user certificates, selects a suitable certificate, and then prompts the user to enter a smart card PIN. If multiple valid user certificates are available, the browser prompts the user to select a certificate.

If a user cannot authenticate, the root CA and intermediate CA might not be set up correctly, or the service has not been restarted after the root and intermediate CAs were uploaded to the server. In these cases, the browser cannot show the installed certificates, the user cannot select the correct certificate, and certificate authentication fails.

Using Certificate Revocation Checking

You can configure certificate revocation checking to prevent users who have their user certificates revoked from authenticating. Certificates are often revoked when a user leaves an organization, loses a smart card, or moves from one department to another.

Certificate revocation checking with certificate revocation lists (CRLs) and with the Online Certificate Status Protocol (OCSP) is supported. A CRL is a list of revoked certificates published by the CA that issued the certificates. OCSP is a certificate validation protocol that is used to get the revocation status of a certificate.

You can configure certificate revocation checking in the administration console Connectors > Auth Adapters > CertificateAuthAdapter page when you configure certificate authentication.

You can configure both CRL and OCSP in the same certificate authentication adapter configuration. When you configure both types of certificate revocation checking and the Use CRL in case of OCSP failure checkbox is enabled, OCSP is checked first and if OCSP fails, revocation checking falls back to CRL. Revocation checking does not fall back to OCSP if CRL fails.

Logging in with CRL Checking

When you enable certificate revocation, the Directories Management server reads a CRL to determine the revocation status of a user certificate.

If a certificate is revoked, authentication through the certificate fails.

Logging in with OCSP Certificate Checking

When you configure Certificate Status Protocol (OCSP) revocation checking, Directories Management sends a request to an OCSP responder to determine the revocation status of a specific user certificate. The Directories Management server uses the OCSP signing certificate to verify that the responses it receives from the OCSP responder are genuine.

If the certificate is revoked, authentication fails.

You can configure authentication to fall back to CRL checking if it does not receive a response from the OCSP responder or if the response is invalid.

Configure Certificate Authentication for Directories Management

You enable and configure certificate authentication from the vRealize Automation administration console Directories Management feature.

Prerequisites

- Obtain the Root certificate and intermediate certificates from the CA that signed the certificates presented by your users.
- (Optional) List of Object Identifier (OID)s of valid certificate policies for certificate authentication.
- For revocation checking, the file location of the CRL, the URL of the OCSP server.
- (Optional) OCSP Response Signing certificate file location.
- Consent form content, if enabling a consent form to display before authentication.

Procedure

- 1 As a tenant administrator, navigate to **Administration > Directories Management > Connectors**
- 2 On the Connectors page, select the Worker link for the connector that is being configured.
- 3 Click **Auth Adapters** and then click **CertificateAuthAdapter**.
You are redirected to the identity manager sign in page.
- 4 In the CertificateAuthAdapter row, click **Edit**.

5 Configure the Certificate Authentication Adapter page.

Note An asterisk indicates a required field. All other fields are optional.

Option	Description
*Name	A name is required. The default name is CertificateAuthAdapter. You can change this name.
Enable certificate adapter	Select the check box to enable certificate authentication.
*Root and intermediate CA certificates	Select the certificate files to upload. You can select multiple root CA and intermediate CA certificates that are encoded as DER or PEM.
Uploaded CA certificates	<p>The uploaded certificate files are listed in the Uploaded Ca Certificates section of the form.</p> <p>You must restart the service before the new certificates are made available.</p> <p>Click Restart Web Service to restart the service and add the certificates to the trusted service.</p> <p>Note Restarting the service does not enable certificate authentication. After the service is restarted, continue configuring this page. Clicking Save at the end of the page enables certificate authentication on the service.</p>
Use email if no UPN in certificate	If the user principal name (UPN) does not exist in the certificate, select this checkbox to use the emailAddress attribute as the Subject Alternative Name extension to validate user accounts.
Certificate policies accepted	<p>Create a list of object identifiers that are accepted in the certificate policies extensions.</p> <p>Enter the object ID numbers (OID) for the Certificate Issuing Policy. Click Add another value to add additional OIDs.</p>
Enable cert revocation	Select the check box to enable certificate revocation checking. This prevents users who have revoked user certificates from authenticating.
Use CRL from certificates	Select the check box to use the certificate revocation list (CRL) published by the CA that issued the certificates to validate a certificate's status, revoked or not revoked.
CRL Location	Enter the server file path or the local file path from which to retrieve the CRL.
Enable OCSP Revocation	Select the check box to use the Online Certificate Status Protocol (OCSP) certificate validation protocol to get the revocation status of a certificate.
Use CRL in case of OCSP failure	If you configure both CRL and OCSP, you can check this box to fall back to using CRL if OCSP checking is not available.
Send OCSP Nonce	Select this check box if you want the unique identifier of the OCSP request to be sent in the response.
OCSP URL	If you enabled OCSP revocation, enter the OCSP server address for revocation checking.
OCSP responder's signing certificate	Enter the path to the OCSP certificate for the responder, <i>/path/to/file.cer</i> .
Enable consent form before authentication	Select this check box to include a consent form page to appear before users log in to their My Apps portal using certificate authentication.
Consent form content	Type the text that displays in the consent form in this text box.

6 Click **Save**.

What to do next

- Add the certificate authentication method to the default access policy. Navigate to **Administration > Directories Management > Policies** and click **Edit Default Policy** to edit the default policy rules and add Certificate and make it the first authentication method for the default policy. Certificate must be first authentication method listed in the policy rule, otherwise certificate authentication fails.
- When Certificate Authentication is configured, and the service appliance is set up behind a load balancer, make sure that the Directories Management connector is configured with SSL pass-through at the load balancer and not configured to terminate SSL at the load balancer. This configuration ensures that the SSL handshake is between the connector and the client in order to pass the certificate to the connector.

Configuring a Third-Party Identity Provider Instance to Authenticate Users

You can configure a third-party identity provider to be used to authenticate users in the Directories Management service.

Complete the following tasks prior to using the administration console to add the third-party identity provider instance.

- Verify that the third-party instances are SAML 2.0 compliant and that the service can reach the third-party instance.
- Obtain the appropriate third-party metadata information to add when you configure the identity provider in the administration console. The metadata information you obtain from the third-party instance is either the URL to the metadata or the actual metadata.

Configure a Third Party Identity Provider Connection

vRealize Automation is supplied with a default identity provider connection instance. Users may want to create additional identity provider connections to support just-in-time user provisioning or other custom configurations.

vRealize Automation is supplied with an default identity provider. In most cases, the default provider is sufficient for customer needs. If you use an existing enterprise identity management solution, you can set up a custom identity provider to redirect users to your existing identity solution.

When using a custom identity provider, Directories Management uses SAML metadata from that provider to establish a trust relationship with the provider. After this relationship is established, Directories Management maps the users from the SAML assertion to the list of internal vRealize Automation users based the subject name ID.

Prerequisites

- Configure the network ranges that you want to direct to this identity provider instance for authentication. See [Add or Edit a Network Range](#).
- Access to the third-party metadata document. This can be either the URL to the metadata or the actual metadata.
- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Directories Management > Identity Providers**.

This page displays all configured Identity Providers.

- 2 Click **Add Identity Provider**.

A menu appears with Identity Provider options.

- 3 Select **Create Third Party IDP**.

- 4 Enter the appropriate information to configure the identity provider.

Option	Description
Identity Provider Name	Enter a name for this identity provider instance.
SAML Metadata	<p>Add the third party IdPs XML-based metadata document to establish trust with the identity provider.</p> <ol style="list-style-type: none"> 1 Enter the SAML metadata URL or the xml content into the text box. 2 Click Process IdP Metadata. The NameID formats supported by the IdP are extracted from the metadata and added to the Name ID Format table. 3 In the Name ID value column, select the user attribute in the service to map to the ID formats displayed. You can add custom third-party name ID formats and map them to the user attribute values in the service. 4 (Optional) Select the NameIDPolicy response identifier string format.
Users	Select the Directories Management directories of the users that can authenticate using this identity provider.
Just-in-Time User Provisioning	<p>Select the appropriate options to support just-in-time provisioning using an appropriate third party identity provider.</p> <p>Enter the Directory Name to use for just-in-time provisioning.</p> <p>Enter one or more Domains that exist within the external identity provider that you will use for just-in-time provisioning.</p>
Network	<p>The existing network ranges configured in the service are listed.</p> <p>Select the network ranges for the users, based on their IP addresses, that you want to direct to this identity provider instance for authentication.</p>
Authentication Methods	Add the authentication methods supported by the third-party identity provider. Select the SAML authentication context class that supports the authentication method.
SAML Signing Certificate	Click Service Provider (SP) Metadata to see URL to Directories Management SAML service provider metadata URL . Copy and save the URL. This URL is configured when you edit the SAML assertion in the third-party identity provider to map Directories Management users.
Hostname	If the Hostname field displays, enter the hostname where the identity provider is redirected to for authentication. If you are using a non-standard port other than 443, you can set this as Hostname:Port. For example, myco.example.com:8443.

- 5 Click **Add**.

What to do next

- Copy and save the Directories Management service provider metadata that is required to configure the third-party identity provider instance. This metadata is available either in the SAML Signing Certificate section of the Identity Provider page.
- Add the authentication method of the identity provider to the services default policy.

See the *Setting Up Resources in Directories Management* guide for information about adding and customizing resources that you add to the catalog.

Managing Authentication Methods to Apply to Users

The Directories Management service attempts to authenticate users based on the authentication methods, the default access policy, network ranges, and the identity provider instances you configure.

When users attempt to log in, the service evaluates the default access policy rules to select which rule in the policy to apply. The authentication methods are applied in the order they are listed in the rule. The first identity provider instance that meets the authentication method and network range requirements of the rule is selected and the user authentication request is forwarded to the identity provider instance for authentication. If authentication fails, the next authentication method configured in the rule is applied.

You can add rules that specify the authentication methods to be used by device type or by device type and from a specific network range. For example, you could configure a rule requiring users that sign in using iOS devices from a specific network to authenticate using RSA SecurID and another rule that specifies all device types signing in from the internal network IP address to authenticate using their password.

Add or Edit a Network Range

You can manage the network ranges to define the IP addresses from which users can log in via an Active Directory link. You add the network ranges you create to specific identity provider instances and to access policy rules.

Define network ranges for your Directories Management deployment based on your network topology.

One network range, called ALL RANGES, is created as the default. This network range includes every IP address available on the Internet, 0.0.0.0 to 255.255.255.255. Even if your deployment has a single identity provider instance, you can change the IP address range and add other ranges to exclude or include specific IP addresses to the default network range. You can create other network ranges with specific IP addresses that you can apply for specific purpose.

Note The default network range, ALL RANGES, and its description, "a network for all ranges," are editable. You can edit the name and description, including changing the text to a different language, by clicking the network range name on the Network Ranges page.

Prerequisites

- You have configured tenants for your vRealize Automation deployment set up an appropriate Active Directory link to support basic Active Directory user ID and password authentication.
- Active Directory is installed and configured for use on your network.

- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Directories Management > Network Ranges**.
- 2 Edit an existing network range or add a new network range.

Option	Description
Edit an existing range	Click the network range name to edit.
Add a range	Click Add Network Range to add a new range.

- 3 Complete the form.

Form Item	Description
Name	Enter a name for the network range.
Description	Enter a description for the Network Range.
View Pods	The View Pods option only appears when the View module is enabled. Client Access URL Host. Enter the correct Horizon Client access URL for the network range. Client Access Port. Enter the correct Horizon Client access port number for the network range.
IP Ranges	Edit or add IP ranges until all desired and no undesired IP addresses are included.

What to do next

- Associate each network range with an identity provider instance.
- Associate network ranges with access policy rule as appropriate. See [Configuring Access Policy Settings](#).

Select Attributes to Sync with Directory

When you set up the Directories Management directory to sync with Active Directory, you specify the user attributes that sync to the directory. Before you set up the directory, you can specify on the User Attributes page which default attributes are required and, if you want, add additional attributes that you want to map to Active Directory attributes.

When you configure the User Attributes page before the directory is created, you can change default attributes from required to not required, mark attributes as required, and add custom attributes.

For a list of the default mapped attributes, see [Managing User Attributes that Sync from Active Directory](#).

After the directory is created, you can change a required attribute to not be required, and you can delete custom attributes. You cannot change an attribute to be a required attribute.

When you add other attributes to sync to the directory, after the directory is created, go to the directory's Mapped Attributes page to map these attributes to Active Directory Attributes.

Procedure

- 1 Log in to vRealize Automation as a system or tenant administrator.
- 2 Click the Administration tab.

3 Select Directories Management > User Attributes

4 In the Default Attributes section, review the required attribute list and make appropriate changes to reflect what attributes should be required.

5 In the Attributes section, add the Directories Management directory attribute name to the list.

6 Click **Save**.

The default attribute status is updated and attributes you added are added on the directory's Mapped Attributes list.

7 After the directory is created, go to the Identity Stores page and select the directory.

8 Click **Sync Settings > Mapped Attributes**.

9 In the drop-down menu for the attributes that you added, select the Active Directory attribute to map to.

10 Click **Save**.

The directory is updated the next time the directory syncs to the Active Directory.

Applying the Default Access Policy

The Directories Management service includes a default access policy that controls user access to their apps portals. You can edit the policy to change the policy rules as necessary.

When you enable authentication methods other than password authentication, you must edit the default policy to add the enabled authentication method to the policy rules.

Each rule in the default access policy requires that a set of criteria be met in order to allow user access to the apps portal. You apply a network range, select which type of user can access content and select the authentication methods to use. See [Managing Access Policies](#).

The number of attempts the service makes to login a user using a given authentication method varies. The service only makes one attempt at authentication for Kerberos or certificate authentication. If the attempt is not successful in logging in a user, the next authentication method in the rule is attempted. The maximum number of failed login attempts for Active Directory password and RSA SecurID authentication is set to five by default. When a user has five failed login attempts, the service attempts to log in the user with the next authentication method on the list. When all authentication methods are exhausted, the service issues an error message.

Apply Authentication Methods to Policy Rules

Only the password authentication method is configured in the default policy rules. You must edit the policy rules to select the other authentication methods you configured and set the order in which the authentication methods are used for authentication.

Prerequisites

Enable and configure the authentication methods that your organization supports. See [Integrating Alternative User Authentication Products with Directories Management](#)

Procedure

- 1 Select **Administration > Directories Management > Policies**
- 2 Click the default access policy to edit.
- 3 To edit a policy rule, click the authentication method to edit in the Policy Rules, Authentication Method column.

The add a new policy rule, click the + icon.

- 4 Click **Save** and click **Save** again on the Policy page.

- 5 Click **Save** and click **Save** again on the Policy page.

Configuring Kerberos for Directories Management

Kerberos authentication provides users who are successfully signed in to their Active Directory domain to access their apps portal without additional credential prompts. You enable Windows authentication to allow the Kerberos protocol to secure interactions between users' browsers and the Directories Management service. You do not need to directly configure Active Directory to make Kerberos function with your deployment.

Currently, interactions between a user's browser and the service are authenticated by Kerberos on the Windows operating systems only. Accessing the service from other operating systems does not take advantage of Kerberos authentication.

■ [Configure Kerberos Authentication](#)

To configure the Directories Management service to provide Kerberos authentication, you must join to the domain and enable Kerberos authentication on the Directories Management connector.

■ [Configure Internet Explorer to Access the Web Interface](#)

You must configure the Internet Explorer browser if Kerberos is configured for your deployment and if you want to grant users access to the Web interface using Internet Explorer.

■ [Configure Firefox to Access the Web Interface](#)

You must configure the Firefox browser if Kerberos is configured for your deployment and you want to grant users access to the Web interface using Firefox.

■ [Configure the Chrome Browser to Access the Web Interface](#)

You must configure the Chrome browser if Kerberos is configured for your deployment and if you want to grant users access to the Web interface using the Chrome browser.

Configure Kerberos Authentication

To configure the Directories Management service to provide Kerberos authentication, you must join to the domain and enable Kerberos authentication on the Directories Management connector.

Procedure

- 1 As a tenant administrator, navigate to **Administration > Directories Management > Connectors**
- 2 On the Connectors page, for the connector that is being configured for Kerberos authentication, click **Join Domain**.
- 3 On the Join Domain page, enter the information for the Active Directory domain.

Option	Description
Domain	Enter the fully qualified domain name of the Active Directory. The domain name you enter must be the same Windows domain as the connector server.
Domain User	Enter the user name of an account in the Active Directory that has permissions to join systems to that Active Directory domain.
Domain Password	Enter the password associated with the AD Username. This password is not stored by Directories Management

Click **Save**.

The Join Domain page is refreshed and displays a message that you are currently joined to the domain.

- 4 In the Worker column for the connector click **Auth Adapters**.
 - 5 Click **KerberosIdpAdapter**
- You are redirected to the identity manager sign in page.
- 6 Click **Edit** in the KerberosIdpAdapter row and configure the Kerberos authentication page.

Option	Description
Name	A name is required. The default name is KerberosIdpAdapter. You can change this.
Directory UID Attribute	Enter the account attribute that contains the user name.
Enable Windows Authentication	Select this to extend authentication interactions between users' browsers and Directories Management.

Option	Description
Enable NTLM	Select this to enable NT LAN Manager (NTLM) protocol-based authentication only if your Active Directory infrastructure relies on NTLM authentication.
Enable Redirect	Select this if round-robin DNS and load balancers do not have Kerberos support. Authentication requests are redirected to Redirect Host Name. If this is selected, enter the redirect host name in Redirect Host Name text box. This is usually the hostname of the service.

7 Click **Save**.

What to do next

Add the authentication method to the default access policy. Navigate to **Administration > Directories Management > Policies** and click **Edit Default Policy** to edit the default policy rules to add the Kerberos authentication method to the rule in the correct authentication order.

Configure Internet Explorer to Access the Web Interface

You must configure the Internet Explorer browser if Kerberos is configured for your deployment and if you want to grant users access to the Web interface using Internet Explorer.

Kerberos authentication works in conjunction with Directories Management on Windows operating systems.

Note Do not implement these Kerberos-related steps on other operating systems.

Prerequisites

Configure the Internet Explorer browser for each user or provide users with the instructions after you configure Kerberos.

Procedure

- 1 Verify that you are logged into Windows as a user in the domain.
- 2 In Internet Explorer, enable automatic log in.
 - a Select **Tools > Internet Options > Security**.
 - b Click **Custom level**.
 - c Select **Automatic login only in Intranet zone**.
 - d Click **OK**.
- 3 Verify that this instance of the connector virtual appliance is part of the local intranet zone.
 - a Use Internet Explorer to access the Directories Management sign in URL at *https://myconnectorhost.domain/authenticate/*.
 - b Locate the zone in the bottom right corner on the status bar of the browser window.
If the zone is Local intranet, Internet Explorer configuration is complete.

- 4 If the zone is not Local intranet, add the Directories Management sign in URL to the intranet zone.
 - a Select **Tools > Internet Options > Security > Local intranet > Sites**.
 - b Select **Automatically detect intranet network**.
If this option was not selected, selecting it might be sufficient for adding the to the intranet zone.
 - c (Optional) If you selected **Automatically detect intranet network**, click **OK** until all dialog boxes are closed.
 - d In the Local Intranet dialog box, click **Advanced**.
A second dialog box named Local intranet appears.
 - e Enter the Directories Management URL in the **Add this Web site to the zone** text box.
https://myconnectorhost.domain/authenticate/
 - f Click **Add > Close > OK**.
- 5 Verify that Internet Explorer is allowed to pass the Windows authentication to the trusted site.
 - a In the Internet Options dialog box, click the **Advanced** tab.
 - b Select **Enable Integrated Windows Authentication**.
This option takes effect only after you restart Internet Explorer.
 - c Click **OK**.
- 6 Log in to the Web interface to check access.
If Kerberos authentication is successful, the test URL goes to the Web interface.

The Kerberos protocol secures all interactions between this Internet Explorer browser instance and Directories Management. Now, users can use single sign-on to access their My Apps portal.

Configure Firefox to Access the Web Interface

You must configure the Firefox browser if Kerberos is configured for your deployment and you want to grant users access to the Web interface using Firefox.

Kerberos authentication works in conjunction with Directories Management on Windows operating systems.

Prerequisites

Configure the Firefox browser, for each user, or provide users with the instructions, after you configure Kerberos.

Procedure

- 1 In the URL text box of the Firefox browser, enter `about:config` to access the advanced settings.
- 2 Click **I'll be careful, I promise!**.
- 3 Double-click **network.negotiate-auth.trusted-uris** in the Preference Name column.

- 4 Enter your Directories Management URL in the text box.

https://myconnectorhost.domain.com

- 5 Click **OK**.

- 6 Double-click **network.negotiate-auth.delegation-uris** in the Preference Name column.

- 7 Enter your Directories Management URL in the text box.

https://myconnectorhost.domain.com/authenticate/

- 8 Click **OK**.

- 9 Test Kerberos functionality by using the Firefox browser to log in to login URL. For example,

https://myconnectorhost.domain.com/authenticate/.

If the Kerberos authentication is successful, the test URL goes to the Web interface.

The Kerberos protocol secures all interactions between this Firefox browser instance and Directories Management. Now, users can use single sign-on access their My Apps portal.

Configure the Chrome Browser to Access the Web Interface

You must configure the Chrome browser if Kerberos is configured for your deployment and if you want to grant users access to the Web interface using the Chrome browser.

Kerberos authentication works in conjunction with Directories Management on Windows operating systems.

Note Do not implement these Kerberos-related steps on other operating systems.

Prerequisites

- Configure Kerberos.
- Since Chrome uses the Internet Explorer configuration to enable Kerberos authentication, you must configure Internet Explorer to allow Chrome to use the Internet Explorer configuration. See Google documentation for information about how to configure Chrome for Kerberos authentication.

Procedure

- 1 Test Kerberos functionality by using the Chrome browser.
- 2 Log in to Directories Management at *https://myconnectorhost.domain.com/authenticate/*.

If Kerberos authentication is successful, the test URL connects with the Web interface.

If all related Kerberos configurations are correct, the relative protocol (Kerberos) secures all interactions between this Chrome browser instance and Directories Management. Users can use single sign-on access their My Apps portal.

Upgrading External Connectors for Directories Management

If you use an external connector with your vRealize Automation Directories Management configuration, you may need to upgrade this connector on occasion.

You may need to upgrade an external connector when upgrading the version of your vRealize Automation deployment or if a new connector build offers a feature you want.

This documentation applies only to users who have deployed additional, stand-alone external connector appliances. In vRealize Automation, external connector appliances are used with smart card authentication, for instance.

By default, the connector uses the VMware Web site for the upgrade procedure, which requires the connector appliance to have Internet connectivity. You must also configure proxy server settings for the connector appliance, if applicable.

If your connector instance does not have an Internet connection, you can perform the upgrade offline. For an offline upgrade, you download the upgrade package and set up a local Web server to host the upgrade file.

Intended Audience

This information is intended for anyone who installs, upgrades, and configures Directories Management. The information is written for experienced Windows or Linux system administrators who are familiar with virtual machine technology.

Preparing to Upgrade an External Connector

To prepare for a connector upgrade, you must check for available upgrades and configuring the proxy server settings for the appliance, if applicable.

- [Check Availability of an External Connector Upgrade Online](#)

If your connector appliance has Internet connectivity, you can check for the availability of upgrades online from the appliance.

- [Configure Proxy Server Settings for the External Connector Appliance](#)

The connector appliance accesses the VMware update servers through the Internet. If your network configuration provides Internet access using an HTTP proxy, you must adjust the proxy settings for the appliance.

Check Availability of an External Connector Upgrade Online

If your connector appliance has Internet connectivity, you can check for the availability of upgrades online from the appliance.

Procedure

- 1 Log in to the connector appliance as the root user.

- 2 Run the following command.

```
/usr/local/horizon/update/updatemgr.hzn updateinstaller
```

- 3 Run the following command to check for an online upgrade.

```
/usr/local/horizon/update/updatemgr.hzn check
```

Configure Proxy Server Settings for the External Connector Appliance

The connector appliance accesses the VMware update servers through the Internet. If your network configuration provides Internet access using an HTTP proxy, you must adjust the proxy settings for the appliance.

Enable your proxy to handle only Internet traffic. To ensure that the proxy is set up correctly, set the parameter for internal traffic to no-proxy within the domain.

Note Proxy servers that require authentication are not supported.

Prerequisites

- Verify that you have the root password for the connector appliance.
- Verify that you have the proxy server information.

Procedure

- 1 Log in to the connector appliance as the root user.
- 2 Enter YaST on the command line to run the YaST utility.
- 3 Select **Network Services** in the left pane, then select **Proxy**.
- 4 Enter the proxy server URLs in the **HTTP Proxy URL** and **HTTPS Proxy URL** fields.
- 5 Select **Finish** and exit the YaST utility.
- 6 Restart the Tomcat server on the connector virtual appliance to use the new proxy settings.

```
service horizon-workspace restart
```

The VMware update servers are now available to the connector appliance.

Upgrade an External Connector Online

You can upgrade a Directories Management external connector online if you have an appropriate connection.

Prerequisites

- Verify that the connector appliance can resolve and reach vapp-updates.vmware.com on port 80 over HTTP.

- Confirm that a connector upgrade exists. Run the appropriate command to check for upgrades. See [Check for the Availability of a Directories Management Connector Upgrade Online](#).
- Verify that at least 2 GB of disk space is available on the primary root partition of the appliance.
- Verify that the connector is properly configured.
- Take a snapshot of your connector appliance to back it up. For information about how to take snapshots, see the vSphere documentation.
- If an HTTP proxy server is required for outbound HTTP access, configure the proxy server settings for the connector appliance. See [Configure Proxy Server Settings for the Directories Management Connector Appliance](#).

Procedure

- 1 Log in to the connector appliance as the root user.
- 2 Run the following command.

```
/usr/local/horizon/update/updatemgr.hzn updateinstaller
```

- 3 Run the following command to check that an online upgrade exists.

```
/usr/local/horizon/update/updatemgr.hzn check
```

- 4 Run the following command to update the appliance.

```
/usr/local/horizon/update/updatemgr.hzn update
```

Messages that occur during the upgrade are saved to the `update.log` file at `/opt/vmware/var/log/update.log`.

- 5 Run the `updatemgr.hzn check` command again to verify that a newer update does not exist.

```
/usr/local/horizon/update/updatemgr.hzn check
```

- 6 Check the version of the upgraded appliance.

```
vamicli version --appliance
```

The new version is displayed.

- 7 Restart the connector appliance.

```
reboot
```

Upgrade an External Connector Offline

If your existing vRealize Automation Directories Management connector appliance cannot connect to the Internet for upgrade, you can perform an offline upgrade. You must set up an upgrade repository on a local Web server and configure the connector appliance to use the local Web server for upgrade.

Prerequisites

- Confirm that a connector upgrade exists. Check the My VMware Downloads site at my.vmware.com for upgrades.
- Verify that at least 2 GB of disk space is available on the primary root partition of the appliance.
- Verify that the connector is properly configured.
- Take a snapshot of your connector appliance to back it up. For information about how to take snapshots, see the vSphere documentation.
- Configure the connector appliance to use a local Web server to host the upgrade file. See Prepare a Local Web Server for Offline Upgrade.

Procedure

1 Prepare a Local Web Server for Offline Upgrade

Before you start the offline connector upgrade, prepare the local Web server by creating a directory structure that includes a subdirectory for the connector appliance.

2 Configure the Connector and Perform Offline Upgrade

Configure the connector appliance to point to the local Web server to perform an offline upgrade. Then upgrade the appliance.

Prepare a Local Web Server for Offline Upgrade

Before you start the offline connector upgrade, prepare the local Web server by creating a directory structure that includes a subdirectory for the connector appliance.

Prerequisites

- Download the `identity-manager-connector-versionNumber-buildNumber-updaterepo.zip` file from My VMware. Go to my.vmware.com, navigate to the VMware Identity Manager Download page, and download the file listed under **VMware Identity Manager Connector offline upgrade package**.
- If you use an IIS Web server, configure the Web server to allow special characters in file names. You configure this in the **Request Filtering** section by selecting the **Allow double escaping** option.

Procedure

- 1 Create a directory on the Web server at `http://YourWebServer/VM/` and copy the downloaded zip file to it.
- 2 Verify that your Web server includes mime types for `.sig` (text/plain) and `.sha256` (text/plain). Without these mime types your Web server fails to check for updates.
- 3 Unzip the file.

The contents of the extracted ZIP file are served by `http://YourWebServer/VM/`.

The extracted contents of the file contain the following subdirectories: `/manifest` and `/package-pool`.

- 4 Run the following `updateLocal.hzn` command to check that the URL has valid update contents.

```
/usr/local/horizon/update/updatesLocal.hzn checkurl http://YourWebServer/VM/
```

Configure the Connector and Perform Offline Upgrade

Configure the connector appliance to point to the local Web server to perform an offline upgrade. Then upgrade the appliance.

Prerequisites

Prepare a local Web server for offline upgrade.

Procedure

- 1 Log in to the connector appliance as the root user.
- 2 Run the following command to configure an upgrade repository that uses a local Web server.

```
/usr/local/horizon/update/updatesLocal.hzn seturl http://YourWebServer/VM/
```

Note To undo the configuration and restore the ability to perform an online upgrade, you can run the following command.

```
/usr/local/horizon/update/updatesLocal.hzn setdefault
```

- 3 Perform the upgrade.
 - a Run the following command.

```
/usr/local/horizon/update/updatesMgr.hzn updateinstaller
```

- b Run the following command to check the version of the available upgrade.

```
/usr/local/horizon/update/updatesMgr.hzn check
```

- c Run the following command to update the connector.

```
/usr/local/horizon/update/updatesMgr.hzn update
```

Messages that occur during the upgrade are saved to the `update.log` file at `/opt/vmware/var/log/update.log`.

- d Run the `updatesMgr.hzn check` command again.

```
/usr/local/horizon/update/updatesMgr.hzn check
```

- e Check the version of the upgraded appliance.

```
vamicli version --appliance
```

The command should display the new version.

- f Restart the connector appliance.

For example, from the command line run the following command.

```
reboot
```

The connector upgrade is complete.

Configuring Settings After Upgrading an External Connector

After upgrading to connector 2016.3.1.0 or later, you may need to configure some settings.

Rejoin Domain with Kerberos Authentication

If you use Kerberos authentication or Active Directory (Integrated Windows Authentication) directories, you must leave the domain and then rejoin it. This is required for all the connector virtual appliances in your deployment.

- 1 Select **Administration > Directories Management > Connectors**
- 2 In the Connectors page, for each connector that is being used for Kerberos authentication or an Active Directory (Integrated Windows Authentication) directory, click **Leave Domain**.
- 3 To join the domain, you need Active Directory credentials with the privileges to join the domain. See [Join a Connector Machine to a Domain](#) for more information.
- 4 If you are using Kerberos authentication, enable the Kerberos authentication adapter again. To access the Auth Adapters page, in the Connectors page click the appropriate link in the **Worker** column and select the **Auth Adapters** tab.
- 5 Verify that the other authentication adapters you are using are enabled.

Update Domains Page

If you are using Active Directory (Integrated Windows Authentication), or Active Directory over LDAP with the **This Directory supports DNS Service Location** option enabled, save the directory's Domains page.

- 1 Select **Administration > Directories Management > Directories**
- 2 Select the applicable directory to edit it.
- 3 Provide the password for the Bind DN user and click **Save**.
- 4 Click **Sync Settings** on the left of the page and select the **Domains** tab.
- 5 Click **Save**.

DNS Service Location and Domain Controllers

Note In connector 2016.3.1.0 and later, a `domain_krb.properties` file is automatically created and auto-populated with domain controllers when a directory with DNS Service Location enabled is created. When you save the Domains page after upgrade, if you had a `domain_krb.properties` file in your original deployment, the file is updated with domains that you may have added subsequently and that were not in the file. If you did not have a `domain_krb.properties` file in your original deployment, the file is created and auto-populated with domain controllers. See [About Domain Controller Selection](#) for more information about the `domain_krb.properties` file.

Troubleshooting External Connector Upgrade Errors

You can troubleshoot vRA Directories Management external connector upgrade problems by reviewing the error logs. If the connector does not start, you can revert to a previous instance by rolling back to a snapshot.

- [Checking the Upgrade Error Logs](#)

Resolve errors that occur during upgrade by reviewing the error logs. Upgrade log files are in the `/opt/vmware/var/log` directory.

- [Rolling Back to Snapshots of Connector](#)

If the connector does not start properly after an upgrade, and you cannot resolve the problem by reviewing the upgrade error logs and running the upgrade command again, you can roll back to a previous connector instance.

- [Collecting a Log File Bundle](#)

You can collect a bundle of log files to send to VMware support. You obtain the bundle from the connector configuration page.

Checking the Upgrade Error Logs

Resolve errors that occur during upgrade by reviewing the error logs. Upgrade log files are in the `/opt/vmware/var/log` directory.

If any errors occurred, the connector may not start after upgrade.

Procedure

- 1 Log in to the connector appliance.
- 2 Go to the `/opt/vmware/var/log` directory.
- 3 Open the `update.log` file and review the error messages.
- 4 Resolve the errors and rerun the upgrade command. The upgrade command resumes from the point where it stopped.

Note Alternatively, you can revert to a snapshot and run the update again.

Rolling Back to Snapshots of Connector

If the connector does not start properly after an upgrade, and you cannot resolve the problem by reviewing the upgrade error logs and running the upgrade command again, you can roll back to a previous connector instance.

Procedure

- ◆ Revert to one of the snapshots you took as a backup of your original connector instance. For information, see the vSphere documentation.

Collecting a Log File Bundle

You can collect a bundle of log files to send to VMware support. You obtain the bundle from the connector configuration page.

The following log files are collected in the bundle.

Table 2-9. Log Files

Component	Location of Log File	Description
Apache Tomcat Logs (catalina.log)	/opt/vmware/horizon/workspace/logs/catalina.log	Apache Tomcat records messages that are not recorded in other log files.
Configurator Logs (configurator.log)	/opt/vmware/horizon/workspace/logs/configurator.log	Requests that the Configurator receives from the REST client and the Web interface.
Connector Logs (connector.log)	/opt/vmware/horizon/workspace/logs/connector.log	A record of each request received from the Web interface. Each log entry also includes the request URL, timestamp, and exceptions. No sync actions are recorded.

Procedure

- 1 Log in to the connector configuration page at <https://connectorURL:8443/cfg/logs>.
- 2 Click **Prepare log bundle**.
- 3 Download the bundle and send it to VMware support.

Scenario: Configure an Active Directory Link for a Highly Available vRealize Automation

As a tenant administrator, you want to configure an Active Directory over LDAP directory connection to support user authentication for your highly available vRealize Automation deployment.

Each vRealize Automation appliance includes a connector that supports user authentication, although only one connector is typically configured to perform directory synchronization. It does not matter which connector you choose to serve as the sync connector. To support Directories Management high availability, you must configure a second connector that corresponds to your second vRealize Automation appliance, which connects to your Identity Provider and points to the same Active Directory. With this configuration, if one appliance fails, the other takes over management of user authentication.

In a high availability environment, all nodes must serve the same set of Active Directories, users, authentication methods, etc. The most direct method to accomplish this is to promote the Identity Provider to the cluster by setting the load balancer host as the Identity Provider host. With this configuration, all authentication requests are directed to the load balancer, which forwards the request to either connector as appropriate.

Prerequisites

- Install a distributed vRealize Automation deployment with appropriate load balancers. See *Installing vRealize Automation 7.3*.
- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Directories Management > Directories**.
- 2 Click **Add Directory**.
- 3 Enter your specific Active Directory account settings, and accept the default options.

Option	Sample Input
Directory Name	Add the IP address of your active directory domain name.
Sync Connector	Every vRealize Automation appliance contains a connector. Use any of the available connectors.
Base DN	Enter the Distinguished Name (DN) of the starting point for directory server searches. For example, cn=users,dc=corp,dc=local .
Bind DN	Enter the full distinguished name (DN), including common name (CN), of an Active Directory user account that has privileges to search for users. For example, cn=config_admin infra,cn=users,dc=corp,dc=local .
Bind DN Password	Enter the Active Directory password for the account that can search for users.

- 4 Click **Test Connection** to test the connection to the configured directory.
If the connection fails, check your entries in all fields and consult your system administrator if necessary.
- 5 Click **Save & Next**.
The Select the Domains page with the list of domains appears.
- 6 Leave the default domain selected and click **Next**.
- 7 Verify that the attribute names are mapped to the correct Active Directory attributes. If not, select the correct Active Directory attribute from the drop-down menu. Click **Next**.
- 8 Select the groups and users you want to sync.
 - a Click the **Add** icon (+).
 - b Enter the user domain and click **Find Groups**.
For example, **cn=users,dc=corp,dc=local**.

- c Select the **Select All** check box.
 - d Click **Select**.
 - e Click **Next**.
 - f Click  to add additional users. For example, enter as **CN=username,CN=Users,OU=myUnit,DC=myCorp,DC=com**.

To exclude users, click + to create a filter to exclude some types of users. You select the user attribute to filter by, the query rule, and the value.
 - g Click **Next**.
- 9** Review the page to see how many users and groups are syncing to the directory and click **Sync Directory**.
- The directory sync process takes some time, but it happens in the background and you can continue working.
- 10** Configure a second connector to support high availability.
- a Log in to the load balancer for your vRealize Automation deployment as a tenant administrator.

The load balancer URL is *load balancer address/vcac/org/tenant_name*.
 - b Select **Administration > Directories Management > Identity Providers**.
 - c Click the Identity Provider that is currently in use for your system.

The existing directory and connector that provide basic identity management for your system appears.
 - d Click the **Add a Connector** drop-down list, and select the connector that corresponds to your secondary vRealize Automation appliance.
 - e Enter the appropriate password in the **Bind DN Password** text box that appears when you select the connector.
 - f Click **Add Connector**.
 - g Edit the host name to point to your load balancer.

You connected your corporate Active Directory to vRealize Automation and configured Directories Management for high availability.

What to do next

To provide enhanced security, you can configure bi-directional trust between your identity provider and your Active Directory. See [Configure a Bi Directional Trust Relationship Between vRealize Automation and Active Directory](#).

Configure External Connectors for Smart Card and Third-party Identity Provider Authentication in vRealize Automation

A system administrator must configure an external connector for your vRealize Automation deployment using Directories Management if you are using third party identity providers such as Keberos or smart card authentication.

Directories Management supports multiple identity providers and connector clusters for each configured Active Directory. To use a third-party identity provider or smart card authentication, you can set up either a single external connector or a connector cluster with an appropriate identity provider behind a load balancer that permits SSL passthrough. See [Managing Connectors and Connector Clusters](#) for more information.

See [Upgrading External Connectors for Directories Management](#) for information about updating an external connector.

There are various certificate configuration options available for use with smart card authentication. See [Configuring a Certificate or Smart Card Adapter for Use with Directories Management](#).

Prerequisites

- Configure an appropriate Active Directory connection for use with your vRealize Automation deployment.
- Download the OVA file required to configure a connector from [VMware vRealize Automation Tools and SDK](#).
- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

1 [Generate a Connector Activation Token](#)

Before you deploy the connector virtual appliance to use for smart card authentication, generate an activation code for the new connector from the vRealize Automation console. The activation code is used to establish communication between Directories Management and the connector.

2 [Deploy the Connector OVA File](#)

After downloading a connector OVA file, you can deploy it using the VMware vSphere Client or vSphere Web Client.

3 [Configure Connector Settings](#)

After deploying the connector OVA, you must run the Setup wizard to activate the appliance and configure the administrator passwords.

4 [Apply Public Certificate Authority](#)

When Directories Management is installed, a default SSL certificate is generated. You can use the default certificate for testing purposes, but you should generate and install commercial SSL certificates for production environments.

5 [Create a Workspace Identity Provider](#)

You must create a Workspace identity provider for use with an external connector.

6 [Configure Certificate Authentication and Configure Default Access Policy Rules](#)

You must configure your external connection for use with your vRealize Automation Active Directory and domain.

Generate a Connector Activation Token

Before you deploy the connector virtual appliance to use for smart card authentication, generate an activation code for the new connector from the vRealize Automation console. The activation code is used to establish communication between Directories Management and the connector.

You can configure a single connector or a connector cluster. If you want to use a connector cluster, repeat this procedure for each connector that you need.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Directories Management > Connectors**
- 2 Type a name for the new connector in the **Connector ID Name** text box.
- 3 Press **Enter**.

The activation code for the connector is displayed in the **Connector Activation Code** box.
- 4 Copy the activation code for use in configuring the connector using the OVA file.

Deploy the Connector OVA File

After downloading a connector OVA file, you can deploy it using the VMware vSphere Client or vSphere Web Client.

You deploy the OVA file using the vSphere Client or the vSphere Web Client.

Prerequisites

- Identify the DNS records and host name to use for your connector OVA deployment.
- If using the vSphere Web Client, use either Firefox or Chrome browsers. Do not use Internet Explorer to deploy the OVA file.
- Download the OVA file required to configure a connector from [VMware vRealize Automation Tools and SDK](#).

Procedure

- 1 In the vSphere Client or the vSphere Web Client, select **File > Deploy OVF Template**.

- 2 In the Deploy OVF Template pages, enter the information specific to your deployment of the connector.

Page	Description
Source	Browse to the OVA package location, or enter a specific URL.
OVA Template Details	Verify that you selected the correct version.
License	Read the End User License Agreement and click Accept .
Name and Location	Enter a name for the virtual appliance. The name must be unique within the inventory folder and can contain up to 80 characters. Names are case sensitive. Select a location for the virtual appliance.
Host / Cluster	Select the host or cluster to run the deployed template.
Resource Pool	Select the resource pool.
Storage	Select the location to store the virtual machine files.
Disk Format	Select the disk format for the files. For production environments, select a Thick Provision format. Use the Thin Provision format for evaluation and testing.
Network Mapping	Map the networks in your environment to the networks in the OVF template.
Properties	<p>a In the Timezone setting field, select the correct time zone.</p> <p>b The Customer Experience Improvement Program checkbox is selected by default. VMware collects anonymous data about your deployment in order to improve VMware's response to user requirements. Deselect the checkbox if you do not want the data collected.</p> <p>c In the Host Name text box, enter the host name to use. If this is blank, reverse DNS is used to look up the host name.</p> <p>d To configure the static IP address for connector, enter the address for each of the following: Default Gateway, DNS, IP Address, and Netmask.</p> <p>Important If any of the four address fields, including Host Name, are left blank, DHCP is used.</p> <p>To configure DHCP, leave the address fields blank.</p>
Ready to Complete	Review your selections and click Finish .

Depending on your network speed, the deployment can take several minutes. You can view the progress in the progress dialog box.

- 3 When the deployment is complete, select the appliance, right-click, and select **Power > Power on**.

The appliance is initialized. You can go to the **Console** tab to see the details. When the virtual appliance initialization is complete, the console screen displays the version and URLs to log in to the Setup wizard to complete the set up.

What to do next

Use the Setup wizard to add the activation code and administrative passwords.

Configure Connector Settings

After deploying the connector OVA, you must run the Setup wizard to activate the appliance and configure the administrator passwords.

Prerequisites

- You have generated an activation code for the connector.
- Ensure the connector appliance is powered on and you know the connector URL.
- Collect a list of password to use for the connector administrator, root account, and sshuser account.

Procedure

- 1 To run the Setup wizard, enter the connector URL that was displayed in the Console tab after the OVA was deployed.
- 2 On the Welcome Page, click **Continue**.
- 3 Create strong passwords for the following connector virtual appliance administrator accounts.

Strong passwords should be at least eight characters long and include uppercase and lowercase characters and at least one digit or special character.

Option	Description
Appliance Administrator	Create the appliance administrator password. The user name is admin and cannot be changed. You use this account and password to log in to the connector services to manage certificates, appliance passwords and syslog configuration. Important The admin user password must be at least 6 characters in length.
Root Account	A default VMware root password was used to install the connector appliance. Create a new root password.
sshuser Account	Create the password to use for remote access to the connector appliance.

- 4 Click **Continue**.
- 5 On the Activate Connector page, paste in the activation code and click **Continue**.
- 6 If you are using a self-signed certificate on the vRealize Automation internal connector, you can get the appropriate certificate by running the following command on the vRealize Automation appliance:

```
cat /etc/apache2/server-cert.pem
```

Select the **Terminate SSL on a Load Balancer** tab, and then click the link for `/horizon_workspace_rootca.pem`.

The activation code is verified and communication between the service and the connector instance is established to complete the connector configuration.

What to do next

In the service, set up your environment based on your needs. For example, if you added an additional connector because you want to sync two Integrated Windows Authentication directories, create the directory and associate it with the new connector.

Apply Public Certificate Authority

When Directories Management is installed, a default SSL certificate is generated. You can use the default certificate for testing purposes, but you should generate and install commercial SSL certificates for production environments.

Note If the Directories Management points to a load balancer, the SSL certificate is applied to the load balancer.

You must check the **Mark this key as exportable** when importing a certificate.

You only need to specify the CN, or certificate authority's site domain name, if you are generating a CSR for a custom certificate.

Prerequisites

Generate a Certificate Signing Request (CSR) and obtain a valid, signed certificate from a CA. If your organization provides SSL certificates that are signed by a CA, you can use these certificates. The certificate must be in the PEM format.

Procedure

- 1 Log in to the connector appliance administrative page as an admin user at the following location:

`https://myconnector.mycompany:8443/cfg`

- 2 In the administrator console, click **Appliance Settings**.

VA Configuration is selected by default.

- 3 Click **Manage Configurations**.

- 4 Enter the VMware Identify Manager server admin user password.

- 5 Select **Install Certificate**.

- 6 In the Terminate SSL on Identity Manager Appliance tab, select **Custom Certificate**.

- 7 In the **SSL Certificate Chain** text box, paste the host, intermediate, and root certificates, in that order.

The SSL certificate works only if you include the entire certificate chain in the correct order. For each certificate, copy everything between and including the lines -----BEGIN CERTIFICATE----- and -----END CERTIFICATE-----

Ensure that the certificate includes the FQDN hostname.

- 8 Paste the private key in the Private Key text box. Copy everything between -----BEGIN RSA PRIVATE KEY and -----END RSA PRIVATE KEY.

- 9 Click **Save**.

Example: Certificate Examples

Certificate Chain Example

-----BEGIN CERTIFICATE-----

jIQt9WdR9Vpg3WQT5+C3HU17bUOwvhp/r0+

-----END RSA PRIVATE KEY-----

Create a Workspace Identity Provider

You must create a Workspace identity provider for use with an external connector.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Directories Management > Identity Providers**.

- 2 Select **Add Identity Provider**.
- 3 Select **Create Workspace IDP** on the displayed menu.
- 4 Type a name for the identity provider in the **Identity Provider Name** field.
- 5 Select the directory that corresponds to the users that will use this identity provider.
The directory selected determine which connectors are displayed for selection with this identity provider.
- 6 Select the external connector or connectors that you configured for smart card authentication.

Note If the deployment is located behind a load balancer, enter the load balancer URL.

- 7 Select the network for access to this identity provider.
- 8 Click **Add**.

Configure Certificate Authentication and Configure Default Access Policy Rules

You must configure your external connection for use with your vRealize Automation Active Directory and domain.

Prerequisites

Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Directories Management > Connectors**.
- 2 Select the Desired connector in the **Worker** column.
The selected worker is shown in the **Worker Name** text box on the Connector **Detail** tab and connector type information appears in the **Connector Type** text box.
- 3 Ensure that the connector is linked to the desired Active Directory by specifying that Directory in the **Associated Directory** text box.
- 4 Enter the appropriate domain name in the **Associated Domains** text box.
- 5 Select the **AuthAdapters** tab and enable CertificateAuthAdapter.
- 6 Configure certificate authentication as appropriate for your deployment.
See [Configure Certificate Authentication for Directories Management](#).
- 7 Select **Administration > Directories Management > Policies**.
- 8 Click **Edit Default Policy**.
- 9 Add Certificate to the policy rules and make it the first authentication method.
Certificate must be the first authentication method listed in the policy rule, otherwise certificate authentication fails.

Create a Multi Domain or Multi Forest Active Directory Link

As a system administrator, you need to configure a multi domain or multi forest Active Directory link.

The procedure for configuring a multi domain or multi forest Active Directory link is essentially the same. For a multi forest link, bi-directional trust is required between all applicable domains.

Prerequisites

- Install a distributed vRealize Automation deployment with appropriate load balancers. See *Installing vRealize Automation 7.3*.
- Log in to the vRealize Automation console as a **tenant administrator**.
- Configure the appropriate domains and Active Directory forests for your deployment.

Procedure

- 1 Select **Administration > Directories Management > Directories**.
- 2 Click **Add Directory**.
- 3 On the Add Directory page, specify a name for the Active Directory server in the **Directory Name** text box.
- 4 Select **Active Directory (Integrated Windows Authentication)** under the **Directory Name** heading.
- 5 Configure the connector that synchronizes users from the Active Directory to the VMware Directories Management directory in the Directory Sync and Authentication section.

Option	Description
Sync Connector	Select the appropriate connector to use for your system. Each vRealize Automation appliance contains a default connector. Consult your system administrator if you need help in choosing the appropriate connector.
Authentication	Click the appropriate radio button to indicate whether the selected connector also performs authentication.
Directory Search Attribute	Select the appropriate account attribute that contains the user name.

Depending on your deployment configuration, you will have one or more connectors available for use.

- 6 Enter the appropriate join domain credentials in the **Domain Name**, **Domain Admin User Name**, and **Domain Admin Password** text boxes.

As an example, you might enter something like the following: **Domain Name:** hs.trcint.com, **Domain Admin Username:** devadmin, **Domain Admin Password:** xxxx.

- 7 In the **Bind User Details** section, enter the appropriate Active Directory (Integrated Windows Authentication) credentials to facilitate directory synchronization.

Option	Description
Bind User UPN	Enter the User Principal Name of the user who can authenticate with the domain. For example, UserName@example.com.
Bind DN Password	Enter the Bind User password.

- 8 Click **Save & Next**.

The Select the Domains page appears with the list of domains.

- 9 Click the appropriate check boxes to select the desired domains for your system deployment.

- 10 Click **Next**.

- 11 Verify that the Directories Management directory attribute names are mapped to the correct Active Directory attributes.

If the directory attribute names are mapped incorrectly, select the correct Active Directory attribute from the drop-down menu.

- 12 Click **Next**.

- 13 Click  to select the groups you want to sync from Active Directory to the directory.

When you add an Active Directory group, if members of that group are not in the Users list, they are added.

Note The Directories Management user authentication system imports data from Active Directory when adding groups and users, and the speed of the system is limited by Active Directory capabilities. As a result, import operations may require a significant amount of time depending on the number of groups and users being added. To minimize the potential for delays or problems, limit the number of groups and users to only those required for vRealize Automation operation. If your system performance degrades or if errors occur, close any unneeded applications and ensure that your system has appropriate memory allocated to Active Directory. If problems persist, increase the Active Directory memory allocation as needed. For systems with large numbers of users and groups, you may need to increase the Active Directory memory allocation to as much as 24 GB.

- 14 Click **Next**.

- 15 Click  to add additional users. For example, enter as **CN=username,CN=Users,OU=myUnit,DC=myCorp,DC=com**.

To exclude users, click  to create a filter to exclude some types of users. You select the user attribute to filter by, the query rule, and the value.

- 16 Click **Next**.

- 17 Review the page to see how many users and groups are syncing to the directory.

If you want to make changes to users and groups, click the Edit links.

18 Click **Push to Workspace** to start the synchronization to the directory.

What to do next

Configuring Groups and User Roles

Tenant administrators create business groups and custom groups, and grant user access rights to the vRealize Automation console.

Assign Roles to Directory Users or Groups

Tenant administrators grant access rights to users by assigning roles to users or groups.

To allow users or groups to modify and trigger a pipeline, you must assign permissions to those users and groups. When you assign users and groups the role of Release Manager, they can modify and trigger the pipeline. When you assign users and groups the role of Release Engineer, they can trigger the pipeline. For more information, see the *Using vRealize Code Stream* guide.

Prerequisites

Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1** Select **Administration > Users & Groups > Directory Users & Groups**.
- 2** Enter a user or group name in the **Search** box and press Enter.
Do not use an at sign (@), backslash (\), or slash (/) in a name. You can optimize your search by typing the entire user or group name in the form user@domain.
- 3** Click the name of the user or group to which you want to assign roles.
- 4** Select one or more roles from the Add Roles to this User list.
The Authorities Granted by Selected Roles list indicates the specific authorities you are granting.
- 5** (Optional) Click **Next** to view more information about the user or group.
- 6** On the **User Details** page, on the **General** tab, scroll the list of roles to add the user.
 - a** To give the user permissions to modify and trigger a pipeline, select the **Release Manager** check box.
 - b** To give the user permissions to trigger a pipeline, select the **Release Engineer** check box.
- 7** Click **Update**.

Users who are currently logged in to the vRealize Automation console must log out and log back in to the vRealize Automation console before they can navigate to the pages to which they have been granted access.

What to do next

Optionally, you can create your own custom groups from users and groups in your Active Directory connections. See [Create a Custom Group](#).

Create a Custom Group

Tenant administrators can create custom groups by combining other custom groups, identity store groups, and individual identity store users. Custom groups provide more granular control over access within vRealize Automation than business groups which correspond to a line of business, department, or other organizational unit.

Custom groups enable you to grant access rights for tasks on a finer basis than the standard vRealize Automation group assignments. For instance, you may want to create a custom group to allow tenant administrators to control who has specific permissions within the tenant.

You can assign roles to your custom group, but it is not necessary in all cases. For example, you can create a custom group called Machine Specification Approvers, to use for all machine pre-approvals. You can also create custom groups to map to your business groups so that you can manage all groups in one place. In those cases, you do not need to assign roles.

Prerequisites

Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Users & Groups > Custom Groups**.

- 2 Click the **Add** icon ()

- 3 Enter a group name in the **New Group Name** text box.

Custom group names cannot contain the combination of a semicolon (;) followed by an equal sign (=).

- 4 (Optional) Enter a description in the **New Group Description** text box.

- 5 Select one or more roles from the Add Roles to this Group list.

The Authorities Granted by Selected Roles list indicates the specific authorities you are granting.

- 6 Click **Next**.

- 7 Add users and groups to create your custom group.

- a Enter a user or group name in the **Search** box and press Enter.

Do not use an at sign (@), backslash (\), or slash (/) in a name. You can optimize your search by typing the entire user or group name in the form user@domain.

- b Select the user or group to add to your custom group.

- 8 Click **Add**.

Users who are currently logged in to the vRealize Automation console must log out and log back in to the vRealize Automation console before they can navigate to the pages to which they have been granted access.

Create a Business Group

Business groups are used to associate a set of services and resources to a set of users. These groups often correspond to a line of business, department, or other organizational unit. You create a business group so that you can configure reservations and entitle users to provision service catalog items for the business group members.

To add multiple users to a business group role, you can add multiple individual users, or you can add multiple users at the same time by adding an identity store group or a custom group to a role. For example, you can create a custom group Sales Support Team and add that group to the support role. You can also use existing identity store user groups. The users and groups you choose must be valid in the identity store.

To support vCloud Director integration, the same business group members in the vRealize Automation business group must also be members of the vCloud Director organization.

After a tenant administrator creates the business group, the business group manager has permission to modify the manager email address and the members. The tenant administrator can modify all the options.

This procedure assumes that IaaS is installed and configured.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator**.
- If you want to add machines created by business group members to a particular Active Directory organizational unit, configure the Active Directory policy. See [Create an Active Directory Policy](#). You can and apply the policy when you create the business group, or add it later.
- If you want to provide a default machine prefix for the group that is prepended to provisioned machine names, request a prefix from a fabric administrator. See [Configure Machine Prefixes](#). Machine prefixes are not applicable to XaaS requests.

Procedure

- 1 Select **Administration > Users and Groups > Business Groups**.
- 2 Click the **New** icon ().
- 3 Configure the business group details.

Option	Description
Name	Enter the name for the business group.
Description	Enter the description.

Option	Description
Send manager emails to	Enter one or more email addresses of users that must receive capacity alert notifications. Email alias addresses are not supported, each email addresses must be for a specific user. Separate multiple entries with a comma. For example, JoeAdmin@mycompany.com,WeiMgr@mycompany.com .
Active Directory Policy	Select the default Active Directory policy for the business group.

4 Add custom properties.

5 Enter a user name or custom user group name and press Enter.

You can add one or more individuals or custom user groups to the business group. You can specify the users now or you can create empty business groups to populate later.

Option	Description
Group manager role	Can create entitlements and assign approval policies for the group.
Support role	Can request and manage service catalog items on behalf of the other members of the business group.
Shared access role	Can use and run actions on the resources that other business group members deploy.
User role	Can request service catalog items to which they are entitled.

6 Click **Next**.

7 Configure default infrastructure options.

Option	Description
Default machine prefix	Select a preconfigured machine prefix for the business group. This prefix is used by machine blueprints. If the blueprint is uses the default prefix and you do not provide it here, a machine prefix is created based on the business group name. The best practice is to provide a default prefix. You can still configure blueprints with specific prefixes or allow service catalog users to override it when they request a blueprint. XaaS blueprints do not use default machine prefixes. If you configure a prefix here and entitle an XaaS blueprint to this business group, it does not affect the provisioning of an XaaS machine.
Active Directory container	Enter an Active Directory container. This option applies only to WIM provisioning. Other provisioning methods require extra configuration to join provisioned machines to an AD container.

8 Click **Add**.

Fabric administrators can allocate resources to your business group by creating a reservation. Business group managers can create entitlements for members of the business group.

What to do next

- Create a reservation for your business group based on where the business group provisions machines. See [Choosing a Reservation Scenario](#).

- If the catalog items are published and the services exist, you can create an entitlement for the business group members. See [Entitle Users to Services, Catalog Items, and Actions](#).

Troubleshooting Slow Performance When Displaying Group Members

The business group or custom group members are slow to display when viewing a group's details.

Problem

When you view user information in environments with a large number of users, the user names are slow to load in the user interface.

Cause

The extended time required to load the names occurs in environments with a large Active Directory environment.

Solution

- ◆ To reduce the retrieval workload, use Active Directory groups or custom groups whenever possible rather than adding hundreds of individual members by name.

Create Additional Tenants

As a system administrator, you can create additional vRealize Automation tenants so that users can access the appropriate applications and resources that they need to complete their work assignments.

A tenant is a group of users with specific privileges who work within a software instance. Typically, a default vRealize Automation tenant is created during system installation and initial configuration. After that, administrators can create additional tenants so that users can log in and complete their work assignments. Administrators can create as many tenants as needed for system operation. When creating tenants, administrators must specify basic configuration such as name, login URL, local users, and administrators. After configuring basic tenant information, the tenant administrator must log in and set up an appropriate Active Directory connection using the Directories Management functionality on the Administrative tab of the vRealize Automation console. In addition, tenant administrators can apply custom branding to tenants.

Prerequisites

Log in to the vRealize Automation console as a **system administrator**.

Procedure

1 [Specify Tenant Information](#)

The first step to configuring a tenant is to name the new tenant and add it to vRealize Automation and create the tenant-specific access URL.

2 [Configure Local Users](#)

The vRealize Automation system administrator must configure local users for each applicable tenant.

3 Appoint Administrators

You can appoint one or more tenant administrators and IaaS administrators from the identity stores you configured for a tenant.

Specify Tenant Information

The first step to configuring a tenant is to name the new tenant and add it to vRealize Automation and create the tenant-specific access URL.

Prerequisites

Log in to the vRealize Automation console as a **system administrator**.

Procedure

- 1 Select **Administration > Tenants**.
- 2 Click the **New** icon (+).
- 3 Enter a name in the **Name** text box.
- 4 (Optional) Enter a description in the **Description** text box.
- 5 Enter a unique identifier for the tenant in the **URL Name** text box.

This URL token is used to append a tenant-specific identifier to the vRealize Automation console URL.

For example, enter **mytenant** to create the URL `https://vrealize-appliance-hostname.domain.name/vcac/org/mytenant`.

Note The tenant URL must use lowercase characters only in vRealize Automation 7.0 and 7.1.

- 6 (Optional) Enter an email address in the **Contact Email** text box.
- 7 Click **Submit and Next**.

Configure Local Users

The vRealize Automation system administrator must configure local users for each applicable tenant.

After an administrator creates the general information for a tenant, the Local users tab becomes active, and the administrator can designate users who can access the tenant. When tenant configuration is complete, local tenant users can log in to their respective tenants to complete work assignments.

Note After you add a user, you cannot change its configuration. If you need to change anything about the user configuration, you must delete the user and recreate it.

Procedure

- 1 Click the **Add** button on the Local users tab.

- 2 Enter the users first and last names into the **First name** and **Last name** fields on the User Details dialog.
- 3 Enter the user email address into the **Email** field.
- 4 Enter the user ID and password for the user in the **User name** and **Password** fields.
- 5 Click the **Add** button.
- 6 Repeat these steps as applicable for all local users of the tenant.

The specified local users are created for the tenant.

Appoint Administrators

You can appoint one or more tenant administrators and IaaS administrators from the identity stores you configured for a tenant.

Tenant administrators are responsible for configuring tenant-specific branding, as well as managing identity stores, users, groups, entitlements, and shared blueprints within the context of their tenant. IaaS Administrators are responsible for configuring infrastructure source endpoints in IaaS, appointing fabric administrators, and monitoring IaaS logs.

Prerequisites

- Before you appoint IaaS administrators, you must install IaaS. For more information about installing IaaS, see *Installing vRealize Automation 7.3*.

Procedure

- 1 Enter the name of a user or group in the **Tenant Administrators** search box and press Enter.
For faster results, enter the entire user or group name, for example myAdmins@mycompany.domain. Repeat this step to appoint additional tenant administrators.
- 2 If you have installed IaaS, enter the name of a user or group in the **IaaS Administrators** search box and press Enter.
For faster results, enter the entire user or group name, for example IaaSAdmins@mycompany.domain. Repeat this step to appoint additional infrastructure administrators.
- 3 Click **Add**.

Delete a Tenant

A system administrator can delete any unwanted tenants from vRealize Automation.

If you delete a tenant, that tenant will be removed from the vRealize Automation interface immediately, but it may take several hours for the tenant to be completely removed from your deployment. If you delete a tenant and want to create another tenant with the same URL, allow several hours for complete deletion before creating the new tenant.

Prerequisites

Log in to the vRealize Automation console as a **system administrator**.

Procedure

1 Select **Administration > Tenants**.

2 Select the tenant that you want to delete.

Do not click the actual name to select the tenant. Doing so will open the tenant for editing.

3 Click **Delete**.

The tenant is deleted from your vRealize Automation deployment.

(Optional) Configuring Custom Branding

vRealize Automation enables you to apply custom branding to tenant login and application pages.

Custom branding can include text and background colors, business logos, company name, privacy policies, copyright statements and other relevant information that you want to appear on tenant login or application pages.

Custom Branding for Tenant Login Page

Use the Login Screen Branding page to apply custom branding to your vRealize Automation tenant login pages.

You can use default vRealize Automation branding on your tenant login pages, or you can configure custom branding using the Login Screen Branding page. Note that custom branding applies in the same manner to all of your tenant applications.

This page enables you to configure branding on all tenant login pages.

The Login Screen Branding page displays the currently implemented tenant login branding in the Preview pane.

Note After saving new tenant login page branding, there may be a delay of up to five minutes before it becomes visible on all login pages.

Prerequisites

To use a custom logo or other image with your branding, you must have the appropriate files available.

Procedure

1 Log in to vRealize Automation as a system or tenant administrator.

2 Click the **Administration** tab.

3 Select the desired visual effects using the check boxes under the Effects heading.

All effects are optional.

- 4 Select **Branding > Login Screen Branding**
- 5 Click **Upload** beneath the Logo field, then navigate to the appropriate folder and select a logo image file.
- 6 If desired, click **Upload** beneath the Image (optional) field, then navigate to the appropriate folder and select an additional image file.
- 7 If desired, enter the appropriate hex codes in the **Background color**, **Masthead color**, **Login button background color** and **Login button foreground color** fields.
Search the internet for a list of hex color codes if needed.
- 8 Click **Save** to apply your settings.

Tenant users see the custom branding on their login pages.

Custom Branding for Tenant Applications

Use the Application Branding page to apply custom branding to vRealize Automation tenant applications.

You can use default vRealize Automation branding on your user applications, or you can configure custom branding using the Application Branding page. This page enables you to configure branding on the header and footer of application pages. Note that custom branding applies in the same manner to all of your user applications.

The Application Branding page displays the currently implemented header or footer branding at the bottom of the page.

Prerequisites

If you want to use a custom logo with your branding, you must have the logo image file available.

Procedure

- 1 Log in to vRealize Automation as a system or tenant administrator.
- 2 Click the **Administration** tab.
- 3 Select **Branding > Application Branding**
- 4 Click the **Header** tab if it is not already active.
- 5 If you want to use the default vRealize Automation branding, click the **Use Default** check box.
- 6 To implement custom branding, make the appropriate selections in the fields on the **Header** and **Footer** tabs.
 - a Click the **Browse** button in the **Header Logo** field, then navigate to the appropriate folder and select an logo image file.
 - b Type the appropriate company name in the **Company name** field.

The specified name appears when a user mouses over the logo.

- c Type the appropriate name into the **Product name** field.

The name you enter here appears in the application header adjacent to the logo.

- d Enter the appropriate hex color code for the application perimeter background color in the **Background hex color** field.

Search the internet for a list of hex color codes if needed.

- e Enter the appropriate hex code for the text color in the **Text hex color** field.

Search the internet for a list of hex text color codes if needed.

- f Click **Next** to activate the Footer tab.

- g Type the desired statement into the **Copyright notice** field.

- h Type the link to your company privacy policy statement in the **Privacy policy link** field.

- i Type the desired company contact information in the **Contact link** field.

- 7 Click **Update** to implement your branding configuration.

Tenant users see the custom branding on their application pages.

(Optional) Checklist for Configuring Notifications

You can configure vRealize Automation to send users notifications when specific events occur. Users can choose which notifications to subscribe to, but they can only select from events you enable as notification triggers.

The Configuring Notifications Checklist provides a high-level overview of the sequence of steps required to configure notifications and provides links to decision points or detailed instructions for each step.

Table 2-10. Checklist for Configuring Notifications

Task	Required Role	Details
<input type="checkbox"/> Configure an outbound email server to send notifications.	<ul style="list-style-type: none"> System administrators configure default global servers. Tenant administrators configure servers for their tenants. 	<p>To configure a server for your tenant for the first time, see Add a Tenant-Specific Outbound Email Server. If you need to override a default global server, see Override a System Default Outbound Email Server. To configure global default servers for all tenants, see Create a Global Outbound Email Server.</p>
<input type="checkbox"/> (Optional) Configure an inbound email server so that users can complete tasks by responding to notifications.	<ul style="list-style-type: none"> System administrators configure default global servers. Tenant administrators configure servers for their tenants. 	<p>To configure a server for your tenant for the first time, see Add a Tenant-Specific Inbound Email Server.</p> <p>If you need to override a default global server, see Override a System Default Inbound Email Server.</p> <p>To configure a global default server for all tenants, see Create a Global Inbound Email Server.</p>
<input type="checkbox"/> (Optional) Specify when to send an email notification prior to a machine expiration date.	System administrator	See Customize the Date for Email Notification for Machine Expiration .
<input type="checkbox"/> Select the vRealize Automation events to trigger user notifications. Users can only subscribe to notifications for events you enable as notification triggers.	Tenant administrator	See Configure Notifications .
<input type="checkbox"/> (Optional) Configure the templates for notifications sent to machine owners concerning events that involve their machines, such as lease expiration.	Anyone with access to the directory \Templates under the vRealize Automation server install directory (typically %SystemDrive%\Program Files x86\VMware\vCAC\Server) can configure the templates for these email notifications.	See Configuring Templates for Automatic IaaS Emails .
<input type="checkbox"/> Provide your users with instructions about how to subscribe to the notifications that you enabled. They can choose to subscribe to only the notifications that are relevant to their roles.	All users	See Subscribe to Notifications .

Configuring Global Email Servers for Notifications

Tenant administrators can add email servers as part of configuring notifications for their own tenants. As a system administrator, you can set up global inbound and outbound email servers that appear to all tenants as the system defaults. If tenant administrators do not override these settings before enabling notifications, vRealize Automation uses the globally configured email servers.

Create a Global Inbound Email Server

System administrators create a global inbound email server to handle inbound email notifications, such as approval responses. You can create only one inbound server, which appears as the default for all tenants. If tenant administrators do not override these settings before enabling notifications, vRealize Automation uses the globally configured email server.

Prerequisites

Log in to the vRealize Automation console as a **system administrator**.

Procedure

- 1 Select **Administration > Email Servers**.
- 2 Click the **Add** icon (.
- 3 Select **Email – Inbound**.
- 4 Click **OK**.
- 5 Enter a name in the **Name** text box.
- 6 (Optional) Enter a description in the **Description** text box.
- 7 (Optional) Select the **SSL** check box to use SSL for security.
- 8 Choose a server protocol.
- 9 Type the name of the server in the **Server Name** text box.
- 10 Type the server port number in the **Server Port** text box.
- 11 Type the folder name for emails in the **Folder Name** text box.
This option is required only if you choose IMAP server protocol.
- 12 Enter a user name in the **User Name** text box.
- 13 Enter a password in the **Password** text box.
- 14 Type the email address that vRealize Automation users can reply to in the **Email Address** text box.
- 15 (Optional) Select **Delete From Server** to delete from the server all processed emails that are retrieved by the notification service.
- 16 Choose whether vRealize Automation can accept self-signed certificates from the email server.
- 17 Click **Test Connection**.

18 Click **Add**.

Create a Global Outbound Email Server

System administrators create a global outbound email server to handle outbound email notifications. You can create only one outbound server, which appears as the default for all tenants. If tenant administrators do not override these settings before enabling notifications, vRealize Automation uses the globally configured email server.

Prerequisites

Log in to the vRealize Automation console as a **system administrator**.

Procedure

- 1 Select **Administration > Email Servers**.
- 2 Click the **Add** icon (+).
- 3 Select **Email – Outbound**.
- 4 Click **OK**.
- 5 Enter a name in the **Name** text box.
- 6 (Optional) Enter a description in the **Description** text box.
- 7 Type the name of the server in the **Server Name** text box.
- 8 Choose an encryption method.
 - Click **Use SSL**.
 - Click **Use TLS**.
 - Click **None** to send unencrypted communications.
- 9 Type the server port number in the **Server Port** text box.
- 10 (Optional) Select the **Required** check box if the server requires authentication.
 - a Type a user name in the **User Name** text box.
 - b Type a password in the **Password** text box.
- 11 Type the email address that vRealize Automation emails should appear to originate from in the **Sender Address** text box.

This email address corresponds to the user name and password you supplied.
- 12 Choose whether vRealize Automation can accept self-signed certificates from the email server.
- 13 Click **Test Connection**.
- 14 Click **Add**.

Add a Tenant-Specific Outbound Email Server

Tenant administrators can add an outbound email server to send notifications for completing work items, such as approvals.

Each tenant can have only one outbound email server. If your system administrator has already configured a global outbound email server, see [Override a System Default Outbound Email Server](#).

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator**.
- If the email server requires authentication, the specified user must be in an identity store and the business group.

Procedure

- 1 Select **Administration > Notifications > Email Servers**.
- 2 Click the **Add** icon ().
- 3 Select **Email – Outbound**.
- 4 Click **OK**.
- 5 Enter a name in the **Name** text box.
- 6 (Optional) Enter a description in the **Description** text box.
- 7 Type the name of the server in the **Server Name** text box.
- 8 Choose an encryption method.
 - Click **Use SSL**.
 - Click **Use TLS**.
 - Click **None** to send unencrypted communications.
- 9 Type the server port number in the **Server Port** text box.
- 10 (Optional) Select the **Required** check box if the server requires authentication.
 - a Type a user name in the **User Name** text box.
 - b Type a password in the **Password** text box.
- 11 Type the email address that vRealize Automation emails should appear to originate from in the **Sender Address** text box.

This email address corresponds to the user name and password you supplied.

- 12 Choose whether vRealize Automation can accept self-signed certificates from the email server.

This option is available only if you enabled encryption.

- Click **Yes** to accept self-signed certificates.
- Click **No** to reject self-signed certificates.

- 13 Click **Test Connection**.

- 14 Click **Add**.

Add a Tenant-Specific Inbound Email Server

Tenant administrators can add an inbound email server so that users can respond to notifications for completing work items, such as approvals.

Each tenant can have only one inbound email server. If your system administrator already configured a global inbound email server, see [Override a System Default Inbound Email Server](#).

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator**.
- Verify that the specified user is in an identity store and in the business group.

Procedure

- 1 Select **Administration > Notifications > Email Servers**.
- 2 Click the **Add** icon (+).
- 3 Select **Email - Inbound** and click **OK**.
- 4 Configure the following inbound email server options.

Option	Action
Name	Enter a name for the inbound email server.
Description	Enter a description of the inbound email server.
Security	Select the Use SSL check box.
Protocol	Choose a server protocol.
Server Name	Enter the server name.
Server Port	Enter the server port number.

- 5 Type the folder name for emails in the **Folder Name** text box.
This option is required only if you choose IMAP server protocol.
- 6 Enter a user name in the **User Name** text box.
- 7 Enter a password in the **Password** text box.
- 8 Type the email address that vRealize Automation users can reply to in the **Email Address** text box.

- 9 (Optional) Select **Delete From Server** to delete from the server all processed emails that are retrieved by the notification service.
- 10 Choose whether vRealize Automation can accept self-signed certificates from the email server.
This option is available only if you enabled encryption.
 - Click **Yes** to accept self-signed certificates.
 - Click **No** to reject self-signed certificates.
- 11 Click **Test Connection**.
- 12 Click **Add**.

Override a System Default Outbound Email Server

If the system administrator configured a system default outbound email server, the tenant administrator can override this global setting.

Prerequisites

Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Notifications > Email Servers**.
- 2 Select the Outbound email server.
- 3 Click **Override Global**.
- 4 Enter a name in the **Name** text box.
- 5 (Optional) Enter a description in the **Description** text box.
- 6 Type the name of the server in the **Server Name** text box.
- 7 Choose an encryption method.
 - Click **Use SSL**.
 - Click **Use TLS**.
 - Click **None** to send unencrypted communications.
- 8 Type the server port number in the **Server Port** text box.
- 9 (Optional) Select the **Required** check box if the server requires authentication.
 - a Type a user name in the **User Name** text box.
 - b Type a password in the **Password** text box.
- 10 Type the email address that vRealize Automation emails should appear to originate from in the **Sender Address** text box.

This email address corresponds to the user name and password you supplied.

- 11 Choose whether vRealize Automation can accept self-signed certificates from the email server.

This option is available only if you enabled encryption.

- Click **Yes** to accept self-signed certificates.
- Click **No** to reject self-signed certificates.

- 12 Click **Test Connection**.

- 13 Click **Add**.

Override a System Default Inbound Email Server

If the system administrator has configured a system default inbound email server, tenant administrators can override this global setting.

Prerequisites

Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Notifications > Email Servers**.
- 2 Select the Inbound email server in the Email Servers table.
- 3 Click **Override Global**.
- 4 Enter the following inbound email server options.

Option	Action
Name	Enter the name of the inbound email server.
Description	Enter a description of the inbound email server.
Security	Select the SSL check box to use SSL for security.
Protocol	Choose a server protocol.
Server Name	Enter the server name.
Server Port	Enter the server port number.

- 5 Type the folder name for emails in the **Folder Name** text box.
This option is required only if you choose IMAP server protocol.
- 6 Enter a user name in the **User Name** text box.
- 7 Enter a password in the **Password** text box.
- 8 Type the email address that vRealize Automation users can reply to in the **Email Address** text box.
- 9 (Optional) Select **Delete From Server** to delete from the server all processed emails that are retrieved by the notification service.

- 10 Choose whether vRealize Automation can accept self-signed certificates from the email server.

This option is available only if you enabled encryption.

- Click **Yes** to accept self-signed certificates.
- Click **No** to reject self-signed certificates.

- 11 Click **Test Connection**.

- 12 Click **Add**.

Revert to System Default Email Servers

Tenant administrators who override system default servers can revert the settings back to the global settings.

Prerequisites

Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Notifications > Email Servers**.
- 2 Select the email server to revert.
- 3 Click **Revert to Global**.
- 4 Click **Yes**.

Configure Notifications

Each user determines whether to receive notifications, but tenant administrators determine which events trigger notifications.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator**.
- Verify that a tenant administrator or system administrator configured an outbound email server. See [Add a Tenant-Specific Outbound Email Server](#).

Procedure

- 1 Select **Administration > Notifications > Scenarios**.
- 2 Select one or more notifications.
- 3 Click **Activate**.

Users who subscribe to notifications in their preference settings now receive the notifications.

Customize the Date for Email Notification for Machine Expiration

You can specify when to send an email notification prior to a machine expiration date.

You can change the setting that defines the number of days before a machine's expiration date that vRealize Automation sends an expiration notification email. The email notifies users of a machine's expiration date. By default, the setting is 7 days prior to machine expiration.

Procedure

- 1 Log in to the vRealize Automation server by using credentials with administrative access.
- 2 Navigate to and open the `/etc/vcac/setenv-user` file.
- 3 Add the following line to the file to specify the number of days prior to machine expiration, where 3 in this example specifies 3 days prior to machine expiration.

```
VCAC_OPTS="$VCAC_OPTS -Dlease.enforcement.prearchive.notification.days=3"
```

- 4 Restart the vCAC services on the virtual appliance by running the following command:

```
service vcac-server restart
```

What to do next

If you are working in a high availability load balancer environment, repeat this procedure for all the virtual appliances in the HA environment.

Configuring Templates for Automatic IaaS Emails

You can configure notification emails to be sent to machine owners about various vRealize Automation events that involve their machines.

The events that trigger notifications can include the expiration or approaching expiration of archive periods and virtual machine leases.

For information about configuring and enabling or disabling vRealize Automation email notifications, see the following blog article and Knowledge Base articles:

- [Email Customization in vRealize Automation](#)
- [Customizing email templates in vRealize Automation \(2088805\)](#)
- [Examples for customizing email templates in vRealize Automation \(2102019\)](#)

Subscribe to Notifications

If your administrators have configured notifications, you can subscribe to receive notifications from vRealize Automation. Notification events can include the successful completion of a catalog request or a required approval.

Prerequisites

Log in to the vRealize Automation console.

Procedure

- 1 Click **Preferences**.

- 2 Select the **Enabled** check box for the Email protocol in the Notifications table.
- 3 Click **Apply**.
- 4 Click **Close**.

(Optional) Create a Custom RDP File to Support RDP Connections for Provisioned Machines

System administrators create a custom remote desktop protocol file that IaaS architects use in blueprints to configure RDP settings. You create the RDP file and provide architects with the full pathname for the file so they can include it in blueprints, then a catalog administrator entitles users to the RDP action.

Note If you are using Internet Explorer with Enhanced Security Configuration enabled, you cannot download .rdp files.

Prerequisites

Log in to the IaaS Manager Service as an administrator.

Procedure

- 1 Set your current directory to `<vRA_installation_dir>\Rdp`.
- 2 Copy the file `Default.rdp` and rename it to `Console.rdp` in the same directory.
- 3 Open the `Console.rdp` file in an editor.
- 4 Add RDP settings to the file.
For example, **connect to console:i:1**.
- 5 If you are working in a distributed environment, log in as a user with administrative privileges to the IaaS Host Machine where the Model Manager Website component is installed.
- 6 Copy the `Console.rdp` file to the directory `vRA_installation_dir\Website\Rdp`.

Your IaaS architects can add the RDP custom properties to Windows machine blueprints, and then catalog administrators can entitle users to the Connect Using RDP action. See [Add RDP Connection Support to Your Windows Machine Blueprints](#).

(Optional) Scenario: Add Datacenter Locations for Cross Region Deployments

As a system administrator, you want to define locations for your Boston and London datacenters so your fabric administrators can apply the appropriate locations to compute resources in each datacenter. When your blueprint architects create blueprints, they can enable the locations feature so users can choose to provision machines in Boston or London when they fill out their catalog item request forms.

You have a datacenter in London, and a datacenter in Boston, and you do not want users in Boston provisioning machines on your London infrastructure or vice versa. To ensure that Boston users provision on your Boston infrastructure, and London users provision on your London infrastructure, you want to allow users to select an appropriate location for provisioning when they request machines.

You cannot filter datacenter locations in the xml file based on the tenant or business group. When working in a multi-tenant environment, you can use property definitions to filter based on the tenant or business group. For information about using property definitions, see blog post [How to use dynamic property definitions](#).

Procedure

- 1 Log in to your IaaS Web Server host using administrator credentials.

This is the machine on which you installed the IaaS Website component.

- 2 Edit the file `WebSite\XmlData\DataCenterLocations.xml` in the Windows server install directory (typically `%SystemDrive%\Program Files x86\VMware\vCAC\Server`).
- 3 Edit the CustomDataType section of the file to create Data Name entries for each location.

```

<CustomDataType>
  <Data Name="London" Description="London datacenter" />
  <Data Name="Boston" Description="Boston datacenter" />
</CustomDataType>

```

- 4 Save and close the file.
- 5 Restart the manager service.
- 6 If you have more than one IaaS Web Server host, repeat this procedure on each redundant instance.

Your fabric administrator can apply the appropriate location to compute resources located in each datacenter. See [Scenario: Apply a Location to a Compute Resource for Cross Region Deployments](#).

What to do next

You can add the `Vrm.DataCenter.Location` property to a blueprint, or enable the **Display Location on Request** option in the blueprint, to require that the user supply a datacenter location when they request machine provisioning.

Configuring vRealize Orchestrator

vRealize Orchestrator is an automation and management engine that extends vRealize Automation to support XaaS and other extensibility. You can configure and use the vRealize Orchestrator server that is preconfigured in the vRealize Automation appliance, or you can deploy vRealize Orchestrator as an external server instance and associate that external instance with vRealize Automation.

vRealize Orchestrator allows administrators and architects to develop complex automation tasks by using the workflow designer, and then access and run the workflows from vRealize Automation.

vRealize Orchestrator can access and control external technologies and applications by using vRealize Orchestrator plug-ins.

Configuring vRealize Automation to use vRealize Orchestrator makes it possible to publish Orchestrator workflows in the vRealize Orchestrator service catalog as part of the XaaS blueprint management.

If you want to run Orchestrator workflows to extend the management of IaaS machines, you must configure vRealize Orchestrator as an endpoint.

Configuration Privileges

System and tenant administrators can configure vRealize Automation to use an external or the embedded vRealize Orchestrator server.

In addition, system administrators can also determine the workflow folders that are available to each tenant.

Tenant administrators can configure the vRealize Orchestrator plug-ins as endpoints.

Role	vRealize Orchestrator-Related Configuration Privileges
System administrators	<ul style="list-style-type: none"> ■ Configure the vRealize Orchestrator server for all tenants. ■ Define the default vRealize Orchestrator workflow folders per tenant.
Tenant administrators	<ul style="list-style-type: none"> ■ Configure the vRealize Orchestrator server for their own tenant. ■ Add vRealize Orchestrator plug-ins as endpoints.

Configure the Embedded vRealize Orchestrator Server

The vRealize Automation Appliance includes a preconfigured instance of vRealize Orchestrator. The vRealize Orchestrator server service is running by default but you must start the configuration service manually to access the Control Center.

Prerequisites

Deploy the vRealize Automation Appliance. For details, see *Deploy the vRealize Automation Appliance* in *Installing vRealize Automation 7.3*.

Procedure

- 1 Log in to the vRealize Automation console as a **system administrator** or **tenant administrator**.
- 2 Select **Administration > VRO Configuration > Server Configuration**.

3 Click **Use the default Orchestrator server**.

Connections to the embedded vRealize Orchestrator server are now configured. The **VCAC** workflows folder and the related utility actions are automatically imported. The **VCAC > ASD** workflows folder contains workflows for configuring endpoints and creating resource mappings.

Configure the Default Workflow Folder for a Tenant

System administrators can group workflows in different folders and then define workflow categories per tenant. By doing this, a system administrator can grant users from different tenants access to different workflow folders on the same vRealize Orchestrator server.

Prerequisites

Log in to the vRealize Automation console as a **system administrator**.

Procedure

- 1 Select **Administration > Advanced Services > Default vRO Folder**.
- 2 Click the name of the tenant you want to edit.
- 3 Browse the vRealize Orchestrator workflow library and select a folder.
- 4 Click **Add**.

You defined the default vRealize Orchestrator workflow folder for a tenant.

What to do next

Repeat the procedure for all of the tenants for which you want to define a default workflow folder.

Log in to the vRealize Orchestrator Configuration Interface

To edit the configuration of the default vRealize Orchestrator instance embedded in vRealize Automation, you must start the vRealize Orchestrator configuration service and log in to the vRealize Orchestrator configuration interface.

The vRealize Orchestrator configuration service is not started by default in the vRealize Automation appliance. You must start the vRealize Orchestrator configuration service to access the vRealize Orchestrator configuration interface.

Procedure

- 1 Start the vRealize Orchestrator Configuration service.
 - a Log in to the vRealize Automation appliance Linux console as root.
 - b Enter **service vco-configurator start** and press Enter.
- 2 Connect to the vRealize Automation URL in a Web browser.
- 3 Click **vRealize Orchestrator Control Center**.

You are redirected to https://vra-va-hostname.domain.name_or_load_balancer_address:8283/vco-controlcenter.

4 Log in to the vRealize Orchestrator Control Center.

The user name is configured by the vRealize Automation appliance administrator.

Log in to the vRealize Orchestrator Client

To perform general administration tasks or to edit and create workflows in the default vRealize Orchestrator instance, you must log in to the vRealize Orchestrator client.

The vRealize Orchestrator client interface is designed for developers with administrative rights who want to develop workflows, actions, and other custom elements.

Procedure

1 Connect to the vRealize Automation URL in a Web browser.

2 Click **vRealize Orchestrator Client**.

The client file is downloaded.

3 Click the download and following the prompts.

4 On the vRealize Orchestrator log in page, enter the IP or the domain name of the vRealize Automation appliance in the **Host name** text box, and **443** as the default port number.

For example, enter `vrealize_automation_appliance_ip:443`.

5 Log in by using the vRealize Orchestrator Client user name and password.

The credentials are the default tenant administrator user name and password.

6 In the **Certificate Warning** window select an option to handle the certificate warning.

The vRealize Orchestrator client communicates with the vRealize Orchestrator server by using an SSL certificate. A trusted CA does not sign the certificate during installation. You receive a certificate warning each time you connect to the vRealize Orchestrator server.

Option	Description
Ignore	Continue using the current SSL certificate. The warning message appears again when you reconnect to the same vRealize Orchestrator server, or when you try to synchronize a workflow with a remote vRealize Orchestrator server.
Cancel	Close the window and stop the login process.
Install this certificate and do not display any security warnings for it anymore.	Select this check box and click Ignore to install the certificate and stop receiving security warnings.

You can change the default SSL certificate with a certificate signed by a CA. For more information about changing SSL certificates, see *Installing and Configuring VMware vRealize Orchestrator*.

What to do next

You can import a package, develop workflows, or set root access rights on the system. See *Using the VMware vRealize Orchestrator Client* and *Developing with VMware vRealize Orchestrator*.

Configure an External vRealize Orchestrator Server

You can set up vRealize Automation to use an external vRealize Orchestrator server.

System administrators can configure the default vRealize Orchestrator server globally for all tenants.

Tenant administrators can configure the vRealize Orchestrator server only for their tenants.

Connections to external vRealize Orchestrator server instances require the user account to have view and execute permissions in vRealize Orchestrator.

- Single Sign-On authentication. The user information is passed to vRealize Orchestrator with the XaaS request and the user is granted view and execute permissions for the requested workflow.
- Basic authentication. The provided user account must be a member of a vRealize Orchestrator group with view and execute permissions or the member of the vcoadmins group.

Prerequisites

- Install and configure an external vRealize Orchestrator Appliance. See *Installing and Configuring vRealize Orchestrator* in the vRealize Orchestrator Information Center at https://www.vmware.com/support/pubs/orchestrator_pubs.html.
- Log in to the vRealize Automation console as a **system administrator** or **tenant administrator**.
- Configure the default workflow folder. See [Configure the Default Workflow Folder for a Tenant](#).

Procedure

- 1 Select **Administration > vRO Configuration > Server Configuration**.
- 2 Click **Use an external Orchestrator server**.
- 3 Enter a name and, optionally, a description.
- 4 Enter the IP or the DNS name of the machine on which the vRealize Orchestrator server runs in the **Host** text box.

Note If the external Orchestrator is configured to work in cluster mode, enter the IP address or host name of the load balancer virtual server that distributes the client requests across the Orchestrator servers in the cluster.

- 5 Enter the port number to communicate with the external vRealize Orchestrator server in the **Port** text box.

8281 is the default port for vRealize Orchestrator.

6 Select the authentication type.

Option	Description
Single Sign-On	Connects to the vRealize Orchestrator server by using vCenter Single Sign-On. This option is applicable only if you configured the vRealize Orchestrator and vRealize Automation to use a common vCenter Single Sign-On instance.
Basic	Connects to the vRealize Orchestrator server with the user name and password that you enter in the User name and Password text boxes. The account that you provide must be a member of the vRealize Orchestrator vcoadmins group or a member of a group with view and execute permissions.

7 Click **Test Connection**.

8 Click **OK**.

You configured the connection to the external vRealize Orchestrator server, and the **VCAC** workflows folder and the related utility actions are automatically imported. The **VCAC > ASD** workflows folder contains workflows for configuring endpoints and creating resource mappings.

What to do next

[Log in to the vRealize Orchestrator Client](#)

Configuring Resources

You can configure resources such as endpoints, reservations, and network profiles to support vRealize Automation blueprint definition and machine provisioning.

Checklist for Configuring IaaS Resources

IaaS administrators and fabric administrators configure IaaS resources to integrate existing infrastructure with vRealize Automation and to allocate infrastructure resources to vRealize Automation business groups.

You can use the Configuring IaaS Resources Checklist to see a high-level overview of the sequence of steps required to configure IaaS resources.

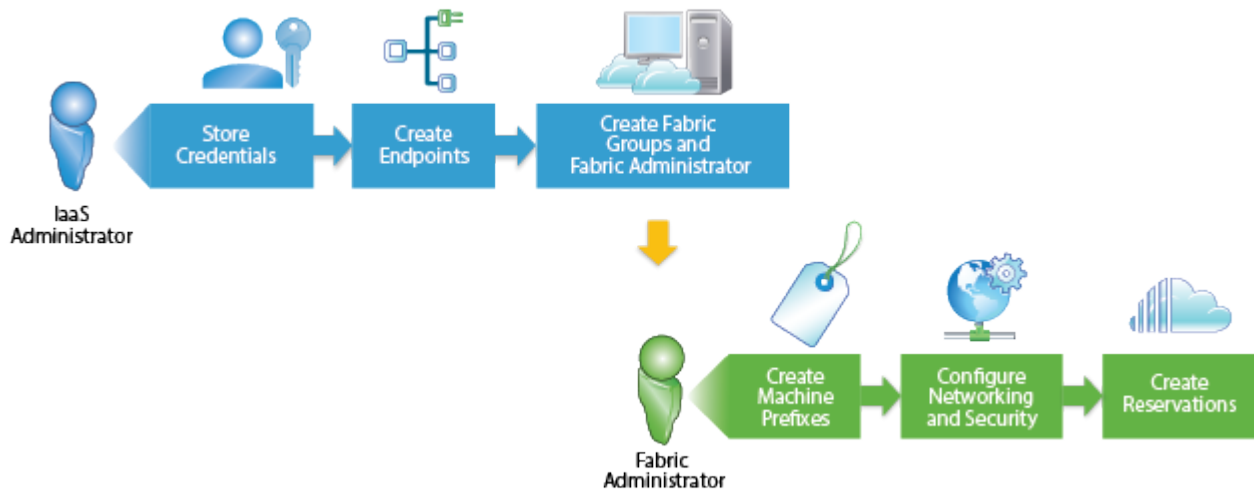

Table 2-11. Checklist for Configuring IaaS Resources

Task	vRealize Automation Role	Details
<input type="checkbox"/> Create endpoints for your infrastructure to bring resources under vRealize Automation management.	IaaS administrator	Choosing an Endpoint Scenario.
<input type="checkbox"/> Create a fabric group to organize infrastructure resources into groups and assign one or more administrators to manage those resources as your vRealize Automation fabric administrators.	IaaS administrator	Create a Fabric Group.
<input type="checkbox"/> Configure machine prefixes used to create names for machines provisioned through vRealize Automation.	Fabric administrator	Configure Machine Prefixes.
<input type="checkbox"/> (Optional) Create network profiles to configure network settings for provisioned machines.	Fabric administrator	Creating a Network Profile.
<input type="checkbox"/> Allocate infrastructure resources to business groups by creating reservations and, optionally, reservation and storage reservation profiles.	<ul style="list-style-type: none"> IaaS administrator if also configured as a Fabric administrator Fabric administrator 	Configuring Reservations and Reservation Policies.

Configuring Endpoints

You create and configure the endpoints that allow vRealize Automation to communicate with your infrastructure.

Endpoints definitions are categorized based on type:

- Cloud

The cloud category contains the vCloud Air, vCloud Director, Amazon EC2, and OpenStack endpoint types

- IPAM

This category is only visible if you have registered a third-party IPAM endpoint type such as Infoblox IPAM in a vRealize Orchestrator workflow.

- Management

This category contains the vRealize Operations Manager endpoint only.

- Network and Security

This category contains the Proxy and NSX endpoint types.

A Proxy endpoint can be associated to an Amazon, vCloud Air, or vCloud Director endpoint.

An NSX endpoint can be associated to a vSphere endpoint.

- Orchestration

This category contains the vRealize Orchestrator endpoint only.

- Storage

This category contains the NetApp ONTAP endpoint.

- Virtual

The virtual category contains the vSphere, Hyper-V (SCVMM), and KVM (RHEV) endpoint types.

You can configure additional endpoint types in vRealize Orchestrator and use them with supported endpoint types in vRealize Automation. You can also import, and export, endpoints programmatically.

For information about working with endpoints after upgrade or migration, see [Considerations When Working With Upgraded or Migrated Endpoints](#).

Choosing an Endpoint Scenario

Choose an endpoint scenario based on the target endpoint type.

For information about available endpoint settings, see [Endpoint Settings Reference](#).

Table 2-12. Choosing an Endpoint Scenario

Endpoint	More Information
vSphere	Create a vSphere Endpoint
NSX	Create an NSX Endpoint and Associate to a vSphere Endpoint
vCloud Air (Subscription or OnDemand)	Create a vCloud Air Endpoint
vCloud Director	Create a vCloud Director Endpoint
vRealize Orchestrator	Create a vRealize Orchestrator Endpoint
vRealize Operations	Create a vRealize Operations Manager Endpoint
Third party IPAM provider	Create a Third-Party IPAM Provider Endpoint
Microsoft Azure	Create a Microsoft Azure Endpoint
Puppet	Create a Puppet Endpoint

Table 2-12. Choosing an Endpoint Scenario (Continued)

Endpoint	More Information
Amazon	<ul style="list-style-type: none"> ■ Create an Amazon Endpoint ■ (Optional) Add an Amazon Instance Type
OpenStack	Create an OpenStack Endpoint
Proxy	Create a Proxy Endpoint and Associate to a Cloud Endpoint
Hyper-V (SCVMM)	Create a Hyper-V (SCVMM) Endpoint
KVM (RHEV)	Endpoint Settings Reference
NetApp ONTAP	<ul style="list-style-type: none"> ■ Space-Efficient Storage for Virtual Provisioning ■ Endpoint Settings Reference
Hyper-V (Standalone), XenServer or Xen Pool Master	Create a Hyper-V, XenServer, or Xen Pool Endpoint
Import endpoints	Import or Export Endpoints Programmatically

Endpoint Settings Reference

Use endpoint settings to define location and access credentials for data collection and service catalog deployment.

General Tab

Most vRealize Automation endpoints contain the following options. Settings that are unique to a particular endpoint type are noted.

Table 2-13. General Tab Settings

Setting	Description
Name	Enter the endpoint name.
Description	Enter the endpoint description.

Table 2-13. General Tab Settings (Continued)

Setting	Description
Address	<p>Enter the endpoint address using the endpoint-specific address format.</p> <ul style="list-style-type: none"> For a KVM (RHEV) or NetApp ONTAP endpoint, the address must be of one of the following formats: <ul style="list-style-type: none"> <code>https://FQDN</code> <code>https://IP_address</code> <p>For example: <code>https://mycompany-kvmrhev1.mycompany.local</code> or <code>netapp-1.mycompany.local</code>.</p> For an OpenStack endpoint, the address must be of the format <code>https://FQDN/powervc/openstack/ service</code>. For example: <code>https://openstack.mycompany.com/powervc/openstack/admin</code>. For an OpenStack endpoint, the address must be of one of the following formats: <ul style="list-style-type: none"> <code>https://FQDN:500</code> <code>https://IP_address:500</code> For a vSphere endpoint, the address must be of the format <code>https://host/sdk</code>. For an NSX endpoint, the address must be of the format <code>https://host</code>. For a vRealize Orchestrator endpoint, the address must be of the https protocol and include the fully qualified name or IP address of the vRealize Orchestrator server and the vRealize Orchestrator port number, for example <code>https://vrealize-automation-appliance-hostname:443/vco</code>. For a vRealize Operations endpoint, the address must be of the format <code>https://host/suite-api</code>.
Integrated credentials	<p>If you choose to use your vSphere integrated credentials you do not need to enter a user name and password.</p> <p>This setting applies to vSphere endpoints only.</p>
User name	Enter the administrator-level user name that you stored for the endpoint in the endpoint-specific format as suggested in the user interface.
Password	Enter the administrator-level password that you stored for the endpoint.
OpenStack project	<p>Enter an OpenStack tenant name.</p> <p>This setting applies to OpenStack endpoints only.</p>
Organization	<p>If you are an organization administrator, you can enter a vCloud Director organization name.</p> <p>This setting applies to vCloud Director only.</p>
Access key ID	<p>Enter the Amazon AWS key ID.</p> <p>This setting applies to Amazon endpoints only.</p>
Secret access key	<p>Enter your Amazon AWS secret access key.</p> <p>This setting applies to Amazon endpoints only.</p>

Table 2-13. General Tab Settings (Continued)

Setting	Description
Port	Enter the port value to connect to on the proxy endpoint address. This setting applies to Proxy endpoints only.
Priority	Enter a priority value as an integer greater than or equal to 1. The lower value specifies a higher priority. The priority value is associated to the embedded VMware.VCenterOrchestrator.Priority custom property. This setting applies to vRealize Orchestrator endpoints only.

Properties Tab

All endpoint types use a properties tab to capture custom properties or property groups and settings. For examples of custom properties for specific endpoint types, see *Custom Properties Reference*.

Association Tab

You can create an association to an NSX endpoint or a Proxy endpoint, depending on the endpoint you are associating from. You can associate a vSphere endpoint with an NSX endpoint to assign NSX settings to the vSphere endpoint. You can also associate a vCloud Air, vCloud Director, or Amazon endpoint with a proxy endpoint to assign proxy settings to the vCloud Air, vCloud Director, or Amazon endpoint.

Test Connection

You can use a test connection action to validate the credentials, host endpoint address, and certificate for a vSphere, NSX, or vRealize Operations Manager endpoint. See [Considerations When Using Test Connection](#).

Create a vSphere Endpoint

You can create endpoints that allow vRealize Automation to communicate with the vSphere environment and discover compute resources, collect data, and provision machines. You can optionally associate NSX settings to the vSphere endpoint by associating to an NSX endpoint.

If you upgraded or migrated a vSphere endpoint that was using an NSX manager, a new NSX endpoint is created that contains an association between the source vSphere endpoint and a new NSX endpoint.

If your vSphere environment is integrated with NSX, see [Create an NSX Endpoint and Associate to a vSphere Endpoint](#).

For more information about validating the connection and certificate trust, see [Considerations When Using Test Connection](#).

Prerequisites

- Log in to the vRealize Automation console as an **laaS administrator**.
- You must install a vSphere proxy agent to manage your vSphere endpoint, and you must use the same exact name for your endpoint and agent. For information about installing the agent, see *Installing vRealize Automation 7.3*.

- If you want to configure additional NSX network and security settings for the vSphere endpoint, create an NSX endpoint. You can associate to the NSX endpoint as you create the vSphere endpoint. See [Create an NSX Endpoint and Associate to a vSphere Endpoint](#).

Procedure

- 1 Select **Infrastructure > Endpoints > Endpoints**.

- 2 Select **New > Virtual > vSphere**.

- 3 Enter a name in the **Name** text box.

The name must match the endpoint name provided to the vSphere proxy agent during installation or data collection fails.

- 4 (Optional) Enter a description in the **Description** text box.

- 5 Enter the URL for the vCenter Server instance in the **Address** text box.

The URL must be of the type: **https://hostname/sdk** or **https://IP_address/sdk**.

For example, **https://vsphereA/sdk**.

- 6 Enter your vSphere administrator-level user name and password or instead use your vSphere integrated credentials.

Provide credentials with permission to modify custom attributes.

The user name format is *domain\username*.

Select **Use Integrated Credentials** to use the vSphere proxy agent's service account to connect to the vCenter Server.

If you choose to use your vSphere integrated credentials you do not need to enter a user name and password.

- 7 (Optional) Click **Properties** and add supplied custom properties, property groups, or your own property definitions for the endpoint.

- 8 (Optional) To configure NSX network and security settings for the endpoint, click **Associations** and associate to an existing NSX endpoint.

You must have at least one NSX endpoint to create an association.

- 9 (Optional) Click **Test Connection** to validate the credentials, host endpoint address, and certificate trust. The action also checks that the manager service and agent are running so that endpoint can be data-collected. The **OK** action tests for these same conditions.

The **Test Connection** action returns information about any of the following conditions:

- Certificate error

If the certificate is not found, trusted, or has expired, you are prompted to accept a certificate thumbprint. If you do not accept the thumbprint, you can still save the endpoint but machine provisioning might fail.

- Agent error

The associated vSphere agent is not found. The agent must be running for the test to succeed.

- Host error

The specified endpoint address is not reachable or the associated manager service is not running. The manager service must be running for the test to succeed.

- Credentials error

The specified user name and password combination is invalid for the endpoint at the specified address.

- Timeout

The test action could not complete in the allowed two-minute time period.

If the **Test Connection** action fails, you can still save the endpoint but machine provisioning might fail.

If there is a trusted certificate issue, for example the certificate has expired, you are prompted to accept a certificate thumbprint.

10 Click **OK** to save the endpoint.

The **OK** action tests for the same conditions as the **Test Connection** action. If it finds any of the preceding conditions, it returns a message. If it can save, it leaves the error on the screen for you to review.

vRealize Automation collects data from your endpoint and discovers your compute resources.

Note Do not rename vSphere data centers after the initial data collection or provisioning might fail.

What to do next

Add the compute resources from your endpoint to a fabric group. See [Create a Fabric Group](#).

Create an NSX Endpoint and Associate to a vSphere Endpoint

You can create an NSX endpoint and associate its NSX settings to an existing vSphere endpoint.

If you upgraded or migrated a vSphere endpoint that was using an NSX manager, a new NSX endpoint is created that contains an association between the source vSphere endpoint and a new NSX endpoint.

For information about validating the NSX connection and certificate trust, see [Considerations When Using Test Connection](#).

Prerequisites

- Log in to the vRealize Automation console as an **laaS administrator**.
- You must install a vSphere proxy agent to manage your vSphere endpoint, and you must use the same exact name for your endpoint and agent. For information about installing the agent, see *Installing vRealize Automation 7.3*.

- Configure your NSX network settings. See [Configuring Network and Security Component Settings](#).
- [Create a vSphere Endpoint](#).

In preparation for using NSX network, security, and load balancing capabilities in vRealize Automation, when using NSX Manager credentials you must use the NSX Manager administrator account.

Procedure

1 Select **Infrastructure > Endpoints > Endpoints**.

2 Select **New > Network and Security > NSX**.

3 Enter a name in the **Name** text box.

4 (Optional) Enter a description in the **Description** text box.

5 Enter the URL for the NSX instance in the **Address** text box.

The URL must be of the type: **https://hostname** or **https://IP_address**.

For example, **https://nsx-manager.local**.

6 Enter the NSX administrator-level user name and password that are stored for the NSX endpoint.

7 (Optional) Click **Properties** and add supplied custom properties, property groups, or your own property definitions for the endpoint.

8 To associate the NSX network and security settings to an existing vSphere endpoint, click **Associations** and select an existing vSphere endpoint.

You must create the vSphere endpoint before you can create the association.

You can only associate an NSX endpoint to one vSphere endpoint. This association constraint means that you cannot provision a universal on-demand network and attach it to vSphere machines that are provisioned on different vCenters.

9 (Optional) Click **Test Connection** to validate the credentials, host endpoint address, and certificate trust. The action also checks that the manager service and agent are running so that endpoint can be data-collected. The **OK** action tests for these same conditions.

The **Test Connection** action returns information about any of the following conditions:

- **Certificate error**

If the certificate is not found, trusted, or has expired, you are prompted to accept a certificate thumbprint. If you do not accept the thumbprint, you can still save the endpoint but machine provisioning might fail.

- **Agent error**

The associated vSphere agent is not found. The agent must be running for the test to succeed.

- **Host error**

The specified endpoint address is not reachable or the associated manager service is not running. The manager service must be running for the test to succeed.

- Credentials error

The specified user name and password combination is invalid for the endpoint at the specified address.

- Timeout

The test action could not complete in the allowed two-minute time period.

If the **Test Connection** action fails, you can still save the endpoint but machine provisioning might fail.

If there is a trusted certificate issue, for example the certificate has expired, you are prompted to accept a certificate thumbprint.

10 Click **OK** to save the endpoint.

The **OK** action tests for the same conditions as the **Test Connection** action. If it finds any of the preceding conditions, it returns a message. If it can save, it leaves the error on the screen for you to review.

vRealize Automation collects data from your endpoint and discovers your compute resources.

What to do next

Add the compute resources from your endpoint to a fabric group. See [Create a Fabric Group](#).

Create a vCloud Air Endpoint

You can create a vCloud Air endpoint for a an OnDemand or subscription service. You can optionally associate proxy settings to the vCloud Director endpoint by associating to a Proxy endpoint.

For information about vCloud Air Management Console, see vCloud Air documentation.

Note Reservations defined for vCloud Air endpoints and vCloud Director endpoints do not support the use of network profiles for provisioning machines.

For vCloud Air endpoints, the Organization name and the vDC name must be identical for a vCloud Air subscription instance.

For information about associating proxy settings to your endpoint, see [Create a Proxy Endpoint and Associate to a Cloud Endpoint](#).

Prerequisites

- Log in to the vRealize Automation console as an **laaS administrator**.
- Verify that you have **Virtual Infrastructure Administrator** authorization for your vCloud Air subscription service or OnDemand account.
- If you want to configure additional security and force connections to pass through a proxy server, create a Proxy endpoint. You can associate to the Proxy endpoint as you create the vCloud Director endpoint. See [Create a Proxy Endpoint and Associate to a Cloud Endpoint](#).

Procedure

1 Select **Infrastructure > Endpoints > Endpoints**.

2 Select **New > Cloud > vCloud Air**.

3 Enter a name and, optionally, a description.

4 Accept the default vCloud Air endpoint address in the **Address** text box or enter a new one.

The default vCloud Air endpoint address is `https://vca.vmware.com`, as specified in the `Default URL for vCloud Air endpoint` global property.

5 Enter your administrator-level user name and password.

The credentials must be those of the vCloud Air subscription service or OnDemand account administrator.

The user name format is `domain\username`.

Provide credentials for an organization administrator with rights to connect by using VMware Remote Console.

6 (Optional) Click **Properties** and add supplied custom properties, property groups, or your own property definitions for the endpoint.

7 (Optional) To configure additional security and force connections to pass through a proxy server, click **Associations** and associate to an existing Proxy endpoint.

You must have at least one Proxy endpoint to create an association.

8 Click **OK**.

What to do next

[Create a Fabric Group](#).

Create a vCloud Director Endpoint

You can create a vCloud Director endpoint to manage all of the vCloud Director virtual data centers (vDCs) in your environment, or you can create separate endpoints to manage each vCloud Director organization. You can optionally associate proxy settings to the vCloud Director endpoint by associating to a Proxy endpoint.

For information about Organization vDCs, see vCloud Director documentation.

Do not create a single endpoint and individual organization endpoints for the same vCloud Director instance.

vRealize Automation uses a proxy agent to manage vSphere resources.

Note Reservations defined for vCloud Air endpoints and vCloud Director endpoints do not support the use of network profiles for provisioning machines.

For information about associating proxy settings to your endpoint, see [Create a Proxy Endpoint and Associate to a Cloud Endpoint](#).

Prerequisites

- Log in to the vRealize Automation console as an **laaS administrator**.
- If you want to configure additional security and force connections to pass through a proxy server, create a Proxy endpoint. You can associate to the Proxy endpoint as you create the vCloud Director endpoint. See [Create a Proxy Endpoint and Associate to a Cloud Endpoint](#).

Procedure

- 1 Select **Infrastructure > Endpoints > Endpoints**.
- 2 Select **New > Cloud > vCloud Director**.
- 3 Enter a name and, optionally, a description.
- 4 Enter the URL of the vCloud Director server in the **Address** text box.

The URL must be of the type *FQDN* or *IP_address*.

For example, <https://mycompany.com>.

- 5 Enter your administrator-level user name and password.
 - To connect to the vCloud Director server and specify the organization for which the user has the administrator role, use organization administrator credentials. With these credentials, the endpoint can access only the associated organization vDCs. You can add endpoints for each additional organization in the vCloud Director instance to integrate with vRealize Automation.
 - To allow access to all Organization vDCs in the vCloud Director instance, use system administrator credentials for a vCloud Director and leave the **Organization** text box empty.
- 6 If you are an organization administrator, you can enter a vCloud Director organization name in the **Organization** text box.

Option	Description
Discover all Organization vDCs	If you have implemented vCloud Director in a private cloud, you can leave the Organization text box blank to allow the application to discover all the available Organization vDCs.
Separate endpoints for each Organization vCD	Enter a vCloud Director organization name in the Organization text box.

The **Organization** name matches your vCloud Director Organization name, which might also appear as your virtual data center (vDC) name. If you are using a Virtual Private Cloud, then this name is a unique identifier in the M123456789-12345 format. In a dedicated cloud, it is the given name of the target vDC.

If you are connecting directly to vCloud Director at the system level, for example leaving the Organization field blank, you need system administrator credentials. If you are entering an Organization in the endpoint, you need a user who has Organization Administrator credentials in that organization.

Provide credentials with rights to connect by using VMware Remote Console.

- To manage all organizations with a single endpoint, provide credentials for a system administrator.
- To manage each organization virtual datacenter (vDC) with a separate endpoint, create separate organization administrator credentials for each vDC.

Do not create a single system-level endpoint and individual organization endpoints for the same vCloud Director instance.

- 7 (Optional) Click **Properties** and add supplied custom properties, property groups, or your own property definitions for the endpoint.
- 8 (Optional) To configure additional security and force connections to pass through a proxy server, click **Associations** and associate to an existing Proxy endpoint.

You must have at least one Proxy endpoint to create an association.

- 9 Click **OK**.

What to do next

[Create a Fabric Group](#).

Create an Amazon Endpoint

You can create an endpoint to connect to an Amazon instance. You can optionally associate proxy settings to the Amazon endpoint by associating to a Proxy endpoint.

vRealize Automation provides several Amazon instance types for you to use when creating blueprints, but if you want to import your own instance types see [Add an Amazon Instance Type](#).

For information about associating proxy settings to your endpoint, see [Create a Proxy Endpoint and Associate to a Cloud Endpoint](#).

Prerequisites

- Log in to the vRealize Automation console as an **laaS administrator**.
- If you want to configure additional security and force connections to pass through a proxy server, create a Proxy endpoint. You can associate to the Proxy endpoint as you create the Amazon endpoint. See [Create a Proxy Endpoint and Associate to a Cloud Endpoint](#).

Procedure

- 1 Select **Infrastructure > Endpoints > Endpoints**.
- 2 Select **New > Cloud > Amazon EC2**.
- 3 Enter a name and, optionally, a description.

Typically this name indicates the Amazon account that corresponds to this endpoint.

- 4 Enter the administrative-level access key ID for the Amazon endpoint.

Only one endpoint can be associated with an Amazon access key ID.

To obtain the access key needed to create the Amazon endpoint, you must either request a key from a user who has AWS Full Access Administrator credentials or be additionally configured with the AWS Full Access Administrator policy. See Amazon documentation for details.

- 5 Enter the secret access key for the Amazon endpoint.
- 6 (Optional) Click **Properties** and add supplied custom properties, property groups, or your own property definitions for the endpoint.
- 7 (Optional) To configure additional security and force connections to pass through a proxy server, click **Associations** and associate to an existing Proxy endpoint.

You must have at least one Proxy endpoint to create an association.

- 8 Click **OK**.

After you create the endpoint, vRealize Automation begins collecting data from the Amazon Web Services regions.

What to do next

Add the compute resources from your endpoint to a fabric group. See [Create a Fabric Group](#).

Add an Amazon Instance Type

Several instance types are supplied with vRealize Automation for use with Amazon blueprints. An administrator can add and remove instance types.

The machine instance types managed by IaaS administrators are available to blueprint architects when they create or edit an Amazon blueprint. Amazon machine images and instance types are made available through the Amazon Web Services product.

Prerequisites

Log in to the vRealize Automation console as an **IaaS administrator**.

Procedure

- 1 Click **Infrastructure > Administration > Instance Types**.
- 2 Click **New**.
- 3 Add a new instance type, specifying the following parameters.

Information about the available Amazon instances types and the setting values that you can specify for these parameters is available from Amazon Web Services documentation in *EC2 Instance Types - Amazon Web Services (AWS)* at aws.amazon.com/ec2 and *Instance Types* at docs.aws.amazon.com.

- Name
- API name

- Type Name
- IO Performance Name
- CPUs
- Memory (GB)
- Storage (GB)
- Compute Units

4 Click the **Save** icon (✔).

When IaaS architects create Amazon Web Services blueprints, they can use your custom instance types.

What to do next

Add the compute resources from your endpoint to a fabric group. See [Create a Fabric Group](#).

Create a Proxy Endpoint and Associate to a Cloud Endpoint

You can create a proxy endpoint and associate its proxy settings to a vCloud Air, vCloud Director, or Amazon endpoint.

If you upgraded or migrated a vCloud Air, vCloud Director, or Amazon endpoint that was using a proxy manager, a new vCloud Air, vCloud Director, or Amazon endpoint is created that contains an association between the vCloud Air, vCloud Director, or Amazon endpoint and a new Proxy endpoint.

Prerequisites

- Log in to the vRealize Automation console as an **IaaS administrator**.
- Create one of the following endpoint types:
 - [Create a vCloud Air Endpoint](#)
 - [Create an Amazon Endpoint](#)
 - [Create a vCloud Director Endpoint](#)

You must have at least one vCloud Air, vCloud Director, or Amazon endpoint to create an association from the Proxy endpoint.

Procedure

- 1 Select **Infrastructure > Endpoints > Endpoints**.
- 2 Select **New > Network and Security > Proxy**.
- 3 Enter a name in the **Name** text box.
- 4 (Optional) Enter a description in the **Description** text box.
- 5 Enter the URL for the installed proxy agent in the **Address** text box.
- 6 Enter the port number to use for connecting to the proxy server in the **Port** text box.
- 7 Enter your administrator-level user name and password.

- 8 (Optional) Click **Properties** and add supplied custom properties, property groups, or your own property definitions for the endpoint.

- 9 To associate the proxy settings to a vCloud Air, vCloud Director, or Amazon endpoint, click **Associations** and select one or more endpoints.

You must have at least one vCloud Air, vCloud Director, or Amazon endpoint to create an association.

You can associate the Proxy endpoint to more than one endpoint.

- 10 Click **OK**.

vRealize Automation collects data from your endpoint and discovers your compute resources.

What to do next

Add the compute resources from your endpoint to a fabric group. See [Create a Fabric Group](#).

Create a vRealize Orchestrator Endpoint

You can create a vRealize Orchestrator endpoint to connect to a vRealize Orchestrator server.

You can configure multiple endpoints to connect to different vRealize Orchestrator servers, but you must configure a priority for each endpoint.

When executing vRealize Orchestrator workflows, vRealize Automation tries the highest priority vRealize Orchestrator endpoint first. If that endpoint is not reachable, then it proceeds to try the next highest priority endpoint until a vRealize Orchestrator server is available to run the workflow.

Prerequisites

- Log in to the vRealize Automation console as an **laaS administrator**.

Procedure

- 1 Select **Infrastructure > Endpoints > Endpoints**.
- 2 Select **New > Orchestration > vRealize Orchestrator**.
- 3 Enter a name and, optionally, a description.
- 4 Enter a URL with the fully qualified name or IP address of the vRealize Orchestrator server and the vRealize Orchestrator port number.

The transport protocol must be HTTPS. If no port is specified, the default port 443 is used.

To use the default vRealize Orchestrator instance embedded in the vRealize Automation appliance, type **https://vrealize-automation-appliance-hostname:443/vco**.

- 5 Provide your vRealize Orchestrator credentials in the **User name** and **Password** text boxes to connect to the vRealize Orchestrator endpoint.

The credentials you use should have Execute permissions for any vRealize Orchestrator workflows to call from laaS.

To use the default vRealize Orchestrator instance embedded in the vRealize Automation appliance, the user name is **administrator@vsphere.local** and the password is the administrator password that was specified when configuring SSO.

- 6 Enter an integer greater than or equal to 1 in **Priority** text box.

A lower value specifies a higher priority.

- 7 (Optional) Click **Properties** and add supplied custom properties, property groups, or your own property definitions for the endpoint.
- 8 Click **OK**.

Configuring vRealize Orchestrator Endpoints for Networking

If you are using vRealize Automation workflows to call vRealize Orchestrator workflows, you must configure the vRealize Orchestrator instance or server as an endpoint.

For information about adding a vRealize Orchestrator endpoint, see [Create a vRealize Orchestrator Endpoint](#).

You can associate a vRealize Orchestrator endpoint with a machine blueprint to make sure that all of the vRealize Orchestrator workflows for machines provisioned from that blueprint are run using that endpoint.

vRealize Automation by default includes an embedded vRealize Orchestrator instance. It is recommended that you use this as your vRealize Orchestrator endpoint for running vRealize Automation workflows in a test environment or creating a proof of concept.

It is also recommended that you use this vRealize Orchestrator endpoint for running vRealize Automation workflows in a production environment.

The vRealize Orchestrator plug-in is automatically installed with vRealize Orchestrator 7.1 and later. There is no separate vRealize Orchestrator plug-in to install.

Create a vRealize Operations Manager Endpoint

You can create a vRealize Operations Manager endpoint to connect to a vRealize Operations Manager host suite API.

For information about validating the vRealize Operations Manager connection and certificate trust, see [Considerations When Using Test Connection](#).

Prerequisites

- Log in to the vRealize Automation console as an **laaS administrator**.

Procedure

- 1 Select **Infrastructure > Endpoints > Endpoints**.
- 2 Select **New > Management > vRealize Operations Manager**.
- 3 Enter a name and, optionally, a description.

- 4 Enter the URL for the vRealize Operations Manager server in the **Address** text box.

The URL must be of the format: **https://hostname/suite-api**.

- 5 Enter your vRealize Operations Manager user name and password credentials.
- 6 (Optional) Click **Properties** and add supplied custom properties, property groups, or your own property definitions for the endpoint.
- 7 (Optional) Click **Test Connection** to validate the credentials, host endpoint address, and certificate trust. The action also checks that the manager service and agent are running so that endpoint can be data-collected. The **OK** action tests for these same conditions.

The **Test Connection** action returns information about any of the following conditions:

- **Certificate error**

If the certificate is not found, trusted, or has expired, you are prompted to accept a certificate thumbprint. If you do not accept the thumbprint, you can still save the endpoint but machine provisioning might fail.

- **Agent error**

The associated vSphere agent is not found. The agent must be running for the test to succeed.

- **Host error**

The specified endpoint address is not reachable or the associated manager service is not running. The manager service must be running for the test to succeed.

- **Credentials error**

The specified user name and password combination is invalid for the endpoint at the specified address.

- **Timeout**

The test action could not complete in the allowed two-minute time period.

If the **Test Connection** action fails, you can still save the endpoint but machine provisioning might fail.

If there is a trusted certificate issue, for example the certificate has expired, you are prompted to accept a certificate thumbprint.

- 8 Click **OK**.

Create a Third-Party IPAM Provider Endpoint

If you registered and configured a third-party IPAM endpoint type in vRealize Orchestrator, you can create an endpoint for that IPAM solution provider in vRealize Automation.

If you imported a vRealize Orchestrator package for providing an external IPAM solution and registered the IPAM endpoint type in vRealize Orchestrator, you can select that IPAM endpoint type when you create a vRealize Automation endpoint.

Note This example is based on use of the Infoblox IPAM plug-in, which is available for download at the VMware Solution Exchange. You can also use this procedure if you created your own IPAM provider package using the VMware-supplied IPAM Solution SDK. The procedure for importing and configuring your own third-party IPAM solution package is the same as described in the prerequisites.

The first IPAM endpoint for vRealize Automation is created when you register the endpoint type for the IPAM solution provider plug-in in vRealize Orchestrator.

Prerequisites

- [Obtain and Import a Third-Party IPAM Provider Package in vRealize Orchestrator.](#)
- [Run Workflow to Register Third-Party IPAM Endpoint Type in vRealize Orchestrator.](#)
- Log in to the vRealize Automation console as an **laaS administrator**.

For this example, create an Infoblox IPAM endpoint using an endpoint type that you registered in vRealize Orchestrator for your third-party IPAM provider plug-in or package.

Procedure

- 1 Select **Infrastructure > Endpoints > Endpoints**.

- 2 Select **New > IPAM > IPAM endpoint type**.

Select a registered external IPAM provider endpoint type such as Infoblox. External IPAM provider endpoints are only available if you imported a third-party vRealize Orchestrator package, and run the package workflows to register the endpoint type.

For Infoblox IPAM, only primary IPAM endpoint types are listed. You can specify secondary IPAM endpoint types by using custom properties.

For this example, select a registered external IPAM endpoint type, for example **Infoblox NIOS**.

- 3 Enter a name and, optionally, a description.
- 4 Enter the location of the registered IPAM endpoint in the **Address** text box using the provider-specific URL format, for example `https://host_name/name`.

For example, you might create several IPAM endpoints, such as `https://nsx62-scale-infoblox` and `https://nsx62-scale-infoblox2`, when you registered the IPAM endpoint type in vRealize Orchestrator. Enter a primary registered endpoint type. To also specify one or more secondary IPAM endpoints, you can use custom properties to emulate the extensible attributes that are specific to the IPAM solution provider.

- 5 Enter the user name and password required to access the IPAM solution provider account.

The IPAM solution provider account credentials are required to create, configure, and edit the endpoint when working in vRealize Automation. vRealize Automation uses the IPAM endpoint credentials to communicate with the specified endpoint type, for example Infoblox, to allocate IP addresses and perform other operations. This behavior is similar to how vRealize Automation uses vSphere endpoint credentials.

- 6 (Optional) Click **Properties** and add endpoint properties that are meaningful to the specific IPAM solution provider.

Each IPAM solution provider, for example Infoblox and Bluecat, use unique extensible attributes that you can emulate by using vRealize Automation custom properties. For example, Infoblox uses extensible attributes to differentiate primary and secondary endpoints.

- 7 Click **OK**.

What to do next

Add the compute resources from your endpoint to a fabric group. See [Create a Fabric Group](#).

Create a Microsoft Azure Endpoint

You can create a Microsoft Azure endpoint to facilitate a credentialed connection between vRealize Automation and an Azure deployment.

An endpoint establishes a connection to a resource, in this case an Azure instance, that you can use to create virtual machine blueprints. You must have an Azure endpoint to use as the basis of blueprints for provisioning Azure virtual machines. If you use multiple Azure subscriptions, you need endpoints for each subscription ID.

As an alternative, you can create an Azure connection directly from vRealize Orchestrator using the Add an Azure Connection command located under **Library > Azure > Configuration** in the vRealize Orchestrator workflow tree. For most scenarios, creating a connection through the endpoint configuration as described herein is the preferred option.

Azure endpoints are supported by vRealize Orchestrator and XaaS functionality. You can create, delete, or edit an Azure endpoint. Note that if you make any changes to an existing endpoint and do not execute any updates on the Azure portal through the updated connection for several hours, then you must restart the vRealize Orchestrator service using the service `vco-service restart` command. Failure to restart the service may result in errors.

Prerequisites

- Configure a Microsoft Azure instance and obtain a valid Microsoft Azure subscription from which you can use the subscription ID. See <http://www.vaficionado.com/2016/11/using-new-microsoft-azure-endpoint-vrealize-automation-7-2/> for more information about configuring Azure and obtaining a subscription ID.
- Your vRealize Automation deployment must have at least one tenant and one business group.

- Create an Active Directory application as described in <https://azure.microsoft.com/en-us/documentation/articles/resource-group-create-service-principal-portal>.
- Make note of the following Azure related information, as you will need it during endpoint and blueprint configuration.
 - subscription ID
 - tenant ID
 - storage account name
 - resource group name
 - location
 - virtual network name
 - client application ID
 - client application secret key
 - virtual machine image URN
- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Endpoints > OrchestratorEndpoints**.
- 2 Click the **New** icon ().
- 3 On the Plug-in tab, click the **Plug-in** drop-down menu and select Azure Plug-in.
- 4 Click **Next**.
- 5 Enter a name and, optionally, a description.
- 6 Click **Next**.
- 7 Populate the text boxes on the **Details** tab as appropriate for the endpoint.

Parameter	Description
Connection settings	
Azure Connection	
Connection name	Unique name for the new endpoint connection. This name appears in the vRealize Orchestrator interface to help you identify a particular connection.
Azure subscription id	The identifier for your Azure subscription. The ID defines the storage accounts, virtual machines and other Azure resources to which you have access.
Resource manager settings	

Parameter	Description
Azure service URI	The URI through which you gain access to your Azure instance. The default value of <code>https://management.azure.com/</code> is appropriate for many typical implementations.
Tenant Id	The Azure tenant ID that you want the endpoint to use.
Client Id	The Azure client identifier that you want the endpoint to use. This is assigned when you create an Active Directory application.
Client secret	The key used with an Azure client ID. This key is assigned when you create an Active Directory application.
Login URL	The URL used to access the Azure instance. The default value of <code>https://login.windows.net/</code> is appropriate for many typical implementations.
Proxy Settings	
Proxy host	If your company uses a proxy Web server, enter the host name of that server.
Proxy port	If your company uses a proxy Web server, enter the port number of that server.

8 Click **Finish**.

What to do next

Create appropriate resource groups, storage accounts, and network security groups in Azure. You should also create load balancers if appropriate for your implementation.

Action	Options
Create an Azure resource group	<ul style="list-style-type: none"> ■ Create the resource group using the Azure portal. See the Azure documentation for specific instructions. ■ Use the appropriate vRealize Orchestrator workflow found under the Library/Azure/Resource/Create resource group. ■ In vRealize Automation, create and publish an XaaS blueprint that contains the vRealize Orchestrator workflow. You can request the resource group after attaching it to the service and entitlements. Note that the Resource Group resource type is not supported or managed by vRealize Automation.
Create an Azure storage account	<ul style="list-style-type: none"> ■ Use Azure to create a storage account. See the Azure documentation for specific instructions. ■ Use the appropriate vRealize Orchestrator workflow found under Library/Azure/Storage/Create storage account. ■ In vRealize Automation, create and publish an XaaS blueprint that contains the vRealize Orchestrator workflow. You can request the storage account after attaching it to the service and entitlements.
Create an Azure network security group	<ul style="list-style-type: none"> ■ Use Azure to create a security group. See the Azure documentation for specific instructions. ■ Use the appropriate vRealize Orchestrator workflow found under the Library/Azure/Network/Create Network security group . ■ In vRealize Automation, create and publish an XaaS blueprint that contains the vRealize Orchestrator workflow. You can request the security group after attaching it to the service and entitlements.

Create a Puppet Endpoint

You can create a Puppet endpoint to support addition of Puppet configuration management components to vSphere virtual machines. These components enable you to use a Puppet Master to enforce configuration management on virtual machines.

An endpoint establishes a connection to an external resource, in this case a Puppet Master instance. The endpoint enables you to place Puppet configuration management components on vSphere virtual machine blueprints. Provisioned virtual machines based on these blueprints contain a Puppet agent that facilitates control by the associated Puppet Master.

Prerequisites

- Install and configure Puppet Enterprise as appropriate for your environment.
- Download and install the Puppet plug-in version 3.0 on your vRealize Orchestrator deployment. You can download the plug-in from <https://solutionexchange.vmware.com/store/products/puppet-plugin-for-vrealize-automation>. See https://docs.puppet.com/pe/latest/vro_intro.html for information about installing and using the plug-in.

Procedure

- 1 Select **Administration > Endpoints > OrchestratorEndpoints**.
- 2 Click the **New** icon (+).
- 3 On the Plug-in tab, click the **Plug-in** drop-down menu and select **Puppet Plug-in**.
- 4 Click **Next**.
- 5 Enter a name and, optionally, a description.
- 6 Click **Next**.
- 7 Populate the text boxes on the **Details** tab as appropriate for the endpoint.

Parameter	Description
Display name for this Puppet Master	The name of the Puppet Master associated with the endpoint connection . This name appears in the vRealize Orchestrator interface to help you identify a particular connection.
Hostname or IP address	The FQDN or IP address of the Puppet Master used by this endpoint.
SSH Port	The port defined for use with secure communication for this Puppet Master.
SSH RBAC and Username	The role based access control username required to connect with the Puppet Master.
SSH and RBAC Password	The role based access control username required for secure configuration with the Puppet Master.
Use sudo for shell commands on this master?	Select this option if you want administrators to be able to use Sudo commands on Linux servers for security options on virtual machines based on this endpoint..

- 8 Click **OK**.

You can now add Puppet configuration management components to vSphere blueprints so that you can deploy vSphere virtual machines that contain Puppet agents.

Create a Hyper-V (SCVMM) Endpoint

You can create endpoints to allow vRealize Automation to communicate with your SCVMM environment and discover compute resources, collect data, and provision machines.

Prerequisites

- Log in to the vRealize Automation console as an **laaS administrator**.
- You must install and configure a DEM agent to manage your Hyper-V (SCVMM) endpoint. For information, see SCVMM requirements information in the *Installing vRealize Automation 7.3*.

For related information, see [Preparing Your SCVMM Environment](#).

Procedure

- 1 Select **Infrastructure > Endpoints > Endpoints**.
- 2 Select **New > Virtual > Hyper-V (SCVMM)**.
- 3 Enter a name in the **Name** text box.
- 4 (Optional) Enter a description in the **Description** text box.
- 5 Enter the URL for the endpoint in the **Address** text box.
 The URL must be of the type: *FQDN* or *IP_address*.
 For example: `mycompany-scvmm1.mycompany.local`.
- 6 Enter the administrative-level user name and password that you stored for this endpoint.
 If you did not already store the credentials, you can do so now.
- 7 (Optional) Click **Properties** and add supplied custom properties, property groups, or your own property definitions for the endpoint.
- 8 Click **OK**.

vRealize Automation collects data from your endpoint and discovers your compute resources.

What to do next

Add the compute resources from your endpoint to a fabric group. See [Create a Fabric Group](#).

Create an OpenStack Endpoint

You create an endpoint to allow vRealize Automation to communicate with your OpenStack instance.

Prerequisites

- Log in to the vRealize Automation console as an **laaS administrator**.
- Verify that your vRealize Automation DEMs are installed on a machine that meets the OpenStack or PowerVC requirements. See *Installing vRealize Automation 7.3*.
- Verify that your flavor of OpenStack is currently supported. See *vRealize Automation Support Matrix*.

After you upgrade or migrate from an earlier vRealize Automation installation, if data collection fails for OpenStack endpoints you can add the `VMware.Endpoint.Openstack.IdentityProvider.Domain.Name` custom property to each Keystone V3 OpenStack endpoint to specify a valid domain name and enable data collection.

Procedure

- 1 Select **Infrastructure > Endpoints > Endpoints**.
- 2 Select **New > Cloud > OpenStack**.
- 3 Enter a name and, optionally, a description.

- 4 Enter the URL for the endpoint in the **Address** text box.

Option	Description
PowerVC	The URL must be of the format <code>http://myPowerVC.com:5000</code> or <code>http://FQDN:5000</code> .
Openstack	The URL must be of the format <code>FQDN:5000</code> or <code>IP_address:5000</code> . Do not include the <code>/v2.0</code> suffix in the endpoint address.

- 5 Enter your administrative-level user name and password.

The credentials you provide must have the administrator role in the OpenStack tenant associated with the endpoint.

- 6 Enter an OpenStack tenant name in the **OpenStack project** text box.

If you set up multiple endpoints with different OpenStack tenants, create reservation policies for each tenant. This ensures that machines are provisioned to the appropriate tenant resources.

- 7 Click **Properties** and add supplied custom properties, property groups, or your own property definitions for the endpoint.

If Keystone V3 is in effect, add the `VMware.Endpoint.Openstack.IdentityProvider.Domain.Name` custom property to designate a specific domain.

- 8 Click **OK**.

vRealize Automation collects data from your endpoint and discovers your compute resources.

What to do next

Add the compute resources from your endpoint to a fabric group. See [Create a Fabric Group](#).

Create a Hyper-V, XenServer, or Xen Pool Endpoint

You can create endpoints to allow vRealize Automation to communicate with the Hyper-V, XenServer, or Xen pool master environment and discover compute resources, collect data, and provision machines.

Prerequisites

- Log in to the vRealize Automation console as an **laaS administrator**.
- A system administrator must install a proxy agent with stored credentials that correspond to your endpoint. See *Installing vRealize Automation 7.3*.

Procedure

- 1 Select **Infrastructure > Endpoints > Agents**.

- 2 Enter the fully qualified DNS name of your Hyper-V server, Xen server, or Xen pool master in the **Compute resource** text box.

Note For a Xen pool endpoint, you must enter the name of the pool master.

To avoid duplicate entries in the vRealize Automation compute resource table, specify an address that matches the configured Xen pool master address. For example, if the Xen pool master address uses the host name, enter the host name and not the FQDN. If the Xen pool master address uses FQDN, then enter the FQDN.

- 3 Select the proxy agent that your system administrator installed for this endpoint from the **Proxy agent name** drop-down menu.
- 4 (Optional) Enter a description in the **Description** text box.
- 5 Click **OK**.

vRealize Automation collects data from your endpoint and discovers your compute resources.

What to do next

Add the compute resources from your endpoint to a fabric group. See [Create a Fabric Group](#).

Considerations When Using Test Connection

You can use a test connection action to validate the credentials, host endpoint address, and certificate for a vSphere, NSX, or vRealize Operations Manager endpoint.

The action also checks that the manager service and agent are running so that endpoint can be data-collected.

The **Test Connection** action returns information about any of the following conditions:

- **Certificate error**
If the certificate is not found, trusted, or has expired, you are prompted to accept a certificate thumbprint. If you do not accept the thumbprint, you can still save the endpoint but machine provisioning might fail.
- **Agent error**
The associated vSphere agent is not found. The agent must be running for the test to succeed.
- **Host error**
The specified endpoint address is not reachable or the associated manager service is not running. The manager service must be running for the test to succeed.
- **Credentials error**
The specified user name and password combination is invalid for the endpoint at the specified address.
- **Timeout**
The test action could not complete in the allowed two-minute time period.

If you receive errors when running **Test Connection** on upgraded or migrated endpoints, see [Considerations When Working With Upgraded or Migrated Endpoints](#) for steps needed to establish certificate trust.

Import or Export Endpoints Programmatically

To programmatically import and export endpoints in vRealize Automation 7.3 or later you must use either new vRealize Automation endpoint-configuration-service REST APIs or use vRealize CloudClient.

The vRealize CloudClient documentation contains all applicable command line formatting, samples, and usage information.

You can download the vRealize CloudClient application and documentation from the vRealize CloudClient product page of the <https://developercenter.vmware.com/tool/cloudclient>.

Viewing Endpoint Sources and Running Data Collection

You can view the machine and compute resource that is associated with a specific endpoint. You can also manually start data collection.

Prerequisites

- Log in to the vRealize Automation console as an **laaS administrator**.
- Verify that at least one endpoint exists.

Procedure

- 1 Select **Infrastructure > Endpoints > Endpoints**.
- 2 Select an existing endpoint row and click **Actions**.

Select any one of the following available actions.

- Click **View Compute Resources** to open the **Infrastructure > Compute Resource** page. You can use this page to view and edit compute resource settings.
- Click **View Machines** to open the **Infrastructure > Managed Machines** page.
- Click **Data Collection** to open the Data Collection page and start data collection for the endpoint. You can refresh the page to display the current status of the request.

Considerations When Working With Upgraded or Migrated Endpoints

After you upgrade or migrate from a pre-vRealize Automation 7.3 release, the following considerations are important to understand and act on.

This information applies to endpoints that were upgraded or migrated to this vRealize Automation release.

- When you upgrade or migrate from a pre-vRealize Automation 7.3 release, each vCloud Air, vCloud Director, and Amazon endpoint that contains proxy settings is associated to a new proxy endpoint that contains its proxy settings.

After upgrade or migration, the new Proxy endpoint name is Proxy_YYYYYY where YYYYYY is a hash of the proxy's URL, port, and credentials. If you used the same proxy settings (for example the same URL, port, and credentials) for a different endpoint (for example, a vCloud Air or Amazon endpoint), after upgrade or migration there is only one Proxy endpoint and an association between the vCloud Air and Amazon endpoint and the new Proxy endpoint. A proxy endpoint can be associated to more than one Amazon, vCloud Air or vCloud Director endpoint.

- When you upgrade or migrate vSphere endpoints that contain NSX manager settings, each vSphere endpoint is associated to a new NSX endpoint that contains its NSX manager settings.

After upgrade or migration, the NSX endpoint name is NSX_XXXXXX where XXXXX is the name of the parent vSphere endpoint in the pre-vRealize Automation 7.3 release.

- When vRealize Automation upgrade or migration is finished, an infrastructure administrator can change the new NSX and Proxy endpoint names.
- The default security setting for upgraded or migrated endpoints is not to accept untrusted certificates.
- After upgrading or migrating from an earlier vRealize Automation installation, if you were using untrusted certificates you must perform the following steps for all vSphere and NSX endpoints to enable certificate validation. Otherwise, the endpoint operations fail with certificate errors. For more information, see VMware Knowledge Base articles *Endpoint communication is broken after upgrade to vRA 7.3 (2150230)* at <http://kb.vmware.com/kb/2150230> and *How to download and install vCenter Server root certificates to avoid Web Browser certificate warnings (2108294)* at <http://kb.vmware.com/kb/2108294>.
 - a After upgrade or migration, log in to the vRealize Automation vSphere agent machine and restart your vSphere agents by using the **Services** tab.
Migration might not restart all agents, so manually restart them if needed.
 - b Wait for at least one ping report to finish. It takes a minute or two for a ping report to finish.
 - c When the vSphere agents have started data collection, log in to vRealize Automation as an IaaS administrator.
 - d Click **Infrastructure > Endpoints > Endpoints**.
 - e Edit a vSphere endpoint and click **Test Connection**.
 - f If a certificate prompt appears, click **OK** to accept the certificate.
If a certificate prompt does not appear, the certificate might currently be correctly stored in a trusted root authority of the Windows machine hosting service for the endpoint, for example as a proxy agent machine or DEM machine.
 - g Click **OK** to apply the certificate acceptance and save the endpoint.
 - h Repeat this procedure for each vSphere endpoint.
 - i Repeat this procedure for each NSX endpoint.

If the **Test Connection** action is successful but some data collection or provisioning operations fail, you can install the same certificate on all the agent machines that serve the endpoint and on all DEM machines. Alternatively, you can uninstall the certificate from existing machines and repeat the preceding procedure for the failing endpoint.

- The vRealize Automation REST APIs that were used to programmatically create, edit, and delete endpoints in vRealize Automation 7.2 and earlier are no longer supported in vRealize Automation 7.3 and later. To programmatically create, edit, and delete endpoints in vRealize Automation 7.3 or later you must use either new vRealize Automation endpoint-configuration-service REST APIs or use vRealize CloudClient.
- After you upgrade or migrate from an earlier vRealize Automation installation, if data collection fails for OpenStack endpoints you can add the `VMware.Endpoint.Openstack.IdentityProvider.Domain.Name` custom property to each Keystone V3 OpenStack endpoint to specify a valid domain name and enable data collection.
- When you upgrade a third-party IPAM endpoint, such as Infoblox IPAM, the vRealize Orchestrator package that contains the `RegisterIPAMEndpoint` workflow is upgraded. You might need to rerun the workflow in vRealize Orchestrator when the vRealize Automation upgrade is finished.
- To make a credentials change to multiple endpoints, you can either edit the endpoints individually or use vRealize CloudClient to perform a bulk update.
- Some endpoint types, such as vCloud Air and vCloud Director, cannot be upgraded or migrated directly from vRealize Automation 6.2.x to vRealize Automation 7.3 or greater.
- After a successful upgrade or migration to vRealize Automation 7.3, if the **Infrastructure > Endpoints** page does not show any endpoints or only shows some endpoint types and endpoints, see [Knowledge Base Article 2150252](#) for a suggested workaround.

Considerations When Deleting Endpoints

You can delete certain endpoint types under certain conditions.

- You can delete endpoints that have not been data-collected.
- You can delete an OpenStack, Amazon and VRO endpoint if it has been data collected, but has no reservations. Other endpoint types cannot be deleted if they have been data collected.
- You can delete a third-party IPAM endpoint if it has no association to a network profile.
- When deleting a vSphere endpoint, the confirmation prompt lists the following dependencies:
 - The endpoint has been data-collected.
 - The endpoint is referenced in a reservation that maps to a compute resource. You cannot delete an endpoint is referenced in a reservation. Reservations require a compute resource.
 - The endpoint contains a template that is referenced in an existing blueprint.
The blueprint is not deleted when you delete the endpoint.
 - The endpoint is used by virtual machines that are in use.

- You can delete endpoints programmatically by using either the new CREATE, EDIT, and DELETE vRealize Automation endpoint-configuration-service REST APIs introduced in vRealize Automation 7.3 or by using vRealize CloudClient. You cannot delete endpoints by using the pre-vRealize Automation 7.3 endpoint-configuration-service REST APIs.

Troubleshooting Attached vSphere Endpoint Cannot be Found

When data collection fails for a vSphere endpoint, it can be due to a mismatch between the proxy name and the endpoint name.

Problem

Data collection fails for a vSphere endpoint. The log messages return an error similar to the following:

```
This exception was caught: The attached endpoint
'vCenter' cannot be found.
```

Cause

The endpoint name you configure in vRealize Automation must match the endpoint name provided to the vSphere proxy agent during installation. Data collection fails for a vSphere endpoint if there is a mismatch between the endpoint name and the proxy agent name. Until an endpoint with a matching name is configured, the log messages return an error similar to the following:

```
This exception was caught: The attached endpoint
'expected endpoint name' cannot be found.
```

Solution

- 1 Select **Infrastructure > Monitoring > Log**.
- 2 Look for an Attached Endpoint Cannot be Found error message.

For example,

```
This exception was caught: The attached endpoint
'expected endpoint name' cannot be found.
```

- 3 Edit your vSphere endpoint to match the expected endpoint name shown in the log message.
 - a Select **Infrastructure > Endpoints > Endpoints**.
 - b Click the name of the endpoint to edit.
 - c Enter the expected endpoint name in the **Name** text box.
 - d Click **OK**.

The proxy agent can commute with the endpoint and data collection is successful.

Create a Fabric Group

You can organize infrastructure resources into fabric groups and assign one or more fabric administrators to manage the resources in the fabric group.

Fabric groups are required for virtual and cloud endpoints. You can grant the fabric administrator role to multiple users by either adding multiple users one at a time or by choosing an identity store group or custom group as your fabric administrator.

Prerequisites

- Log in to the vRealize Automation console as an **laaS administrator**.
- Create at least one endpoint. See [Choosing an Endpoint Scenario](#).

Procedure

- 1 Select **Infrastructure > Fabric Groups**.
- 2 Click **New Fabric Group**.
- 3 Enter a name in the **Name** text box.
- 4 (Optional) Enter a description in the **Description** text box.
- 5 Enter a user name or group name in the **Fabric administrators** text box and press Enter.

Repeat this step to add multiple users or groups to the role.

- 6 Click one or more **Compute resources** to include in your fabric group.

Only resources that exist on the clusters you select for your fabric group are discovered during data collection. For example, only templates that exist on the clusters you select are discovered and available for cloning on reservations you create for business groups.

- 7 Click **OK**.

Fabric administrators can now configure machine prefixes. See [Configure Machine Prefixes](#).

Users who are currently logged in to the vRealize Automation console must log out and log back in to the vRealize Automation console before they can navigate to the pages to which they have been granted access.

Configure Machine Prefixes

You can create machine prefixes that are used to create names for machines provisioned through vRealize Automation. A machine prefix is required when defining a machine component in the blueprint design canvas.

A prefix is a base name to be followed by a counter of a specified number of digits. When the digits are all used, vRealize Automation rolls back to the first number.

Machine prefixes must conform to the following limitations:

- Contain only the case-insensitive ASCII letters a through z, the digits 0 through 9, and the hyphen (-).

- Not begin with a hyphen.
- No other symbols, punctuation characters, or blank spaces can be used.
- No longer than 15 characters, including the digits, to conform to the Windows limit of 15 characters in host names.

Longer host names are truncated when a machine is provisioned, and updated the next time data collection is run. However, for WIM provisioning names are not truncated and provisioning fails when the specified name is longer than 15 characters.

- vRealize Automation does not support multiple virtual machines of the same name in a single instance. If you choose a naming convention that causes an overlap in machine names, vRealize Automation does not provision a machine with the redundant name. If possible, vRealize Automation skips the name that is already in use and generates a new machine name using the specified machine prefix. If a unique name cannot be generated, provisioning fails.

Prerequisites

Log in to the vRealize Automation console as a **fabric administrator**.

Procedure

- 1 Click **Infrastructure > Administration > Machine Prefixes**.
- 2 Click **New**.
- 3 Enter the machine prefix in the **Name** text box.
- 4 Enter the number of counter digits in the **Number of Digits** text box.
- 5 Enter the counter start number in the **Next Number** text box.
- 6 Click the **Save** icon (👍).

Tenant administrators can create business groups so that users can access vRealize Automation to request machines.

Creating a Network Profile

A network profile contains IP information such as gateway, subnet, and address range.

vRealize Automation uses vSphere DHCP or a specified IPAM provider to assign IP addresses to the machines it provisions.

You can create a network profile to define a type of available network, including external network profiles and templates for on-demand network address translation (NAT) and routed network profiles that build NSX logical switches and appropriate routing settings for a new network path. Network profiles are required when adding network components to a blueprint.

Network profiles are used to configure network settings when machines are provisioned. Network profiles also specify the configuration of NSX Edge devices that are created when you provision machines. You identify a network profile when you create reservations and blueprints. In a reservation, you can assign a network profile to a network path and specify any one of those paths for a machine component in a blueprint.

A blueprint creator specifies an appropriate network profile when defining network components in the blueprint. You can use an existing network profile and an on-demand NAT or routed network profile as you define network adapters and load balancers for the provisioning machine.

Network profiles also support third party IP Address Management (IPAM) providers, such as Infoblox. When you configure a network profile for IPAM, your provisioned machines can obtain their IP address data, and related information such as DNS and gateway, from the configured IPAM solution. You can use an external IPAM package for a third party provider, such as Infoblox, to define an IPAM endpoint for use with a network profile.

Note If you are using a third-party IPAM provider and want to specify on which network to deploy your machine, use a separate network profile for each VLAN to avoid the known issue described in [Knowledge Base Article 2148656](#).

If you do not use a third-party IPAM provider, but instead use the vRealize Automation-supplied IPAM endpoint, you can specify the ranges of IP addresses that network profiles can use. Each IP address in the specified ranges that are allocated to a machine is reclaimed for reassignment when the machine is destroyed. You can create a network profile to define a range of static IP addresses that can be assigned to machines. When provisioning virtual machines by cloning or by using kickstart/autoYaST provisioning, the requesting machine owner can assign static IP addresses from a predetermined range.

You can assign a network profile to a specific network path on a reservation. For some machine component types, such as vSphere, you can assign a network profile when you create or edit blueprints.

Note While you cannot change the network profile of a deployed virtual machine, you can change the network to which the VM is connected. If the network is associated to a different network profile, vRealize Automation assigns an IP address from that network profile to the VM. However the VM continues to use the old IP address until you update the IP address on the guest operating system. Alternatively you can use the Reconfigure action on the deployed VM, which also requires you to update the IP address on the guest operating system.

If you specify a network profile in a reservation and a blueprint, the blueprint value takes precedence. For example, if you specify a network profile in the blueprint by using the `VirtualMachine.NetworkN.ProfileName` custom property and in a reservation that is used by the blueprint, the network profile specified in the blueprint takes precedence. However, if the custom property is not used in the blueprint, and you select a network profile for a machine NIC, vRealize Automation uses the reservation network path for the machine NIC for which the network profile is specified.

For more information about these network types, see *NSX Administration Guide* in the NSX Information Center at https://www.vmware.com/support/pubs/nsx_pubs.html.

Table 2-14. Available Network Types for a vRealize Automation Network Profile

Network Type	Description
External	<p>Existing network configured on the vSphere server. They are the external part of the NAT and routed networks types. An external network profile can define a range of static IP addresses available on the external network.</p> <p>You can use IP ranges obtained from the supplied VMware IPAM endpoint or from a third-party IPAM service provider endpoint that you have registered and configured in vRealize Orchestrator, such as Infoblox IPAM. An IP range is created from an IP block during allocation.</p> <p>An external network profile with a static IP range is a prerequisite for NAT and routed networks.</p> <p>See Creating an External Network Profile For an Existing Network.</p>
NAT	<p>On-demand network created during provisioning. NAT networks that use one set of IP addresses for external communication and another set for internal communications.</p> <p>With one-to-one NAT networks, every virtual machine is assigned an external IP address from the external network profile and an internal IP address from the NAT network profile. With one-to-many NAT networks, all machines share a single IP address from the external network profile for external communication.</p> <p>You can use IP ranges obtained from the supplied VMware IPAM endpoint or from a third-party IPAM service provider endpoint that you have registered and configured in vRealize Orchestrator, such as Infoblox IPAM. An IP range is created from an IP block during allocation.</p> <p>A NAT network profile defines local and external networks that use a translation table for mutual communication.</p> <p>See Creating a NAT Network Profile For an On-Demand Network.</p>
Routed	<p>On-demand network created during provisioning. Routed networks contain a routable IP space divided across subnets that are linked together using Distributed Logical Router (DLR).</p> <p>Every new routed network has the next available subnet assigned to it and is associated with other routed networks that use the same network profile. The virtual machines that are provisioned with routed networks that have the same routed network profile can communicate with each other and the external network.</p> <p>You can use IP ranges obtained from the supplied VMware IPAM endpoint or from a third-party IPAM service provider endpoint that you have registered and configured in vRealize Orchestrator, such as Infoblox IPAM. An IP range is created from an IP block during allocation.</p> <p>A routed network profile defines a routable space and available subnets.</p> <p>See Creating a Routed Network Profile For an On-Demand Network.</p>

Using Network Profiles to Control IP Address Ranges

You can use network profiles to assign static IP addresses from a predefined range to virtual machines that are provisioned by cloning, by using Linux kickstart or autoYaST, or to cloud machines that are provisioned in OpenStack by using kickstart.

By default, vRealize Automation uses Dynamic Host Configuration Protocol (DHCP) to assign IP addresses to provisioned machines.

You can create network profiles to define a range of static IP addresses that you can assign to machines. You can assign network profiles to specific network paths on a reservation. Machines that are provisioned by cloning or by kickstart or autoYaST and are attached to a network path with an associated network profile are provisioned with an assigned static IP address. For provisioning with a static IP address assignment, you must use a customization specification.

You can assign a network profile to a vSphere machine component in a blueprint by adding an existing, on-demand NAT, or on-demand routed network component to the design canvas and selecting a network profile to which to connect the vSphere machine component. You can also assign network profiles to blueprints by using the custom property `VirtualMachine.NetworkN.ProfileName`, where *N* is the network identifier.

You can optionally use the supplied vRealize Automation IPAM or a registered and configured third-part IPAM service provider endpoint in your network profile to obtain and configure IP addresses. For information about external IPAM requirements, see [Checklist For Providing Third-Party IPAM Provider Support](#).

When you select a third-party IPAM service provider endpoint in a network profile, vRealize Automation retrieves IP ranges from the registered external IPAM provider endpoint, such as Infoblox. It then allocates IP values from that endpoint. The specified range subnet mask is used to allocate subnets from the IP block.

If you specify a network profile in a reservation and a blueprint, the blueprint value takes precedence. For example, if you specify a network profile in the blueprint by using the `VirtualMachine.NetworkN.ProfileName` custom property and in a reservation that is used by the blueprint, the network profile specified in the blueprint takes precedence. However, if the custom property is not used in the blueprint, and you select a network profile for a machine NIC, vRealize Automation uses the reservation network path for the machine NIC for which the network profile is specified.

Understanding CSV File Format for Importing Network Profile IP Addresses

You can import IP address network ranges to a vRealize Automation network profile by using a properly formatted CSV file.

The CSV file entries must adhere to the following format.

CSV Field	Description
<code>ip_address</code>	An IP address in IPv4 format.
<code>machine_name</code>	Name of a managed machine in vRealize Automation. If the field is empty, the default is no name. If the field is empty, the <code>status</code> field value cannot be <code>Allocated</code> .
<code>status</code>	<code>Allocated</code> or <code>Unallocated</code> , case-sensitive. If the field is empty, the default value is <code>Unallocated</code> . If the status is <code>Allocated</code> , the <code>machine_name</code> field cannot be empty.
<code>NIC_offset</code>	A non-negative integer. Optional.

The following example entry does not specify a NIC offset:

```
100.10.100.1,mymachine01,Allocated
```

Import IP Addresses To a Network Profile From a CSV File

You can add IP addresses to a network profile range by importing a properly formatted CSV file. You can also change the addresses in the network profile range by editing the range in vRealize Automation or by importing a changed or different CSV file.

You can add or change the IP addresses in a network profile range by importing from a CSV file or by entering values manually. Alternatively, you can allow a third-party IPAM provider to supply IP addresses.

- Import an initial range of IP addresses into a vRealize Automation network profile.
- Apply the imported values to create our first named network range in the network profile.
- Delete one or more IP addresses from the network range vRealize Automation.
- Import a changed or different CSV file to examine how the network range values are changed.

You cannot use the **Import from CSV** option for network profiles that use a third-party IPAM endpoint because the IP addresses are managed by the third-party IPAM provider, not by vRealize Automation.

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.
- Create a CSV file containing IP addresses for import to a network range. See [Create an External Network Profile by Using A Third-Party IPAM Provider](#) and [Understanding CSV File Format for Importing Network Profile IP Addresses](#).

Procedure

- 1 Select **Infrastructure > Reservations > Network Profiles**.

- 2 Click **New** and select a network profile type from the drop-down menu.

For this example, select *External*.

- 3 Enter **My Network Profile with CSV** in the **Name** text box.

- 4 Enter **Testing network range IP addresses with CSV** in the **Description** text box.

The CSV file import option applies to settings on the **Network Ranges** and **IP Addresses** tab pages. so we will move quickly through the first two tabs to enter basic network profile information.

- 5 Optionally select a configured IPAM endpoint if you have one available. If not, skip this step.

- 6 Enter an appropriate IP address value in the **Subnet mask** and **Gateway** text boxes.

- 7 Click the **DNS** tab.

- 8 Enter applicable information such as a DNS suffix and click the **Network Ranges** tab.

The **Import from CVS** option is available when you click the **Network Ranges** tab.

- 9 Click **New** to enter a new network range name and IP address range manually or click **Import from CSV** to import the IP address information from a properly formatted CSV file.

- Click **New**.
 - a Enter a network range name.
 - b Enter a network range description.
 - c Enter the start IP address of the range.

d Enter the end IP address of the range.

■ Click **Import from CSV**.

a Browse to and select the CSV file or drag the CSV file into the **Import from CSV** dialog box.

A row in the CSV file has the format *ip_address, machine_name, status, NIC offset*. For example:

```
100.10.100.1,mymachine01,Allocated
```

CSV Field	Description
ip_address	An IP address in IPv4 format.
machine_name	Name of a managed machine in vRealize Automation. If the field is empty, the default is no name. If the field is empty, the status field value cannot be Allocated.
status	Allocated or Unallocated, case-sensitive. If the field is empty, the default value is Unallocated. If the status is Allocated, the machine_name field cannot be empty.
NIC_offset	A non-negative integer. Optional.

b Click **Apply**.

10 Click **OK**.

The IP range name appears in the defined ranges list. The IP addresses in the range appear in the defined IP addresses list.

The uploaded IP addresses appear on the **IP Addresses** page when you click **Apply** or after you save and then edit the network profile.

11 Click the **IP Addresses** tab to display the IP address data for the specified range address space.

If you imported the IP address information from a CSV file, the range name is generated as *Imported from CSV*.

12 (Optional) Select IP address information from the **Network range** drop-down menu to filter IP address entries.

You can display information about all defined network ranges, the network ranges imported from a CSV file, or a named network range. Details include the start IP address, machine name, last modification date and timestamp, and IP status.

What to do next

If you import IP addresses from a CSV file again, the previous IP addresses are replaced with the information from the imported CSV file.

Creating an External Network Profile For an Existing Network

You can create external network profiles to specify network settings to configure existing networks for provisioning machines, including the configuration of NSX Edge devices to be used during provisioning.

You can use the supplied vRealize Automation IPAM provider endpoint or a third-party IPAM provider endpoint, such as Infoblox, that you have registered in vRealize Orchestrator.

Create an External Network Profile By Using the Supplied IPAM Endpoint

You can create an external network profile to define network properties and a range of static IP addresses for use when provisioning machines on an existing network.

You can define one or more network ranges of static IP addresses in the network profile for use in provisioning a machine. If you do not specify a range, you can use a network profile as a network reservation policy to select a reservation network path for a virtual machine network card (vNIC).

For information about creating an external network profile and using an external IPAM provider endpoint, see [Create an External Network Profile by Using A Third-Party IPAM Provider](#).

Procedure

1 Specify External Network Profile Information By Using the Supplied IPAM Endpoint

An external network profile identifies network properties and settings for an existing network. An external network profile is a requirement of NAT and routed network profiles.

2 Configure External Network Profile IP Ranges By Using the Supplied IPAM Endpoint

You can define one or more network ranges of static IP addresses in the network profile for use in provisioning a machine. If you do not specify a range, you can use a network profile as a network reservation policy to select a reservation network path for a virtual machine network card (vNIC).

What to do next

You can assign a network profile to a network path in a reservation or a blueprint architect can specify the network profile in a blueprint. You can use the external network profile when you create an on-demand NAT or routed network profile.

Specify External Network Profile Information By Using the Supplied IPAM Endpoint

An external network profile identifies network properties and settings for an existing network. An external network profile is a requirement of NAT and routed network profiles.

For information about how you can create an external network profile by obtaining IPAM address information from a registered third-party IPAM endpoint such as Infoblox, see [Checklist For Providing Third-Party IPAM Provider Support](#) and [Create an External Network Profile by Using A Third-Party IPAM Provider](#). Use the following procedure to create a network profile by using the VMware internal IPAM endpoint.

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.

Procedure

- 1 Select **Infrastructure > Reservations > Network Profiles**.
- 2 Click **New** and select **Existing** or **External** from the drop-down menu.
- 3 Enter a name and, optionally, a description.
- 4 Accept the default **IPAM endpoint** value for the supplied **vRealize Automation IPAM** endpoint.

- 5 Enter an IP subnet mask in the **Subnet mask** text box.

The subnet mask specifies the size of the entire routable address space that you want to define for your network profile.

For example, enter 255.255.0.0.

- 6 Enter an Edge or routed gateway address in the **Gateway** text box.

Use a standard IPv4 address format. For example, enter 10.10.110.1.

The gateway IP address defined in the network profile is assigned to the NIC during allocation. If no value is assigned in the **Gateway** text box in the network profile, then you must use the `VirtualMachine.Network0.Gateway` custom property when provisioning the Edge machine.

- 7 Click the **DNS** tab.

- 8 Enter DNS and WINS values as needed.

DNS values are used for DNS name registration and resolution. The DNS and WINS fields are optional if you are using an internal IPAM endpoint. If you are using an external IPAM endpoint, the DNS and WINS values are provided by the third-party IPAM provider.

- a (Optional) Enter a **Primary DNS** server value.
- b (Optional) Enter a **Secondary DNS** server value.
- c (Optional) Enter a **DNS suffixes** value.
- d (Optional) Enter a **DNS search suffixes** value.
- e (Optional) Enter a **Preferred WINS** server value.
- f (Optional) Enter an **Alternate WINS** server value.

What to do next

You can configure IP ranges for static IP addresses. See [Configure External Network Profile IP Ranges By Using the Supplied IPAM Endpoint](#).

Configure External Network Profile IP Ranges By Using the Supplied IPAM Endpoint

You can define one or more network ranges of static IP addresses in the network profile for use in provisioning a machine. If you do not specify a range, you can use a network profile as a network reservation policy to select a reservation network path for a virtual machine network card (vNIC).

You can define IP range values manually, from an imported CSV file, or by using IP addresses supplied by an external IPAM provider. You can combine manually defined IP ranges and IP addresses imported via CSV. For example, you can define some ranges by using the user interface and others by importing from a CSV file.

If you import from a CSV file a second time, regardless of the CSV file name, the IP ranges imported from the previous CSV file import are erased and the new IP range information is added. Thus the previous import is overwritten when you import a second or more time. You can repeat the process of updating a CSV file and re-importing that CSV file into the network profile indefinitely.

If an external network profile does not have IP ranges defined, you can use it to specify which network is picked for a virtual network card (vNIC). If you are using the existing network profile in a routed or NAT network profile, it must have at least one static IP range.

Prerequisites

[Specify External Network Profile Information By Using the Supplied IPAM Endpoint.](#)

Procedure

- 1 Click the **Network Ranges** tab.
- 2 Click **New** to enter a new network range name and IP address range manually or click **Import from CSV** to import the IP address information from a properly formatted CSV file.

- Click **New**.

- a Enter a network range name.
- b Enter a network range description.
- c Enter the start IP address of the range.
- d Enter the end IP address of the range.

- Click **Import from CSV**.

- a Browse to and select the CSV file or drag the CSV file into the **Import from CSV** dialog box.

A row in the CSV file has the format *ip_address, machine_name, status, NIC offset*. For example:

```
100.10.100.1,mymachine01,Allocated
```

CSV Field	Description
ip_address	An IP address in IPv4 format.
machine_name	Name of a managed machine in vRealize Automation. If the field is empty, the default is no name. If the field is empty, the status field value cannot be Allocated.
status	Allocated or Unallocated, case-sensitive. If the field is empty, the default value is Unallocated. If the status is Allocated, the machine_name field cannot be empty.
NIC_offset	A non-negative integer. Optional.

- b Click **Apply**.

- 3 Click **OK**.

The IP range name appears in the defined ranges list. The IP addresses in the range appear in the defined IP addresses list.

The uploaded IP addresses appear on the **IP Addresses** page when you click **Apply** or after you save and then edit the network profile.

- 4 Click the **IP Addresses** tab to display the IP address data for the specified range address space.

If you imported the IP address information from a CSV file, the range name is generated as *Imported from CSV*.

- 5 (Optional) Select IP address information from the **Network range** drop-down menu to filter IP address entries.

You can display information about all defined network ranges, the network ranges imported from a CSV file, or a named network range. Details include the start IP address, machine name, last modification date and timestamp, and IP status.

- 6 (Optional) Select a status type from the **IP status** drop-down menu to filter IP address entries to only those that match the selected IP status. Status settings are allocated, unallocated, destroyed, and expired.

For IP addresses that are in an expired or destroyed state, you can click **Reclaim** to make those IP address ranges available for allocation. You must save the profile for the reclamation to take effect. Addresses are not reclaimed immediately, so the status column does not immediately change from Expired or Destroyed to Allocated.

- 7 Click **OK** to complete the network profile.

You can assign a network profile to a network path in a reservation or a blueprint architect can specify the network profile in a blueprint. If you created an external network profile, you can use the external network profile when creating a NAT or routed network profile.

Create an External Network Profile by Using A Third-Party IPAM Provider

You can use a third-party IPAM provider solution that you have imported, configured, and registered in vRealize Orchestrator to obtain IP addresses from that third-party provider.

You can create an external network profile that uses a registered third-party IPAM solution provider endpoint to obtain gateway, subnet mask, and DHCP/WINS settings.

You can define one or more network ranges of static IP addresses in the network profile for use in provisioning a machine. If you do not specify a range, you can use a network profile as a network reservation policy to select a reservation network path for a virtual machine network card (vNIC).

For information about how to create an external network profile without using an IPAM provider or by using the supplied internal IPAM provider endpoint, see [Create an External Network Profile By Using the Supplied IPAM Endpoint](#).

Procedure

- 1 [Specify External Network Profile Information By Using a Third-Party IPAM Endpoint](#)

An external network profile identifies network properties and settings for an existing network. An external network profile is a requirement of NAT and routed network profiles. If you registered and configured an IPAM endpoint in vRealize Orchestrator, you can specify that IP address information be supplied by an IPAM provider.

2 Configure External Network Profile IP Ranges By Using a Third-Party IPAM Endpoint

You can define one or more network ranges of static IP addresses in the network profile for use in provisioning a machine. If you do not specify a range, you can use a network profile as a network reservation policy to select a reservation network path for a virtual machine network card (vNIC).

What to do next

You can assign a network profile to a network path in a reservation or a blueprint architect can specify the network profile in a blueprint. You can use the external network profile when you create an on-demand NAT or routed network profile.

Specify External Network Profile Information By Using a Third-Party IPAM Endpoint

An external network profile identifies network properties and settings for an existing network. An external network profile is a requirement of NAT and routed network profiles. If you registered and configured an IPAM endpoint in vRealize Orchestrator, you can specify that IP address information be supplied by an IPAM provider.

Prerequisites

- Verify that you imported and configured an external IPAM provider plug-in in vRealize Orchestrator and registered the IPAM provider endpoint type in vRealize Orchestrator. In this example, the supported external IPAM solution provider is Infoblox. See [Checklist For Providing Third-Party IPAM Provider Support](#).
- [Create a Third-Party IPAM Provider Endpoint](#).
- Configure the vRealize Orchestrator Appliance with the registered IPAM Endpoint workflow as the standalone Orchestrator in the global tenant (administrator @ vsphere.local).
- Log in to the vRealize Automation console as a **fabric administrator**.

Procedure

- 1 Select **Infrastructure > Reservations > Network Profiles**.
- 2 Click **New** and select **Existing** or **External** from the drop-down menu.
- 3 Enter a name and, optionally, a description.
- 4 If you have configured one or more third-party IPAM provider endpoints, select a third-party IPAM endpoint in the **IPAM endpoint** drop-down menu.

When you select a third-party IPAM provider endpoint that you have registered in vRealize Orchestrator, IP addresses are obtained from the specified IPAM service provider. IP specifications such as subnet mask and DNS/WINS options are not available because their functions are controlled by the selected third-party IPAM endpoint.

What to do next

You can now define network ranges for IP addresses to complete the network profile definition.

Configure External Network Profile IP Ranges By Using a Third-Party IPAM Endpoint

You can define one or more network ranges of static IP addresses in the network profile for use in provisioning a machine. If you do not specify a range, you can use a network profile as a network reservation policy to select a reservation network path for a virtual machine network card (vNIC).

You can define IP ranges by using the IP addresses that are supplied by a third-party IPAM provider.

vRealize Automation only saves external IPAM range IDs in the database, not range details. If you edit a network profile on this page or on a blueprint, vRealize Automation calls the IPAM service to get range details based on the selected range IDs.

Note There is a known issue with some third-party IPAM providers in which a query can time out when returning network ranges, resulting in an empty list. As a workaround, you can provide search criteria to avoid the timeout and obtain the network range information.

For example, depending on your IPAM provider, you may be able to add a property named VLAN to each network in the IPAM provider application and assign a value to that property, such as 4. You could then filter on the property and value, for example VLAN=4, in the **Select Network Range** text box on the vRealize Automation network profile page.

As an alternative, you can increase the timeout setting by using the following procedure:

- 1 On each of the vRealize Automation appliance cnodes, open the `/etc/vcac/webapps/o11n-gateway-service/WEB-INF/classes/META-INF/spring/root/o11n-gateway-service-context.xml` file.
- 2 Change the timeout value from 30 seconds to a higher number.
- 3 Restart vcac-server by entering `service vcac-server restart`.

Prerequisites

[Specify External Network Profile Information By Using a Third-Party IPAM Endpoint.](#)

Procedure

- 1 Click the **Network Ranges** tab to create a new network range or select an existing network range.
Details about the selected range appear, including each name, description, and start and end IP address. Status-related information is also provided.
- 2 Select an address space from the list of all addresses spaces that are available for the endpoint from the **Address space** drop-down menu.

- 3 Click **Add** and select one or more available network ranges for the specified address space.

Selecting a network range may result in an empty list when using a third-party IPAM provider. For details, see Knowledge Base article 2148656 at <http://kb.vmware.com/kb/2148656>.

- 4 Click **OK**.

The IP range name appears in the defined ranges list. The IP addresses in the range appear in the defined IP addresses list.

The uploaded IP addresses appear on the **IP Addresses** page when you click **Apply** or after you save and then edit the network profile.

- 5 Click **OK** to complete the network profile.

What to do next

You can assign a network profile to a network path in a reservation or a blueprint architect can specify the network profile in a blueprint.

Creating a Routed Network Profile For an On-Demand Network

You can create an on-demand routed network profile that uses either the supplied vRealize Automation IPAM endpoint or a properly configured and registered third-party IPAM endpoint.

A routed network profile represent routeable IP space that is divided across multiple networks. Each new routed network allocates the next available subnet from the routeable IP space. A routed network can access all other routed networks that use the same network profile. Each routed subnet can access all other subnets created by the same network profile.

For a third-party IPAM provider, the routeable IP space is created and managed by the third-party IPAM provider. The network administrator uses a third-party IPAM provider to define a routeable IP space and create an IP block for it. You can select one or more IP blocks retrieved from the third-party IPAM provider when you create or edit a routed network profile.

When a new instance of a routed network profile is allocated from the third-party IPAM provider, vRealize Automation calls the provider to reserve the next available subnet and creates a range, using IP blocks that are determined by the routed network profile and the subnet size. The resulting range is used to allocate IP addresses for machines that are assigned to the routed network in the same deployment.

Create a Routed Network Profile By Using the Supplied IPAM Endpoint

When using a routed network profile with the supplied IPAM endpoint, you can define a routeable IP space and available subnets for an on-demand routed network.

Using the supplied vRealize Automation IPAM endpoint, you can assign ranges of static IP addresses and a base IP address to the routed network profile.

You can use IP ranges obtained from the supplied VMware IPAM endpoint or from a third-party IPAM service provider endpoint that you have registered and configured in vRealize Orchestrator, such as Infoblox IPAM. An IP range is created from an IP block during allocation.

Procedure

1 Specify Routed Network Profile Information with the vRealize Automation IPAM Endpoint

The network profile information identifies the routed network properties, its underlying external network profile, and other values used in provisioning the network when using the supplied IPAM endpoint.

2 Configure Routed Network Profile IP Ranges with the vRealize Automation IPAM Endpoint

You can define one or more ranges of static IP addresses for use in provisioning a network.

Specify Routed Network Profile Information with the vRealize Automation IPAM Endpoint

The network profile information identifies the routed network properties, its underlying external network profile, and other values used in provisioning the network when using the supplied IPAM endpoint.

If you want to create a routed network profile by using a third-party IPAM endpoint, see [Specify Routed Network Profile Information with a Third-Party IPAM Endpoint](#).

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.
- Create an external network profile. See [Create an External Network Profile By Using the Supplied IPAM Endpoint](#).

Procedure

- 1 Select **Infrastructure > Reservations > Network Profiles**.
- 2 Click **New** and select **Routed** from the drop-down menu.
- 3 Enter a name and, optionally, a description.
- 4 Accept the default **IPAM endpoint** value for the supplied **vRealize Automation IPAM** endpoint.
- 5 Select an existing external network profile from the **External Network Profile** drop-down menu.
- 6 Enter the subnet mask in the **Subnet mask** text box that is associated with the external network profile.

The subnet mask specifies the size of the entire routable address space that you want to define for your network profile.

For example, enter 255.255.0.0.

- 7 Select a value in the **Range subnet mask** text box drop-down menu to determine how ranges are generated by the **Generate Ranges** option on the **IP Ranges** page.

For example, enter 255.255.255.0.

The range subnet mask defines how you want to partition that space into individual address blocks that are allocated to every deployment instance of that network profile. When choosing a value for the range subnet mask, consider the number of deployments that you expect to use the routed network.

A range is used for each deployment that uses a routed network profile. The number of available routed ranges is equal to the subnet mask divide by the range subnet mask, for example $255.255.0.0/255.255.255.0 = 256$.

- 8 Enter the first available IP address in the **Base IP** text box.

This option is not available if you select a for third-party endpoint.

For example, enter 120.120.0.1.

- 9 Click the **DNS** tab.

- 10 Enter DNS and WINS values as needed.

DNS values are used for DNS name registration and resolution. The DNS and WINS fields are optional if you are using an internal IPAM endpoint. If you are using an external IPAM endpoint, the DNS and WINS values are provided by the third-party IPAM provider.

- a (Optional) Enter a **Primary DNS** server value.
- b (Optional) Enter a **Secondary DNS** server value.
- c (Optional) Enter a **DNS suffixes** value.
- d (Optional) Enter a **DNS search suffixes** value.
- e (Optional) Enter a **Preferred WINS** server value.
- f (Optional) Enter an **Alternate WINS** server value.

What to do next

[Configure Routed Network Profile IP Ranges with the vRealize Automation IPAM Endpoint.](#)

Configure Routed Network Profile IP Ranges with the vRealize Automation IPAM Endpoint

You can define one or more ranges of static IP addresses for use in provisioning a network.

During provisioning, every new routed network allocates the next available range and uses it as its IP space.

Prerequisites

[Specify Routed Network Profile Information with the vRealize Automation IPAM Endpoint.](#)

Procedure

- 1 Click the **Network Ranges** tab to create a new network range or select an existing network range.

Details about the selected range appear, including each name, description, and start and end IP address. Status-related information is also provided.

- 2 Click **Generate Ranges** to generate network ranges based on the subnet mask, range subnet mask, and base IP address information that you entered on the General tab.

Starting with the base IP address, vRealize Automation generates ranges based on the range subnet mask.

For example, vRealize Automation generates ranges of 255 IP ranges if the subnet mask is 255.255.0.0 and the range subnet mask is 255.255.255.0 using the name Range1 through Rangen.

- 3 Click **OK**.

Create a Routed Network Profile By Using a Third-Party IPAM Endpoint

When you use a routed network profile with a third-party IPAM endpoint, routable IP space is created and managed by the third-party IPAM provider.

When you use a third-party IPAM endpoint in your routed network profile, the provider creates new IP ranges for each instance of the on-demand network.

You can use IP ranges obtained from the supplied VMware IPAM endpoint or from a third-party IPAM service provider endpoint that you have registered and configured in vRealize Orchestrator, such as Infoblox IPAM. An IP range is created from an IP block during allocation.

Procedure

- 1 [Specify Routed Network Profile Information with a Third-Party IPAM Endpoint](#)

The network profile information identifies the routed network properties, its underlying external network profile, and other values used in provisioning the network when using a third-party IPAM endpoint.

- 2 [Configure Routed Network Profile IP Ranges with a Third-Party IPAM Endpoint](#)

You can manage one or more named ranges of static IPv4 network addresses for use in provisioning a network.

Specify Routed Network Profile Information with a Third-Party IPAM Endpoint

The network profile information identifies the routed network properties, its underlying external network profile, and other values used in provisioning the network when using a third-party IPAM endpoint.

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.
- Create an external network profile. See [Create an External Network Profile By Using the Supplied IPAM Endpoint](#) or [Create an External Network Profile by Using A Third-Party IPAM Provider](#).
- Create and configure a third-party IPAM endpoint. See [Create a Third-Party IPAM Provider Endpoint](#).

Procedure

- 1 Select **Infrastructure > Reservations > Network Profiles**.
- 2 Click **New** and select **Routed** from the drop-down menu.
- 3 Enter a name and, optionally, a description.

- 4 If you have configured one or more third-party IPAM provider endpoints, select a third-party IPAM endpoint in the **IPAM endpoint** drop-down menu.

When you select a third-party IPAM provider endpoint that you have registered in vRealize Orchestrator, IP addresses are obtained from the specified IPAM service provider. IP specifications such as subnet mask and DNS/WINS options are not available because their functions are controlled by the selected third-party IPAM endpoint.

- 5 Select an existing external network profile from the **External Network Profile** drop-down menu.

Only external network profiles that are configured to use the specified IPAM endpoint are listed and available to select.

- 6 Select a value in the **Range subnet mask** text box drop-down menu to determine how many network subnets are created for provisioning.

For example, enter 255.255.255.0.

The range subnet mask defines how you want to partition that space into individual address blocks that are allocated to every deployment instance of that network profile. When choosing a value for the range subnet mask, consider the number of deployments that you expect to use the routed network.

A range is used for each deployment that uses a routed network profile. The number of available routed ranges is equal to the subnet mask divide by the range subnet mask, for example $255.255.0.0/255.255.255.0 = 256$.

- 7 Click the **IP Blocks** tab to define an address space and manage one or more named ranges of static IPv4 network addresses.

The available IP blocks are the source for IP ranges that are created or allocated for on-demand routing.

What to do next

[Configure Routed Network Profile IP Ranges with a Third-Party IPAM Endpoint.](#)

Configure Routed Network Profile IP Ranges with a Third-Party IPAM Endpoint

You can manage one or more named ranges of static IPv4 network addresses for use in provisioning a network.

During provisioning, each new routed network allocates the next available range and uses that allocated range as its IP space. The IP blocks are obtained from the third-party IPAM provider. During provisioning, a routed network is allocated from the block with a subnet mask that matches the provided range subnet mask.

Prerequisites

[Specify Routed Network Profile Information with a Third-Party IPAM Endpoint.](#)

Procedure

- 1 Select an address space from the **Address space** drop-down menu to limit the available IP blocks that are available for provisioning.

After you add one or more IP blocks in the section below the Address space text box, you can no longer select an **Address space** value. A routed network profile cannot span more than one address space.

- 2 Add one or more IP blocks, or IPAM provider ranges, by using the provider-specific search syntax or selecting from the Search drop-down menu.

The IP blocks are retrieved from the third-party IPAM provider.

Selecting a network range may result in an empty list when using a third-party IPAM provider. For details, see Knowledge Base article 2148656 at <http://kb.vmware.com/kb/2148656>.

- a Click **Add**.
 - b Click **Search**.
 - c Enter search syntax or select one or more IP blocks from the drop-down menu.
 - d Click **OK**.
- 3 Click **Apply**.
- 4 Click **OK**.

Creating a NAT Network Profile For an On-Demand Network

You can create an on-demand NAT network profile that uses either the supplied vRealize Automation IPAM endpoint or a properly configured and registered third-party IPAM endpoint.

Create a NAT Network Profile By Using the Supplied IPAM Endpoint

You can create an on-demand NSX NAT network profile relative to an external network profile. When using the supplied vRealize Automation IPAM endpoint, you can assign ranges of static IP and DHCP addresses to the NAT network profile.

NAT networks use one set of IP addresses for external communication and another set of IP addresses for internal communication. External IP addresses are allocated from an external network profile and internal NAT IP addresses are defined by a NAT network profile. When you provision a new NAT network, a new instance of the NAT network profile is created and used to allocate machine IP addresses.

You can use IP ranges obtained from the supplied VMware IPAM endpoint or from a third-party IPAM service provider endpoint that you have registered and configured in vRealize Orchestrator, such as Infoblox IPAM. An IP range is created from an IP block during allocation.

For a NAT one-to-many network, you can define NAT rules that can be configured when you add a NAT network component to the blueprint and can be changed when you edit the NAT network in a deployment.

Procedure

1 Specify NAT Network Profile Information with the vRealize Automation IPAM Endpoint

The network profile identifies the NAT network properties, underlying external network profile, NAT type, and other values used to provision the network by using the embedded vRealize Automation IPAM.

2 Configure NAT Network Profile IP Ranges with the vRealize Automation IPAM Endpoint

You can define one or more ranges of static IP addresses for use in provisioning a network.

Specify NAT Network Profile Information with the vRealize Automation IPAM Endpoint

The network profile identifies the NAT network properties, underlying external network profile, NAT type, and other values used to provision the network by using the embedded vRealize Automation IPAM.

If you want to create a NAT network profile that uses a third-party IPAM endpoint, see [Specify NAT Network Profile Information with a Third-Party IPAM Endpoint](#).

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.
- Create an external network profile. See [Create an External Network Profile By Using the Supplied IPAM Endpoint](#).

Procedure

- 1 Select **Infrastructure > Reservations > Network Profiles**.
- 2 Click **New** and select **NAT** from the drop-down menu.
- 3 Enter a name and, optionally, a description.
- 4 Accept the default **IPAM endpoint** value for the supplied **vRealize Automation IPAM** endpoint.
- 5 Select an existing external network profile from the **External Network Profile** drop-down menu.
- 6 Select a one-to-one or one-to-many network address translation type from the **NAT type** drop-down menu.

Option	Description
One-to-One	<p>Assign an external static IP address to each network adapter. Every machine can access the external network and is accessible from the external network.</p> <p>All external IP addresses that are assigned to an NSX edge uplink must be part of the same subnet. When using NAT 1:1 in vRealize Automation, the corresponding external network profile must contain only IP ranges that exist within a single subnet.</p>
One-to-Many	<p>One external IP address is shared among all machines on the network. An internal machine can have either DHCP or static IP addresses. Every machine can access the external network, but no machine is accessible from the external network. Selecting this option enables the Enabled check box in the DHCP group.</p> <p>The NAT one-to-many translation type allows you to define NAT rules when you add a NAT network component to a blueprint.</p>

- 7 Enter an IP subnet mask in the **Subnet mask** text box.

The subnet mask specifies the size of the entire routable address space that you want to define for your network profile.

For example, enter 255.255.0.0.

- 8 Enter an Edge or routed gateway address in the **Gateway** text box.

Use a standard IPv4 address format. For example, enter 10.10.110.1.

The gateway IP address defined in the network profile is assigned to the NIC during allocation. If no value is assigned in the **Gateway** text box in the network profile, then you must use the `VirtualMachine.Network0.Gateway` custom property when provisioning the Edge machine.

- 9 (Optional) In the DHCP group, select the **Enabled** check box and enter the **IP range start** and **IP range end** values.

You can select the check box only if you set the NAT type to one-to-many.

- 10 (Optional) Set a DHCP lease time to define how long a machine can use an IP address.

- 11 Click the **DNS** tab.

- 12 Enter DNS and WINS values as needed.

DNS values are used for DNS name registration and resolution. The DNS and WINS fields are optional if you are using an internal IPAM endpoint. If you are using an external IPAM endpoint, the DNS and WINS values are provided by the third-party IPAM provider.

- a (Optional) Enter a **Primary DNS** server value.
- b (Optional) Enter a **Secondary DNS** server value.
- c (Optional) Enter a **DNS suffixes** value.
- d (Optional) Enter a **DNS search suffixes** value.
- e (Optional) Enter a **Preferred WINS** server value.
- f (Optional) Enter an **Alternate WINS** server value.

What to do next

[Configure NAT Network Profile IP Ranges with the vRealize Automation IPAM Endpoint.](#)

Configure NAT Network Profile IP Ranges with the vRealize Automation IPAM Endpoint

You can define one or more ranges of static IP addresses for use in provisioning a network.

You cannot overlap the start and end network range IP addresses with the DHCP addresses. If you attempt to save a profile that contains address ranges that overlap, vRealize Automation displays a validation error.

Prerequisites

[Specify NAT Network Profile Information with the vRealize Automation IPAM Endpoint.](#)

Procedure

- 1 Click the **Network Ranges** tab to create a new network range or select an existing network range.

Details about the selected range appear, including each name, description, and start and end IP address. Status-related information is also provided.

- 2 Click **New** to enter a new network range name and IP address range manually or click **Import from CSV** to import the IP address information from a properly formatted CSV file.

- Click **New**.

- a Enter a network range name.
- b Enter a network range description.
- c Enter the start IP address of the range.
- d Enter the end IP address of the range.

- Click **Import from CSV**.

- a Browse to and select the CSV file or drag the CSV file into the **Import from CSV** dialog box.

A row in the CSV file has the format *ip_address, machine_name, status, NIC offset*. For example:

```
100.10.100.1,mymachine01,Allocated
```

CSV Field	Description
ip_address	An IP address in IPv4 format.
machine_name	Name of a managed machine in vRealize Automation. If the field is empty, the default is no name. If the field is empty, the status field value cannot be Allocated.
status	Allocated or Unallocated, case-sensitive. If the field is empty, the default value is Unallocated. If the status is Allocated, the machine_name field cannot be empty.
NIC_offset	A non-negative integer. Optional.

- b Click **Apply**.

- 3 Click **OK**.

The IP range name appears in the defined ranges list. The IP addresses in the range appear in the defined IP addresses list.

The uploaded IP addresses appear on the **IP Addresses** page when you click **Apply** or after you save and then edit the network profile.

- 4 Click the **IP Addresses** tab to display the IP addresses for the named network range.
- 5 (Optional) Select IP address information from the **Network range** drop-down menu to filter IP address entries.

You can display information about all defined network ranges, the network ranges imported from a CSV file, or a named network range. Details include the start IP address, machine name, last modification date and timestamp, and IP status.

- 6 (Optional) Select a status type from the **IP status** drop-down menu to filter IP address entries to only those that match the selected IP status. Status settings are allocated, unallocated, destroyed, and expired.

For IP addresses that are in an expired or destroyed state, you can click **Reclaim** to make those IP address ranges available for allocation. You must save the profile for the reclamation to take effect. Addresses are not reclaimed immediately, so the status column does not immediately change from Expired or Destroyed to Allocated.

- 7 Click **OK**.

Create a NAT Network Profile By Using a Third-Party IPAM Endpoint

You can create an on-demand NSX NAT network profile relative to an external network profile. When using an NSX NAT network profile with a third-party IPAM endpoint, IP space is created and managed by the third-party IPAM provider.

When you use a third-party IPAM endpoint in your NAT network profile, the provider creates new IP ranges for each instance of the on-demand network. An internal set of IP addresses defined with one or more ranges is created in the third-party IPAM provider endpoint for every instance of the NAT network. These IP ranges are used to allocate IP addresses for machines assigned to the NAT network in the same deployment. Because there cannot be duplicate IP addresses defined within a single address space, a new address space is created by the provider for each instance of NAT network. When a NAT network is destroyed, its ranges are destroyed in the IPAM provider endpoint and in the new address space.

You can use IP ranges obtained from the supplied VMware IPAM endpoint or from a third-party IPAM service provider endpoint that you have registered and configured in vRealize Orchestrator, such as Infoblox IPAM. An IP range is created from an IP block during allocation.

For a NAT one-to-many network, you can define NAT rules that can be configured when you add a NAT network component to the blueprint and can be changed when you edit the NAT network in a deployment.

Procedure

- 1 [Specify NAT Network Profile Information with a Third-Party IPAM Endpoint](#)

The network profile information identifies the NAT network properties, its underlying external network profile, and other values used in provisioning the network when using a third-party IPAM endpoint.

- 2 [Configure NAT Network Profile IP Ranges with a Third-Party IPAM Endpoint](#)

You can define one or more IP address ranges for use in provisioning a network by using NAT.

Specify NAT Network Profile Information with a Third-Party IPAM Endpoint

The network profile information identifies the NAT network properties, its underlying external network profile, and other values used in provisioning the network when using a third-party IPAM endpoint.

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.

- Create an external network profile. See [Create an External Network Profile By Using the Supplied IPAM Endpoint](#) or [Create an External Network Profile by Using A Third-Party IPAM Provider](#).
- Create and configure a third-party IPAM endpoint. See [Create a Third-Party IPAM Provider Endpoint](#).

Procedure

- 1 Select **Infrastructure > Reservations > Network Profiles**.
- 2 Click **New** and select **NAT** from the drop-down menu.
- 3 Enter a name and, optionally, a description.
- 4 If you have configured one or more third-party IPAM provider endpoints, select a third-party IPAM endpoint in the **IPAM endpoint** drop-down menu.

When you select a third-party IPAM provider endpoint that you have registered in vRealize Orchestrator, IP addresses are obtained from the specified IPAM service provider. IP specifications such as subnet mask and DNS/WINS options are not available because their functions are controlled by the selected third-party IPAM endpoint.

- 5 Select an existing external network profile from the **External Network Profile** drop-down menu.

Only external network profiles that are configured to use the specified IPAM endpoint are listed and available to select.

- 6 Select a one-to-one or one-to-many network address translation type from the **NAT type** drop-down menu.

Option	Description
One-to-One	Assign an external static IP address to each network adapter. Every machine can access the external network and is accessible from the external network. All external IP addresses that are assigned to an NSX edge uplink must be part of the same subnet. When using NAT 1:1 in vRealize Automation, the corresponding external network profile must contain only IP ranges that exist within a single subnet.
One-to-Many	One external IP address is shared among all machines on the network. An internal machine can use only static IP addresses. Every machine can access the external network, but no machine is accessible from the external network. DHCP is not supported when using NAT with a third-party IPAM provider. The NAT one-to-many translation type allows you to define NAT rules when you add a NAT network component to a blueprint.

- 7 Enter an IP subnet mask in the **Subnet mask** text box.

The subnet mask specifies the size of the entire routable address space that you want to define for your network profile.

For example, enter 255.255.0.0.

- 8 Enter an Edge or routed gateway address in the **Gateway** text box.

Use a standard IPv4 address format. For example, enter 10.10.110.1.

The gateway IP address defined in the network profile is assigned to the NIC during allocation. If no value is assigned in the **Gateway** text box in the network profile, then you must use the `VirtualMachine.Network0.Gateway` custom property when provisioning the Edge machine.

- 9 Click the **DNS** tab.

- 10 Enter DNS and WINS values as needed.

DNS values are used for DNS name registration and resolution. The DNS and WINS fields are optional if you are using an internal IPAM endpoint. If you are using an external IPAM endpoint, the DNS and WINS values are provided by the third-party IPAM provider.

- a (Optional) Enter a **Primary DNS** server value.
- b (Optional) Enter a **Secondary DNS** server value.
- c (Optional) Enter a **DNS suffixes** value.
- d (Optional) Enter a **DNS search suffixes** value.
- e (Optional) Enter a **Preferred WINS** server value.
- f (Optional) Enter an **Alternate WINS** server value.

What to do next

[Configure NAT Network Profile IP Ranges with a Third-Party IPAM Endpoint.](#)

Configure NAT Network Profile IP Ranges with a Third-Party IPAM Endpoint

You can define one or more IP address ranges for use in provisioning a network by using NAT.

Prerequisites

[Specify NAT Network Profile Information with a Third-Party IPAM Endpoint.](#)

Procedure

- 1 Click the **Network Ranges** tab to create a new network range or select an existing network range.
Details about the selected range appear, including each name, description, and start and end IP address. Status-related information is also provided.
- 2 Click **New** to enter a new network range name and IP address range manually or click **Import from CSV** to import the IP address information from a properly formatted CSV file.
 - Click **New**.
 - a Enter a network range name.
 - b Enter a network range description.
 - c Enter the start IP address of the range.

d Enter the end IP address of the range.

■ Click **Import from CSV**.

a Browse to and select the CSV file or drag the CSV file into the **Import from CSV** dialog box.

A row in the CSV file has the format *ip_address*, *machine_name*, *status*, *NIC offset*. For example:

```
100.10.100.1,mymachine01,Allocated
```

CSV Field	Description
ip_address	An IP address in IPv4 format.
machine_name	Name of a managed machine in vRealize Automation. If the field is empty, the default is no name. If the field is empty, the status field value cannot be Allocated.
status	Allocated or Unallocated, case-sensitive. If the field is empty, the default value is Unallocated. If the status is Allocated, the machine_name field cannot be empty.
NIC_offset	A non-negative integer. Optional.

b Click **Apply**.

3 Click **OK**.

The IP range name appears in the defined ranges list. The IP addresses in the range appear in the defined IP addresses list.

The uploaded IP addresses appear on the **IP Addresses** page when you click **Apply** or after you save and then edit the network profile.

4 Click the **IP Addresses** tab to display the IP addresses for the named network range.

5 (Optional) Select IP address information from the **Network range** drop-down menu to filter IP address entries.

You can display information about all defined network ranges, the network ranges imported from a CSV file, or a named network range. Details include the start IP address, machine name, last modification date and timestamp, and IP status.

6 (Optional) Select a status type from the **IP status** drop-down menu to filter IP address entries to only those that match the selected IP status. Status settings are allocated, unallocated, destroyed, and expired.

For IP addresses that are in an expired or destroyed state, you can click **Reclaim** to make those IP address ranges available for allocation. You must save the profile for the reclamation to take effect. Addresses are not reclaimed immediately, so the status column does not immediately change from Expired or Destroyed to Allocated.

7 Click **OK**.

Releasing IP Addresses By Destroying Provisioned Machines

When you destroy a deployment, its IP addresses are deleted. The allocated IPs, for example the IPS in a network profile range, are released and made available for subsequent provisioning.

When you destroy a machine that has a static IP address, its IP address is made available for other machines to use. Unused addresses might not be available immediately because the process to reclaim static IP addresses runs every 30 minutes.

If you are using a third-party IPAM provider, vRealize Automation deletes the associated IP addresses by using the vRealize Orchestrator workflow in the third-party IPAM provider plug-in or package.

Configuring Reservations and Reservation Policies

A vRealize Automation reservation can define policies, priorities, and quotas that determine machine placement for provisioning requests.

Reservation policies restrict machine provisioning to a subset of available reservations. Storage reservation policies allow blueprint architects to assign machine volumes to different datastores.

To provision successfully, the reservation must have sufficient available storage. The reservation's storage availability depends on:

- How much storage is available on the datastore/cluster.
- How much of that storage is reserved for that datastore/cluster.
- How much of that storage is already allocated in vRealize Automation

For example, even if the vCenter Server has storage available for the datastore/cluster, if sufficient storage is not reserved in the reservation then provisioning fails with a "No reservation is available to allocate..." error. The allocated storage on a reservation depends on the number of VMs (regardless of their state) on that specific reservation. See the VMware Knowledge Base article *Machine XXX: No reservation is available to allocate within the group XXX. Total XX GB of storage was requested (2151030)* at <http://kb.vmware.com/kb/2151030> for more information.

Reservations

You can create a vRealize Automation reservation to allocate provisioning resources in the fabric group to a specific business group.

For example, you can use reservations to specify that a share of the memory, CPU, networking, and storage resources of a single compute resource belongs to a particular business group or that certain machines be allocated to a specific business group.

Note Storage and memory that are assigned to a provisioned machine by a reservation are released when the machine to which they are assigned is deleted in vRealize Automation by the Destroy action. The storage and memory are not released if the machine is deleted in the vCenter Server.

You can create a reservation for the following machine types:

- vSphere
- vCloud Air
- vCloud Director
- Amazon EC2

- Azure
- Hyper V (SCVMM)
- Hyper-V Stand-alone
- KVM (RHEV)
- OpenStack
- XenServer

You can configure security settings for the virtual machines to be provisioned by specifying information in a reservation, blueprint, or guest agent script. If the machines to be provisioned requires a guest agent, you must add a security rule that contains that requirement to the reservation or the blueprint. For example, if you use a default security policy that denies communication between all machines, and rely on a separate security policy to allow communication between specific machines, the guest agent might be unable to communicate with vRealize Automation during the customization phase. To avoid this problem during machine provisioning, use a default security policy that allows communication during the customization phase.

Choosing a Reservation Scenario

You can create reservations to allocate resources to business groups. Depending on your scenario, the procedure to create a reservation differs.

Choose a reservation scenario based on the target endpoint type.

Each business group must have at least one reservation for its members to provision machines of that type. For example, a business group with an OpenStack reservation but not an Amazon reservation, cannot request a machine from Amazon. In this example, the business group must be allocated a reservation specifically for Amazon resources.

Table 2-15. Choosing a Reservation Scenario

Scenario	Procedure
Create a vSphere reservation.	Create a Reservation for Hyper-V, KVM, SCVMM, vSphere, or XenServer
Create a reservation to allocate resources for a vCloud Air endpoint.	Create a vCloud Air Reservation
Create a reservation to allocate resources for a vCloud Director endpoint.	Create a vCloud Director Reservation
Create a reservation to allocate resources on an Amazon resource (with or without using Amazon Virtual Private Cloud).	Create an Amazon EC2 Reservation
Create a reservation to allocate resources on an OpenStack resource.	Create an OpenStack Reservation
Create a reservation to allocate resources for Hyper-V.	Create a Reservation for Hyper-V, KVM, SCVMM, vSphere, or XenServer
Create a reservation to allocate resources for KVM.	Create a Reservation for Hyper-V, KVM, SCVMM, vSphere, or XenServer

Table 2-15. Choosing a Reservation Scenario (Continued)

Scenario	Procedure
Create a reservation to allocate resources on an OpenStack resource.	Create an OpenStack Reservation
Create a reservation to allocate resources for SCVMM.	Create a Reservation for Hyper-V, KVM, SCVMM, vSphere, or XenServer
Create a reservation to allocate resources for XenServer.	Create a Reservation for Hyper-V, KVM, SCVMM, vSphere, or XenServer
Create a reservation to allocate resources for Microsoft Azure.	Create a Reservation for Microsoft Azure

Creating Cloud Category Reservations

A cloud category type reservation provides access to the provisioning services of a cloud service account for a particular vRealize Automation business group. Available cloud reservation types include Amazon, OpenStack, vCloud Air, and vCloud Director.

A reservation is a share of the memory, CPU, networking, and storage resources of one compute resource allocated to a particular vRealize Automation business group.

A business group can have multiple reservations on one endpoint or reservations on multiple endpoints.

The allocation model for a reservation depends on the allocation model in the associated datacenter. Available allocation models are Allocation Pool, Pay As You Go, and reservation pool. For information about allocation models, see the vCloud Director or vCloud Air documentation.

In addition to defining the share of fabric resources allocated to the business group, a reservation can define policies, priorities, and quotas that determine machine placement.

To provision successfully, the reservation must have sufficient available storage. The reservation's storage availability depends on:

- How much storage is available on the datastore/cluster.
- How much of that storage is reserved for that datastore/cluster.
- How much of that storage is already allocated in vRealize Automation

For example, even if the vCenter Server has storage available for the datastore/cluster, if sufficient storage is not reserved in the reservation then provisioning fails with a "No reservation is available to allocate..." error. The allocated storage on a reservation depends on the number of VMs (regardless of their state) on that specific reservation. See the VMware Knowledge Base article *Machine XXX: No reservation is available to allocate within the group XXX. Total XX GB of storage was requested (2151030)* at <http://kb.vmware.com/kb/2151030> for more information.

Understanding Selection Logic for Cloud Reservations

When a member of a business group creates a provisioning request for a cloud machine, vRealize Automation selects a machine from one of the reservations that are available to that business group. Cloud reservations include Amazon, OpenStack, vCloud Air, and vCloud Director.

The reservation for which a machine is provisioned must satisfy the following criteria:

- The reservation must be of the same platform type as the blueprint from which the machine was requested.
- The reservation must be enabled.
- The reservation must have capacity remaining in its machine quota or have an unlimited quota.

The allocated machine quota includes only machines that are powered on. For example, if a reservation has a quota of 50, and 40 machines have been provisioned but only 20 of them are powered on, the reservation's quota is 40 percent allocated, not 80 percent.

- The reservation must have the security groups specified in the machine request.
- The reservation must be associated with a region that has the machine image specified in the blueprint.
- The reservation must have sufficient unallocated memory and storage resources to provision the machine.

In a Pay As You Go reservation, resources can be unlimited.

- For Amazon machines, the request specifies an availability zone and whether the machine is to be provisioned a subnet in a Virtual Private Cloud (VPC) or in a non-VPC location. The reservation must match the network type (VPC or non-VPC).
- For vCloud Air or vCloud Director, if the request specifies an allocation model, the virtual datacenter associated with the reservation must have the same allocation model.
- For vCloud Director or vCloud Air, the specified organization must be enabled.
- Any blueprint templates must be available on the reservation. If the reservation policy maps to more than one resources, the templates should be public.
- If the cloud provider supports network selection and the blueprint has specific network settings, the reservation must have the same networks.

If the blueprint or reservation specifies a network profile for static IP address assignment, an IP address must be available to assign to the new machine.

- If the request specifies an allocation model, the allocation model in the reservation must match the allocation model in the request.
- If the blueprint specifies a reservation policy, the reservation must belong to that reservation policy.

Reservation policies are a way to guarantee that the selected reservation satisfies any additional requirements for provisioning machines from a specific blueprint. For example, if a blueprint uses a specific machine image, you can use reservation policies to limit provisioning to reservations associated with the regions that have the required image.

If no reservation is available that meets all of the selection criteria, provisioning fails.

If multiple reservations meet all of the criteria, the reservation from which to provision a requested machine is determined by the following logic:

- A reservation with a lower priority value is selected before a reservation with a higher priority value.
- If multiple reservations have the same priority, the reservation with the lowest percentage of its machine quota allocated is selected.
- If multiple reservations have the same priority and quota usage, machines are distributed among reservations in round-robin fashion.

Note While round-robin selection of network profiles is not supported, round-robin selection of networks (if any) is supported, which can be associated with different network profiles.

If multiple storage paths are available on a reservation with sufficient capacity to provision the machine volumes, storage paths are selected according to the following logic.

- A storage path with a lower priority value is selected before a storage path with a higher priority value.
- If the blueprint or request specifies a storage reservation policy, the storage path must belong to that storage reservation policy.

If the custom property `VirtualMachine.DiskN.StorageReservationPolicyMode` is set to Not Exact, and no storage path with sufficient capacity is available in the storage reservation policy, then provisioning proceeds with a storage path outside the specified storage reservation policy. The default value of `VirtualMachine.DiskN.StorageReservationPolicyMode` is Exact.

- If multiple storage paths have the same priority, machines are distributed among storage paths by using round-robin scheduling.

Create an Amazon EC2 Reservation

You must allocate resources to machines by creating a reservation before members of a business group can request machine provisioning.

You can work with Amazon reservations for Amazon Virtual Private Cloud or Amazon non-VPC. Amazon Web Services users can create a Amazon Virtual Private Cloud to design a virtual network topology according to your specifications. If you plan to use Amazon VPC, you must assign an Amazon VPC to a vRealize Automation reservation. See .

When you create an Amazon reservation or configure a machine component in the blueprint, you can choose from the list of security groups that are available to the specified Amazon region. Security groups are imported during data collection.

Note After you create a reservation, you cannot change the business group or compute resource associations.

For information about creating an Amazon VPC by using the AWS Management Console, see Amazon Web Services documentation.

Procedure

1 Specify Amazon Reservation Information

Each reservation is configured for a specific business group to grant them access to request machines on a specified compute resource.

2 Specify Resource and Network Settings for Amazon Reservations

Specify resource and network settings for provisioning machines from this vRealize Automation reservation.

3 Specify Custom Properties and Alerts for Amazon Reservations

You can associate custom properties with a vRealize Automation reservation. You can also configure alerts to send email notifications when reservation resources are low.

Specify Amazon Reservation Information

Each reservation is configured for a specific business group to grant them access to request machines on a specified compute resource.

Note After you create a reservation, you cannot change the business group or compute resource associations.

You can control the display of reservations when adding, editing, or deleting by using the **Filter By Category** option on the Reservations page. Note that test agent reservations do not appear in the reservations list when filtering by category.

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.
- Verify that a tenant administrator created at least one business group.
- Verify that a compute resource exists.
- Configure network settings.
- (Optional) Configure network profile information.
- Verify that you have access to a desired Amazon network. For example, if you want to use VPC, verify that you have access to an Amazon Virtual Private Cloud (VPC) network.
- Verify that any required key pairs exist. See [Managing Key Pairs](#).

Procedure

1 Select **Infrastructure > Reservations > Reservations**.

2 Click the **New** icon () and select the type of reservation to create. Select **Amazon EC2**.

3 (Optional) Select an existing reservation from the **Copy from existing reservation** drop-down menu. Data from the selected reservation appears. You can make changes as required for your new reservation.

- 4 Enter a name in the **Name** text box.
- 5 Select a tenant from the **Tenant** drop-down menu.
- 6 Select a business group from the **Business group** drop-down menu.
Only users in this business group can provision machines by using this reservation.
- 7 (Optional) Select a reservation policy from the **Reservation policy** drop-down menu.
This option requires that one or more reservation policies exist. You can edit the reservation later to specify a reservation policy.
You use a reservation policy to restrict provisioning to specific reservations.
- 8 Enter a number in the **Priority** text box to set the priority for the reservation.
The priority is used when a business group has more than one reservation. A reservation with priority 1 is used for provisioning over a reservation with priority 2.
- 9 (Optional) Deselect the **Enable this reservation** check box if you do not want this reservation active.

Do not navigate away from this page. Your reservation is not complete.

Specify Resource and Network Settings for Amazon Reservations

Specify resource and network settings for provisioning machines from this vRealize Automation reservation.

When you create an Amazon reservation or configure a machine component in the blueprint, you can choose from the list of security groups that are available to the specified Amazon account region. Security groups are imported during data collection. A security group acts as a firewall to control access to a machine. Every region includes at least the default security group. Administrators can use the Amazon Web Services Management Console to create additional security groups, configure ports for Microsoft Remote Desktop Protocol or SSH, and set up a virtual private network for an Amazon VPN. For information about creating and using security groups in Amazon Web Services, see [Amazon documentation](#).

For related information about load balancers, see *Configuring vRealize Automation*.

Prerequisites

[Specify Amazon Reservation Information](#).

Procedure

- 1 Click the **Resources** tab.
- 2 Select a compute resource on which to provision machines from the **Compute resource** drop-down menu.
Available Amazon regions are listed.

- 3 (Optional) Enter a number in the **Machine quota** text box to set the maximum number of machines that can be provisioned on this reservation.

Only machines that are powered on are counted towards the quota. Leave blank to make the reservation unlimited.

- 4 Select a method of assigning key pairs to compute instances from the **Key pair** drop-down menu.

Option	Description
Not Specified	Controls key pair behavior at the blueprint level rather than the reservation level.
Auto-Generated per Business Group	Every machine provisioned in the same business group has the same key pair, including machines provisioned on other reservations when the machine has the same compute resource and business group. Because key pairs generated this way are associated with a business group, the key pairs are deleted when the business group is deleted.
Auto-Generated per Machine	Each machine has a unique key pair. This is the most secure method because no key pairs are shared among machines.
Specific Key Pair	Every machine provisioned on this reservation has the same key pair. Browse for a key pair to use for this reservation.

- 5 If you selected **Specific key Pair** in the **Key pair** drop-down menu, select a key pair value from the **Specific key pair** drop-down menu.

- 6 If you are configured for Amazon Virtual Private Cloud, enable the **Assign to a subnet in a VPC** check mark box. Otherwise, leave the box unchecked.

If you select **Assign to a subnet in a VPC**, the following locations or subnets, security groups, and load balancers options appear in a popup menu rather than on this same page.

For a VPC reservation, specify the security groups and subnets for each VPC that is allowed in the reservation.

- 7 Select one or more available locations (non-VPC) or subnets (VPC) from the **Locations** or **Subnets** list.

Select each available location or subnet that you want to be available for provisioning.

- 8 Select one or more security groups that can be assigned to a machine during provisioning from the **Security groups** list.

Select each security group that can be assigned to a machine during provisioning. Each available region requires at least one specified security group.

- 9 Select one or more available load balancers from the **Load balancers** list.

If you are using the elastic load balancer feature, select one or more available load balancers that apply to the selected locations or subnets.

You can save the reservation now by clicking **Save**. Or you can add custom properties to further control reservation specifications. You can also configure email alerts to send notifications when resources allocated to this reservation become low.

Specify Custom Properties and Alerts for Amazon Reservations

You can associate custom properties with a vRealize Automation reservation. You can also configure alerts to send email notifications when reservation resources are low.

Custom properties and email alerts are optional configurations for the reservation. If you do not want to associate custom properties or set alerts, click **Save** to finish creating the reservation.

You can add as many custom properties as apply to your needs.

If configured, alerts are generated daily, rather than when the specified thresholds are reached.

Important Notifications are only sent if email alerts are configured and notifications are enabled.

Prerequisites

[Specify Resource and Network Settings for Amazon Reservations.](#)

Procedure

- 1 Click the **Properties** tab.
- 2 Click **New**.
- 3 Enter a valid custom property name.
- 4 If applicable, enter a property value.
- 5 Click **Save**.
- 6 (Optional) Add any additional custom properties.
- 7 Click the **Alerts** tab.
- 8 Enable the **Capacity Alerts** check box to configure alerts to be sent.
- 9 Use the slider to set thresholds for available resource allocation.
- 10 Enter the AD user or group names (not email addresses) to receive alert notifications in the **Recipients** text box.
Enter a name on each line. Press Enter to separate multiple entries.
- 11 Select **Send alerts to group manager** to include group managers in the email alerts.
The email alerts are sent to the users included in the business group **Send manager emails to** list.
- 12 Specify a reminder frequency (days).
- 13 Click **Save**.

The reservation is saved and appears in the Reservations list.

What to do next

You can configure optional reservation policies or begin preparing for provisioning.

Users who are authorized to create blueprints can create them now.

Create an OpenStack Reservation

You must allocate resources to machines by creating a reservation before members of a business group can request machine provisioning.

Create an OpenStack reservation.

Procedure

1 Specify OpenStack Reservation Information

Each reservation is configured for a specific business group to grant them access to request machines on a specified compute resource.

2 Specify Resources and Network Settings for OpenStack Reservations

Specify resource and network settings available to machines that are provisioned from this vRealize Automation reservation.

3 Specify Custom Properties and Alerts for OpenStack Reservations

You can associate custom properties with a vRealize Automation reservation. You can also configure alerts to send email notifications when reservation resources are low.

Specify OpenStack Reservation Information

Each reservation is configured for a specific business group to grant them access to request machines on a specified compute resource.

Note After you create a reservation, you cannot change the business group or compute resource associations.

You can control the display of reservations when adding, editing, or deleting by using the **Filter By Category** option on the Reservations page. Note that test agent reservations do not appear in the reservations list when filtering by category.

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.
- Verify that a tenant administrator created at least one business group.
- Verify that a compute resource exists.
- Verify that any optional security groups or floating IP addresses are configured.
- Verify that any required key pairs exist. See [Managing Key Pairs](#).
- Verify that a compute resource exists.
- Configure network settings.

Procedure

- 1 Select **Infrastructure > Reservations > Reservations**.
- 2 Click the **New** icon () and select the type of reservation to create.
Select **OpenStack**.

- 3 (Optional) Select an existing reservation from the **Copy from existing reservation** drop-down menu.
Data from the selected reservation appears. You can make changes as required for your new reservation.
- 4 Enter a name in the **Name** text box.
- 5 Select a tenant from the **Tenant** drop-down menu.
- 6 Select a business group from the **Business group** drop-down menu.
Only users in this business group can provision machines by using this reservation.
- 7 (Optional) Select a reservation policy from the **Reservation policy** drop-down menu.
This option requires that one or more reservation policies exist. You can edit the reservation later to specify a reservation policy.
You use a reservation policy to restrict provisioning to specific reservations.
- 8 Enter a number in the **Priority** text box to set the priority for the reservation.
The priority is used when a business group has more than one reservation. A reservation with priority 1 is used for provisioning over a reservation with priority 2.
- 9 (Optional) Deselect the **Enable this reservation** check box if you do not want this reservation active.

Do not navigate away from this page. Your reservation is not complete.

Specify Resources and Network Settings for OpenStack Reservations

Specify resource and network settings available to machines that are provisioned from this vRealize Automation reservation.

Prerequisites

[Specify OpenStack Reservation Information.](#)

Procedure

- 1 Click the **Resources** tab.
- 2 Select a compute resource on which to provision machines from the **Compute resource** drop-down menu.

Only templates located on the cluster you select are available for cloning with this reservation.

During provisioning, machines are placed on a host that is connected to the local storage. If the reservation uses local storage, all the machines that are provisioned by the reservation are created on the host that contains that local storage. However, if you use the `VirtualMachine.Admin.ForceHost` custom property, which forces a machine to be provisioned to a different host, provisioning fails. Provisioning also fails if the template from which the machine is cloned is on local storage, but attached to a machine on a different cluster. In this case, provisioning fails because it cannot access the template.

- 3 (Optional) Enter a number in the **Machine quota** text box to set the maximum number of machines that can be provisioned on this reservation.

Only machines that are powered on are counted towards the quota. Leave blank to make the reservation unlimited.

- 4 Select a method of assigning key pairs to compute instances from the **Key pair** drop-down menu.

Option	Description
Not Specified	Controls key pair behavior at the blueprint level rather than the reservation level.
Auto-Generated per Business Group	Every machine provisioned in the same business group has the same key pair, including machines provisioned on other reservations when the machine has the same compute resource and business group. Because key pairs generated this way are associated with a business group, the key pairs are deleted when the business group is deleted.
Auto-Generated per Machine	Each machine has a unique key pair. This is the most secure method because no key pairs are shared among machines.
Specific Key Pair	Every machine provisioned on this reservation has the same key pair. Browse for a key pair to use for this reservation.

- 5 If you selected **Specific key Pair** in the **Key pair** drop-down menu, select a key pair value from the **Specific key pair** drop-down menu.

- 6 Select one or more security groups that can be assigned to a machine during provisioning from the **Security groups** list.

- 7 Click the **Network** tab.

- 8 Configure a network path for machines provisioned by using this reservation.

- a (Optional) If the option is available, select a storage endpoint from the **Endpoint** drop-down menu.

The FlexClone option is visible in the endpoint column if a NetApp ONTAP endpoint exists and if the host is virtual. If there is a NetApp ONTAP endpoint, the reservation page displays the endpoint assigned to the storage path. When you add, update, or delete an endpoint for a storage path, the change is visible in all the applicable reservations.

When you add, update, or delete an endpoint for a storage path, the change is visible in the reservation page.

- b Select a network paths for machines provisioned by this reservation from the **Network Paths** list.
- c (Optional) Select a listed network profile from the **Network Profile** drop-down menu.

This option requires that one or more network profiles exists.

You can select more than one network path on a reservation, but only one network is used when provisioning a machine.

You can save the reservation now by clicking **Save**. Or you can add custom properties to further control reservation specifications. You can also configure email alerts to send notifications when resources allocated to this reservation become low.

Specify Custom Properties and Alerts for OpenStack Reservations

You can associate custom properties with a vRealize Automation reservation. You can also configure alerts to send email notifications when reservation resources are low.

Custom properties and email alerts are optional configurations for the reservation. If you do not want to associate custom properties or set alerts, click **Save** to finish creating the reservation.

You can add as many custom properties as apply to your needs.

Important Notifications are only sent if email alerts are configured and notifications are enabled.

If configured, alerts are generated daily, rather than when the specified thresholds are reached.

Prerequisites

[Specify Resources and Network Settings for OpenStack Reservations.](#)

Procedure

- 1 Click the **Properties** tab.
- 2 Click **New**.
- 3 Enter a valid custom property name.
- 4 If applicable, enter a property value.
- 5 Click **Save**.
- 6 (Optional) Add any additional custom properties.
- 7 Click the **Alerts** tab.
- 8 Enable the **Capacity Alerts** check box to configure alerts to be sent.
- 9 Use the slider to set thresholds for available resource allocation.
- 10 Enter the AD user or group names (not email addresses) to receive alert notifications in the **Recipients** text box.

Enter a name on each line. Press Enter to separate multiple entries.

- 11 Select **Send alerts to group manager** to include group managers in the email alerts.

The email alerts are sent to the users included in the business group **Send manager emails to** list.

- 12 Specify a reminder frequency (days).
- 13 Click **Save**.

The reservation is saved and appears in the Reservations list.

What to do next

You can configure optional reservation policies or begin preparing for provisioning.

Users who are authorized to create blueprints can create them now.

Create a vCloud Air Reservation

You must allocate resources to machines by creating a vRealize Automation reservation before members of a business group can request machine provisioning.

Each business group must have at least one reservation for its members to provision machines of that type.

Procedure

1 Specify vCloud Air Reservation Information

You can create a reservation for each vCloud Air machine subscription or OnDemand resource. Each reservation is configured for a specific business group to grant them access to request machines.

2 Specify Resources and Network Settings for a vCloud Air Reservation

Specify resource and network settings available to vCloud Air machines that are provisioned from this vRealize Automation reservation.

3 Specify Custom Properties and Alerts for a vCloud Air Reservation

You can associate custom properties with a vRealize Automation reservation. You can also configure alerts to send email notifications when reservation resources are low.

What to do next

You can configure optional reservation policies or begin preparing for provisioning.

Users who are authorized to create blueprints can create them now.

Specify vCloud Air Reservation Information

You can create a reservation for each vCloud Air machine subscription or OnDemand resource. Each reservation is configured for a specific business group to grant them access to request machines.

You can control the display of reservations when adding, editing, or deleting by using the **Filter By Category** option on the Reservations page. Note that test agent reservations do not appear in the reservations list when filtering by category.

Note After you create a reservation, you cannot change the business group or compute resource associations.

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.
- Verify that a tenant administrator created at least one business group.
- Verify that a compute resource exists.
- Configure network settings.
- (Optional) Configure network profile information.

Procedure

- 1 Select **Infrastructure > Reservations > Reservations**.
- 2 Click the **New** icon () and select the type of reservation to create.
The available cloud reservation types are Amazon, OpenStack, vCloud Air, and vCloud Director.
Select **vCloud Air**.
- 3 (Optional) Select an existing reservation from the **Copy from existing reservation** drop-down menu.
Data from the selected reservation appears. You can make changes as required for your new reservation.
- 4 Enter a name in the **Name** text box.
- 5 Select a tenant from the **Tenant** drop-down menu.
- 6 Select a business group from the **Business group** drop-down menu.
Only users in this business group can provision machines by using this reservation.
- 7 (Optional) Select a reservation policy from the **Reservation policy** drop-down menu.
This option requires that one or more reservation policies exist. You can edit the reservation later to specify a reservation policy.
You use a reservation policy to restrict provisioning to specific reservations.
- 8 Enter a number in the **Priority** text box to set the priority for the reservation.
The priority is used when a business group has more than one reservation. A reservation with priority 1 is used for provisioning over a reservation with priority 2.
- 9 (Optional) Deselect the **Enable this reservation** check box if you do not want this reservation active.

Do not navigate away from this page. Your reservation is not complete.

Specify Resources and Network Settings for a vCloud Air Reservation

Specify resource and network settings available to vCloud Air machines that are provisioned from this vRealize Automation reservation.

The available resource allocation models for machines provisioned from a vCloud Director reservation are Allocation Pool, Pay As You Go, and Reservation Pool. For Pay As You Go, you do not need to specify storage or memory amounts but do need to specify a priority for the storage path. For details about these allocation models, see vCloud Air documentation.

You can specify a standard or disk-level storage profile. Multi-level disk storage is available vCloud Air endpoints.

For integrations that use Storage Distributed Resource Scheduler (SDRS) storage, you can select a storage cluster to allow SDRS to automatically handle storage placement and load balancing for machines provisioned from this reservation. The SDRS automation mode must be set to Automatic. Otherwise, select a datastore within the cluster for standalone datastore behavior. SDRS is not supported for FlexClone storage devices.

Note Reservations defined for vCloud Air endpoints and vCloud Director endpoints do not support the use of network profiles for provisioning machines.

Prerequisites

[Specify vCloud Director Reservation Information.](#)

Procedure

- 1 Click the **Resources** tab.
- 2 Select a compute resource on which to provision machines from the **Compute resource** drop-down menu.

Only templates located on the cluster you select are available for cloning with this reservation.
- 3 Select an allocation model.
- 4 (Optional) Enter a number in the **Machine quota** text box to set the maximum number of machines that can be provisioned on this reservation.

Only machines that are powered on are counted towards the quota. Leave blank to make the reservation unlimited.
- 5 Specify the amount of memory, in GB, to be allocated to this reservation from the Memory table.

The overall memory value for the reservation is derived from your compute resource selection.
- 6 Select one or more listed storage paths.

The available storage path options are derived from your compute resource selection.
 - a Enter a value in the **This Reservation Reserved** text box to specify how much storage to allocate to this reservation.
 - b Enter a value in the **Priority** text box to specify the priority value for the storage path relative to other storage paths that pertain to this reservation.

The priority is used for multiple storage paths. A storage path with priority 0 is used before a path with priority 1.
 - c Click the **Disable** option if you do not want to enable the storage path for use by this reservation.
 - d Repeat this step to configure clusters and datastores as needed.
- 7 Click the **Network** tab.

8 Configure a network path for machines provisioned by using this reservation.

- a (Optional) If the option is available, select a storage endpoint from the **Endpoint** drop-down menu.

The FlexClone option is visible in the endpoint column if a NetApp ONTAP endpoint exists and if the host is virtual. If there is a NetApp ONTAP endpoint, the reservation page displays the endpoint assigned to the storage path. When you add, update, or delete an endpoint for a storage path, the change is visible in all the applicable reservations.

When you add, update, or delete an endpoint for a storage path, the change is visible in the reservation page.

- b Select a network paths for machines provisioned by this reservation from the **Network Paths** list.
- c (Optional) Select a listed network profile from the **Network Profile** drop-down menu.

This option requires that one or more network profiles exists.

You can select more than one network path on a reservation, but only one network is used when provisioning a machine.

You can save the reservation now by clicking **Save**. Or you can add custom properties to further control reservation specifications. You can also configure email alerts to send notifications when resources allocated to this reservation become low.

Specify Custom Properties and Alerts for a vCloud Air Reservation

You can associate custom properties with a vRealize Automation reservation. You can also configure alerts to send email notifications when reservation resources are low.

Custom properties and email alerts are optional configurations for the reservation. If you do not want to associate custom properties or set alerts, click **Save** to finish creating the reservation.

You can add as many custom properties as apply to your needs.

If configured, alerts are generated daily, rather than when the specified thresholds are reached.

Important Notifications are only sent if email alerts are configured and notifications are enabled.

Alerts are not available for Pay As You Go reservations that were created with no specified limits.

Prerequisites

[Specify Resources and Network Settings for a vCloud Air Reservation](#)

Procedure

- 1 Click the **Properties** tab.
- 2 Click **New**.
- 3 Enter a valid custom property name.
- 4 If applicable, enter a property value.

- 5 (Optional) Check the **Encrypted** check box to encrypt the property value.
- 6 (Optional) Check the **Prompt User** check box to require that the user enter a value.
This option cannot be overridden when provisioning.
- 7 Click **Save**.
- 8 (Optional) Add any additional custom properties.
- 9 Click the **Alerts** tab.
- 10 Enable the **Capacity Alerts** check box to configure alerts to be sent.
- 11 Use the slider to set thresholds for available resource allocation.
- 12 Enter the AD user or group names (not email addresses) to receive alert notifications in the **Recipients** text box.
Enter a name on each line. Press Enter to separate multiple entries.
- 13 Select **Send alerts to group manager** to include group managers in the email alerts.
The email alerts are sent to the users included in the business group **Send manager emails to** list.
- 14 Specify a reminder frequency (days).
- 15 Click **Save**.

The reservation is saved and appears in the Reservations list.

Create a vCloud Director Reservation

You must allocate resources to machines by creating a vRealize Automation reservation before members of a business group can request machine provisioning.

Each business group must have at least one reservation for its members to provision machines of that type.

Procedure

- 1 [Specify vCloud Director Reservation Information](#)
You can create a reservation for each vCloud Director organization virtual datacenter (VDC). Each reservation is configured for a specific business group to grant them access to request machines on a specified compute resource.
- 2 [Specify Resources and Network Settings for a vCloud Director Reservation](#)
Specify resource and network settings available to vCloud Director machines that are provisioned from this vRealize Automation reservation.
- 3 [Specify Custom Properties and Alerts for vCloud Director Reservations](#)
You can associate custom properties with a vRealize Automation reservation. You can also configure alerts to send email notifications when reservation resources are low.

What to do next

You can configure optional reservation policies or begin preparing for provisioning.

Users who are authorized to create blueprints can create them now.

Specify vCloud Director Reservation Information

You can create a reservation for each vCloud Director organization virtual datacenter (VDC). Each reservation is configured for a specific business group to grant them access to request machines on a specified compute resource.

You can control the display of reservations when adding, editing, or deleting by using the **Filter By Category** option on the Reservations page. Note that test agent reservations do not appear in the reservations list when filtering by category.

Note After you create a reservation, you cannot change the business group or compute resource associations.

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.
- Verify that a tenant administrator created at least one business group.
- Verify that a compute resource exists.
- Configure network settings.
- (Optional) Configure network profile information.

Procedure

- 1 Select **Infrastructure > Reservations > Reservations**.
- 2 Click the **New** icon () and select the type of reservation to create.
The available cloud reservation types are Amazon, OpenStack, vCloud Air, and vCloud Director.
Select **vCloud Director**.
- 3 (Optional) Select an existing reservation from the **Copy from existing reservation** drop-down menu.
Data from the selected reservation appears. You can make changes as required for your new reservation.
- 4 Enter a name in the **Name** text box.
- 5 Select a tenant from the **Tenant** drop-down menu.
- 6 Select a business group from the **Business group** drop-down menu.
Only users in this business group can provision machines by using this reservation.

- 7 (Optional) Select a reservation policy from the **Reservation policy** drop-down menu.

This option requires that one or more reservation policies exist. You can edit the reservation later to specify a reservation policy.

You use a reservation policy to restrict provisioning to specific reservations.

- 8 Enter a number in the **Priority** text box to set the priority for the reservation.

The priority is used when a business group has more than one reservation. A reservation with priority 1 is used for provisioning over a reservation with priority 2.

- 9 (Optional) Deselect the **Enable this reservation** check box if you do not want this reservation active.

Do not navigate away from this page. Your reservation is not complete.

Specify Resources and Network Settings for a vCloud Director Reservation

Specify resource and network settings available to vCloud Director machines that are provisioned from this vRealize Automation reservation.

The available resource allocation models for machines provisioned from a vCloud Director reservation are Allocation Pool, Pay As You Go, and Reservation Pool. For Pay As You Go, you do not need to specify storage or memory amounts but do need to specify a priority for the storage path. For details about these allocation models, see vCloud Director documentation.

You can specify a standard or disk-level storage profile. Multi-level disk storage is available for vCloud Director 5.6 and greater endpoints. Multi-level disk storage is not supported for vCloud Director 5.5 endpoints.

For integrations that use Storage Distributed Resource Scheduler (SDRS) storage, you can select a storage cluster to allow SDRS to automatically handle storage placement and load balancing for machines provisioned from this reservation. The SDRS automation mode must be set to Automatic. Otherwise, select a datastore within the cluster for standalone datastore behavior. SDRS is not supported for FlexClone storage devices.

Note Reservations defined for vCloud Air endpoints and vCloud Director endpoints do not support the use of network profiles for provisioning machines.

Prerequisites

[Specify vCloud Director Reservation Information.](#)

Procedure

- 1 Click the **Resources** tab.
- 2 Select a compute resource on which to provision machines from the **Compute resource** drop-down menu.

Only templates located on the cluster you select are available for cloning with this reservation.
- 3 Select an allocation model.

- 4 (Optional) Enter a number in the **Machine quota** text box to set the maximum number of machines that can be provisioned on this reservation.

Only machines that are powered on are counted towards the quota. Leave blank to make the reservation unlimited.

- 5 Specify the amount of memory, in GB, to be allocated to this reservation from the Memory table.

The overall memory value for the reservation is derived from your compute resource selection.

- 6 Select one or more listed storage paths.

The available storage path options are derived from your compute resource selection.

- a Enter a value in the **This Reservation Reserved** text box to specify how much storage to allocate to this reservation.

- b Enter a value in the **Priority** text box to specify the priority value for the storage path relative to other storage paths that pertain to this reservation.

The priority is used for multiple storage paths. A storage path with priority 0 is used before a path with priority 1.

- c Click the **Disable** option if you do not want to enable the storage path for use by this reservation.
- d Repeat this step to configure clusters and datastores as needed.

- 7 Click the **Network** tab.

- 8 Configure a network path for machines provisioned by using this reservation.

- a (Optional) If the option is available, select a storage endpoint from the **Endpoint** drop-down menu.

The FlexClone option is visible in the endpoint column if a NetApp ONTAP endpoint exists and if the host is virtual. If there is a NetApp ONTAP endpoint, the reservation page displays the endpoint assigned to the storage path. When you add, update, or delete an endpoint for a storage path, the change is visible in all the applicable reservations.

When you add, update, or delete an endpoint for a storage path, the change is visible in the reservation page.

- b Select a network paths for machines provisioned by this reservation from the **Network Paths** list.
- c (Optional) Select a listed network profile from the **Network Profile** drop-down menu.

This option requires that one or more network profiles exists.

You can select more than one network path on a reservation, but only one network is used when provisioning a machine.

You can save the reservation now by clicking **Save**. Or you can add custom properties to further control reservation specifications. You can also configure email alerts to send notifications when resources allocated to this reservation become low.

Specify Custom Properties and Alerts for vCloud Director Reservations

You can associate custom properties with a vRealize Automation reservation. You can also configure alerts to send email notifications when reservation resources are low.

Custom properties and email alerts are optional configurations for the reservation. If you do not want to associate custom properties or set alerts, click **Save** to finish creating the reservation.

You can add as many custom properties as apply to your needs.

If configured, alerts are generated daily, rather than when the specified thresholds are reached.

Important Notifications are only sent if email alerts are configured and notifications are enabled.

Alerts are not available for Pay As You Go reservations that were created with no specified limits.

Prerequisites

[Specify Resources and Network Settings for a vCloud Director Reservation.](#)

Procedure

- 1 Click the **Properties** tab.
- 2 Click **New**.
- 3 Enter a valid custom property name.
- 4 If applicable, enter a property value.
- 5 (Optional) Check the **Encrypted** check box to encrypt the property value.
- 6 (Optional) Check the **Prompt User** check box to require that the user enter a value.
This option cannot be overridden when provisioning.
- 7 Click **Save**.
- 8 (Optional) Add any additional custom properties.
- 9 Click the **Alerts** tab.
- 10 Enable the **Capacity Alerts** check box to configure alerts to be sent.
- 11 Use the slider to set thresholds for available resource allocation.
- 12 Enter the AD user or group names (not email addresses) to receive alert notifications in the **Recipients** text box.
Enter a name on each line. Press Enter to separate multiple entries.
- 13 Select **Send alerts to group manager** to include group managers in the email alerts.
The email alerts are sent to the users included in the business group **Send manager emails to** list.
- 14 Specify a reminder frequency (days).
- 15 Click **Save**.

The reservation is saved and appears in the Reservations list.

Create a Reservation for Microsoft Azure

Create an Azure reservation for a specific business group to grant users in that group the ability to request Azure virtual machines on a specified compute resource.

If your deployment supports single sign-on through a VPN tunnel, you can configure support for this functionality with Azure virtual machines using the settings on the Properties tab.

Note Ignore the Alerts tab when creating an Azure reservation as it does not apply. After you create a reservation, you cannot change the business group associations. Also, unlike other machine types, there is no direct link between an Azure reservation and a blueprint.

You can control the display of reservations when adding, editing, or deleting by using the **Filter By Category** option on the Reservations page. Note that test agent reservations do not appear in the reservations list when filtering by category.

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.
- Verify that a tenant administrator created at least one business group.
- (Optional) Configure network profile information.
- Verify that you have access to any required Azure resources.
- Verify that any required key pairs exist. See *Configuring vRealize Automation* for information about key pairs.
- Obtain a valid Azure Subscription ID, and this ID must match the one used with the applicable Azure endpoint. If you use multiple Azure subscriptions, you must create a reservation for each subscription.
- If your deployment supports single sign-on through a VPN tunnel, you must configure the appropriate VPC connectivity before creating a reservation. See [Configure Network-to-Azure VPC Connectivity](#).

Configure Microsoft Azure Basic Reservation Information

Specify basic information for a Microsoft Azure reservation.

All information on the Reservation Information page are required except the Reservation Policy. All information on subsequent Azure reservation pages is optional.

Procedure

- 1 Select **Infrastructure > Administration > Reservations**.
- 2 Click the **New** icon () and select the type of reservation to create.
Select **Azure**.
- 3 (Optional) Select an existing reservation from the **Copy from existing reservation** drop-down menu.
Data from the selected reservation appears. You can make changes as required for your new reservation.
- 4 Enter a name in the **Name** text box.

- 5 Select a business group from the **Business group** drop-down menu.

Only users in this business group can provision machines by using this reservation.

- 6 Ignore the **Reservation policy** text box, as it does not apply to Azure reservations.

- 7 Enter a number in the **Priority** text box to set the priority for the reservation.

The priority is used when a business group has more than one reservation. A reservation with priority 1 is used for provisioning over a reservation with priority 2.

- 8 (Optional) Deselect the **Enable this reservation** check box if you do not want this reservation active.

- 9 Click **OK**.

Configure Azure Reservation Resource Information

When setting up an Azure reservation, you can assign resource group and storage account information based on the Azure instance you are using. When you set up a reservation, the vRealize Automation provisioning logic attempts to allocate resources, such as resource groups and storage accounts, according to the resource information specified by the reservation while provisioning a virtual machine.

You can configure Resource Group and Storage Account information for an Azure virtual machine in the reservation, but you can also choose to leave these fields blank in the reservation. If you leave the fields blank, the default resource group and storage account information related to the specified Azure subscription ID will be used for any related blueprints. You can also update this information when creating a blueprint or when you provision a virtual machine.

Prerequisites

Obtain the subscription ID for your Azure instance.

Procedure

- 1 Type or paste your Azure subscription ID in the **Subscription ID** text box.

- 2 Select the location for the reservation by clicking the **Location** drop-down.

You can leave this field blank to create a location agnostic reservation, but if you do location information must be specified either when creating a blueprint or when provisioning an Azure virtual machine.

- 3 Click **New** in the Resource Groups table.

- a Paste the appropriate Resource Group name information from your Azure instance in the **Name** text box.

Note The **Name** box cannot be left empty.

- b Assign a numerical priority value in the **Priority** text box.

This assignment determines priority when a Resource Group has more than one resource group, with lower numbers taking precedence.

- c Click **Save** to add the Resource Group to the reservation.

4 Click **New** in the Storage Accounts table.

- a Paste the appropriate Storage Account name information from your Azure instance in the **Name** text box.

Note The **Name** box cannot be left empty.

- b Assign a numerical priority value in the **Priority** text box.
- c Click **Save** to add the Storage Account to the reservation.

This assignment determines priority when a reservation has more than one Storage Account, with lower numbers taking precedence.

5 Click **OK** to proceed to the next tab.

Configure Azure Properties

You can add custom properties to an Azure reservation to support options such as VPN tunneling to support communication between multiple networks. This functionality also facilitates the addition of software components to blueprints.

You must create custom properties that define the appropriate URLs to support VPN tunneling on your network. In addition, you must create properties that define the path to the Azure tunneling configuration scripts downloaded previously.

Use the private IP address of your Azure tunnel physical machine and port 1443, which you assigned for *vRealize_automation_appliance_fqdn* when you invoked the SSH tunnel.

The following table shows the names and values for the properties required to support VPN tunneling.

Name	Value
Azure.Windows.ScriptPath	Specifies the path to the downloaded script that configures tunneling for Windows-based systems. Update the path as appropriate for your deployment.
Azure.Linux.ScriptPath	Specifies the path to the downloaded script that configures tunneling for Linux-based systems. Update the path as appropriate for your deployment.
agent.download.url	Specifies the URL for the VPN agent on your deployment. The URL format is <code>https:// Private_IP:1443/software-service//resources/noble-agent.jar</code>
software.agent.service.url	Enter the VPN software agent service URL for your deployment, The URL format is <code>https:// Private_IP:1443/software-service/api</code>
software.ebs.url	Enter the event broker service URL for your deployment. The URL format is <code>https:// Private_IP:1443/event-broker-service/api</code>

Prerequisites

- Download the VMware-supplied Azure scripts from the **Guest and Software Agent Installers** page on your vRealize Automation Appliance.

These scripts install Azure extensions required to support VPN tunneling. There are two scripts: `script.ps1` and `script.sh`. The `.ps1` file is for Windows systems, and the `.sh` file is for Linux systems.

- a Run `https://vrealize-automation-appliance-fqdn/software` to open the VMware vRealize Automation Appliance page.
- b Click the **Guest and software agents** link under the To install vRealize Automation components (IaaS, Guest and Software Agents, Tools) heading.
- c Download the Azure script files under the Azure Machines heading. Save the script files to an appropriate location. You must point to this location when configuring Azure reservation custom properties.

Procedure

- 1 Click the **Properties** tab.
- 2 Click **New**.
- 3 Enter the appropriate Name and Value for the custom property in the Properties dialog box.
- 4 As you create each property, click **OK** on the dialog box to add that property.
- 5 When you finish adding all required properties, click **OK** to save your settings.

What to do next

After you create the custom properties to support VPN tunneling, you can create software components for your Azure blueprints. See *Configuring vRealize Automation* for more information.

When setting up a software component for Azure, select **Azure Virtual Machine** in the Container drop-down on the New Software page.

Configure Azure Reservation Network Information

You can configure virtual network and load balancer information for an Azure virtual machine in the reservation.

You can also choose to leave this page partly or completely blank and configure virtual network and load balancer information when you provision a virtual machine.

If you specify a network profile and do not specify a subnet, then the name of the first existing network range of the specified network profile is used as the subnet name. If a network profile is specified, you can choose to leave the vNet text box blank. In this case, the name of this first network range of the specified network profile is used as the subnet name, and the vNet name is resolved to the first Azure vNet that contains an applicable subnet.

Prerequisites

Obtain the appropriate virtual network and load balancer information from your Azure instance where applicable.

Procedure

- 1 Click **New** in the Networks table to configure the appropriate Azure virtual network to use with your virtual machine.

- a Paste the appropriate vNet name information from your Azure instance into the **vNet** text box.
- b Paste the appropriate Subnet name information from your Azure instance into the **Subnet** text box.

The Subnet specification is optional. If you leave this box empty, the subnet of the specified vNet is used by default.

- c Type or paste the appropriate name in the **Network Profile** text box. You can use the network profile in the blueprint to associate a network interface card with a network.

The network profile specification is optional. Use if you want to create your blueprint based on the network profile is defined in vRealize Automation rather than have it coupled with Azure network constructs.

- d Assign a numerical priority value in the **Priority** text box if applicable.

This assignment determines priority when a virtual network has more than one reservation, with lower numbers taking precedence.

- e Click **Save** to add the Resource Group to the reservation.

- 2 Click **New** in the Load Balancers table if you are deploying multiple machines and use a load balancer.

- a Paste the appropriate load balancer name from your Azure instance into the **Name** text box.
- b Paste the appropriate name from your Azure instance into the **Backend Address Pool** text box.
- c Assign a numerical priority value in the **Priority** text box if applicable.

This assignment determines priority when a virtual network has more than one load balancer, with lower numbers taking precedence.

- d Click **Save** to add the load balancer to the reservation.

- 3 Click **New** in the Security Groups table if you are deploying multiple machines that must communicate through a firewall.

- a Paste the security group name from your Azure instance into the **Name** text box.
- b Assign a numerical priority value in the **Priority** text box if applicable.

This assignment determines priority when a virtual network has more than one security group, with lower numbers taking precedence.

- c Click **Save** to add the security group to the reservation.

- 4 Click **OK**.

Scenario: Create an Amazon Reservation for a Proof of Concept Environment

Because you used an SSH tunnel to temporarily establish network-to-Amazon VPC connectivity for your proof of concept environment, you have to add custom properties to your Amazon reservations to ensure the Software bootstrap agent and guest agent run communications through the tunnel.

Network-to-Amazon VPC connectivity is only required if you want to use the guest agent to customize provisioned machines, or if you want to include Software components in your blueprints. For a production environment, you would configure this connectivity officially through Amazon Web Services, but because you are working in a proof of concept environment, you configured a temporary SSH tunnel instead.

Using your fabric administrator privileges, you create a reservation to allocate your Amazon Web Services resources and you include several custom properties to support the SSH tunneling. You also configure the reservation on the same region and VPC as your tunnel machine.

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.
- Configure an SSH tunnel to establish network-to-Amazon VPC connectivity. Make a note of the subnet, security group, and private IP address of your Amazon AWS tunnel machine. See [Scenario: Configure Network-to-Amazon VPC Connectivity for a Proof of Concept Environment](#).
- Create a business group for members of your IT organization who need to architect blueprints in your proof of concept environment. See [Create a Business Group](#).
- Verify that a tenant administrator created at least one business group.

Procedure

1 [Scenario: Specify Amazon AWS Reservation Information for a Proof of Concept Environment](#)

You want to reserve resources for your team of blueprint architects so they can test the functionality in your proof of concept environment, so you configure this reservation to allocate resources to your architects business group.

2 [Scenario: Specify Amazon AWS Network Settings for a Proof of Concept Environment](#)

You configure the reservation to use the same region and networking settings that your tunnel machine is using, and you restrict the number of machines that can be powered on for this reservation to manage resource usage.

3 [Scenario: Specify Custom Properties to Run Agent Communications Through Your Tunnel](#)

When you configured network-to-Amazon VPC connectivity, you configured port forwarding to allow your Amazon AWS tunnel machine to access vRealize Automation resources.

Scenario: Specify Amazon AWS Reservation Information for a Proof of Concept Environment

You want to reserve resources for your team of blueprint architects so they can test the functionality in your proof of concept environment, so you configure this reservation to allocate resources to your architects business group.

Note After you create a reservation, you cannot change the business group or compute resource associations.

Procedure

- 1 Select **Infrastructure > Reservations > Reservations**.
- 2 Click the **New** icon (+) and select the type of reservation to create.
Select **Amazon**.
- 3 Enter **Amazon Tunnel POC** in the **Name** text box.
- 4 Select the business group you created for your blueprint architects from the **Business Group** drop-down menu.
- 5 Enter a **1** in the **Priority** text box to set this reservation as the highest priority.

You configured the business group and the priority for the reservation, but you still need to allocate resources and configure the custom properties for the SSH tunnel.

Scenario: Specify Amazon AWS Network Settings for a Proof of Concept Environment

You configure the reservation to use the same region and networking settings that your tunnel machine is using, and you restrict the number of machines that can be powered on for this reservation to manage resource usage.

Procedure

- 1 Click the **Resources** tab.
- 2 Select a compute resource on which to provision machines from the **Compute resource** drop-down menu.
Select the Amazon AWS region where your tunnel machine is located.
- 3 (Optional) Enter a number in the **Machine quota** text box to set the maximum number of machines that can be provisioned on this reservation.
Only machines that are powered on are counted towards the quota. Leave blank to make the reservation unlimited.
- 4 Select **Specify Key Pair** from the **Key pair** drop-down menu.
Because this is a proof of concept environment, you choose to share a single key pair for all machines provisioned by using this reservation.
- 5 Select the key pair you want to share with your architect users from the **Key Pair** drop-down menu.
- 6 Enable the **Assign to a subnet in a VPC** checkbox.
- 7 Select the same subnet and security groups that your tunnel machine is using.

You configured the reservation to use the same region and networking settings as your tunnel machine, but you still need to add custom properties to ensure the Software bootstrap agent and guest agent run communications through the tunnel.

Scenario: Specify Custom Properties to Run Agent Communications Through Your Tunnel

When you configured network-to-Amazon VPC connectivity, you configured port forwarding to allow your Amazon AWS tunnel machine to access vRealize Automation resources.

You need to add tunnel custom properties on the reservation to configure the agents to access those ports.

Note If you are using a PAT or NAT system network between your organization's network and the vRealize Automation network, you can use these properties to access your private IP address and port.

Procedure

- 1 Click the **Properties** tab.
- 2 Click **New**.
- 3 Configure the tunnel custom properties.

Use the private IP address of your Amazon AWS tunnel machine and port 1443, which you assigned for *vRealize_automation_appliance_fqdn* when you invoked the SSH tunnel.

Option	Value
<code>software.ebs.url</code>	<code>https://Private_IP:1443/event-broker-service/api</code>
<code>software.agent.service.url</code>	<code>https://Private_IP:1443/software-service/api</code>
<code>agent.download.url</code>	<code>https://Private_IP:1443/software-service/resources/nobel-agent.jar</code>

- 4 Click **Save**.

You created a reservation to allocate Amazon AWS resources to your architects business group. You configured the reservation to support the guest agent and the Software bootstrap agent. Your architects can create blueprints that leverage the guest agent to customize deployed machines or include Software components.

Creating Virtual Category Reservations

A virtual category type reservation provides access to the provisioning services of a virtual machine deployment for a particular vRealize Automation business group. Available virtual reservation types include vSphere, Hyper-V, KVM, SCVMM, and XenServer.

A reservation is a share of the memory, CPU, networking, and storage resources of one compute resource allocated to a particular vRealize Automation business group.

A business group can have multiple reservations on one endpoint or reservations on multiple endpoints.

To provision virtual machines, a business group must have at least one reservation on a virtual compute resource. Each reservation is for one business group only, but a business group can have multiple reservations on a single compute resource, or multiple reservations on compute resources of different types.

In addition to defining the share of fabric resources allocated to the business group, a reservation can define policies, priorities, and quotas that determine machine placement.

To provision successfully, the reservation must have sufficient available storage. The reservation's storage availability depends on:

- How much storage is available on the datastore/cluster.
- How much of that storage is reserved for that datastore/cluster.
- How much of that storage is already allocated in vRealize Automation

For example, even if the vCenter Server has storage available for the datastore/cluster, if sufficient storage is not reserved in the reservation then provisioning fails with a "No reservation is available to allocate..." error. The allocated storage on a reservation depends on the number of VMs (regardless of their state) on that specific reservation. See the VMware Knowledge Base article *Machine XXX: No reservation is available to allocate within the group XXX. Total XX GB of storage was requested (2151030)* at <http://kb.vmware.com/kb/2151030> for more information.

Understanding Selection Logic for Reservations

When a member of a business group create a provisioning request for a virtual machine, vRealize Automation selects a machine from one of the reservations that are available to that business group.

The reservation for which a machine is provisioned must satisfy the following criteria:

- The reservation must be of the same platform type as the blueprint from which the machine was requested.

A generic virtual blueprint can be provisioned on any type of virtual reservation.

- The reservation must be enabled.
- The compute resource must be accessible and not in maintenance mode.
- The reservation must have capacity remaining in its machine quota or have an unlimited quota.

The allocated machine quota includes only machines that are powered on. For example, if a reservation has a quota of 50, and 40 machines have been provisioned but only 20 of them are powered on, the reservation's quota is 40 percent allocated, not 80 percent.

- The reservation must have sufficient unallocated memory and storage resources to provision the machine.

When a virtual reservation's machine quota, memory, or storage is fully allocated, no further virtual machines can be provisioned from it. Resources may be reserved beyond the physical capacity of a virtualization compute resource (overcommitted), but when the physical capacity of a compute resource is 100% allocated, no further machines can be provisioned on any reservations with that compute resource until the resources are reclaimed.

- If the blueprint has specific network settings, the reservation must have the same networks.

If the blueprint or reservation specifies a network profile for static IP address assignment, an IP address must be available to assign to the new machine.

- If the blueprint or request specifies a location, the compute resource must be associated with that location.

If the value of the custom property *VRM.Datacenter.Policy* is **Exact** and there is no reservation for a compute resource associated with that location that satisfies all the other criteria, then provisioning fails.

If the value of *VRM.Datacenter.Policy* is **NotExact** and there is no reservation for a compute resource associated with that location that satisfies all the other criteria, provisioning can proceed on another reservation regardless of location. This option is the default.

- If the blueprint or request specifies the custom property *VirtualMachine.Host.TpmEnabled*, trusted hardware must be installed on the compute resource for the reservation.
- If the blueprint specifies a reservation policy, the reservation must belong to that reservation policy.

Reservation policies are a way to guarantee that the selected reservation satisfies any additional requirements for provisioning machines from a specific blueprint. For example, you can use reservation policies to limit provisioning to compute resources with a specific template for cloning.

If no reservation is available that meets all of the selection criteria, provisioning fails.

If multiple reservations meet all of the criteria, the reservation from which to provision a requested machine is determined by the following logic:

- A reservation with a lower priority value is selected before a reservation with a higher priority value.
- If multiple reservations have the same priority, the reservation with the lowest percentage of its machine quota allocated is selected.
- If multiple reservations have the same priority and quota usage, machines are distributed among reservations in round-robin fashion.

Note While round-robin selection of network profiles is not supported, round-robin selection of networks (if any) is supported, which can be associated with different network profiles.

If multiple storage paths are available on a reservation with sufficient capacity to provision the machine volumes, storage paths are selected according to the following logic:

- If the blueprint or request specifies a storage reservation policy, the storage path must belong to that storage reservation policy.

If the value of the custom property *VirtualMachine.DiskN.StorageReservationPolicyMode* is **NotExact** and there is no storage path with sufficient capacity within the storage reservation policy, then provisioning can proceed with a storage path outside the specified storage reservation policy. The default value of *VirtualMachine.DiskN.StorageReservationPolicyMode* is **Exact**.

- A storage path with a lower priority value is selected before a storage path with a higher priority value.
- If multiple storage paths have the same priority, machines are distributed among storage paths in round-robin fashion.

Creating a vSphere Reservation for NSX Network and Security Virtualization

You can create a vSphere reservation to assign external networks and routed gateways to network profiles for networks, specify the transport zone, and assign security groups to machine components.

If you have configured NSX you can specify NSX transport zone, Edge and routed gateway reservation policy, and app isolation settings when you create or edit a blueprint. These settings are available on the **NSX Settings** tab on the **Blueprint** and **Blueprint Properties** pages.

The network and security component settings that you add to the design canvas are derived from your NSX configuration and require that you have run data collection for the NSX inventory for vSphere clusters. Network and security components are specific to NSX and are available for use with vSphere machine components only. For information about configuring NSX, see *NSX Administration Guide*.

When vRealize Automation provisions machines with NAT or routed networking, it provisions a routed gateway as the network router. The Edge or routed gateway is a management machine that consumes compute resources. It also manages the network communications for the provisioned machine components. The reservation used to provision the Edge or routed gateway determines the external network used for NAT and routed network profiles. It also determines the reservation Edge or routed gateway used to configure routed networks. The reservation routed gateway links routed networks together with entries in the routing table.

You can specify an Edge or routed gateway reservation policy to identify which reservations to use when provisioning the machines using the Edge or routed gateway. By default, vRealize Automation uses the same reservations for the routed gateway and the machine components.

You select one or more security groups in the reservation to enforce baseline security policy for all component machines provisioned with that reservation in vRealize Automation. Every provisioned machine is added to these specified security groups.

Successful provisioning requires the transport zone of the reservation to match the transport zone of a machine blueprint when that blueprint defines machine networks. Similarly, provisioning a machine's routed gateway requires that the transport zone defined in the reservation matches the transport zone defined for the blueprint.

When you select an Edge or routed gateway and network profile on a reservation when configuring routed networks, select the network path to be used in linking routed networks together and assign it the external network profile used to configure the routed network profile. The list of network profiles available to be assigned to a network path is filtered to match the subnet of the network path based on the subnet mask and primary IP address selected for the network interface.

If you want to use an Edge or routed gateway in vRealize Automation reservations, configure the routed gateway externally in the NSX environment and then run inventory data collection. For NSX, you must have a working NSX Edge instance before you can configure the default gateway for static routes or dynamic routing details for an Edge services gateway or distributed router. See *NSX Administration Guide*.

Create a Reservation for Hyper-V, KVM, SCVMM, vSphere , or XenServer

You must allocate resources to machines by creating a reservation before members of a business group can request machine provisioning.

Each business group must have at least one reservation for its members to provision machines of that type. For example, a business group with a vSphere reservation, but not a KVM (RHEV) reservation, cannot request a KVM (RHEV) virtual machine. In this example, the business group must be allocated a reservation specifically for KVM (RHEV) resources.

Procedure

1 Specify Virtual Reservation Information

Each reservation is configured for a specific business group to grant users access to request machines on a specified compute resource.

2 Specify Resource and Networking Settings for a Virtual Reservation

Specify resource and network settings for provisioning machines from this vRealize Automation reservation.

3 Specify Custom Properties and Alerts for Virtual Reservations

You can associate custom properties with a vRealize Automation reservation. You can also configure alerts to send email notifications when reservation resources are low.

Specify Virtual Reservation Information

Each reservation is configured for a specific business group to grant users access to request machines on a specified compute resource.

You can control the display of reservations when adding, editing, or deleting by using the **Filter By Category** option on the Reservations page. Note that test agent reservations do not appear in the reservations list when filtering by category.

Note After you create a reservation, you cannot change the business group or compute resource associations.

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.
- Verify that a tenant administrator created at least one business group.
- Verify that a compute resource exists.
- Configure network settings.
- (Optional) Configure network profile information.

Procedure

1 Select **Infrastructure > Reservations > Reservations**.

2 Click the **New** icon () and select the type of reservation to create.

The available virtual reservation types are Hyper-V, KVM, SCVMM, vSphere, and XenServer.

For example, select **vSphere**.

- 3 (Optional) Select an existing reservation from the **Copy from existing reservation** drop-down menu.
Data from the selected reservation appears. You can make changes as required for your new reservation.
- 4 Enter a name in the **Name** text box.
- 5 Select a tenant from the **Tenant** drop-down menu.
- 6 Select a business group from the **Business group** drop-down menu.
Only users in this business group can provision machines by using this reservation.
- 7 (Optional) Select a reservation policy from the **Reservation policy** drop-down menu.
This option requires that one or more reservation policies exist. You can edit the reservation later to specify a reservation policy.
You use a reservation policy to restrict provisioning to specific reservations.
- 8 Enter a number in the **Priority** text box to set the priority for the reservation.
The priority is used when a business group has more than one reservation. A reservation with priority 1 is used for provisioning over a reservation with priority 2.
- 9 (Optional) Deselect the **Enable this reservation** check box if you do not want this reservation active.

Do not navigate away from this page. Your reservation is not complete.

Specify Resource and Networking Settings for a Virtual Reservation

Specify resource and network settings for provisioning machines from this vRealize Automation reservation.

You can select a FlexClone datastore in your reservation if you have a vSphere environment and storage devices that use Net App FlexClone technology. SDRS is not supported for FlexClone storage devices.

To provision successfully, the reservation must have sufficient available storage. The reservation's storage availability depends on:

- How much storage is available on the datastore/cluster.
- How much of that storage is reserved for that datastore/cluster.
- How much of that storage is already allocated in vRealize Automation

For example, even if the vCenter Server has storage available for the datastore/cluster, if sufficient storage is not reserved in the reservation then provisioning fails with a "No reservation is available to allocate..." error. The allocated storage on a reservation depends on the number of VMs (regardless of their state) on that specific reservation. See the VMware Knowledge Base article *Machine XXX: No reservation is available to allocate within the group XXX. Total XX GB of storage was requested (2151030)* at <http://kb.vmware.com/kb/2151030> for more information.

Prerequisites

[Specify Virtual Reservation Information.](#)

Procedure

- 1 Click the **Resources** tab.
- 2 Select a compute resource on which to provision machines from the **Compute resource** drop-down menu.

Only templates located on the cluster you select are available for cloning with this reservation.

During provisioning, machines are placed on a host that is connected to the local storage. If the reservation uses local storage, all the machines that are provisioned by the reservation are created on the host that contains that local storage. However, if you use the `VirtualMachine.Admin.ForceHost` custom property, which forces a machine to be provisioned to a different host, provisioning fails. Provisioning also fails if the template from which the machine is cloned is on local storage, but attached to a machine on a different cluster. In this case, provisioning fails because it cannot access the template.

- 3 (Optional) Enter a number in the **Machine quota** text box to set the maximum number of machines that can be provisioned on this reservation.

Only machines that are powered on are counted towards the quota. Leave blank to make the reservation unlimited.

- 4 Specify the amount of memory, in GB, to be allocated to this reservation from the Memory table.

The overall memory value for the reservation is derived from your compute resource selection.

- 5 Select one or more listed storage paths.

The available storage path options are derived from your compute resource selection.

For integrations that use Storage Distributed Resource Scheduler (SDRS) storage, you can select a storage cluster to allow SDRS to automatically handle storage placement and load balancing for machines provisioned from this reservation. The SDRS automation mode must be set to Automatic. Otherwise, select a datastore within the cluster for standalone datastore behavior. SDRS is not supported for FlexClone storage devices.

You can select either individual disks in the cluster or a storage cluster, but not both. If you select a storage cluster, SDRS controls storage placement and load balancing for machines that are provisioned from this reservation.

- 6 If available for the compute resource, select a resource pool in the **Resource Pool** drop-down menu.
- 7 Click the **Network** tab.

8 Configure a network path for machines provisioned by using this reservation.

- a (Optional) If the option is available, select a storage endpoint from the **Endpoint** drop-down menu.

The FlexClone option is visible in the endpoint column if a NetApp ONTAP endpoint exists and if the host is virtual. If there is a NetApp ONTAP endpoint, the reservation page displays the endpoint assigned to the storage path. When you add, update, or delete an endpoint for a storage path, the change is visible in all the applicable reservations.

When you add, update, or delete an endpoint for a storage path, the change is visible in the reservation page.

- b Select a network paths for machines provisioned by this reservation from the **Network Paths** list.
- c (Optional) Select a listed network profile from the **Network Profile** drop-down menu.

This option requires that one or more network profiles exists.

You can select more than one network path on a reservation, but only one network is used when provisioning a machine.

You can save the reservation now by clicking **Save**. Or you can add custom properties to further control reservation specifications. You can also configure email alerts to send notifications when resources allocated to this reservation become low.

Specify Custom Properties and Alerts for Virtual Reservations

You can associate custom properties with a vRealize Automation reservation. You can also configure alerts to send email notifications when reservation resources are low.

Custom properties and email alerts are optional configurations for the reservation. If you do not want to associate custom properties or set alerts, click **Save** to finish creating the reservation.

You can add as many custom properties as apply to your needs.

Important Notifications are only sent if email alerts are configured and notifications are enabled.

If configured, alerts are generated daily, rather than when the specified thresholds are reached.

Prerequisites

[Specify Resource and Networking Settings for a Virtual Reservation.](#)

Procedure

- 1 Click the **Properties** tab.
- 2 Click **New**.
- 3 Enter a valid custom property name.
- 4 If applicable, enter a property value.
- 5 (Optional) Check the **Encrypted** check box to encrypt the property value.

- 6 (Optional) Check the **Prompt User** check box to require that the user enter a value.
This option cannot be overridden when provisioning.
- 7 (Optional) Add any additional custom properties.
- 8 Click the **Alerts** tab.
- 9 Enable the **Capacity Alerts** check box to configure alerts to be sent.
- 10 Use the slider to set thresholds for available resource allocation.
- 11 Enter the AD user or group names (not email addresses) to receive alert notifications in the **Recipients** text box.
Enter a name on each line. Press Enter to separate multiple entries.
- 12 Select **Send alerts to group manager** to include group managers in the email alerts.
The email alerts are sent to the users included in the business group **Send manager emails to** list.
- 13 Specify a reminder frequency (days).
- 14 Click **Save**.

The reservation is saved and appears in the Reservations list.

What to do next

You can configure optional reservation policies or begin preparing for provisioning.

Users who are authorized to create blueprints can create them now.

Edit a Reservation to Assign a Network Profile

You can assign a network profile to a reservation, for example to enable static IP assignment for machines that are provisioned on that reservation.

You can also assign a network profile to a blueprint by using the custom property `VirtualMachine.NetworkN.ProfileName` on the **Properties** tab of the **New Blueprint** or **Blueprint Properties** page.

If you specify a network profile in a reservation and a blueprint, the blueprint value takes precedence. For example, if you specify a network profile in the blueprint by using the `VirtualMachine.NetworkN.ProfileName` custom property and in a reservation that is used by the blueprint, the network profile specified in the blueprint takes precedence. However, if the custom property is not used in the blueprint, and you select a network profile for a machine NIC, vRealize Automation uses the reservation network path for the machine NIC for which the network profile is specified.

Note This information does not apply to Amazon Web Services.

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.
- Create a network profile. See [Creating a Network Profile](#).

Procedure

- 1 Select **Infrastructure > Reservations > Reservations**.
- 2 Point to a reservation and click **Edit**.
- 3 Click the **Network** tab.
- 4 Assign a network profile to a network path.
 - a Select a network path on which to enable static IP addresses.
 The network path options are derived from settings on the **Resources** tab.
 - b Map an available network profile to the path by selecting a profile from the **Network Profile** drop-down menu.
 - c (Optional) Repeat this step to assign network profiles to additional network paths on this reservation.
- 5 Click **OK**.

Reservation Policies

You can use a reservation policy to control how reservation requests are processed. When you provision machines from the blueprint, provisioning is restricted to the resources specified in your reservation policy.

Reservation policies provide an optional means of controlling how reservation requests are processed. You can apply a reservation policy to a blueprint to restrict the machines provisioned from that blueprint to a subset of available reservations.

You can use a reservation policy to collect resources into groups for different service levels, or to make a specific type of resource easily available for a particular purpose. When a user requests a machine, it can be provisioned on any reservation of the appropriate type that has sufficient capacity for the machine. The following scenarios provide a few examples of possible uses for reservation policies:

- To ensure that provisioned machines are placed on reservations with specific devices that support NetApp FlexClone.
- To restrict provisioning of cloud machines to a specific region containing a machine image that is required for a specific blueprint.
- As an additional means of using a Pay As You Go allocation model for machine types that support that capability.

You can add multiple reservations to a reservation policy, but a reservation can belong to only one policy. You can assign a single reservation policy to more than one blueprint. A blueprint can have only one reservation policy.

Note Reservations defined for vCloud Air endpoints and vCloud Director endpoints do not support the use of network profiles for provisioning machines.

Note If you have SDRS enabled on your platform, you can allow SDRS to load balance storage for individual virtual machine disks, or all storage for the virtual machine. If you are working with SDRS datastore clusters, conflicts can occur when you use reservation policies and storage reservation policies. For example, if a standalone datastore or a datastore within an SDRS cluster is selected on one of the reservations in a policy or storage policy, your virtual machine storage might be frozen instead of driven by SDRS. If you request reprovisioning for a machine with storage placement on an SDRS cluster, the machine is deleted if the SDRS automation level is disabled.

Configure a Reservation Policy

You can create reservation policies to collect resources into groups for different service levels, or to make a specific type of resource easily available for a particular purpose. After you create the reservation policy, you then must populate it with reservations before tenant administrators and business group managers can use the policy effectively in a blueprint.

A reservation policy can include reservations of different types, but only reservations that match the blueprint type are considered when selecting a reservation for a particular request.

Procedure

1 Create a Reservation Policy

You can use reservation policies to group similar reservations together.

2 Assign a Reservation Policy to a Reservation

You can assign a reservation policy to a reservation when you create the reservation. You can also edit an existing reservation to assign a reservation policy to it, or change its reservation policy assignment.

Create a Reservation Policy

You can use reservation policies to group similar reservations together.

Create the reservation policy first, then add the policy to reservations to allow a blueprint creator to use the reservation policy in a blueprint.

The policy is created as an empty container.

You can control the display of reservation policies when adding, editing, or deleting by using the **Filter By Type** option on the Reservation Policies page.

Prerequisites

Log in to the vRealize Automation console as a **fabric administrator**.

Procedure

- 1 Select **Infrastructure > Reservations > Reservation Policies**.
- 2 Click **Add**.
- 3 Enter a name in the **Name** text box.
- 4 Select **Reservation Policy** from the **Type** drop-down menu.
- 5 Enter a description in the **Description** text box.
- 6 Click **Update** to save the policy.

Assign a Reservation Policy to a Reservation

You can assign a reservation policy to a reservation when you create the reservation. You can also edit an existing reservation to assign a reservation policy to it, or change its reservation policy assignment.

Prerequisites

[Create a Reservation Policy](#).

Procedure

- 1 Select **Infrastructure > Reservations > Reservations**.
- 2 Point to a reservation and click **Edit**.
- 3 Select a reservation policy from the **Reservation Policy** drop-down menu.
- 4 Click **Save**.

Storage Reservation Policies

You can create storage reservation policies to allow blueprint architects to assign the volumes of a virtual machine to different datastores for the vSphere, KVM (RHEV), and SCVMM platform types or different storage profiles for other resources, such as vCloud Air or vCloud Director resources.

Assigning the volumes of a virtual machine to different datastores or to a different storage profile allows blueprint architects to control and use storage space more effectively. For example, they might deploy the operating system volume to a slower, less expensive datastore, or storage profile, and the database volume to a faster datastore or storage profile.

Some machine endpoints only support a single storage profile, while others support multi-level disk storage. Multi-level disk storage is available for vCloud Director 5.6 and greater endpoints and for vCloud Air endpoints. Multi-level disk storage is not supported for vCloud Director 5.5 endpoints.

When you create a blueprint, you can assign a single datastore or a storage reservation policy that represents multiple datastores to a volume. When they assign a single datastore, or storage profile, to a volume, vRealize Automation uses that datastore or storage profile at provisioning time, if possible. When they assign a storage reservation policy to a volume, vRealize Automation uses one of its datastores, or storage profiles if working with other resources, such as vCloud Air or vCloud Director, at provisioning time.

A storage reservation policy is essentially a tag applied to one or more datastores or storage profiles by a fabric administrator to group datastores or storage profiles that have similar characteristics, such as speed or price. A datastore or storage profile can be assigned to only one storage reservation policy at a time, but a storage reservation policy can have many different datastores or storage profiles.

You can create a storage reservation policy and assign it to one or more datastores or storage profiles. A blueprint creator can then assign the storage reservation policy to a volume in a virtual blueprint. When a user requests a machine that uses the blueprint, vRealize Automation uses the storage reservation policy specified in the blueprint to select a datastore or storage profile for the machine's volume.

Note If you have SDRS enabled on your platform, you can allow SDRS to load balance storage for individual virtual machine disks, or all storage for the virtual machine. If you are working with SDRS datastore clusters, conflicts can occur when you use reservation policies and storage reservation policies. For example, if a standalone datastore or a datastore within an SDRS cluster is selected on one of the reservations in a policy or storage policy, your virtual machine storage might be frozen instead of driven by SDRS. If you request reprovisioning for a machine with storage placement on an SDRS cluster, the machine is deleted if the SDRS automation level is disabled.

Storage and memory that are assigned to a provisioned machine by a reservation are released when the machine to which they are assigned is deleted in vRealize Automation by the Destroy action. The storage and memory are not released if the machine is deleted in the vCenter Server.

For example, you cannot delete a reservation that is associated with machines in an existing deployment. If you move or delete deployed machines manually in the vCenter Server, vRealize Automation continues to recognize the deployed machines as live and prevents you from deleting associated reservations.

Configure a Storage Reservation Policy

You can create storage reservation policies to group datastores that have similar characteristics, such as speed or price. After you create the storage reservation policy, you must populate it with datastores before using the policy in a blueprint.

Procedure

1 Create a Storage Reservation Policy

You can use a storage reservation policy to group datastores that have similar characteristics, such as speed or price.

2 Assign a Storage Reservation Policy to a Datastore

You can associate a storage reservation policy to a compute resource. After the storage reservation policy is created, populate it with datastores. A datastore can belong to only one storage reservation policy. Add multiple datastores to create a group of datastores for use with a blueprint.

Create a Storage Reservation Policy

You can use a storage reservation policy to group datastores that have similar characteristics, such as speed or price.

The policy is created as an empty container.

You can control the display of reservation policies when adding, editing, or deleting by using the **Filter By Type** option on the Reservation Policies page.

Prerequisites

Log in to the vRealize Automation console as a **fabric administrator**.

Procedure

- 1 Select **Infrastructure > Reservations > Reservation Policies**.
- 2 Click **Add**.
- 3 Enter a name in the **Name** text box.
- 4 Select **Storage Reservation Policy** from the **Type** drop-down menu.
- 5 Enter a description in the **Description** text box.
- 6 Click **Update** to save the policy.

Assign a Storage Reservation Policy to a Datastore

You can associate a storage reservation policy to a compute resource. After the storage reservation policy is created, populate it with datastores. A datastore can belong to only one storage reservation policy. Add multiple datastores to create a group of datastores for use with a blueprint.

Prerequisites

[Create a Storage Reservation Policy](#).

Procedure

- 1 Select **Infrastructure > Compute Resources > Compute Resources**.
- 2 Point to a compute resource and click **Edit**.
- 3 Click the **Configuration** tab.
- 4 Locate the datastore to add to your storage reservation policy in the Storage table.
- 5 Click the **Edit** icon (✎) next to the desired **Storage Path** object.
- 6 Select a storage reservation policy from the **Storage Reservation Policy** column drop-down menu.
 After you provision a machine, you cannot change its storage reservation policy if doing so would change the storage profile on a disk.
- 7 Click the **Save** icon (✓).
- 8 Click **OK**.
- 9 (Optional) Assign additional datastores to your storage reservation policy.

Workload Placement

When you deploy a blueprint, workload placement uses collected data to recommend where to deploy the blueprint based on available resources. vRealize Automation and vRealize Operations Manager work together to provide placement recommendations for workloads in the deployment of new blueprints.

While vRealize Automation manages organizational policies, such as business groups, reservations, and quotas, it integrates with the capacity analytics of vRealize Operations Manager to place machines. Workload placement is only available for vSphere endpoints.

Workload Placement Terms Used

Several terms are used with workload placement.

- Clusters in vSphere map to compute resources in vRealize Automation.
- Reservations include compute and storage, where the storage can consist of individual datastores or datastore clusters. A reservation can include multiple datastores, datastore clusters, or both.
- Multiple reservations can refer to the same cluster.
- Virtual machines can move to multiple clusters.
- When workload placement is enabled, the provisioning workflow uses the placement policy to recommend where to deploy the blueprint.

Provisioning Blueprints with Workload Placement

When you use workload placement to provision blueprints, the provisioning workflow uses the reservations in vRealize Automation, and the placement optimization from vRealize Operations Manager.

- 1 vRealize Automation provides the governance rules to allow placement destinations.
- 2 vRealize Operations Manager provides placement optimization recommendations according to analytics data.
- 3 vRealize Automation continues the provisioning process according to the placement recommendations from vRealize Operations Manager.

If vRealize Operations Manager cannot provide a recommendation, or the recommendation cannot be used, then vRealize Automation falls back to its default placement logic.

When a developer selects a catalog item and completes the form to request the catalog item, vRealize Automation accounts for the following considerations to provision the virtual machines.

Table 2-16. Considerations to Provision Virtual Machines

Consideration	Effect
Policies	The vRealize Automation reservation policy might indicate more than one reservation.
Reservations	<p>vRealize Automation evaluates the request, and determines which reservations can satisfy the constraints made in the request.</p> <ul style="list-style-type: none"> ■ If placement is enabled and based on vRealize Operations Manager analytics, vRealize Automation passes the list of reservations to vRealize Operations Manager to determine which reservation is best suited for placement based on operational metrics. ■ If placement is not based on vRealize Operations Manager, vRealize Automation decides the placement based on priorities and availability. <p>The reservations are updated to track that resources have been consumed.</p> <p>If vRealize Operations Manager recommends a cluster or datastore that vRealize Automation considers to be out of capacity or no longer applicable, vRealize Automation logs the exception.</p> <p>vRealize Automation allows provisioning to continue according to its default placement mechanisms.</p>

To identify resources for a virtual machine, vRealize Automation provides a list of candidate reservations. Each candidate in the list can include a cluster and one or more datastores or datastore clusters. vRealize Operations Manager uses the candidate reservations to create the list of destination candidates and locate the best target.

The policy in vRealize Operations Manager sets the level of balance, utilization, and buffer space for the cluster. For a single reservation, which is a cluster or datastore cluster, vRealize Automation validates whether the recommendation is viable placement destination.

- If the destination is viable, vRealize Automation deploys the blueprint according to the recommendation.
- If the destination is not viable, vRealize Automation uses the default placement behavior to place the virtual machines.

Placement considerations must also account for health and utilization problems. While the cloud administrator and virtual infrastructure administrator manage the infrastructure, developers care about the health of their applications. To support developers, the workload placement strategy must also consider health and utilization problems.

Table 2-17. Considerations for Health and Utilization Problems

Workload Problem	Placement Solution
Developer notices a health problem in the environment.	vRealize Automation is provisioning blueprints in clusters that are experiencing problems, or that are overutilized because of large workloads. vRealize Automation must integrate with the capacity analytics in vRealize Operations Manager to ensure that blueprints are provisioned in clusters that have sufficient capacity.
Developer notices a utilization problem.	The clusters in the environment are underutilized. vRealize Automation must integrate with the capacity analytics that vRealize Operations Manager provides to ensure that blueprints are provisioned in a cluster where the utilization is maximized.

Users Who Provision Blueprints

The following users perform actions to provision blueprints.

Table 2-18. Users and Roles to Provision Blueprints

Step	User	Action	Role Required
1	Cloud Administrator or Virtual Infrastructure (VI) Administrator	Ensures that the initial placement of virtual machines meets organizational policies, and that they are optimized according to the operational analytics data.	IaaS Admin role
1	Fabric Administrator	Defines the reservations, reservation policies, and placement policy in vRealize Automation.	Fabric Administrator role, Infrastructure Architect
1	IaaS Administrator	Defines the endpoints for vSphere and vRealize Operations Manager, which are necessary for workload placement.	IaaS Admin role
2	Infrastructure Architect	As a blueprint architect who works directly with virtual machine component types, assigns the reservation policies to virtual machines when authoring a blueprint. Specifies the reservation policy as a property of the machine component in the blueprint.	Infrastructure Architect
3	Infrastructure Architect, Application Architect, Software Architect, and XaaS Architect	<p>Creates and publishes the blueprint to provision the virtual machines. Only the Infrastructure Architect works directly with machine components. The other architect roles can reuse infrastructure blueprints in nesting, but they cannot edit the machine component settings.</p> <p>The blueprint can include a single component, or it can include nested blueprints, XaaS components, multiple virtual machines in a multi-tier application, and so on.</p> <p>vRealize Automation places the virtual machines according to the configuration of the reservations, and optionally includes the reservation policy at the machine component level for the blueprint. For example, your blueprint might include two machines, with a different policy applied to each machine.</p> <p>vRealize Automation also optimizes the virtual machines according to the operational analytics data that vRealize Operations Manager provides.</p>	Infrastructure Architect
4	Cloud Administrator or VI Administrator	<p>Selects the policies that govern the initial placement of the virtual machines that vRealize Automation provisions.</p> <p>The Administrator can:</p> <ul style="list-style-type: none"> ■ Select the policies by using an API. ■ Use the default placement policy, which uses each server in vRealize Automation in turn to balance workloads. This approach does not require input from vRealize Operations Manager. 	IaaS Admin role, Infrastructure Architect
5	VI Administrator	Builds the custom data center and custom groups in vRealize Operations Manager. Then, the VI Administrator applies the policy used to consolidate and balance workloads to those custom data centers.	IaaS Admin role, Infrastructure Architect

Table 2-18. Users and Roles to Provision Blueprints (Continued)

Step	User	Action	Role Required
6	Fabric Administrator	Selects the placement policy in vRealize Automation. Use the workload placement policy to have vRealize Automation determine where to place machines when you deploy new blueprints. The placement policy requires input from vRealize Operations Manager	Fabric Administrator role
7	Developer	Requests a blueprint to provision virtual machines. The blueprint can consist of multiple machines to run a three-tier application.	
8	Developer	When the developer deploys the blueprint, vRealize Operations Manager searches for a placement policy that fits the relevant clusters for the request.	

For more information about the placement policy, see [Placement Policy](#).

To configure workload placement, see [Configuring Workload Placement](#).

Distributed Resource Scheduler (DRS) Is Required to Place Virtual Machines

vSphere DRS is the placement engine that vRealize Automation and vRealize Operations Manager use to provision and place virtual machines.

For vRealize Automation to suggest the best placement for the virtual machines, you must enable DRS on the cluster, and set it to fully automated. vRealize Automation then uses the vSphere DRS APIs to determine the correct placement for the virtual machines.

vRealize Automation integrates with the vRealize Operations Manager placement service.

vRealize Operations Manager only provides placement recommendations for clusters that have DRS enabled and fully automated.

Limitations on Workload Placement

When you use the placement policy for workload placement to place machines when you deploy new blueprints, be aware of the limitations.

- In vRealize Operations Manager, the vRealize Automation solution identifies the clusters and virtual machines that vRealize Automation manages.
- When vRealize Automation manages the child objects of a data center or custom data center container in vRealize Operations Manager, the ability to rebalance or move those objects is not available. You cannot turn on or turn off the exclusion of actions on vRealize Automation managed objects.
- For the objects that vRealize Automation manages, the workload placement behavior is as follows:
 - When a custom data center or data center includes a cluster that vRealize Automation manages, workload placement does not allow you to rebalance the cluster.
 - When a cluster includes virtual machines that vRealize Automation manages, workload placement does not allow you to move those virtual machines.

- vRealize Operations Manager does not support workload placement on resource pools in vCenter Server.
- vRealize Operations Manager does not support vSAN in the current release.

Permissions to Configure Workload Placement

You must have permissions in vRealize Automation and vRealize Operations Manager to configure workload placement and the placement policy.

In vRealize Automation, you must have the Fabric Administrator role to configure workload placement. See [User Roles Overview](#) in the vRealize Automation Information Center.

In vRealize Operations Manager, you must create a user role for workload placement, and assign permissions to the role.

- On the user account, assign the read-only permission to vSphere Hosts and Clusters, and vSphere Storage, in the object hierarchy.
- To have the user role use API calls in workload placement, assign read and write permissions on APIs. Select **Administration > Access Control > Permissions**, and select **REST APIs > All other Read, Write APIs**.

vRealize Automation uses the vRealize Operations Manager role when you register the endpoint, and to request placement recommendations during provisioning on behalf of users who request catalog items.

For more information, see [Access Control](#) in the vRealize Operations Manager Information Center.

Placement Policy

You can use the placement policy to have vRealize Automation determine where to place machines when you deploy new blueprints. The placement policy uses the analytics of vRealize Operations Manager to identify workloads on your clusters so that it can suggest placement destinations.

You must perform several steps before you can use the placement policy. In vRealize Automation, you create endpoints for the vRealize Operations Manager and vCenter Server instances. Then, you create a fabric group, and add reservations to your vCenter Server endpoint.

To ensure that vRealize Operations Manager provides workload placement analytics to vRealize Automation, you must:

- Install the vRealize Automation Solution in the vRealize Operations Manager instance that is being used for workload placement.
- Configure vRealize Operations Manager to monitor the vCenter Server.

To configure vRealize Automation and vRealize Operations Manager for workload placement, see [Configuring Workload Placement](#).

Locating the Placement Policy

In your vRealize Automation instance, select **Infrastructure > Reservations > Placement Policy**.

To use the workload placement analytics that vRealize Operations Manager provides, select **Use vRealize Operations Manager for placement recommendations**

If you do not use the workload placement policy, vRealize Automation uses default placement method.

Configuring Workload Placement

To use the placement policy to place machines when you deploy new blueprints, you configure vRealize Automation to use the analytics that vRealize Operations Manager provides. You also configure vRealize Operations Manager to apply a policy to consolidate and balance workloads to your cluster compute resources.

In vRealize Automation, you configure endpoints, create a fabric group, and add reservations. In vRealize Operations Manager, you configure a policy to support workload balance, and apply that policy to a custom group that includes your custom compute resources.

Prerequisites

Before the placement policy can suggest placement destinations for blueprints, you must perform several steps.

- Understand the placement policy. See [Placement Policy](#).
- Verify that an endpoint exists in vRealize Automation for the vRealize Operations Manager instance being used for workload placement. See [Create a vRealize Operations Manager Endpoint](#).
- Verify that an endpoint exists in vRealize Automation for the vCenter Server instance. See [Create a vSphere Endpoint](#).
- Add reservations to the vCenter Server endpoint. See [Reservations](#).
- Add a fabric group, and verify that your user is a fabric group administrator. See [Create a Fabric Group](#).
- Verify that vRealize Operations Manager is monitoring the same infrastructure that vRealize Automation is monitoring, to ensure that they include the same vCenter Server instances. See [VMware vSphere Solution in vRealize Operations Manager](#) in the vRealize Operations Manager Information Center.
- Understand reservations, storage reservation, blueprints, and delegate providers. See the vRealize Automation Information Center.
- Understand and define the fill and balance settings in the vRealize Operations Manager policy used for workload placement. See [Workload Automation Details](#) in the vRealize Operations Manager Information Center.

Procedure

1 [Configure vRealize Automation for Workload Placement](#)

To use workload placement analytics to place machines when you deploy new blueprints, you must prepare the vRealize Automation instance.

2 [Configure vRealize Operations Manager for Workload Placement in vRealize Automation](#)

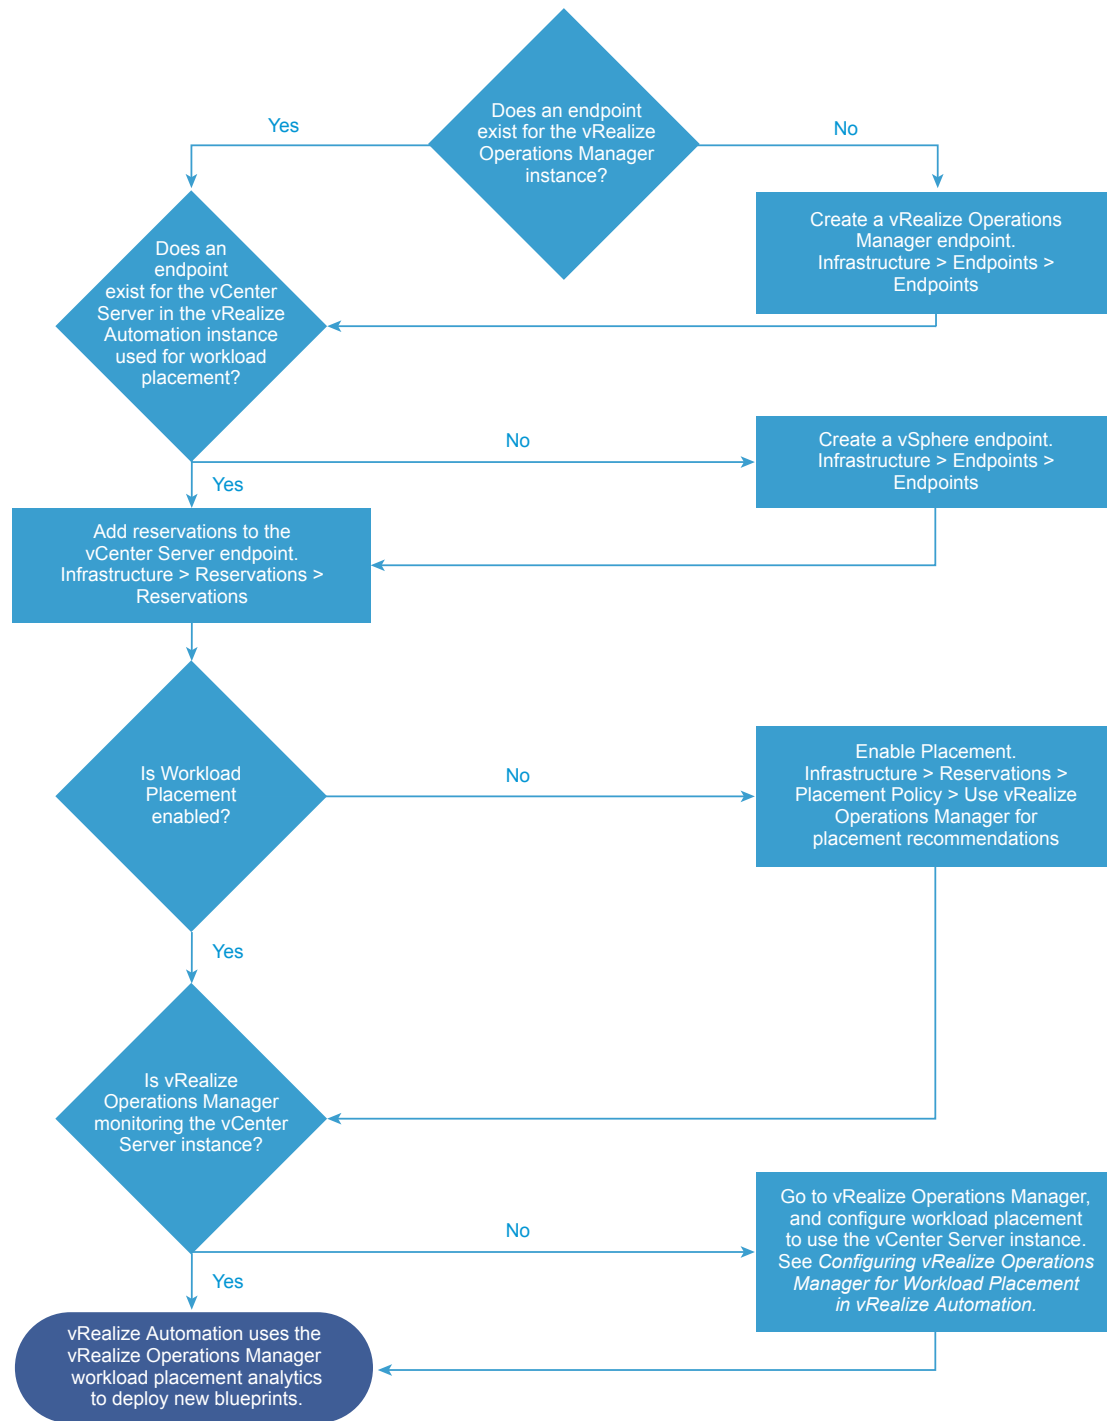

To provide workload placement analytics to vRealize Automation to place machines when you deploy new blueprints, you must prepare the vRealize Operations Manager instance.

You configured vRealize Automation and vRealize Operations Manager to use workload placement analytics to suggest placement destinations for new blueprints.

Configure vRealize Automation for Workload Placement

To use workload placement analytics to place machines when you deploy new blueprints, you must prepare the vRealize Automation instance.

To prepare your vRealize Automation instance to use the placement policy, you configure endpoints, create a fabric group, and add reservations.

Prerequisites

- To use workload placement, understand the requirements. See [Configuring Workload Placement](#).
- In vRealize Automation, add a specific user role and permissions for vRealize Operations Manager to validate credentials. See User Roles Overview in the vRealize Automation Information Center.

Procedure

- 1 In your vRealize Automation instance, add an endpoint for the vRealize Operations Manager instance, and click **OK**.
 - a Select **Infrastructure > Endpoint > Endpoints**.
 - b Select **New > Management > vRealize Operations Manager**.
 - c Enter the general information for the **vRealize Operations Manager** endpoint.
You do not need to specify properties for the endpoint.
- 2 In your vRealize Automation instance, add an endpoint for the vCenter Server instance, and click **OK**.
 - a Select **Infrastructure > Endpoint > Endpoints**.
 - b Select **New > Virtual > vSphere (vCenter)**.
 - c Enter the general information, properties, and associations for the vCenter Server endpoint.

After you add endpoints, and vRealize Automation collects data from them, the compute resources for those endpoints are available. You can then add those compute resources to the fabric group that you create.
- 3 Create a fabric group so that other users can create reservations and enable the placement policy.
 - a Select **Infrastructure > Endpoint > Fabric Groups**.
 - b Click **New**, and enter information about the fabric group.

Option	Description
Name	Enter a meaningful name for the fabric group.
Description	Enter a useful description.
Fabric administrators	Enter the email address for each person to designate as a fabric administrator.
Compute resources	Select the compute resource clusters that the administrators can manage.

After you add compute resources to a fabric group, and vRealize Automation collects data from them, fabric administrators can create reservations for the compute resources.

4 Create reservations for the compute resources in the vCenter Server instance.

- a Select **Infrastructure > Reservations > Reservations**.
- b Select **New > vSphere (vCenter)**.
- c On each tab, enter the information for the reservation.

Option	Action
General	Select a reservation policy, the priority for the policy, and click Enable this reservation .
Resources	Select the machine quota, memory, and storage. You do not have to select a resource pool.
Network	Select the network adapter. You do not have to select a network profile.
Properties	If necessary, add custom properties to the reservation.
Alert	If necessary, select Capacity alerts to notify recipients when the capacity exceeds the threshold for the reservation.

5 Enable the placement policy.

- a Select **Infrastructure > Reservations > Placement Policy**.
- b Select the check box named **Use vRealize Operations Manager for placement recommendations**.

You configured vRealize Automation to use the analytics of vRealize Operations Manager to place machines when users deploy blueprints.

What to do next

Configure vRealize Operations Manager to monitor the vCenter Server instance, and apply a workload placement policy to your cluster compute resources. See [Configure vRealize Operations Manager for Workload Placement in vRealize Automation](#).

Configure vRealize Operations Manager for Workload Placement in vRealize Automation

To provide workload placement analytics to vRealize Automation to place machines when you deploy new blueprints, you must prepare the vRealize Operations Manager instance.

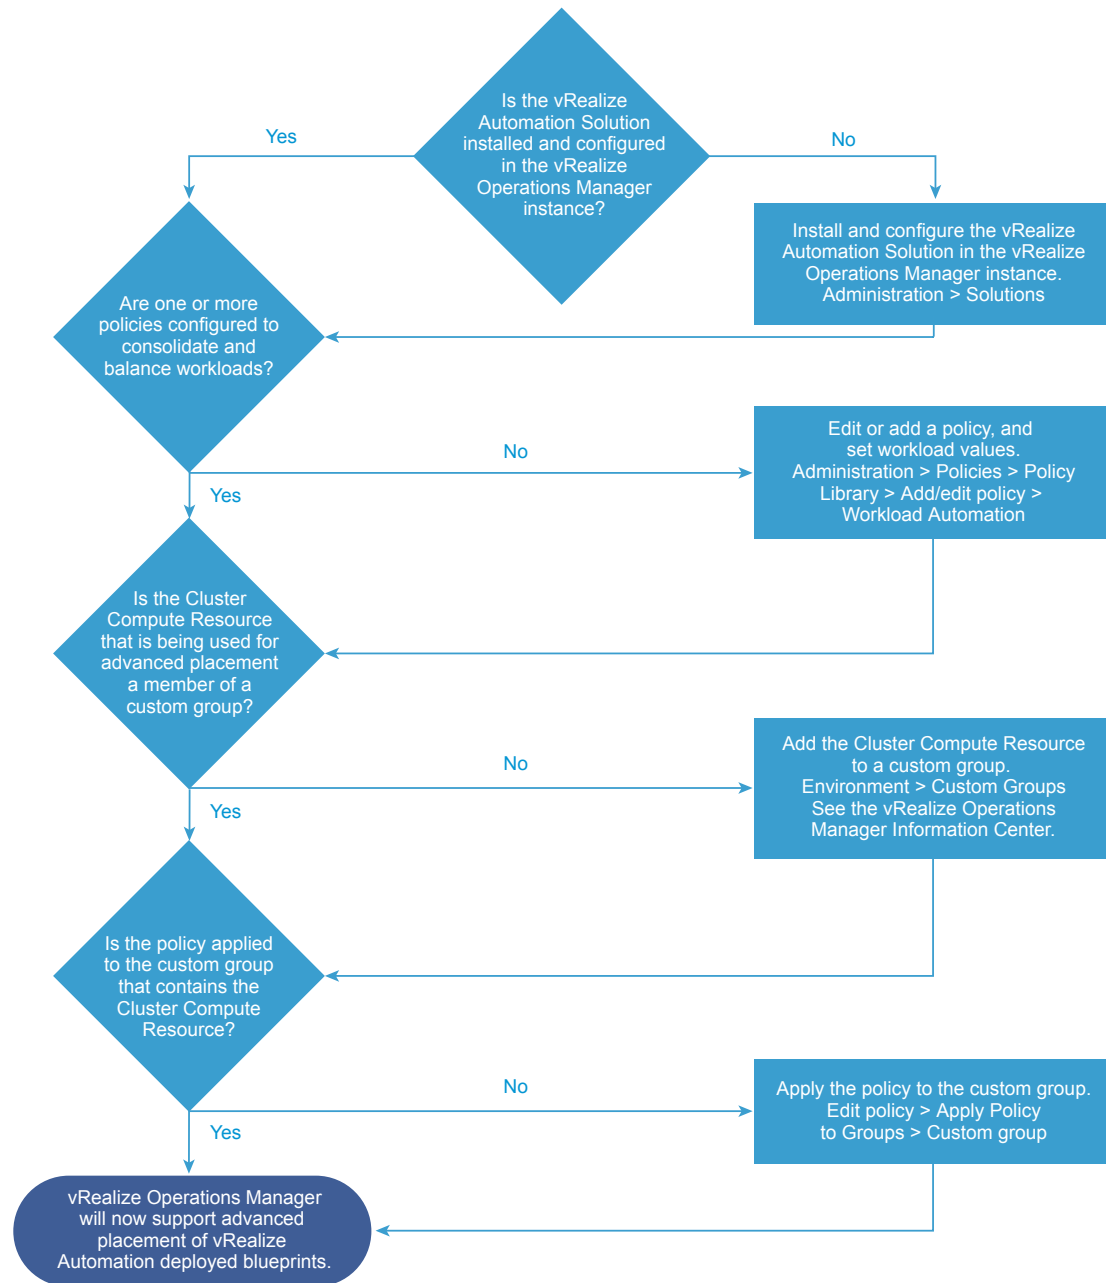

Caution You must install the vRealize Automation solution, which includes the management pack, on only a single vRealize Operations Manager instance.

To prepare your vRealize Operations Manager instance to provide analytics to vRealize Automation, you install and configure the vRealize Automation solution. You must also configure a policy, and apply the policy to your cluster compute resources.

After you configure the vRealize Automation solution, you cannot move or rebalance any virtual machines that vRealize Automation manages.

If the vRealize Automation solution is not installed in the vRealize Operations Manager instance, workload placement can still move or rebalance virtual machines that vRealize Automation manages.

To allow workload placement to move virtual machines, those virtual machines must reside in a data center or custom data center.

Prerequisites

- Configure vRealize Automation to use workload placement analytics. See [Configure vRealize Automation for Workload Placement](#).

- Verify that the vRealize Automation Solution is installed and configured in the vRealize Operations Manager instance that is being used for workload placement. For details about this solution, see the [Management Pack for vRealize Automation on Solution Exchange](#). For information about how workload placement works in vRealize Operations Manager, see [Workload Automation Details](#) and related topics in the vRealize Operations Manager documentation.

Procedure

- 1 In the instance of vRealize Operations Manager that manages workload placement, install and configure the vRealize Automation solution.

The solution might already be installed.

- a To see the solutions that are installed in vRealize Operations Manager, click **Administration > Solutions**.

- b Verify whether the vRealize Automation solution is already installed.

If the vRealize Automation solution does not appear in the list, download and install the solution. See [Management Pack for vRealize Automation on Solution Exchange](#).

- c If the solution appears in the list, select the **VMware vRealize Automation solution**, and click **Configure**.

- d Configure the vRealize Automation solution, and save the settings.

For more information to configure the solution, see [Solutions in vRealize Operations Manager](#) in the vRealize Operations Manager Information Center.

- 2 If you do not use the vRealize Operations Manager Default Policy, you must create a custom group. Then, add your cluster compute resources to the custom group.

To apply a policy other than Default Policy to your clusters, add a custom group. You then apply the policy to the custom group. If you use Default Policy, you do not have to create a custom group, because Default Policy applies to all objects.

- a Click **Environment > Custom Groups**.

- b If a custom group does not exist for your clusters, create a custom group.

For details, see [User Scenario: Creating Custom Object Groups](#) in the vRealize Operations Manager Information Center.

- c Add the cluster to the custom group, and save the custom group.

- 3 Configure a policy to consolidate and balance workloads on your clusters, and apply that policy to the custom group.

You configure a policy in vRealize Operations Manager to establish the settings for consolidation, balance, fill, CPU, memory, and disk space. For example, you modify the setting named Consolidate Workloads to determine the best placement for new managed workloads based on the cluster status and capacity. You also modify the threshold setting for Balance Workloads to the level of aggressiveness required to place workloads. You can configure one or more policies, and apply them to your cluster compute resources.

- a To locate the policies, click **Administration > Policies > Policy Library**.
- b To set workload values, click **Add/Edit Policy**, and click **Workload Automation**.

The settings named Consolidate Workloads and Cluster Headroom apply to the initial placement of virtual machines.

- When you set Consolidate Workloads to **none**, workload placement balances the workload across all the clusters to which the policy is applied. When you set Consolidate Workloads to a value other than none, workload placement fills the busiest cluster first.
 - Cluster Headroom is the buffer space reserved in a cluster, as a percentage of the total capacity. For example, if you set the cluster headroom to 20%, that buffer might prevent workload placement from placing virtual machines on that cluster. The reason it prevents the placement is because the cluster has 20% less of the free capacity for CPU, memory, or disk space.
- c In the policy workspace, click **Apply Policy to Groups**.
 - d Select the custom group.
 - e Save the policy.

You configured vRealize Operations Manager so that vRealize Automation uses the workload placement analytics to suggest placement destinations of machines when users deploy blueprints.

What to do next

Wait for vRealize Automation and vRealize Operations Manager to collect data from the endpoints and objects in your environment. Then, when you deploy new blueprints, vRealize Automation displays the workload placement recommendations, destination candidates, and selected placement for your confirmation.

Troubleshooting Workload Placement

If you experience problems with workload placement, use the troubleshooting information to resolve them.

The vRealize Automation Solution Is Required for Workload Placement to Operate Properly

Workload placement is based on individual machines, and placement is done at the machine level. When vRealize Automation and vRealize Operations Manager are installed together, the vRealize Automation Solution must also be installed.

The solution, which includes the management pack and adapter, identifies the clusters on which the `rebalance` container or `move VM` actions are disabled. The `rebalance` action is disabled on the custom data center to which the cluster belongs.

- For unmanaged vRealize Automation clusters that belong to a custom data center that does not have any managed vRealize Automation clusters, the `move VM` and `rebalance container` actions are enabled. For managed vRealize Automation clusters, these actions are disabled.
- In vRealize Operations Manager, the vRealize Automation Adapter causes VMs on clusters that map reservations not to be available for `move` or `rebalance`.

Caution The vRealize Automation solution must only be installed on a single vRealize Operations Manager instance.

High Availability Is Enabled, but Must Be Disabled

When HA is enabled, if vRealize Operations Manager is down, the timeout used for workload placement to call vRealize Operations Manager might fail.

vRealize Automation logs workload placement errors in the `catalina.out` log file.

vSphere Endpoints in vRealize Automation Are Not Monitored

vRealize Operations Manager is not monitoring the vSphere vCenter Server instance that contains the reservation clusters.

If vRealize Operations Manager does not recognize the vRealize Automation candidate reservations for a cluster, datastore, or datastore cluster when it attempts to place them, it ignores them. In the placement response, vRealize Operations Manager communicates to vRealize Automation that it does not recognize them.

As a result, in the placement details on the request execution, vRealize Automation displays a warning icon on the candidate reservation to indicate that it is unrecognized.

When Mismatches Occur, vRealize Automation Appears at the Top of the List

vRealize Automation and vRealize Operations Manager manage different views of the infrastructure. But they must both manage the same instances of vCenter Server in the same infrastructure.

Must identify disconnects and mismatches, and display details.

What to Do If the vRealize Automation Adapter Is Down

The initial placement always honors the list of destination candidates that it receives from vRealize Operations Manager, such as when a user adds a cluster immediately after installation.

If the vRealize Automation solution, which includes the management pack and adapter, is not available in the vRealize Operations Manager, the `move VM` and `rebalance container` actions are available.

Managing Key Pairs

Key pairs are used to provision and connect to a cloud instance. A key pair is used to decrypt Windows passwords or to log in to a Linux machine.

Key pairs are required for provisioning with Amazon AWS. For Red Hat OpenStack, key pairs are optional.

Existing key pairs are imported as part of data collection when you add a cloud endpoint. A fabric administrator can also create and manage key pairs by using the vRealize Automation console. If you delete a key pair from the vRealize Automation console, it is also deleted from the cloud service account.

In addition to managing key pairs manually, you can configure vRealize Automation to generate key pairs automatically per machine or per business group.

- A fabric administrator can configure the automatic generation of key pairs at a reservation level.
- If the key pair is going to be controlled at the blueprint level, the fabric administrator must select **Not Specified** on the reservation.
- A tenant administrator or business group manager can configure the automatic generation of key pairs at a blueprint level.
- If key pair generation is configured at both the reservation and blueprint level, the reservation setting overrides the blueprint setting.

Create a Key Pair

You can create key pairs for use with endpoints by using vRealize Automation.

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.
- Create a cloud endpoint and add your cloud compute resources to a fabric group. See [Choosing an Endpoint Scenario](#) and [Create a Fabric Group](#).

Procedure

- 1 Select **Infrastructure > Reservations > Key Pairs**.
- 2 Click **New**.
- 3 Enter a name in the **Name** text box.
- 4 Select a cloud region from the **Compute resource** drop-down menu.
- 5 Click the **Save** icon (✓).

The key pair is ready to use when the Secret Key column has the value *****.

Upload the Private Key for a Key Pair

You can upload the private key for a key pair in PEM format.

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.
- You must already have a key pair. See [Create a Key Pair](#).

Procedure

- 1 Select **Infrastructure > Reservations > Key Pairs**.
- 2 Locate the key pair for which you want to upload a private key.
- 3 Click the **Edit** icon ().
- 4 Use one of the following methods to upload the key.
 - Browse for a PEM-encoded file and click **Upload**.
 - Paste the text of the private key, beginning with -----BEGIN RSA PRIVATE KEY----- and ending with -----END RSA PRIVATE KEY-----.
- 5 Click the **Save** icon (.

Export the Private Key from a Key Pair

You can export the private key from a key pair to a PEM-encoded file.

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.
- A key pair with a private key must exist. See [Upload the Private Key for a Key Pair](#).

Procedure

- 1 Select **Infrastructure > Reservations > Key Pairs**.
- 2 Locate the key pair from which to export the private key.
- 3 Click the **Export** icon (.
- 4 Browse to the location that you want to save the file and click **Save**.

Scenario: Apply a Location to a Compute Resource for Cross Region Deployments

As a fabric administrator, you want to label your compute resources as belonging to your Boston or London datacenter to support cross region deployments. When your blueprint architects enable the locations feature on their blueprints, users are able to choose whether to provision machines in your Boston or London datacenter.

You have a datacenter in London, and a datacenter in Boston, and you don't want users in Boston provisioning machines on your London infrastructure or vice versa. To ensure that Boston users provision on your Boston infrastructure, and London users provision on your London infrastructure, you want to allow users to select an appropriate location for provisioning when they request machines.

Prerequisites

- Log in to the vRealize Automation console as a **fabric administrator**.
- As a system administrator, define the datacenter locations. See [Scenario: Add Datacenter Locations for Cross Region Deployments](#).

Procedure

- 1 Select **Infrastructure > Compute Resources > Compute Resources**.
- 2 Point to the compute resource located in your Boston datacenter and click **Edit**.
- 3 Select Boston from the **Locations** drop-down menu.
- 4 Click **OK**.
- 5 Repeat this procedure as necessary to associate your compute resources to your Boston and London locations.

IaaS architects can enable the locations feature so users can choose to provision machines in Boston or London when they fill out their catalog item request forms. See [Scenario: Enable Users to Select Datacenter Locations for Cross Region Deployments](#).

Provisioning a vRealize Automation Deployment Using a Third-Party IPAM Provider

You can obtain IP addresses and ranges for use in a vRealize Automation network profile from a supported third-party IPAM solution provider, such as Infoblox.

The IP address ranges in the network profile are used in an associated reservation, which you specify in a blueprint. When an entitled user requests machine provisioning using the blueprint catalog item, an IP address is obtained from the third-party IPAM-specified range of IP addresses. After machine deployment, you can discover the IP address used by querying its vRealize Automation item details page.

Table 2-19. Preparing for Provisioning a vRealize Automation Deployment Using Infoblox IPAM Checklist

Task	Description	Details
Obtain, import, and configure the third-party IPAM solution provider plug-in or package.	Obtain and import the vRealize Orchestrator plug-in, run the vRealize Orchestrator configuration workflows, and register the IPAM provider endpoint type in vRealize Orchestrator. If the VMware Solution Exchange at https://marketplace.vmware.com/vsx does not contain the IPAM provider package that you need, you can create your own using an IPAM Solution Provider SDK and supporting documentation. See the vRealize Automation Example Third-Party IPAM Package page at code.vmware.com/web/sdk .	See Checklist For Providing Third-Party IPAM Provider Support .
Create an third-party IPAM solution provider endpoint.	Create a new IPAM endpoint in vRealize Automation.	See Create a Third-Party IPAM Provider Endpoint .
Specify third-party IPAM solution provider endpoint settings in an external network profile.	Create an external network profile and specify the defined IPAM endpoint in vRealize Automation.	See Create an External Network Profile by Using A Third-Party IPAM Provider .
Optionally specify third-party IPAM solution provider endpoint settings in a routed network profile.	Create an on-demand network profile and specify the defined IPAM endpoint in vRealize Automation.	See Create a Routed Network Profile By Using a Third-Party IPAM Endpoint or Create a NAT Network Profile By Using a Third-Party IPAM Endpoint .
Define a reservation to use the network profile.	Create a reservation that calls the network profile in vRealize Automation.	See Create a Reservation for Hyper-V, KVM, SCVMM, vSphere, or XenServer .
Define a blueprint that uses the network profile.	Create a blueprint that uses the reservation in vRealize Automation.	See Chapter 3 Providing Service Blueprints to Users .
Publish the blueprint to the catalog to make it available for use.	Publish the blueprint to the catalog in vRealize Automation. Add any required entitlements.	See Publish a Blueprint .
Request machine provisioning by using the blueprint catalog item.	Use the blueprint catalog item to request machine provisioning in vRealize Automation.	See Managing the Service Catalog .

Configuring XaaS Resources

By configuring XaaS endpoints you can connect the vRealize Automation to your environment. When you configure vRealize Orchestrator plug-ins as endpoints, you use the vRealize Automation user interface to configure the plug-ins instead of using the vRealize Orchestrator configuration interface.

To use vRealize Orchestrator capabilities and the vRealize Orchestrator plug-ins to expose VMware and third-party technologies to vRealize Automation, you can configure the vRealize Orchestrator plug-ins by adding the plug-ins as endpoints. This way, you create connections to different hosts and servers, such as vCenter Server instances, a Microsoft Active Directory host, and so on.

When you add a vRealize Orchestrator plug-in as an endpoint by using the vRealize Automation UI, you run a configuration workflow in the default vRealize Orchestrator server. The configuration workflows are located in the **vRealize Automation > XaaS > Endpoint Configuration** workflows folder.

Important Configuring a single plug-in in vRealize Orchestrator and in the vRealize Automation console is not supported and results in errors.

Configure the Active Directory Plug-In as an Endpoint

You add an endpoint and configure the Active Directory plug-in to connect to a running Active Directory instance and manage users and user groups, Active Directory computers, organizational units, and so on.

After you add an Active Directory endpoint, you can update it at any time.

Prerequisites

- Verify that you have access to a Microsoft Active Directory instance. See the Microsoft Active Directory documentation.
- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Endpoints > OrchestratorEndpoints**.
- 2 Click the **New** icon ().
- 3 In the **Plug-in** drop-down menu, select **Active Directory**.
- 4 Click **Next**.
- 5 Enter a name and, optionally, a description.
- 6 Click **Next**.
- 7 Configure the Active Directory server details.
 - a Enter the IP address or the DNS name of the host on which Active Directory runs in the **Active Directory host IP/URL** text box.
 - b Enter the lookup port of your Active Directory server in the **Port** text box.

vRealize Orchestrator supports the Active Directory hierarchical domains structure. If your domain controller is configured to use Global Catalog, you must use port 3268. You cannot use the default port 389 to connect to the Global Catalog server. In addition to ports 389 and 3268, you can use 636 for LDAPS.

- c Enter the root element of the Active Directory service in the **Root** text box.

For example, if your domain name is *mycompany.com*, then your root Active Directory is **dc=mycompany,dc=com**.

This node is used for browsing your service directory after entering the appropriate credentials. For large service directories, specifying a node in the tree narrows the search and improves performance. For example, rather than searching in the entire directory, you can specify **ou=employees,dc=mycompany,dc=com**. This root element displays all the users in the Employees group.

- d (Optional) To activate encrypted certification for the connection between vRealize Orchestrator and Active Directory, select **Yes** from the **Use SSL** drop-down menu.

The SSL certificate is automatically imported without prompting for confirmation even if the certificate is self-signed.

- e (Optional) Enter the domain in the **Default Domain** text box.

For example, if your domain name is *mycompany.com*, type **@mycompany.com**.

8 Configure the shared session settings.

The credentials are used by vRealize Orchestrator to run all the Active Directory workflows and actions.

- a Enter the user name for the shared session in the **User name for the shared session** text box.
- a Enter the password for the shared session in the **Password for the shared session** text box.

9 Click **Finish**.

You added an Active Directory instance as an endpoint. XaaS architects can use XaaS to publish Active Directory plug-in workflows as catalog items and resource actions.

What to do next

- To use vRealize Automation blueprints to manage your Active Directory users in your environment, create an XaaS blueprint based on Active Directory. For an example, see [Create an XaaS Blueprint and Action for Creating and Modifying a User](#).
- To use vRealize Automation to create Active Directory records when a machine is deployed, you can create different Active Directory policies and apply them to different business groups and blueprints. See [Create and Apply Active Directory Policies](#).

Configure the HTTP-REST Plug-In as an Endpoint

You can add an endpoint and configure the HTTP-REST plug-in to connect to a REST host.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator**.
- Verify that you have access to a REST host.

Procedure

1 Select **Administration > Endpoints > OrchestratorEndpoints**.

2 Click the **New** icon (.

3 Select **HTTP-REST** from the **Plug-in** drop-down menu.

4 Click **Next**.

5 Enter a name and, optionally, a description.

6 Click **Next**.

7 Provide information about the REST host.

a Enter the name of the host in the **Name** text box.

b Enter the address of the host in the **URL** text box.

Note If you use Kerberos access authentication, you must provide the host address in FDQN format.

c (Optional) Enter the number of seconds before a connection times out in the **Connection timeout (seconds)** text box.

The default value is 30 seconds.

d (Optional) Enter the number of seconds before an operation times out in the **Operation timeout (seconds)** text box.

The default value is 60 seconds.

8 (Optional) Configure proxy settings.

a Select **Yes** to use a proxy from the **Use Proxy** drop-down menu.

b Enter the IP of the proxy server in the **Proxy address** text box.

c Enter the port number to communicate with the proxy server in the **Proxy port** text box.

9 Click **Next**.

10 Select the authentication type.

Option	Action
None	No authentication is required.
OAuth 1.0	<p>Uses OAuth 1.0 protocol. You must provide the required authentication parameters under OAuth 1.0.</p> <ol style="list-style-type: none"> Enter the key used to identify the consumer as a service provider in the Consumer key text box. Enter the secret to establish ownership of the consumer key in the Consumer secret text box. (Optional) Enter the access token that the consumer uses to gain access to the protected resources in the Access token text box. (Optional) Enter the secret that the consumer uses to establish ownership of a token in the Access token secret text box.
OAuth 2.0	<p>Uses OAuth 2.0 protocol.</p> <p>Enter the authentication token in the Token text box.</p>
Basic	<p>Provides basic access authentication. The communication with the host is in shared session mode.</p> <ol style="list-style-type: none"> Enter the user name for the shared session in the Authentication user name text box. Enter the password for the shared session in the Authentication password text box.
Digest	<p>Provides digest access authentication that uses encryption. The communication with the host is in shared session mode.</p> <ol style="list-style-type: none"> Enter the user name for the shared session in the Authentication user name text box. Enter the password for the shared session in the Authentication password text box.
NTLM	<p>Provides NT LAN Manager (NTLM) access authentication within the Window Security Support Provider (SSP) framework. The communication with the host is in shared session mode.</p> <ol style="list-style-type: none"> Provide the user credentials for the shared session. <ul style="list-style-type: none"> Enter the user name for the shared session in the Authentication user name text box. Enter the password for the shared session in the Authentication password text box. Configure the NTLM details <ul style="list-style-type: none"> (Optional) Enter the workstation name in the Workstation for NTLM authentication text box. Enter the domain name in the Domain for NTLM authentication text box.
Kerberos	<p>Provides Kerberos access authentication. The communication with the host is in shared session mode.</p> <ol style="list-style-type: none"> Enter the user name for the shared session in the Authentication user name text box. Enter the password for the shared session in the Authentication password text box.

11 Click **Finish**.

You configured the endpoint and added a REST host. XaaS architects can use XaaS to publish HTTP-REST plug-in workflows as catalog items and resource actions.

Configure the PowerShell Plug-In as an Endpoint

You can add an endpoint and configure the PowerShell plug-in to connect to a running PowerShell host, so that you can call PowerShell scripts and cmdlets from vRealize Orchestrator actions and workflows, and work with the result.

Prerequisites

- Verify that you have access to a Windows PowerShell host. For more information about Microsoft Windows PowerShell, see the Windows PowerShell documentation.
- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Endpoints > OrchestratorEndpoints**.
- 2 Click the **New** icon ().
- 3 Select **PowerShell** from the **Plug-in** drop-down menu.
- 4 Click **Next**.
- 5 Enter a name and, optionally, a description.
- 6 Click **Next**.
- 7 Specify the PowerShell host details.
 - a Enter the name of the host in the **Name** text box.
 - b Enter the IP address or the FQDN of the host in the **Host/IP** text box.
- 8 Select the PowerShell host type to which the plug-in connects.

Option	Action
WinRM	<ol style="list-style-type: none"> a Enter the port number to use for communication with the host in the Port text box under the PowerShell host details. b Select a transport protocol from the Transport protocol drop-down menu. <div style="border: 1px solid #ccc; padding: 5px; margin-top: 5px;"> <p>Note If you use the HTTPS transport protocol, the certificate of the remote PowerShell host is imported to the vRealize Orchestrator keystore.</p> </div> c Select the authentication type from the Authentication drop-down menu. <div style="border: 1px solid #ccc; padding: 5px; margin-top: 5px;"> <p>Note To use Kerberos authentication, enable it on the WinRM service. For information about configuring Kerberos authentication, see <i>Using the PowerShell Plug-In</i>.</p> </div>
SSH	None.

- 9 Enter the credentials for a shared session communication with the PowerShell host in the **User name** and **Password** text boxes.

10 Click **Finish**.

You added an Windows PowerShell host as an endpoint. XaaS architects can use the XaaS to publish PowerShell plug-in workflows as catalog items and resource actions.

Configure the SOAP Plug-In as an Endpoint

You can add an endpoint and configure the SOAP plug-in to define a SOAP service as an inventory object, and perform SOAP operations on the defined objects.

Prerequisites

- Verify that you have access to a SOAP host. The plug-in supports SOAP Version 1.1 and 1.2, and WSDL 1.1 and 2.0.
- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Endpoints > OrchestratorEndpoints**.
- 2 Click the **New** icon ().
- 3 From the **Plug-in** drop-down menu, select **SOAP**.
- 4 Click **Next**.
- 5 Enter a name and, optionally, a description.
- 6 Click **Next**.
- 7 Provide the details about the SOAP host.
 - a Enter the name of the host in the **Name** text box.
 - b Select whether to provide the WSDL content as text from the **Provide WSDL content** drop-down menu.

Option	Action
Yes	Enter the WSDL text in the WSDL content text box.
No	Enter the correct path in the WSDL URL text box.

- c (Optional) Enter the number of seconds before a connection times out in the **Connection timeout (in seconds)** text box.

The default value is 30 seconds.
- d (Optional) Enter the number of seconds before an operation times out in the **Request timeout (in seconds)** text box.

The default value is 60 seconds.

8 (Optional) Specify the proxy settings.

- a To use a proxy, select **Yes** from the **Proxy** drop-down menu.
- b Enter the IP of the proxy server in the **Address** text box.
- c Enter the port number to communicate with the proxy server in the **Port** text box.

9 Click **Next**.**10** Select the authentication type.

Option	Action
None	No authentication is required.
Basic	<p>Provides basic access authentication. The communication with the host is in shared session mode.</p> <ul style="list-style-type: none"> a Enter the user name for the shared session in the User name text box. b Enter the password for the shared session in the Password text box.
Digest	<p>Provides digest access authentication that uses encryption. The communication with the host is in shared session mode.</p> <ul style="list-style-type: none"> a Enter the user name for the shared session in the User name text box. b Enter the password for the shared session in the Password text box.
NTLM	<p>Provides NT LAN Manager (NTLM) access authentication in the Window Security Support Provider (SSP) framework. The communication with the host is in shared session mode.</p> <ul style="list-style-type: none"> a Provide the user credentials. <ul style="list-style-type: none"> ■ Enter the user name for the shared session in the User name text box. ■ Enter the password for the shared session in the Password text box. b Provide the NTLM settings. <ul style="list-style-type: none"> ■ Enter the domain name in the NTLM domain text box. ■ (Optional) Enter the workstation name in the NTLM workstation text box.
Negotiate	<p>Provides Kerberos access authentication. The communication with the host is in shared session mode.</p> <ul style="list-style-type: none"> a Provide the user credentials. <ul style="list-style-type: none"> 1 Enter the user name for the shared session in the User name text box. 2 Enter the password for the shared session in the Password text box. b Enter the Kerberos service SPN in the Kerberos service SPN text box.

11 Click **Finish**.

You added a SOAP service. XaaS architects can use XaaS to publish SOAP plug-in workflows as catalog items and resource actions.

Configure the vCenter Server Plug-In as an Endpoint

You can add an endpoint and configure the vCenter Server plug-in to connect to a running vCenter Server instance to create XaaS blueprints to manage vSphere inventory objects.

Prerequisites

- Install and configure vCenter Server. See *vSphere Installation and Setup*.

- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Endpoints > OrchestratorEndpoints**.
- 2 Click the **New** icon (+).
- 3 Select **vCenter Server** from the **Plug-in** drop-down menu.
- 4 Click **Next**.
- 5 Enter a name and, optionally, a description.
- 6 Click **Next**.
- 7 Provide information about the vCenter Server instance.
 - a Enter the IP address or the DNS name of the machine in the **IP or host name of the vCenter Server instance to add** text box.

This is the IP address or DNS name of the machine on which the vCenter Server instance you want to add is installed.
 - b Enter the port to communicate with the vCenter Server instance in the **Port of the vCenter Server instance** text box.

The default port is 443.
 - c Enter the location of the SDK to use for connecting to your vCenter Server instance in the **Location of the SDK that you use to connect to the vCenter Server instance** text box.

For example, `/sdk`.
- 8 Click **Next**.
- 9 Define the connection parameters.
 - a Enter the HTTP port of the vCenter Server instance in the **HTTP port of the vCenter Server instance - applicable for VC plugin version 5.5.2 or earlier** text box.
 - b Enter the credentials for vRealize Orchestrator to use to establish the connection to the vCenter Server instance in the **User name of the user that Orchestrator will use to connect to the vCenter Server instance** and **Password of the user that Orchestrator will use to connect to the vCenter Server instance** text boxes.

The user that you select must be a valid user with privileges to manage vCenter Server extensions and a set of custom defined privileges.
- 10 Click **Finish**.

You added a vCenter Server instance as an endpoint. XaaS architects can use the XaaS to publish vCenter Server plug-in workflows as catalog items and resource actions.

Create a Microsoft Azure Endpoint

You can create a Microsoft Azure endpoint to facilitate a credentialed connection between vRealize Automation and an Azure deployment.

An endpoint establishes a connection to a resource, in this case an Azure instance, that you can use to create virtual machine blueprints. You must have an Azure endpoint to use as the basis of blueprints for provisioning Azure virtual machines. If you use multiple Azure subscriptions, you need endpoints for each subscription ID.

As an alternative, you can create an Azure connection directly from vRealize Orchestrator using the Add an Azure Connection command located under **Library > Azure > Configuration** in the vRealize Orchestrator workflow tree. For most scenarios, creating a connection through the endpoint configuration as described herein is the preferred option.

Azure endpoints are supported by vRealize Orchestrator and XaaS functionality. You can create, delete, or edit an Azure endpoint. Note that if you make any changes to an existing endpoint and do not execute any updates on the Azure portal through the updated connection for several hours, then you must restart the vRealize Orchestrator service using the service `vco-service restart` command. Failure to restart the service may result in errors.

Prerequisites

- Configure a Microsoft Azure instance and obtain a valid Microsoft Azure subscription from which you can use the subscription ID. See <http://www.vaficionado.com/2016/11/using-new-microsoft-azure-endpoint-vrealize-automation-7-2/> for more information about configuring Azure and obtaining a subscription ID.
- Your vRealize Automation deployment must have at least one tenant and one business group.
- Create an Active Directory application as described in <https://azure.microsoft.com/en-us/documentation/articles/resource-group-create-service-principal-portal>.
- Make note of the following Azure related information, as you will need it during endpoint and blueprint configuration.
 - subscription ID
 - tenant ID
 - storage account name
 - resource group name
 - location
 - virtual network name
 - client application ID
 - client application secret key
 - virtual machine image URN

- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Endpoints > OrchestratorEndpoints**.
- 2 Click the **New** icon (+).
- 3 On the Plug-in tab, click the **Plug-in** drop-down menu and select Azure Plug-in.
- 4 Click **Next**.
- 5 Enter a name and, optionally, a description.
- 6 Click **Next**.
- 7 Populate the text boxes on the **Details** tab as appropriate for the endpoint.

Parameter	Description
Connection settings	
Azure Connection	
Connection name	Unique name for the new endpoint connection. This name appears in the vRealize Orchestrator interface to help you identify a particular connection.
Azure subscription id	The identifier for your Azure subscription. The ID defines the storage accounts, virtual machines and other Azure resources to which you have access.
Resource manager settings	
Azure service URI	The URI through which you gain access to your Azure instance. The default value of <code>https://management.azure.com/</code> is appropriate for many typical implementations.
Tenant Id	The Azure tenant ID that you want the endpoint to use.
Client Id	The Azure client identifier that you want the endpoint to use. This is assigned when you create an Active Directory application.
Client secret	The key used with an Azure client ID. This key is assigned when you create an Active Directory application.
Login URL	The URL used to access the Azure instance. The default value of <code>https://login.windows.net/</code> is appropriate for many typical implementations.
Proxy Settings	
Proxy host	If your company uses a proxy Web server, enter the host name of that server.
Proxy port	If your company uses a proxy Web server, enter the port number of that server.

- 8 Click **Finish**.

What to do next

Create appropriate resource groups, storage accounts, and network security groups in Azure. You should also create load balancers if appropriate for your implementation.

Action	Options
Create an Azure resource group	<ul style="list-style-type: none"> ■ Create the resource group using the Azure portal. See the Azure documentation for specific instructions. ■ Use the appropriate vRealize Orchestrator workflow found under the Library/Azure/Resource/Create resource group. ■ In vRealize Automation, create and publish an XaaS blueprint that contains the vRealize Orchestrator workflow. You can request the resource group after attaching it to the service and entitlements. Note that the Resource Group resource type is not supported or managed by vRealize Automation.
Create an Azure storage account	<ul style="list-style-type: none"> ■ Use Azure to create a storage account. See the Azure documentation for specific instructions. ■ Use the appropriate vRealize Orchestrator workflow found under Library/Azure/Storage/Create storage account. ■ In vRealize Automation, create and publish an XaaS blueprint that contains the vRealize Orchestrator workflow. You can request the storage account after attaching it to the service and entitlements.
Create an Azure network security group	<ul style="list-style-type: none"> ■ Use Azure to create a security group. See the Azure documentation for specific instructions. ■ Use the appropriate vRealize Orchestrator workflow found under the Library/Azure/Network/Create Network security group . ■ In vRealize Automation, create and publish an XaaS blueprint that contains the vRealize Orchestrator workflow. You can request the security group after attaching it to the service and entitlements.

Creating and Configuring Containers

You can use the Containers tab in vRealize Automation to open the Containers for vRealize Automation integrated application and create and configure the containers and container network settings to make available to vRealize Automation blueprint architects.

You can define containers by using new and existing templates and images in the integrated Containers application. You can then add container components, and their associated network settings, to vRealize Automation blueprints.

Managing Container Hosts

You can view and manage the hosts that you add from the Hosts. In the context of Containers, the host is a virtual machine or infrastructure that lets you run containers.

The Hosts tab contains the controls for adding new hosts, monitoring the state of the provision requests of existing hosts, viewing event logs for your containers, and performing data collection on hosts. The Requests and Event Log panels are located on the right side of the page.

Add a Container Host

You must add a host to deploy containers.

When you add or create hosts in Containers, you can click one of the four panels on the right to expand toolbars with additional options. You can add or manage placement zones, credentials, certificates, and deployment policies.

Procedure

- 1 Log in to the vRealize Automation console as a **container administrator**.
- 2 Click the **Containers** tab.
- 3 Click **Add a Host**.
- 4 Enter your host IP address or host name using the format **http(s)://<hostname>:<port>**.
- 5 In **Host type** select whether you entered the address of a Docker host or a virtual container host (VCH).
- 6 Select your login credentials from the list.
Containers supports credentials authentication and public-private key authentication.
- 7 Click **Verify** to confirm that the configured parameters are valid.
If the verification is successful, new text boxes appear for you to add additional information.
- 8 (Optional) Select a placement zone from the list.

Note If you are configuring a VCH, the placement zone and placement are automatically created and connected to the host.

- 9 (Optional) Select a deployment policy from the list.
- 10 (Optional) Define custom properties for the host.
- 11 Click **Add**.

You successfully added a host to Containers.

What to do next

[Create and Manage Container Placements and Placement Zones](#)

Using Container Deployment Policies

You can link deployment policies to hosts and container definitions. You use deployment policies in Containers for vRealize Automation to set a preference for the specific host and quotas for when you deploy a container.

Deployment policies that are applied to a container have a higher priority than placements that are applied to container hosts.

Create and Manage Container Placements and Placement Zones

You can use placements and placement zones to limit and reserve resources used by a business group. You can also set a priority to the reserved amount of memory.

You can edit or delete the placements you created by pointing at them and clicking the corresponding button.

When you create or manage placements, you can click the **Placement Zones** button to the right to add or manage placement zones.

Note If you configured a VCH, the placement and placement zone are automatically configured and cannot be changed. You must assign a business group to the placement, by clicking the **Edit** icon.

Prerequisites

- Log in to the vRealize Automation console as a **container administrator**.
- Verify that the specified memory resources are available.
- Verify that at least one host is configured and available for container network configuration.

Procedure

- 1 Click the **Containers** tab.
- 2 Click **Placements**.
- 3 Click **Add**.
- 4 Enter a name for your placement.
- 5 Assign the placement to a business group.
- 6 Select a placement zone from the list.
- 7 Select a deployment policy from the list.
- 8 (Optional) Enter a priority value for the placement.

Enter a positive number, with **1** representing the highest priority. To specify the lowest priority, leave the field blank.

- 9 Specify the number of instances.

- 10 Select the maximum amount of memory that can be used.

Select a number between 0 and the amount of memory available in the placement zone. This is the total memory available for resources in this placement. Enter 0 to specify no limit.

- 11 Click **Save**.

Set a Deployment Policy on a Host

Set a preference for the specific host and quotas for when you deploy a container.

Procedure

- 1 Create or edit a container host.
- 2 Click **Deployment Policies** on the right to expand a toolbar with additional options.
- 3 Click **Add** and set a deployment policy name and description.
- 4 In the **Add Host** or **Edit Host** view, select the policy from the **Deployment Policies** drop-down menu.

Set a Deployment Policy for a Placement

Set a deployment policy for a placement configuration.

Prerequisites

Procedure

- 1 Click the **Containers** tab.
- 2 Click **Placements**.
- 3 Hover over a placement and click the **Edit** icon.
- 4 From the **Deployment Policy** drop-down list, select an existing policy.

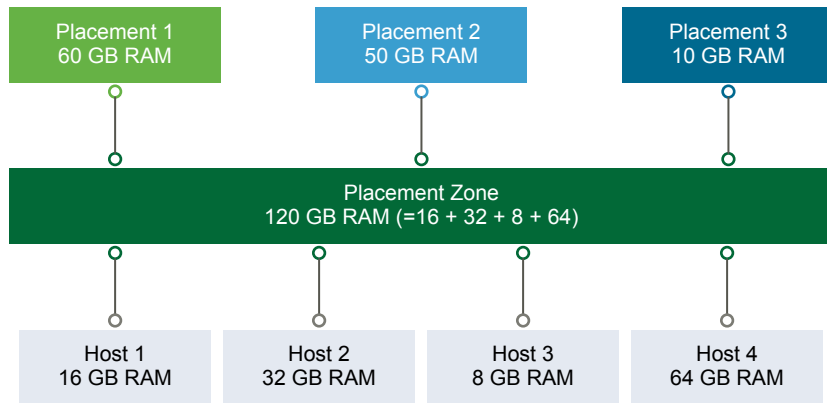

This drop-down list also includes controls for searching for a policy, creating a new policy, and managing policies. You can also click the **Deployment Policy** icon on the right side of the Placements page to access controls for configuring policies.

- 5 Click the **Save**.

Using Container Placement Zones

A placement zone is a set of hosts and the resources available in a placement zone are the sum of all the resources of the hosts inside it. Each placement is assigned to a placement zone in Containers for vRealize Automation. More than one placement can manage a single placement zone.

The placements that manage a placement zone cannot collectively reserve more resources than those available in the pool.

When a container is provisioned, the placements are filtered based on the business group, available resources, and priority.

Configuring Container Settings

You can define a single container or a multi-container application by using new and existing container configuration properties and settings.

In addition to the core Containers for vRealize Automation settings, the following vRealize Automation settings are available for deployments that use container components:

- Health configuration
- Links
- Exposed services
- Cluster size and scale in-and scale out parameters

Configure Health Checks in Containers

You can configure a health check method to update the status of a container based on custom criteria.

You can use HTTP or TCP protocols when executing a command on the container. You can also specify a health check method.

Prerequisites

- Verify that Containers for vRealize Automation is enabled in your supported vRealize Automation deployment.
- Verify that you have **container administrator** or **container architect** role privileges.

Procedure

- 1 Log in to vRealize Automation.
- 2 Click the **Containers** tab.
- 3 Click **Templates** in the left pane.

4 Edit the template or image.

Option	Description
To edit a template	<ul style="list-style-type: none"> Click Edit in the upper-right section of the template that you want to open. If the template contains multiple templates, point to the template that you want to edit, and click Edit in the upper-right section of the template that you want to open.
To edit an image.	Click the arrow next to the image's Provision button, and click Enter additional info .

5 Click the **Health Config** tab.

6 Select a health mode.

Table 2-20. Health Configuration Modes

Mode	Description
None	Default. No health checks are configured.
HTTP	<p>If you select HTTP, you must provide an API to access and an HTTP method and version to use . The API is relative and you do not need to enter the address of the container. You can also specify a timeout period for the operation and set health thresholds.</p> <p>For example, a healthy threshold of 2 means that two consecutive successful calls must occur for the container to be considered healthy and in the RUNNING status. An unhealthy threshold of 2 means that two unsuccessful calls must occur for the container to be considered unhealthy and in the ERROR status. For all the states in between the healthy and unhealthy thresholds, the container status is DEGRADED.</p>
TCP connection	If you select TCP connection , you must only enter a port for the container. The health check attempts to establish a TCP connection with the container on the provided port. You can also specify a timeout value for the operation and set healthy or unhealthy thresholds as with HTTP.
Command	If you select Command , you must enter a command to be executed on the container. The success of the health check is determined by the exit status of the command.
Ignore health check on provision	Uncheck this option to force health check on provision. By forcing it, a container is not considered provisioned until one successful health check passes.
Autodeploy	Automatic redeployment of containers when they are in ERROR state.

7 Click **Save as Template** to save the settings or select a business group and click **Provision** to deploy the container.

Configure Links in Containers

Links and exposed services address communication across container services and load balancing across hosts. You can configure link settings for your containers in Containers.

You can use links to enable communication between multiple services in your application. Links in Containers are similar to Docker links, but connect containers across hosts. A link consists of two parts: a service name and an alias. The service name is the name of the service or template being called. The alias is the host name that you use to communicate with that service.

For example, if you have an application that contains a Web and database service and you define a link in the Web service to the database service by using an alias of **my-db**, the Web service application opens a TCP connection to `my-db:{PORT_OF_DB}`. The `PORT_OF_DB` is the port that the database listens to, regardless of the public port that is assigned to the host by the container settings. If MySQL is checking for updates on its default port of 3306, and the published port for the container host is 32799, the Web application accesses the database at `my-db:3306`.

Note It is recommended that you use networks instead of links. Links are now a legacy Docker feature with significant limitations when linking container clusters, including:

- Docker does not support multiple links with the same alias. It is recommended that you allow Containers for vRealize Automation to generate link aliases for you.
 - You cannot update the links of a container runtime. When scaling up or down a linked cluster, the dependent container's links will not be updated.
-

Prerequisites

- Verify that Containers for vRealize Automation is enabled in your supported vRealize Automation deployment.
- Verify that you have **container administrator** or **container architect** role privileges.
- Verify that a bridge network is available for linking services.
- Verify that the internal port of the target service is published. For cross communication, the service can be mapped to any other port but must be accessible from outside the host.
- Verify that the service hosts are able to access each other.

Procedure

- 1 Log in to vRealize Automation.
- 2 Click the **Containers** tab.
- 3 Click **Templates** in the left pane.

4 Edit the template or image.

Option	Description
To edit a template	<ul style="list-style-type: none"> Click Edit in the upper-right section of the template that you want to open. If the template contains multiple templates, point to the template that you want to edit, and click Edit in the upper-right section of the template that you want to open.
To edit an image.	Click the arrow next to the image's Provision button, and click Enter additional info .

5 To edit a template

- a Click **Edit** in the upper-right section of the template that you want to open.
- b If the template contains multiple templates, point to the template that you want to edit, and click **Edit** in the upper-right section of the template that you want to open.

6 To edit an image.

- a Click the arrow next to the image's **Provision** button, and click **Enter additional info**.

The **Provision a Container** or **Edit Container Definition** page appears, providing access to categorized sets of editable properties and settings.

7 Click the **Basic** tab.

8 In the **Services** text box, enter a comma-separated list of services that the container is dependant on.

9 In the **Alias** text box, enter a descriptive name for the service or comma-separated list of services.

10 Click **Save**.

Configure Exposed Services in Containers

You can use a unique host name for a load balancer by providing an address and a placeholder in your container settings.

The placeholder determines the location of an automatically generated part of the URL. This value is unique for each host name. The address supports the %s format character to specify where the placeholder is located.

Note If the placeholder is not used, it is positioned as a prefix or suffix of the host name, depending on the system configuration.

It is recommended you use a load balancer that can target requests to each node if you build an application which includes a service that must be publicly exposed and which must also scale in and out. After you provision the application, the load balancer configuration is updated whenever the service is scaled in or out by vRealize Automation.

Prerequisites

- Verify that Containers for vRealize Automation is enabled in your supported vRealize Automation deployment.

- Verify that you have **container administrator** or **container architect** role privileges.

Procedure

- 1 Log in to vRealize Automation.
- 2 Click the **Containers** tab.
- 3 Click **Templates** in the left pane.
- 4 Edit the template or image.

Option	Description
To edit a template	<ul style="list-style-type: none"> ■ Click Edit in the upper-right section of the template that you want to open. ■ If the template contains multiple templates, point to the template that you want to edit, and click Edit in the upper-right section of the template that you want to open.
To edit an image.	Click the arrow next to the image's Provision button, and click Enter additional info .

- 5 Click the **Network** tab.
- 6 In the **Address** text box, enter the location of the placeholder.

The address host acts as a virtual host. To access the address host, you can add mapping information in the `etc/hosts` file or use a DNS that maps the container address to the host name.
- 7 In the **Container Port** text box, enter the port number used to expose the service.

Use the sample format provided in the form. If your container application exposes more than one port, specify which internal port or ports can expose the service.
- 8 Click **Save**.

Configure Cluster Size and Scale in Containers

You can create container clusters by using Containers placement settings to specify cluster size.

When you configure a cluster, the Containers provisions the specified number of containers. Requests are load balanced among all containers in the cluster.

You can modify the cluster size on a provisioned container or application to increase or decrease the size of the cluster by one. When you modify the cluster size at runtime, all affinity filters and placement rules are considered.

Prerequisites

- Verify that Containers for vRealize Automation is enabled in your supported vRealize Automation deployment.
- Verify that you have **container administrator** or **container architect** role privileges.

Procedure

- 1 Log in to vRealize Automation.

- 2 Click the **Containers** tab.
- 3 Click **Templates** in the left pane.
- 4 Edit the template or image.

Option	Description
To edit a template	<ul style="list-style-type: none"> ■ Click Edit in the upper-right section of the template that you want to open. ■ If the template contains multiple templates, point to the template that you want to edit, and click Edit in the upper-right section of the template that you want to open.
To edit an image.	Click the arrow next to the image's Provision button, and click Enter additional info .

- 5 Click the **Policy** tab.
- 6 Set the container cluster size.
- 7 Save the template or provision it.

Option	Description
When you edit a template	Click Save .
When you edit an image	<ol style="list-style-type: none"> a Select a business group. b Click Save as Template to save the settings or Provision to deploy the container.

Configuring and Using Templates and Images in Containers

Containers uses templates to provision containers.

A template is a reusable configuration for provisioning a container or a suite of containers. In a template, you can define a multi-tier application that consists of linked services.

A service is defined as one or more containers of the same type or image.

You can create a custom container template based on an existing template on the **Templates** page or import a properly formatted YAML file. You can also provision a container template or image.

Create a Custom Container Template

You can create a custom template and use it to define a container.

A template is a reusable configuration that you can use for provisioning a container or a suite of containers.

The Templates page displays template images that are available to you based on registries that you define. You can create a custom template, based on an existing template image or import a template or Docker Compose file. See [Import a Container Template or Docker Compose File](#).

You can also create a custom template or image by using the **Provision > Enter additional info** option described in [Provision a Container from a Template or Image](#).

Prerequisites

- Verify that you have **container administrator** role privileges.

Procedure

1 Log in to the vRealize Automation console as a **container administrator**.

2 Click the **Containers** tab.

3 Click **Templates** in the left pane.

A list displays the templates and images that are available for provisioning.

- Configured templates in the Images view.
- Existing or custom templates in the **Template** view.
- All available templates and images based on your specified registries in the **All** view.

The **Import** and **Export** options are also available to import or export templates and images.

4 Click the arrow next to the **Provision** button of an image you want to include in the template.

5 Click **Enter additional info**.

6 Click **Save as Template** to save your changes as a new container template in Containers for vRealize Automation.

What to do next

You can edit a template for future provisioning. Existing applications that were provisioned from the template are not affected by changes that you make to the template after provisioning.

Import a Container Template or Docker Compose File

You can use an imported Docker Container template or a Docker Compose YAML file as a custom template in the Containers for vRealize Automation.

If using a YAML file, enter the content of the YAML file as text or browse to and upload the YAML file. The YAML file represents the template, the configuration for the different containers, and their connections. The supported format types are Docker Compose YAML and Containers for vRealize Automation YAML.

Containers for vRealize Automation YAML is similar to Docker Compose, but it uses the vRealize Automation blueprint YAML format visible in the vRealize Automation REST API or in vRealize CloudClient. The Containers for vRealize Automation YAML allows you to import existing Docker Compose applications and modify, provision, and manage them by using Containers.

Prerequisites

- Verify that Containers for vRealize Automation is enabled in your supported vRealize Automation deployment.
- Log in to the vRealize Automation console as a **container administrator**.

For information about the YAML format used by vRealize Automation service REST APIs, see *vRealize Automation API Reference*.

Procedure

- 1 Click the **Containers** tab.

- 2 Click **Templates** in the left pane.

A list displays the templates and images that are available for provisioning.

- Configured templates in the **Images** view.
- Existing or custom templates in the **Template** view.
- All available templates and images based on your specified registries in the **All** view.

The **Import** and **Export** options are also available to import or export templates and images.

- 3 Click the **Import template or Docker Compose** icon.

The Import Template page appears.

- 4 Provide the YAML file content.

Option	Description
Load from File	Click Load from File to browse to and select the YAML file from a directory.
Enter template or Docker Compose	Paste the content of a properly formatted YAML file in the Enter template or Docker Compose text box.

- 5 Click **Import**.

The new template appears in the **Templates** view.

Provision a Container from a Template or Image

You can provision a container from a template or image in your Templates view.

The provisioning process creates a container based on the configuration settings that exist in the template or image from which you provision.

You can provision a container from a template or image either by using existing configuration settings or by editing configuration settings and then provisioning.

You can also edit and save configuration settings to create a new, customized container template or image.

Prerequisites

- Verify that Containers for vRealize Automation is enabled in your supported vRealize Automation deployment.
- Log in to the vRealize Automation console as a **container administrator**.

Procedure

- 1 Click the **Containers** tab.

2 Click **Templates** in the left pane.

A list displays the templates and images that are available for provisioning.

- Configured templates in the Images view.
- Existing or custom templates in the **Template** view.
- All available templates and images based on your specified registries in the **All** view.

The **Import** and **Export** options are also available to import or export templates and images.

3 Use the **All**, **Images**, or **Templates** view options to view the image or template to provision.

4 Provision the template or image.

Option	Description
Provision using existing settings.	<p>a Click Provision.</p> <p>The Provision Requests view displays information about provisioning success.</p>
Provision by editing settings.	<p>a Click the arrow next to the Provision button.</p> <p>b Click Enter additional info.</p> <p>c Enter the additional information for the container in the Provision a Container form.</p> <p>d When you have completed the form updates, click Provision to provision using the modified settings.</p> <p>e Click Save as Template to save your changes as a new container template in Containers for vRealize Automation.</p> <p>The Provision Requests view displays information about provisioning success.</p>

Export a Container Template or Docker Compose File

You can export a container template as a Docker Compose YAML file or a Containers for vRealize Automation YAML file.

You can import a template, modify it programmatically by using the vRealize Automation REST API or vRealize CloudClient, or graphically in Containers. You can then export the modified file. For example, you can import in Docker Compose format and export in the blueprint YAML format used in the vRealize Automation composition-service API. However, some configurations that are specific to Containers, such as health configuration and affinity constraints are not included if you export the template in Docker Compose format.

Prerequisites

- Verify that Containers for vRealize Automation is enabled in your supported vRealize Automation deployment.
- Log in to the vRealize Automation console as a **container administrator**.

For information about the YAML format used by vRealize Automation service REST APIs, see *vRealize Automation API Reference*.

Procedure

1 Click the **Containers** tab.

2 Click **Templates** in the left pane.

A list displays the templates and images that are available for provisioning.

- Configured templates in the Images view.
- Existing or custom templates in the **Template** view.
- All available templates and images based on your specified registries in the **All** view.

The **Import** and **Export** options are also available to import or export templates and images.

3 Point to a template and click its **Export** icon.

4 When prompted, select an output format type:

■ **YAML Blueprint**

This format adheres to the blueprint YAML format used in the vRealize Automation composition-service API.

■ **Docker Compose**

This format adheres to the YAML format used in the Docker Compose application.

5 Click **Export**.

6 Save the file or open it with an appropriate application when prompted.

Using Container Registries

A Docker registry is a stateless, server-side application. You can use registries in Containers for vRealize Automation to store and distribute Docker images.

To configure a registry, you need to provide its address, a custom registry name, and optionally credentials. The address must start with HTTP or HTTPS to designate whether the registry is secured or unsecured. If the connection type is not provided, HTTPS is used by default.

Note For HTTP you must declare port 80; for HTTPS you must declare port 443. If no port is specified, the Docker engine expects port 5000, which can result in broken connections.

Note It is recommended you do not use HTTP registries because HTTP is considered insecure. If you want to use HTTP, you must modify the `DOCKER_OPTS` property on each host as follows:

```
DOCKER_OPTS="--insecure-registry myregistrydomain.com:5000".
```

For more information, see the Docker documentation at <https://docs.docker.com/registry/insecure/>.

Containers can interact with both Docker Registry HTTP API V1 and V2 in the following manner:

V1 over HTTP (unsecured, plain HTTP registry)	You can freely search this kind of registry, but you must manually configure each Docker host with the <code>--insecure-registry</code> flag to provision containers based on images from insecure registries. You must restart the Docker daemon after setting the property.
V1 over HTTPS	Use behind a reverse proxy, such as NGINX. The standard implementation is available through open source at https://github.com/docker/docker-registry .
V2 over HTTPS	The standard implementation is open sourced at https://github.com/docker/distribution .
V2 over HTTPS with basic authentication	The standard implementation is open sourced at https://github.com/docker/distribution .
V2 over HTTPS with authentication through a central service	You can run a Docker registry in standalone mode, in which there are no authorization checks. Supported third-party registries are JFrog Artifactory and Harbor. Docker Hub is enabled by default for all tenants and is not present in the registry list, but it can be disabled with a system property.

Note Docker does not normally interact with secure registries configured with certificates signed by unknown authority. The container service handles this case by automatically uploading untrusted certificates to all docker hosts and enabling the hosts to connect to these registries. If a certificate cannot be uploaded to a given host, the host is automatically disabled.

Create and Manage Container Registries

You can configure multiple registries to gain access to both public and private images.

Registries are public or private stores, from which you upload or download images. You can disable, edit, or delete the registries that you created. The images shown in the **Templates** tab are based on the registries that you define.

When you create or manage registries in the Existing Registries page, you can click the **Credentials** or **Certificate** buttons to add or manage credentials and certificates.

Prerequisites

- Log in to the vRealize Automation console as a **container administrator**.
- Verify that at least one host is configured and available for container network configuration.

Procedure

- 1 Click the **Containers** tab.
- 2 Click **Templates**
- 3 Click **Manage Registry**.

The Existing Registries page appears.

- 4 Click **Add**.
- 5 Enter the registry address.
- 6 Enter a name for the registry.
- 7 Select your login credentials from the drop-down list.
- 8 (Optional) Click **Verify** to confirm that the configured parameters are valid.
- 9 Click **Save** to add the registry.

Configuring Network Resources for Containers

You can create, modify, and attach network configurations to containers and container templates in the Containers for vRealize Automation application.

When you provision a container, the network configuration is embedded and available. You can customize the network settings for container components that you added to a vRealize Automation blueprint.

Create a New Network for Containers

If a suitable network configuration is not available, you can create a new one in vRealize Automation.

Prerequisites

- Verify that you have **container administrator**, **container architect**, or **laaS administrator** role privileges.
- Verify that at least one host is configured and available for container network configuration.

Procedure

- 1 Log in to vRealize Automation.
- 2 Click the **Containers** tab.
- 3 Select **Networks** in the left pane.

The main panel displays the existing network configurations that can be provisioned as a part of the container deployment. The network configurations include both those collected from added Docker hosts and those created in vRealize Automation. The icons representing the network configurations display the network and IPAM drivers, subnet, gateway, and IP range information, the number of containers using the network configuration, and the number of hosts.

- 4 Click **Create Network**.
- 5 Enter a name for the network.

When you finish creating the new configuration, the name value will be appended with a unique identifier.

- 6 (Optional) To add more detailed configuration settings, select the **Advanced** check box.
Additional network configuration settings appear in the Add Network panel.

7 Configure the advanced network configuration settings.

Option	Description	
IPAM configuration	Subnet	Provide subnet and gateway addresses that are unique to this network configuration. They must not overlap with any other networks on the same container host.
Custom properties	Optionally, specify custom properties for the new network configuration.	
	containers.ipam.driver	<p>For use with containers only. Specifies the IPAM driver to be used when adding a Containers network component to a blueprint. The supported values depend on the drivers installed in the container host environment in which they are used. For example, a supported value might be <code>infoblox</code> or <code>calico</code> depending on the IPAM plug-ins that are installed on the container host.</p> <p>This property name and value are case-sensitive. The property value is not validated when you add it. If the specified driver does not exist on the container host at provisioning time, an error message is returned and provisioning fails.</p>
	containers.network.driver	<p>For use with containers only. Specifies the network driver to be used when adding a Containers network component to a blueprint. The supported values depend on the drivers installed in the container host environment in which they are used. By default, Docker-supplied network drivers include <code>bridge</code>, <code>overlay</code>, and <code>macvlan</code>, while Virtual Container Host (VCH)-supplied network drivers include the <code>bridge</code> driver. Third-party network drivers such as <code>weave</code> and <code>calico</code> might also be available, depending on what network plug-ins are installed on the container host.</p> <p>This property name and value are case-sensitive. The property value is not validated when you add it. If the specified driver does not exist on the container host at provisioning time, an error message is returned and provisioning fails.</p>

Note If you create the network without advanced settings, vRealize Automation supplies the settings automatically.

8 From the drop-down menu, select the host to which you want to connect the network.

9 Click **Create**.

Add a Network to a Container Template

You can add a network configuration to a container template to connect the containers to each other. This network configuration is automatically implemented for any applications that use the template. You can add either an existing network or configure and add a new network, as necessary.

Prerequisites

- Verify that you have a template available. If not, you must first create one.
- Verify that you have **container administrator**, **container architect**, or **laaS administrator** role privileges.
- Verify that at least one host is configured and available for container network configuration.

Procedure

1 Log in to vRealize Automation.

2 Click the **Containers** tab.

3 Click **Templates** in the left pane.

An array of icons displays the templates and images that are available for provisioning.

4 (Optional) Modify the view to show only templates by clicking **View: Templates** in the upper right header above the icons.

5 Click **Edit** in the upper-right section of the template that you want to customize.

The Edit Template page appears, displaying the container icons and a blank icon with a plus-sign.

6 Point to the blank icon.

The **Add Network** icon appears.

7 Click the **Add Network** icon.

The Add Network panel appears.

8 Add an existing network or create and add a new network.

Option	Description
Add an existing network.	<ul style="list-style-type: none"> a Click the Existing check box. b Click inside the Name field to display a list of existing networks. c Select the network you want to use and click Save.
Configure and add a new network.	<ul style="list-style-type: none"> a Enter a name for the network. b To add more detailed configuration settings, click the Advanced check box. c Click Save.

The Add Network Configuration panel disappears and the added network appears as a horizontal icon below the container icons in the Edit Template page. A network icon also appears on the bottom border of the container icons.

9 Connect the network to a container, by dragging the network connector icon from the container to any point on the horizontal icon representing the network.

Configuring Volumes for Containers

You can create, modify, and attach volumes to containers and container templates in the Containers for vRealize Automation application.

Containers for vRealize Automation uses Docker volumes for persistent data management. With volumes you can perform the following tasks:

- Share volumes between different containers within the same host.
- Update data instantly.
- Save the volume data after the container is deleted.

Create a New Volume for Containers

To extend your container storage, you must first create a data volume.

Prerequisites

- Verify that you have **container administrator**, **container architect**, or **laaS administrator** role privileges.
- Verify that at least one host is configured and available for container volume configuration.

Procedure

- 1 Log in to vRealize Automation.
- 2 Click the **Containers** tab.
- 3 Select **Resources > Volumes** in the left pane.

The main panel displays the existing volume configurations that can be connected to the deployed containers. The volume configurations include both those collected from added Docker hosts and those created in vRealize Automation. The volume instances display the driver, scope, and driver options.

- 4 Click **Create Volume**.
- 5 Enter a name for the volume.

When you finish creating the configuration, the name value is appended with a unique identifier.

- 6 In the **Driver** text box, enter the driver of the volume plug-in you want to use. If you do not enter anything, local is used as the default value.
- 7 (Optional) To add more detailed configuration settings, click the **Advanced** check box.

Additional configuration settings appear.

- 8 (Optional) Configure the advanced volume settings.

Option	Description
Driver Options	Specify the driver options you want to use. The options depend on the volume plug-in you are using.
Custom properties	Specify custom properties for the new configuration.

- 9 From the drop-down menu, select the host to which you want to connect the volume.

10 Click **Create**.

The Create Volume panel disappears and the added volume appears in the Volumes tab.

What to do next

[Add a Volume to a Container Template](#)

Add a Volume to a Container Template

Connect a volume to a container by adding it to a template.

Prerequisites

- Verify that you have a template available. If not, you must first create one.
- Verify that you have **container administrator**, **container architect**, or **laaS administrator** role privileges.
- Verify that at least one host is configured and available for container volume configuration.

Procedure

1 Log in to vRealize Automation.

2 Click the **Containers** tab.

3 Click **Templates** in the left pane.

An array of icons displays the templates and images that are available for provisioning.

4 (Optional) Modify the view to show only templates by clicking **View: Templates** in the upper right header above the icons.

5 Click **Edit** in the upper-right section of the template that you want to customize.

The Edit Template page appears, displaying the container icons, including a blank icon with a plus-sign.

6 Hover the cursor over the blank icon with the plus sign until the **Add Volume** icon appears.

7 Click the **Add Volume** icon.

8 Add an existing volume or create and add a new volume.

Option	Description
Add an existing volume.	<ul style="list-style-type: none"> a Click the Existing check box. b Click inside the Name field to display a list of existing volumes. c Select the volume you want to use and click Save.
Configure and add a new volume.	<ul style="list-style-type: none"> a Enter a name for the volume. b In the Driver text box, enter the driver of the volume plug-in you want to use. If you are not using an external storage system, enter local. c To add more detailed configuration settings, click the Advanced check box. d Click Save.

The Add Volume panel disappears and the added volume appears as a horizontal icon below the container icons in the Edit Template page. A volume icon also displays on the bottom border of the container icons.

- 9 Connect the volume to a container, by dragging the volume connector icon from the container to any point on the horizontal icon representing the volume.
- 10 (Optional) Click on the container path to change the location where the volume is mounted.

What to do next

[Provision a Container from a Template or Image](#)

Installing Additional Plug-Ins on the Default vRealize Orchestrator Server

You can install additional packages and plug-ins on the default vRealize Orchestrator server by using the vRealize Orchestrator configuration interface.

You can install additional plug-ins on the default vRealize Orchestrator server and use the workflows with XaaS.

You can also import additional packages on the default vRealize Orchestrator server for configuration as vRealize Automation external IPAM provider endpoint types. For example, for information about obtaining, importing, and configuring the Infoblox IPAM package, see [Checklist For Providing Third-Party IPAM Provider Support](#).

Package files (.package) and plug-in installation files (.vmoapp or .dar) are available from the VMware Solution Exchange at https://solutionexchange.vmware.com/store/category_groups/cloud-management. For information about plug-in files, see vRealize Orchestrator Plug-Ins Documentation at https://www.vmware.com/support/pubs/vco_plugins_pubs.html.

For more information about installing new plug-ins, see *Installing and Configuring VMware vCenter Orchestrator*.

Working With Active Directory Policies

Active Directory policies define the properties of a machine record, for example, domain, as well as the organizational unit in which the record is created using a vRealize Automation blueprint.

If you apply a policy to a business group, all the machine requests from the business group members are added to the specified organizational unit. You can create different policies for different organizational units, and then apply the different policies to different business groups.

Active Directory policies are a tech preview feature in vRealize Automation 7.1 and should not be used in a production environment.

Using Custom Properties to Override an Active Directory Policy

Using the provided Active Directory custom properties, you can override the Active Directory policy, domain, organizational unit, and other values on a particular blueprint when it is deployed.

The list of the provided Active Directory custom properties is included in the *Custom Properties Reference*. The custom property prefix is `ext.policy.activedirectory`.

In addition to the provided properties, you can create your own custom properties. You must prefix your custom properties with `ext.policy.activedirectory`. For example, `ext.policy.activedirectory.domain.extension` or `ext.policy.activedirectory.yourproperty`. The properties are passed to your custom vRealize Orchestrator Active Directory workflows.

For more information about custom properties, see *Custom Properties Reference*. Depending on what values you are overriding, you might need to create a property definition. For example, you might create a property definition that retrieves the available Active Directory policies from vRealize Automation. Alternatively, you might create definition that allows the requesting user to select from two or more alternative organizational units. See *Custom Properties Reference*.

Create and Apply Active Directory Policies

You create one or more Active Directory policies so that you can assign different policies to different business groups. You can use the different policies to add machine records to different organizational units based on business group membership.

If necessary, you can override the assigned Active Directory policy.

Procedure

1 [Create an Active Directory Policy](#)

You create an Active Directory policy to define where records are added in an Active Directory instance when your users deploy machines. You can assign a policy to a business group so that all machines deployed by the business group members result in a record created in the specified organizational unit.

2 [Scenario: Add a Custom Property to Blueprints to Override an Active Directory Policy](#)

As a blueprint architect for the development business group, you have a blueprint that includes an application machine and a database machine. You want the database machine record added to an organizational unit that is different from the applied Active Directory policy.

Create an Active Directory Policy

You create an Active Directory policy to define where records are added in an Active Directory instance when your users deploy machines. You can assign a policy to a business group so that all machines deployed by the business group members result in a record created in the specified organizational unit.

You create different Active Directory policies when you want machines deployed by different business groups to have different domains or to be added to different Active Directory instances.

Prerequisites

- Verify that you created an Active Directory endpoint. See [Configure the Active Directory Plug-In as an Endpoint](#).

- If you use an external vRealize Orchestrator server, verify that it is set up correctly. See [Configure an External vRealize Orchestrator Server](#).
- Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > AD Policies**.
- 2 Click the **New** icon (+).
- 3 Configure the Active Directory policy details.

Option	Description
ID	Enter the permanent value. The value cannot include any spaces or special characters. You cannot change this value at a later time. You can only re-create the policy with a different ID.
Description	Describe of the policy.
Active Directory Endpoint	Select the Active Directory endpoint for which this policy is created.
Domain	Enter the root domain. The format is <i>mycompany.com</i> .
Organizational Unit	Enter the organizational unit distinguished name for this policy. The hierarchy must be entered as a comma-separated list. For example, ou=development,dc=corp,dc=domain,dc=com.

- 4 Click **OK**.

The vRealize Orchestrator Active Directory endpoint is added to the list. You can apply the policy in business groups or use the policy in blueprints or business groups.

What to do next

- To provide multiple policy options, create more policies.
- To add records to Active Directory based on business group membership when a blueprint is deployed, add the appropriate Active Directory policy to a business group. See [Create a Business Group](#). You can apply the policy when you create the business group, or you can add it later.
- To override the Active Directory policy for the business group for a particular blueprint, add Active Directory custom properties to the blueprint. See [Scenario: Add a Custom Property to Blueprints to Override an Active Directory Policy](#).

Scenario: Add a Custom Property to Blueprints to Override an Active Directory Policy

As a blueprint architect for the development business group, you have a blueprint that includes an application machine and a database machine. You want the database machine record added to an organizational unit that is different from the applied Active Directory policy.

You have an existing policy that is applied to the development business group. The policy adds machine records to `ou=development,dc=corp,dc=domain,dc=com`. You want all database machines to be added to `ou=databases,dc=corp,dc=domain,dc=com`. In a blueprint that includes a database server, you override the Active Directory organizational unit to add the database machine record to `ou=databases,dc=corp,dc=domain,dc=com`.

This scenario makes the following assumptions:

- Your Active Directory includes organizational units for development and databases.
- You have a test blueprint that is included in a service and the service is entitled.

In addition to this simple example of how you can override the policy, you can use custom properties with Active Directory policy to make other changes to Active Directory when you deploy blueprints. See [Working With Active Directory Policies](#).

Prerequisites

- Verify that you have at least one Active Directory policy. See [Create an Active Directory Policy](#). For example, you create a development policy that adds records to `ou=development,dc=corp,dc=domain,dc=com`.
- Verify that you have a business group to which you applied an Active Directory policy. See [Create a Business Group](#). For example, your development business group uses the development policy.

Procedure

- 1 In your test blueprint, select the database machine in the canvas.
- 2 Click the **Properties** tab.
- 3 Click the **Custom Properties** tab.
- 4 Click the **New** icon ().
- 5 Add the custom property to change the default organizational unit.
 - a In the **Name** text box, enter `ext.policy.activedirectory.orgunit`.
 - b In the **Value** text box, enter `ou=databases,dc=corp,dc=domain,dc=com`.
 - c Deselect **Overridable**.
 - d Click **OK**.
- 6 Click **Finish**.

The test blueprint includes the custom property, but your users do not see the custom property in the request form.

What to do next

Request your test blueprint. Verify that the record for the database machine was added to the database organizational unit, and that the record for the application machine is added to the development organizational unit. When you are satisfied with the results, you can add the custom property to your production blueprints.

User Preferences for Notifications and Delegates

You use the user preference to individually override the default configuration of for your system approver notifications and your notification language preferences.

To access the user preferences, click **Preferences** on the toolbar next to your name.

The following options are specific to you as the logged in user.

Table 2-21. User Preference Options

Option	Description
Assign Delegates	Allows you to reassign your approval requests to other users. For example, you are an approver for catalog requests, but you are going on holiday. You delegate all your approval notifications to one or more approvers. This assignment immediately forwards the requests to your delegate. The delegates are active until you remove them from the list.
Notifications	Allows you to change your notification language so that the email messages are sent to you in the language of your choice rather than the default language. Select the language and add the notification subscription that supports your language preference.

Providing Service Blueprints to Users

3

You deliver on-demand services to users by creating catalog items and actions, then carefully controlling who can request those services by using entitlements and approvals.

This chapter includes the following topics:

- [Designing Blueprints](#)
- [Exporting and Importing Blueprints and Content](#)
- [Building Your Design Library](#)
- [Assembling Composite Blueprints](#)
- [Managing the Service Catalog](#)
- [Managing Deployed Catalog Items](#)

Designing Blueprints

Blueprint architects build Software components, machine blueprints, and custom XaaS blueprints and assemble those components into the blueprints that define the items users request from the catalog.

You can create and publish blueprints for a single machine, or a single custom XaaS blueprint, but you can also combine machine components and XaaS blueprints with other building blocks to design elaborate catalog item blueprints that include multiple machines, networking and security, software with full life cycle support, and custom XaaS functionality.

Depending on the catalog item you want to define, the process can be as simple as a single infrastructure architect publishing one machine component as a blueprint, or the process can include multiple architects creating many different types of components to design a complete application stack for users to request.

Software Components

You can create and publish software components to install software during the machine provisioning process and support the software life cycle. For example, you can create a blueprint for developers to request a machine with their development environment already installed and configured. Software components are not catalog items by themselves, and you must combine them with a machine component to create a catalog item blueprint.

Machine Blueprints

You can create and publish simple blueprints to provision single machines or you can create more complex blueprints that contain additional machine components and optionally any combination of the following component types:

- Software components
- Existing blueprints
- NSX network and security components
- XaaS components
- Containers components
- Custom or other components

XaaS Blueprints

You can publish your vRealize Orchestrator workflows as XaaS blueprints. For example, you can create a custom resource for Active Directory users, and design an XaaS blueprint to allow managers to provision new users in their Active Directory group. You create and manage XaaS components outside of the design tab. You can reuse published XaaS blueprints to create application blueprints, but only in combination with at least one machine component.

Application Blueprints with Multi-Machine, XaaS , and Software Components

You can add any number of machine components, Software components, and XaaS blueprints to a machine blueprint to deliver elaborate functionality to your users.

For example, you can create a blueprint for managers to provision a new hire setup. You can combine multiple machine components, software components, and a XaaS blueprint for provisioning new Active Directory users. The QE Manager can request your New Hire catalog item, and their new quality engineering employee is provisioned in Active Directory and given two working virtual machines, one Windows and one Linux, each with all the required software for running test cases in these environments.

Exporting and Importing Blueprints and Content

You can programmatically export blueprints and content from one vRealize Automation environment to another by using the vRealize Automation REST API or by using the vRealize CloudClient.

For example, you can create and test your blueprints in a development environment and then import them into your production environment. Or you can import a property definition from a community forum into your active vRealize Automation tenant instance.

You can programmatically import and export any of the following vRealize Automation content items:

- Application blueprints and all their components

- IaaS machine blueprints
- Software components
- XaaS blueprints
- Component profiles
- Property groups

Property group information is tenant-specific and is only imported with the blueprint if the property group already exists in the target vRealize Automation instance.

When you export a blueprint from one vRealize Automation instance tenant into another, the property group information defined for that blueprint is not recognized for the imported blueprint unless the property group already exists in the target tenant instance. For example, if you import a blueprint that contains a property group named `mica1`, the `mica1` property group is not present in the imported blueprint unless the `mica1` property group already exists in the vRealize Automation instance in which you import the blueprint. To avoid losing property group information when exporting a blueprint from one vRealize Automation instance to another, use vRealize CloudClient to create an export package zip file that contains the property group and import that package zip file into the target tenant before you import the blueprint. For more information about using vRealize CloudClient to list, package, export, and import property groups, as well as other vRealize Automation items, see the VMware Developer Center at <https://developercenter.vmware.com/tool/cloudclient>.

Table 3-1. Choosing Your Import and Export Tool

Tool	More information
vRealize CloudClient	See the VMware Developer site at https://developercenter.vmware.com/tool/cloudclient .
vRealize Automation REST API	See the <i>Programming Guide</i> in the vRealize Automation Information Center at https://www.vmware.com/support/pubs/vcac-pubs.html .

Note When exporting and importing blueprints programmatically across vRealize Automation deployments, for example from a test to a production environment or from one organization to another, it is important to recognize that clone template data is included in the package. When you import the blueprint package, default settings are populated based on information in the package. For example, if you export and then import a blueprint that was created using a clone-style workflow, and the template from which that clone data was derived does not exist in an endpoint in the vRealize Automation deployment in which you import the blueprint, some imported blueprint settings are not applicable for that deployment.

Scenario: Importing the Dukes Bank for vSphere Sample Application and Configuring for Your Environment

As an IT professional evaluating or learning vRealize Automation, you want to import a robust sample application into your vRealize Automation instance so you can quickly explore the available functionality and determine how you might build vRealize Automation blueprints that suit the needs of your organization.

Prerequisites

- Prepare a CentOS 6.x Linux reference machine, convert it to a template, and create a customization specification. See [Scenario: Prepare for Importing the Dukes Bank for vSphere Sample Application Blueprint](#).
- Create an external network profile to provide a gateway and a range of IP addresses. See [Create an External Network Profile by Using A Third-Party IPAM Provider](#).
- Map your external network profile to your vSphere reservation. See [Create a Reservation for Hyper-V, KVM, SCVMM, vSphere, or XenServer](#). The sample application cannot provision successfully without an external network profile.
- Verify that you have both the **infrastructure architect** and **software architect** privileges. Both roles are required to import the Dukes Bank sample application and to interact with the Dukes Bank blueprints and software components.

Procedure

1 [Scenario: Import the Dukes Bank for vSphere Sample Application](#)

You download the Dukes Bank for vSphere application from your vRealize Automation appliance. You import the sample application into your vRealize Automation tenant to view a working sample of a multi-tiered vRealize Automation blueprint that includes multiple machine components with networking and software components.

2 [Scenario: Configure Dukes Bank vSphere Sample Components for Your Environment](#)

Using your infrastructure architect privileges, you configure each of the Dukes Bank machine components to use the customization specification, template, and machine prefixes that you created for your environment.

You have configured the Dukes Bank for vSphere sample application for your environment to use as a starting point for developing your own blueprints, as a tool to evaluate vRealize Automation, or as a learning resource to assist you in understanding vRealize Automation functionality and components.

Scenario: Import the Dukes Bank for vSphere Sample Application

You download the Dukes Bank for vSphere application from your vRealize Automation appliance. You import the sample application into your vRealize Automation tenant to view a working sample of a multi-tiered vRealize Automation blueprint that includes multiple machine components with networking and software components.

Procedure

- 1 Log in to your vRealize Automation appliance as root by using SSH.
- 2 Download the Dukes Bank for vSphere sample application from your vRealize Automation appliance to /tmp.

```
wget --no-check-certificate https://vRealize_VA_Hostname_fqdn:5480/blueprints/DukesBankAppForvSphere.zip
```

Do not unzip the package.

- 3 Download vRealize CloudClient from <http://developercenter.vmware.com/tool/cloudclient> to /tmp.
- 4 Unzip the cloudclient-4x-dist.zip package.
- 5 Run vRealize CloudClient under the /bin directory.

```
$>./bin/cloudclient.sh
```

- 6 If prompted, accept the license agreement.
- 7 Using vRealize CloudClient, log in to the vRealize Automation appliance as a user with **software architect** and **infrastructure architect** privileges.

```
CloudClient>vra login userpass --server https://vRealize_VA_Hostname_fqdn --user <user@domain.com> --tenant <TenantName>
```

- 8 When prompted, enter your login password.
- 9 Validate that the DukesBankAppForvSphere.zip content is available.

```
vra content import --path /<Path>/DukesBankAppForvSphere.zip --dry-run true --resolution OVERWRITE
```

Note that the OVERWRITE entry is case-specific and requires uppercase.

By configuring the resolution to overwrite instead of *skip*, you allow vRealize Automation to correct conflicts when possible.

- 10 Import the Dukes Bank sample application.

```
vra content import --path /<Path>/DukesBankAppForvSphere.zip --dry-run false --resolution OVERWRITE
```

Note that the OVERWRITE entry is case-specific and requires uppercase.

When you log in to the vRealize Automation console as a user with software architect and infrastructure architect privileges, you see Dukes Bank blueprints and software components on the **Design > Blueprints** tab and the **Design > Software Components** tab.

Scenario: Configure Dukes Bank vSphere Sample Components for Your Environment

Using your infrastructure architect privileges, you configure each of the Dukes Bank machine components to use the customization specification, template, and machine prefixes that you created for your environment.

This scenario configures the machine components to clone machines from the template you created in the vSphere Web Client. If you want to create space-efficient copies of a virtual machine based on a snapshot, the sample application also supports linked clones. Linked clones use a chain of delta disks to track differences from a parent machine, are provisioned quickly, reduce storage cost, and are ideal to use when performance is not a high priority.

Procedure

- 1 Log in to the vRealize Automation console as an **infrastructure architect**.

You can configure the Dukes Bank sample application to work in your environment with only the **infrastructure architect** role, but if you want to view or edit the sample software components you also need the **software architect** role.

- 2 Select **Design > Blueprints**.
- 3 Select the **DukesBankApplication** blueprint and click the **Edit** icon.

- 4 Edit the appserver-node so vRealize Automation can provision this machine component in your environment.

You configure the blueprint to provision multiple instances of this machine component so you can verify the load balancer node functionality.

- a Click the **appserver-node** component on the design canvas.
Configuration details appear in the bottom panel.
- b Select your machine prefix from the **Machine prefix** drop-down menu.
- c Configure your blueprint to provision at least two and up to ten instances of this node by selecting a minimum of 2 instances and a maximum of 10.

On the request form, users are able to provision at least two and up to ten appserver nodes. If users are entitled to the scale in and scale out actions, they can scale their deployment to meet changing needs.

- d Click the **Build Information** tab.
- e Select **Cloneworkflow** from the **Provisioning workflow** drop-down menu.
- f Select your **dukes_bank_template** from the **Clone from** dialog.
- g Enter your **Customspecs_sample** in the **Customization spec** text box.

This field is case sensitive.

- h Click the **Machine Resources** tab.
 - i Verify that memory settings are at least 2048 MB.
- 5** Edit the loadbalancer-node so vRealize Automation can provision this machine component in your environment.
- a Click the **loadbalancer-node** component on the design canvas.
 - b Select your machine prefix from the **Machine prefix** drop-down menu.
 - c Click the **Build Information** tab.
 - d Select **Cloneworkflow** from the **Provisioning workflow** drop-down menu.
 - e Select your **dukes_bank_template** from the **Clone from** dialog.
 - f Enter your **Customspecs_sample** in the **Customization spec** text box.
This field is case sensitive.
 - g Click the **Machine Resources** tab.
 - h Verify that memory settings are at least 2048 MB.
- 6** Repeat for the **database-node** machine component.
- 7** Click **Save and Finish**.
Your changes are saved and you return to the **Blueprints** tab.
- 8** Select the **DukesBankApplication** blueprint and click **Publish**.

You configured the Dukes Bank sample application blueprint for your environment and published the finished blueprint.

What to do next

Published blueprints do not appear to users in the catalog until you configure a catalog service, add the blueprint to a service, and entitle users to request your blueprint. See [Checklist for Configuring the Service Catalog](#).

After you configure your Dukes Bank blueprint to display in the catalog, you can request to provision the sample application. See [Scenario: Test the Dukes Bank Sample Application](#).

Scenario: Test the Dukes Bank Sample Application

You request the Dukes Bank catalog item, and log in to the sample application to verify your work and view vRealize Automation blueprint functionality.

Prerequisites

- Import the Dukes Bank sample application and configure the blueprint components to work in your environment. See [Scenario: Importing the Dukes Bank for vSphere Sample Application and Configuring for Your Environment](#).

- Configure the service catalog and make your published Dukes Bank blueprint available for users to request. See [Checklist for Configuring the Service Catalog](#).
- Verify that virtual machines you provision can reach the yum repository.

Procedure

- 1 Log in to the vRealize Automation console as a user who is entitled to the Dukes Bank catalog item.
- 2 Click the **Catalog** tab.
- 3 Locate the Dukes Bank sample application catalog item and click **Request**.
- 4 Fill in the required request information for each component that has a red asterisk.
 - a Navigate to the JBossAppServer component to fill in the required request information.
 - b Enter the fully qualified domain name of your vRealize Automation appliance in the **app_content_server_ip** text box.
 - c Navigate to the Dukes_Bank_App software components to fill in the required request information.
 - d Enter the fully qualified domain name of your vRealize Automation appliance in the **app_content_server_ip** text boxes.
- 5 Click **Submit**.

Depending on your network and your vCenter Server instance, it can take approximately 15-20 minutes for the Dukes Bank sample application to fully provision. You can monitor the status under the **Requests** tab, and after the application provisions you can view the catalog item details on the **Items** tab.

- 6 After the application provisions, locate the IP address of the load balancer server so you can access the Dukes Bank sample application.
 - a Select **Items > Deployments**.
 - b Expand your Dukes Bank sample application deployment and select the Apache load balancer server.
 - c Click **View Details**.
 - d Select the **Network** tab.
 - e Make a note of the IP address.
- 7 Log in to the Dukes Bank sample application.
 - a Navigate to your load balancer server at `http://IP_Apache_Load_Balancer:8081/bank/main.faces`.
If you want to access the application servers directly, you can navigate to `http://IP_AppServer:8080/bank/main.faces`.
 - b Enter **200** in the **Username** text box.
 - c Enter **foobar** in the **Password** text box.

You have a working Dukes Bank sample application to use as a starting point for developing your own blueprints, as a tool to evaluate vRealize Automation, or as a learning resource to assist you in understanding vRealize Automation functionality and components.

Building Your Design Library

You can build out a library of reusable blueprint components that your architects can assemble into application blueprints for delivering elaborate on-demand services to your users.

Build out a library of the smallest blueprint design components: single machine blueprints, Software components, and XaaS blueprints, then combine these base building blocks in new and different ways to create elaborate catalog items that deliver increasing levels of functionality to your users.

Note that sample blueprints are available at the VMware Solution Exchange at <https://solutionexchange.vmware.com> and at <https://code.vmware.com>.

Table 3-2. Building Your Design Library

Catalog Item	Role	Components	Description	Details
Machines	Infrastructure architect	Create machine blueprints on the Blueprints tab.	<p>You can create machine blueprints to rapidly deliver virtual, private and public, or hybrid cloud machines to your users.</p> <p>Published machine blueprints are available for catalog administrators to include in the catalog as standalone blueprints, but you can also combine machine blueprints with other components to create more elaborate catalog items that include multiple machine blueprints, Software, or XaaS blueprints.</p>	Configure a Machine Blueprint
NSX Network and security on machines	Infrastructure architect	Add NSX network and security components to vSphere machine blueprints on the Blueprints tab.	<p>You can configure network and security components such as network profiles and security groups, to allow virtual machines to communicate with each other over physical and virtual networks securely and efficiently.</p> <p>You must combine network and security components with at least one vSphere machine component before catalog administrators can include them in the catalog. You can only apply NSX network and security components to vSphere machine blueprints.</p>	Designing Blueprints with NSX Settings

Table 3-2. Building Your Design Library (Continued)

Catalog Item	Role	Components	Description	Details
Software on machines	Software architect To successfully add software components to the design canvas, you must also have business group member, business group administrator, or tenant administrator role access to the target catalog.	Create and publish Software Components on the Software tab, then combine them with machine blueprints on the Blueprints tab.	Add Software components to your machine blueprints to standardize, deploy, configure, update, and scale complex applications in cloud environments. These applications can range from simple Web applications to elaborate custom applications and packaged applications. Software components cannot appear in the catalog alone. You must create and publish your Software components and then assemble an application blueprint that contains at least one machine.	Create a Software Component
Custom IT Services	XaaS architects	Create and publish XaaS blueprints on the XaaS tab.	You can create XaaS catalog items that extend vRealize Automation functionality beyond machine, networking, security, and software provisioning. Using existing vRealize Orchestrator workflows and plug-ins, or custom scripts you develop in vRealize Orchestrator, you can automate the delivery of any IT services. Published XaaS blueprints are available for catalog administrators to include in the catalog as standalone blueprints, but you can also combine them with other components on the Blueprints tab to create more elaborate catalog items.	Designing XaaS Blueprints and Resource Actions
Assemble published blueprint building blocks into new catalog items	<ul style="list-style-type: none"> ■ Application architect ■ Infrastructure architect ■ Software architect 	Combine additional machine blueprints, XaaS blueprints, and Software components with at least one machine component or machine blueprint on the Blueprints tab.	You can reuse published components and blueprints, combining them in new ways to create IT service packages that deliver elaborate functionality to your users.	Assembling Composite Blueprints

Designing Machine Blueprints

Machine blueprints are the complete specification for a machine, determining a machine's attributes, the manner in which it is provisioned, and its policy and management settings. Depending on the complexity of the catalog item you are building, you can combine one or more machine components in the blueprint with other components in the design canvas to create more elaborate catalog items that include networking and security, Software components, XaaS components, and other blueprint components.

Space-Efficient Storage for Virtual Provisioning

Space-efficient storage technology eliminates the inefficiencies of traditional storage methods by using only the storage actually required for a machine's operations. Typically, this is only a fraction of the storage actually allocated to machines. vRealize Automation supports two methods of provisioning with space-efficient technology, thin provisioning and FlexClone provisioning.

When standard storage is used, the storage allocated to a provisioned machine is fully committed to that machine, even when it is powered off. This can be a significant waste of storage resources because few virtual machines actually use all of the storage allocated to them, just as few physical machines operate with a 100% full disk. When a space-efficient storage technology is used, the storage allocated and the storage used are tracked separately and only the storage used is fully committed to the provisioned machine.

Thin Provisioning

Thin provisioning is supported for all virtual provisioning methods. Depending on your virtualization platform, storage type, and default storage configuration, thin provisioning might always be used during machine provisioning. For example, for vSphere ESX Server integrations using NFS storage, thin provisioning is always employed. However, for vSphere ESX Server integrations that use local or iSCSI storage, thin provisioning is only used to provision machines if the custom property `VirtualMachine.Admin.ThinProvision` is specified in the blueprint. For more information about thin provisioning, please see the documentation provided by your virtualization platform.

Net App FlexClone Provisioning

You can create a blueprint for Net App FlexClone provisioning if you are working in a vSphere environment that uses Network File System (NFS) storage and FlexClone technology.

You can only use NFS storage, or machine provisioning fails. You can specify a FlexClone storage path for other types of machine provisioning, but the FlexClone storage path behaves like standard storage.

The following is a high-level overview of the sequence of steps required to provision machines that use FlexClone technology:

- 1 An IaaS administrator creates a NetApp ONTAP endpoint. See [Endpoint Settings Reference](#).
- 2 An IaaS administrator runs data collection on the endpoint to enable the endpoint to be visible on the compute resource and reservation pages.

The FlexClone option is visible on a reservation page in the endpoint column if a NetApp ONTAP endpoint exists and if the host is virtual. If there is a NetApp ONTAP endpoint, the reservation page displays the endpoint assigned to the storage path.

- 3 A fabric administrator creates a vSphere reservation, enables FlexClone storage, and specifies an NFS storage path that uses FlexClone technology. See [Create a Reservation for Hyper-V, KVM, SCVMM, vSphere, or XenServer](#).
- 4 An infrastructure architect or other authorized user creates a blueprint for FlexClone provisioning.

Understanding and Using Blueprint Parameterization

You can use component profiles to parameterize blueprints. Rather than create a separate small, medium, and large blueprint for a particular deployment type, you can create a single blueprint with a choice of small, medium, or large size virtual machine. Users can select one of these sizes when they deploy the catalog item.

Component profiles minimize blueprint sprawl and simplify your catalog offerings. You can use component profiles to define vSphere machine components in a blueprint. The available component profile types are Size and Image. When you add component profiles to a machine component, the component profile settings override other settings on the machine component, such as number of CPUs or amount of storage.

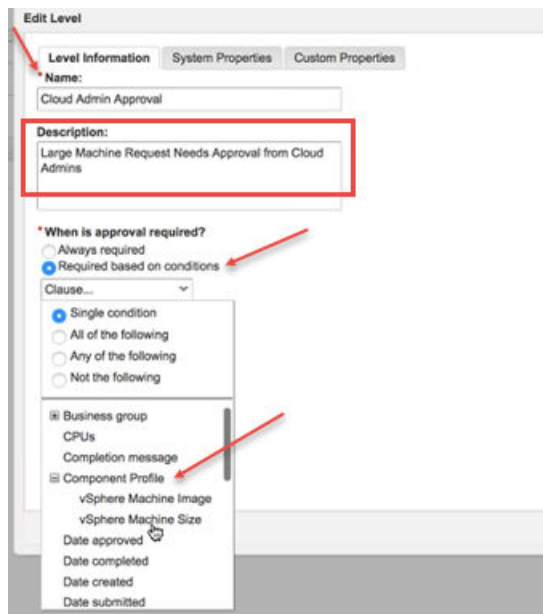

Component profiles are only available for vSphere machine components.

For information about defining value sets for the Size and Image component profiles, see in *Custom Properties Reference*

For information about adding component profiles and selected value sets for a vSphere machine component in a blueprint, see [vSphere Machine Component Settings](#).

For information about using component profiles when requesting machine provisioning, see [Request Machine Provisioning By Using a Parameterized Blueprint](#).

Note You can create approval policies to require pre-approval when requesting machine provisioning of blueprints relative to value set conditions for the Size and Image component profile. For more information, see [Examples of Approval Policies Based on the Virtual Machine Policy Type](#)

For information about using blueprint parameterization when requesting machine provisioning from the catalog, see [Request Machine Provisioning By Using a Parameterized Blueprint](#).

Configure a Machine Blueprint

Configure and publish a machine component as a standalone blueprint that other architects can reuse as a component in application blueprints, and catalog administrators can include in catalog services.

Prerequisites

- Log in to the vRealize Automation console as an **infrastructure architect**.
- Complete external preparations for provisioning, such as creating templates, WinPEs, and ISOs, or gather the information about external preparations from your administrators.
- Configure your tenant. [Configuring Tenant Settings](#).
- Configure your IaaS resources. [Checklist for Configuring IaaS Resources](#).
- See *Configuring vRealize Automation*.

Procedure

- 1 Select **Design > Blueprints**.
- 2 Click the **New** icon ().
- 3 Follow the prompts on the **New Blueprint** dialog box to configure general settings.
- 4 Click **OK**.
- 5 Click **Machine Types** in the Categories area to display a list of available machine types.
- 6 Drag the type of machine you want to provision onto the design canvas.
- 7 Follow the prompts on each of the tabs to configure machine provisioning details.
- 8 Click **Finish**.
- 9 Select your blueprint and click **Publish**.

You configured and published a machine component as a standalone blueprint. Catalog administrators can include this machine blueprint in catalog services and entitle users to request this blueprint. Other architects can reuse this machine blueprint to create more elaborate application blueprints that include Software components, XaaS blueprints, or additional machine blueprints.

What to do next

You can combine a machine blueprint with Software components, XaaS blueprints, or additional machine blueprints to create more elaborate application blueprints. See [Assembling Composite Blueprints](#).

Machine Blueprint Settings

You can define configuration settings and custom properties for the overall blueprint.

Blueprint Properties Settings

You can specify settings that apply to the entire blueprint by using the **New Blueprint** page when you create the blueprint. After you create the blueprint, you can edit these settings on the Blueprint Properties page.

General Tab

Apply settings across your entire blueprint, including all components you intend to add now or later.

Table 3-3. General Tab Settings

Setting	Description
Name	Enter a name for your blueprint.
Identifier	The identifier field automatically populates based on the name you entered. You can edit this field now, but after you save the blueprint you can never change it. Because identifiers are permanent and unique within your tenant, you can use them to programmatically interact with blueprints and to create property bindings.
Description	Summarize your blueprint for the benefit of other architects. This description also appears to users on the request form.
Archive days	You can specify an archival period to temporarily retain deployments instead of destroying deployments as soon as their lease expires. Specify 0 (default) to destroy the deployment when its lease expires. The archive period begins on the day the lease expires. When the archive period ends, the deployment is destroyed.
Deployment limit	Specify the maximum number of deployments that can be created when this blueprint is used to provision machines.
Lease days: Minimum and Maximum	Enter a minimum and maximum value to allow users to choose from within a range of lease lengths. When the lease ends, the deployment is either destroyed or archived. If you do not specify a minimum or maximum value, the lease is set to never expire.

NSX Settings Tab

If you have configured NSX you can specify NSX transport zone, Edge and routed gateway reservation policy, and app isolation settings when you create or edit a blueprint. These settings are available on the **NSX Settings** tab on the **Blueprint** and **Blueprint Properties** pages.

For information about NSX settings, see [New Blueprint and Blueprint Properties Page Settings with NSX](#).

Properties Tab

Custom properties you add at the blueprint level apply to the entire blueprint, including all components. However, they can be overridden by custom properties assigned later in the precedence chain. For more information about order of precedence for custom properties, see *Custom Properties Reference*.

Table 3-4. Properties Tab Settings

Tab	Setting	Description
Property Groups		Property groups are reusable groups of properties that are designed to simplify the process of adding custom properties to blueprints. Your tenant administrators and fabric administrators can group properties that are often used together so you can add the property group to a blueprint instead of individually inserting custom properties.
	Add	Add one or more existing property groups and apply them to the overall blueprint. The following Containers-related property groups are supplied: <ul style="list-style-type: none"> ■ Container host properties with certificate authentication ■ Container host properties with user/password authentication
	Move up /Move down	Control the order of precedence given to each property group in relation to one another by prioritizing the groups. The first group in the list has the highest priority, and its custom properties have first precedence. You can also drag and drop to reorder.
	View properties	View the custom properties in the selected property group.
	View merged properties	If a custom property is included in more than one property group, the value included in the property group with the highest priority takes precedence. You can view these merged properties to assist you in prioritizing property groups.
Custom Properties		You can add individual custom properties instead of property groups.
	New	Add an individual custom property and apply it to the overall blueprint.
	Name	Enter the property name. For a list of custom properties and their definitions, see <i>Custom Properties Reference</i> .
	Value	Enter the value for the custom property.
	Encrypted	You can choose to encrypt the property value, for example, if the value is a password.

Table 3-4. Properties Tab Settings (Continued)

Tab	Setting	Description
	Overridable	You can specify that the property value can be overridden by the next or subsequent person who uses the property. Typically, this is another architect, but if you select Show in request, your business users are able to see and edit property values when they request catalog items.
	Show in request	If you want to display the property name and value to your end users, you can select to display the property on the request form when requesting machine provisioning. You must also select overridable if you want users to provide a value.

vSphere Machine Component Settings

Understand the settings and options that you can configure for a vSphere machine component in the vRealize Automation blueprint design canvas. vSphere is the only machine component type that can use NSX network and security component settings in the design canvas.

General Tab

Configure general settings for a vSphere machine component.

Table 3-5. General Tab Settings

Setting	Description
ID	Enter a name for your machine component, or accept the default.
Description	Summarize your machine component for the benefit of other architects.
Display location on request	<p>In a cloud environment, such as vCloud Air, this allows users to select a region for their provisioned machines.</p> <p>For a virtual environment, such as vSphere, you can configure the locations feature to allow users to select a particular data center location at which to provision a requested machine. To fully configure this option, a system administrator adds data center location information to a locations file and a fabric administrator edits a compute resource to associate it with a location.</p>
Reservation policy	Apply a reservation policy to a blueprint to restrict the machines provisioned from that blueprint to a subset of available reservations. Fabric administrators create reservation policies to provide an optional and helpful means of controlling how reservation requests are processed, for example to collect resources into groups for different service levels, or to make a specific type of resource easily available for a particular purpose. If your fabric administrator did not configure reservation policies, you do not see any available options in this drop-down menu.

Table 3-5. General Tab Settings (Continued)

Setting	Description
Machine prefix	<p>Machine prefixes are created by fabric administrators and are used to create the names of provisioned machines. If you select Use group default, machines provisioned from your blueprint are named according to the machine prefix configured as the default for the user's business group. If no machine prefix is configured, one is generated for you based on the name of the business group.</p> <p>If your fabric administrator configures other machine prefixes for you to select, you can apply one prefix to all machines provisioned from your blueprint, no matter who the requestor is.</p>
Instances: Minimum and Maximum	<p>Configure the maximum and minimum number of instances users can request for a deployment or for a scale in or scale out action. If you do not want to give users a choice, entering the same value in the Minimum and Maximum fields configures exactly how many instances to provision and disables scale actions against this machine component.</p> <p>XaaS components are not scalable and are not updated during a scale operation. If you are using XaaS components in your blueprint, you could create a resource action for users to run after a scale operation, which could either scale or update your XaaS components as required.</p> <p>Alternatively, you could disable scale by configuring exactly the number of instances you want to allow for each machine component.</p>

Build Information Tab

Configure build information settings for a vSphere machine component.

Table 3-6. Build Information Tab

Setting	Description
Blueprint type	For record-keeping and licensing purposes, select whether machines provisioned from this blueprint are classified as Desktop or Server.
Action	<p>The options you see in the action drop-down menu depend on the type of machine you select.</p> <p>The following actions are available:</p> <ul style="list-style-type: none"> ■ Create <p>Create the machine component specification without use of a cloning option.</p> ■ Clone <p>Make copies of a virtual machine from a template and customization object.</p> ■ Linked Clone <p>Provision a space-efficient copy of a virtual machine called a linked clone. Linked clones are based on a snapshot of a VM and use a chain of delta disks to track differences from a parent machine.</p> <p>The VM snapshot identified in the blueprint should be powered off before you provision the linked clone VMs.</p> ■ NetApp FlexClone <p>If your fabric administrators configured your reservations to use NetApp FlexClone storage, you can clone space-efficient copies of machines using this technology.</p>

Table 3-6. Build Information Tab (Continued)

Setting	Description
Provisioning workflow	<p>The options you see in the provisioning workflow drop-down menu depend on the type of machine you select, and the action you select.</p> <ul style="list-style-type: none"> ■ BasicVmWorkflow Provision a machine with no guest operating system. ■ ExternalProvisioningWorkflow Create a machine by starting from either a virtual machine instance or cloud-based image. ■ LinuxKickstartWorkflow Provision a machine by booting from an ISO image, using a kickstart or autoYaSt configuration file and a Linux distribution image to install the operating system on the machine. ■ VirtualSccmProvisioningWorkflow Provision a machine and pass control to an SCCM task sequence to boot from an ISO image, deploy a Windows operating system, and install the vRealize Automation guest agent. ■ WIMImageWorkflow Provision a machine by booting into a WinPE environment and installing an operating system using a Windows Imaging File Format (WIM) image of an existing Windows reference machine. <p>When using a WIM provisioning workflow in a blueprint, specify a storage value that accounts for the size of each disk to be used on the machine. Use the total value of all disks as the minimum storage value for the machine component. Also specify a size for each disk that is large enough to accommodate the operating system.</p>
Clone from	<p>Select a machine template to clone from. You can refine the list of available templates by using the Filters option in each column drop-down menu, for example the Filters menu option in the Names column.</p> <p>For Linked Clone, you only see machines that have available snapshots to clone from and that you manage as a tenant administrator or business group manager.</p> <p>You can only clone from templates that exist on machines that you manage as a business group manager or tenant administrator.</p>

Table 3-6. Build Information Tab (Continued)

Setting	Description
Clone from snapshot	<p>For Linked Clone, select an existing snapshot to clone from based on the selected machine template. Machines only appear in the list if they already have an existing snapshot, and if you manage that machine as a tenant administrator or business group manager.</p> <p>If you select Use current snapshot, the clone is defined with the same characteristics as the latest state of the virtual machine. If you instead want to clone relative to an actual snapshot, click the drop-down menu option and select the specific snapshot from the list.</p> <hr/> <p>Note Use of the term snapshot can be confusing. If you select an existing snapshot, the option creates a new disk that is parented by the snapshot. The Use current snapshot option has no base disk to use as a parent and silently performs a full clone action. As a workaround, you can create snapshots on the base disk, or use a vRealize Orchestrator workflow to create a snapshot and then clone immediately from the snapshot.</p> <hr/> <p>This option is only available for the Linked Clone action.</p>
Customization spec	<p>Specify an available customization specification. A customization spec is required only if you are cloning with static IP addresses.</p> <p>You cannot perform customization of Windows machines without a customization specification. For Linux clone machines, you can perform customization by using a customization spec, an external script, or both.</p>

Machine Resources Tab

Specify CPU, memory, and storage settings for your vSphere machine component.

Table 3-7. Machine Resources Tab

Setting	Description
CPUs: Minimum and Maximum	Enter a minimum and maximum number of CPUs that can be provisioned by this machine component.
Memory (MB): Minimum and Maximum	Enter a minimum and maximum amount of memory that can be consumed by machines that are provisioned by this machine component.
Storage (GB): Minimum and Maximum	<p>Enter a minimum and maximum amount of storage that can be consumed by machines that are provisioned by this machine component. For vSphere, KVM (RHEV), SCVMM, vCloud Air, and vCloud Director, minimum storage is set based on what you enter on the Storage tab.</p> <p>When using a WIM provisioning workflow in a blueprint, specify a storage value that accounts for the size of each disk to be used on the machine. Use the total value of all disks as the minimum storage value for the machine component. Also specify a size for each disk that is large enough to accommodate the operating system.</p>

Storage Tab

You can add storage volume settings, including one or more storage reservation policies, to the machine component to control storage space.

Table 3-8. Storage Tab Settings

Setting	Description
ID	Enter an ID or name for the storage volume.
Capacity (GB)	Enter the storage capacity for the storage volume.
Drive Letter/Mount Path	Enter a drive letter or mount path for the storage volume.
Label	Enter a label for the drive letter and mount path for the storage volume.
Storage Reservation Policy	Enter the existing storage reservation policy to use with this storage volume.
Custom Properties	Enter any custom properties to use with this storage volume.
Maximum volumes	Enter the maximum number of allowed storage volumes that can be used when provisioning from the machine component. Enter 0 to prevent others from adding storage volumes. The default value is 60.
Allow users to see and change storage reservation policies	Select the check box to allow users to remove an associated reservation policy or specify a different reservation policy when provisioning.

Network Tab

You can configure network settings for a vSphere machine component based on NSX network and load balancer settings that are configured outside vRealize Automation. You can use settings from one or more existing and on-demand NSX network components in the design canvas.

For information about adding and configuring NSX network and security components before using network tab settings on a vSphere machine component, see [Configuring Network and Security Component Settings](#).

For information about specifying blueprint-level NSX settings that apply to vSphere machine components, see [New Blueprint and Blueprint Properties Page Settings with NSX](#).

Table 3-9. Network Tab Settings

Setting	Description
Network	Select a network component from the drop-down menu. Only network components that exist in the design canvas are listed.
Assignment Type	Accept the default assignment derived from the network component or select an assignment type from the drop-down menu. The DHCP and Static option values are derived from settings in the network component.
Address	Specify the IP address for the network. The option is available only for the static address type.
Load Balancing	Enter the service to use for load balancing.
Custom Properties	Display custom properties that are configured for the selected network component or network profile.
Maximum network adapters	Specify the maximum number of network adapters, or NICs, to allow for this machine component. The default is unlimited. Set to 0 to disable adding NICs for the machine components.

Security Tab

You can configure security settings for a vSphere machine component based on NSX settings that are configured outside vRealize Automation. You can optionally use settings from existing and on-demand NSX security components in the design canvas.

The security settings from existing and on-demand security group and security tag components in the design canvas are automatically available.

For information about adding and configuring NSX network and security components before using security tab settings on a vSphere machine component, see [Configuring Network and Security Component Settings](#).

For information about specifying blueprint-level NSX information that applies to vSphere machine components, see [New Blueprint and Blueprint Properties Page Settings with NSX](#).

Table 3-10. Security Tab Settings

Setting	Description
Name	Display the name of an NSX security group or tag. The names are derived from security components in the design canvas. Select the check box next to a listed security group or tag to use that group or tag for provisioning from this machine component.
Type	Indicate if the security element is an on-demand security group, an existing security group, or a security tag.
Description	Display the description defined for the security group or tag.
Endpoint	Display the endpoint used by the NSX security group or tag.

Properties Tab

Optionally specify custom property and property group information for your vSphere machine component.

You can add individual and groups of custom properties to the machine component by using the **Properties** tab. You can add also custom properties and property groups to the overall blueprint by using the **Properties** tab when you create or edit a blueprint by using the **New Blueprint** or **Blueprint Properties** page, respectively.

You can use the **Custom Properties** tab to add and configure options for existing custom properties. Custom properties are supplied with vRealize Automation and you can also create property definitions.

Table 3-11. Properties > Custom Properties Tab Settings

Setting	Description
Name	Enter the name of a custom property or select an available custom property from the drop-down menu. For example, enter the custom property name <code>Machine.SSH</code> to specify whether machines provisioned by using this blueprint allow SSH connections. Properties only appear in the drop-down menu if your tenant administrator or fabric administrator created property definitions.
Value	Enter or edit a value to associate with the custom property name. For example, set the value as <code>true</code> to allow entitled users to connect by using SSH to machines provisioned by using your blueprint.
Encrypted	You can choose to encrypt the property value, for example, if the value is a password.
Overridable	You can specify that the property value can be overridden by the next or subsequent person who uses the property. Typically, this is another architect, but if you select Show in Request , your business users are able to see and edit property values when they request catalog items.
Show in Request	If you want to display the property name and value to your end users, you can select to display the property on the request form when requesting machine provisioning. You must also select overridable if you want users to provide a value.

You can use the **Property Groups** tab to add and configure settings for existing custom property groups. You can create your own property groups or use property groups that have been created for you.

Table 3-12. Properties > Property Groups Tab Settings

Setting	Description
Name	Select an available property group from the drop-down menu.
Move Up and Move Down	Control the precedence level of listed property groups in descending order. The first-listed property group has precedence over the next-listed property group and so on.
View Properties	Display the custom properties in the selected property group.
View Merged Properties	Display all the custom properties in the listed property groups in the order in which they appear in the list of property groups. Where the same property appears in more than one property group, the property name appears only once in the list based on when it is first encountered in the list.

Profiles Tab

Component profiles provide a means of parameterizing blueprints, for example rather than creating a separate small, medium, and large blueprint you can create a single blueprint with a small, medium, and large capability and enable your use to select one of the sizes when the deploy the catalog item.

Component profiles are specifically designed to minimize blueprint sprawl and simplify your catalog.

If you have created value sets for the supplied vRealize Automation component profiles **Size** and **Image**, you can add and configure those settings for the machine component in the blueprint. You can also select different a value set when you deploy the catalog item.

Component profiles are only available for vSphere machine components.

When you add a component profile to the vSphere machine component in a blueprint, the settings defined in the profile's selected value set or value sets override other settings on the machine component, such as number of CPUs and storage.

The component profile value set is applied to all vSphere machines in a cluster.

You cannot reconfigure machines by using the **Size** or **Image** component profiles but the range of CPU, memory, and storage that is calculated based on the profile remains available for reconfigure actions. For example if you used a small (1 CPU, 1024MB memory, and 10 GB storage), medium (3 CPUs, 2048 MB memory, 12 GB storage) and large (5 CPUs, 3072 MB memory, 15 GB storage) **Size** value set, the available ranges during machine reconfiguration are 1-5 CPUs, 1024-3072 memory, and 1-15 GB storage.

For more information about defining value sets for component profiles, see *Custom Properties Reference*.

Table 3-13. Profiles Tab Settings

Setting	Description
Add	Add the Size or Image component profile.
Edit Value Sets	Assign one or more value sets for the selected component profile by selecting from a list of defined value sets. You can select one of the value sets as the default.
Remove	Remove the Size or Image component profile.

vCloud Air Machine Component Settings

Understand the settings and options that you can configure for a vCloud Air machine component in the vRealize Automation blueprint design canvas.

General Tab

Configure general settings for a vCloud Air machine component.

Table 3-14. General Tab Settings

Setting	Description
ID	Enter a name for your machine component, or accept the default.
Description	Summarize your machine component for the benefit of other architects.
Display location on request	<p>In a cloud environment, such as vCloud Air, this allows users to select a region for their provisioned machines.</p> <p>For a virtual environment, such as vSphere, you can configure the locations feature to allow users to select a particular data center location at which to provision a requested machine. To fully configure this option, a system administrator adds data center location information to a locations file and a fabric administrator edits a compute resource to associate it with a location.</p>
Reservation policy	Apply a reservation policy to a blueprint to restrict the machines provisioned from that blueprint to a subset of available reservations. Fabric administrators create reservation policies to provide an optional and helpful means of controlling how reservation requests are processed, for example to collect resources into groups for different service levels, or to make a specific type of resource easily available for a particular purpose. If your fabric administrator did not configure reservation policies, you do not see any available options in this drop-down menu.

Table 3-14. General Tab Settings (Continued)

Setting	Description
Machine prefix	<p>Machine prefixes are created by fabric administrators and are used to create the names of provisioned machines. If you select Use group default, machines provisioned from your blueprint are named according to the machine prefix configured as the default for the user's business group. If no machine prefix is configured, one is generated for you based on the name of the business group.</p> <p>If your fabric administrator configures other machine prefixes for you to select, you can apply one prefix to all machines provisioned from your blueprint, no matter who the requestor is.</p>
Instances: Minimum and Maximum	<p>Configure the maximum and minimum number of instances users can request for a deployment or for a scale in or scale out action. If you do not want to give users a choice, entering the same value in the Minimum and Maximum fields configures exactly how many instances to provision and disables scale actions against this machine component.</p> <p>XaaS components are not scalable and are not updated during a scale operation. If you are using XaaS components in your blueprint, you could create a resource action for users to run after a scale operation, which could either scale or update your XaaS components as required.</p> <p>Alternatively, you could disable scale by configuring exactly the number of instances you want to allow for each machine component.</p>

Build Information Tab

Configure build information settings for a vCloud Air machine component.

Table 3-15. Build Information Tab

Setting	Description
Blueprint type	For record-keeping and licensing purposes, select whether machines provisioned from this blueprint are classified as Desktop or Server.
Action	<p>The options you see in the action drop-down menu depend on the type of machine you select.</p> <p>The only provisioning action available for a vCloud Air machine component is Clone.</p> <ul style="list-style-type: none"> ■ Clone <p>Make copies of a virtual machine from a template and customization object.</p>

Table 3-15. Build Information Tab (Continued)

Setting	Description
Provisioning workflow	<p>The options you see in the provisioning workflow drop-down menu depend on the type of machine you select, and the action you select.</p> <p>The only provisioning action available for a vCloud Air machine component is CloneWorkflow.</p> <ul style="list-style-type: none"> ■ CloneWorkflow <p>Make copies of a virtual machine, either by Clone, Linked Clone, or NetApp Flexclone.</p>
Clone from	<p>Select a machine template to clone from. You can refine the list of available templates by using the Filters option in each column drop-down menu, for example the Filters menu option in the Names column.</p> <p>For Linked Clone, you only see machines that have available snapshots to clone from and that you manage as a tenant administrator or business group manager.</p> <p>You can only clone from templates that exist on machines that you manage as a business group manager or tenant administrator.</p>

Machine Resources Tab

Specify CPU, memory and storage settings for your vCloud Air machine component.

Table 3-16. Machine Resources Tab

Setting	Description
CPUs: Minimum and Maximum	Enter a minimum and maximum number of CPUs that can be provisioned by this machine component.
Memory (MB): Minimum and Maximum	Enter a minimum and maximum amount of memory that can be consumed by machines that are provisioned by this machine component.
Storage (GB): Minimum and Maximum	Enter a minimum and maximum amount of storage that can be consumed by machines that are provisioned by this machine component. For vSphere, KVM (RHEV), SCVMM, vCloud Air, and vCloud Director, minimum storage is set based on what you enter on the Storage tab.

Storage Tab

You can add storage volume settings, including one or more storage reservation policies, to the machine component to control storage space.

Table 3-17. Storage Tab Settings

Setting	Description
ID	Enter an ID or name for the storage volume.
Capacity (GB)	Enter the storage capacity for the storage volume.

Table 3-17. Storage Tab Settings (Continued)

Setting	Description
Drive Letter/Mount Path	Enter a drive letter or mount path for the storage volume.
Label	Enter a label for the drive letter and mount path for the storage volume.
Storage Reservation Policy	Enter the existing storage reservation policy to use with this storage volume.
Custom Properties	Enter any custom properties to use with this storage volume.
Maximum volumes	Enter the maximum number of allowed storage volumes that can be used when provisioning from the machine component. Enter 0 to prevent others from adding storage volumes. The default value is 60.
Allow users to see and change storage reservation policies	Select the check box to allow users to remove an associated reservation policy or specify a different reservation policy when provisioning.

Properties Tab

Optionally specify custom property and property group information for your vCloud Air machine component.

You can add individual and groups of custom properties to the machine component by using the **Properties** tab. You can add also custom properties and property groups to the overall blueprint by using the **Properties** tab when you create or edit a blueprint by using the **New Blueprint** or **Blueprint Properties** page, respectively.

You can use the **Custom Properties** tab to add and configure options for existing custom properties. Custom properties are supplied with vRealize Automation and you can also create property definitions.

Table 3-18. Properties > Custom Properties Tab Settings

Setting	Description
Name	Enter the name of a custom property or select an available custom property from the drop-down menu. For example, enter the custom property name <code>Machine.SSH</code> to specify whether machines provisioned by using this blueprint allow SSH connections. Properties only appear in the drop-down menu if your tenant administrator or fabric administrator created property definitions.
Value	Enter or edit a value to associate with the custom property name. For example, set the value as <code>true</code> to allow entitled users to connect by using SSH to machines provisioned by using your blueprint.
Encrypted	You can choose to encrypt the property value, for example, if the value is a password.

Table 3-18. Properties > Custom Properties Tab Settings (Continued)

Setting	Description
Overridable	You can specify that the property value can be overridden by the next or subsequent person who uses the property. Typically, this is another architect, but if you select Show in request, your business users are able to see and edit property values when they request catalog items.
Show in Request	If you want to display the property name and value to your end users, you can select to display the property on the request form when requesting machine provisioning. You must also select overridable if you want users to provide a value.

You can use the **Property Groups** tab to add and configure settings for existing custom property groups. You can create your own property groups or use property groups that have been created for you.

Table 3-19. Properties > Property Groups Tab Settings

Setting	Description
Name	Select an available property group from the drop-down menu.
Move Up and Move Down	Control the precedence level of listed property groups in descending order. The first-listed property group has precedence over the next-listed property group and so on.
View Properties	Display the custom properties in the selected property group.
View Merged Properties	Display all the custom properties in the listed property groups in the order in which they appear in the list of property groups. Where the same property appears in more than one property group, the property name appears only once in the list based on when it is first encountered in the list.

Amazon Machine Component Settings

Understand the settings and options that you can configure for an Amazon machine component in the vRealize Automation blueprint design canvas.

General Tab

Configure general settings for an Amazon machine component.

Table 3-20. General Tab Settings

Setting	Description
ID	Enter a name for your machine component, or accept the default.
Description	Summarize your machine component for the benefit of other architects.
Display location on request	In a cloud environment, such as vCloud Air, this allows users to select a region for their provisioned machines. For a virtual environment, such as vSphere, you can configure the locations feature to allow users to select a particular data center location at which to provision a requested machine. To fully configure this option, a system administrator adds data center location information to a locations file and a fabric administrator edits a compute resource to associate it with a location.

Table 3-20. General Tab Settings (Continued)

Setting	Description
Reservation policy	Apply a reservation policy to a blueprint to restrict the machines provisioned from that blueprint to a subset of available reservations. Fabric administrators create reservation policies to provide an optional and helpful means of controlling how reservation requests are processed, for example to collect resources into groups for different service levels, or to make a specific type of resource easily available for a particular purpose. If your fabric administrator did not configure reservation policies, you do not see any available options in this drop-down menu.
Machine prefix	Machine prefixes are created by fabric administrators and are used to create the names of provisioned machines. If you select Use group default , machines provisioned from your blueprint are named according to the machine prefix configured as the default for the user's business group. If no machine prefix is configured, one is generated for you based on the name of the business group. If your fabric administrator configures other machine prefixes for you to select, you can apply one prefix to all machines provisioned from your blueprint, no matter who the requestor is.
Instances: Minimum and Maximum	Configure the maximum and minimum number of instances users can request for a deployment or for a scale in or scale out action. If you do not want to give users a choice, entering the same value in the Minimum and Maximum fields configures exactly how many instances to provision and disables scale actions against this machine component. XaaS components are not scalable and are not updated during a scale operation. If you are using XaaS components in your blueprint, you could create a resource action for users to run after a scale operation, which could either scale or update your XaaS components as required. Alternatively, you could disable scale by configuring exactly the number of instances you want to allow for each machine component.

Build Information Tab

Configure build information settings for an Amazon machine component.

Table 3-21. Build Information Tab

Setting	Description
Blueprint type	For record-keeping and licensing purposes, select whether machines provisioned from this blueprint are classified as Desktop or Server.
Provisioning workflow	The only provisioning workflow available for an Amazon machine component is CloudProvisioningWorkflow. <ul style="list-style-type: none"> ■ CloudProvisioningWorkflow Create a machine by starting from either a virtual machine instance or cloud-based image.

Table 3-21. Build Information Tab (Continued)

Setting	Description
Amazon machine image	Select an available Amazon machine image. An Amazon machine image is a template that contains a software configuration, including an operating system. Machine images are managed by Amazon Web Services accounts. You can refine the list of Amazon machine image names in the display by using the Filters option in the AMI ID column drop-down menu.
Key pair	<p>Key pairs are required for provisioning with Amazon Web Services.</p> <p>Key pairs are used to provision and connect to a cloud instance. They are also used to decrypt Windows passwords and to log in to a Linux machine.</p> <p>The following key pair options are available:</p> <ul style="list-style-type: none"> ■ Not specified <p>Controls key pair behavior at the blueprint level rather than at the reservation level.</p> ■ Auto-generated per business group <p>Specifies that each machine provisioned in the same business group has the same key pair, including machines provisioned on other reservations when the machine has the same compute resource and business group. Because the key pairs are associated with a business group, the key pairs are deleted when the business group is deleted.</p> ■ Auto-generated per machine <p>Specifies that each machine has a unique key pair. The auto-generated per machine option is the most secure method because no key pairs are shared among machines.</p>
Enable Amazon network options on machine	Choose whether to allow users to provision a machine in a virtual private cloud (VPC) or a non-VPC location when they submit the request.
Instance types	<p>Select one or more Amazon instance types. An Amazon instance is a virtual server that can run applications in Amazon Web Services. Instances are created from an Amazon machine image and by choosing an appropriate instance type. vRealize Automation manages the machine image instance types that are available for provisioning.</p> <p>For information about using Amazon instance types in vRealize Automation, see Understanding Amazon Instance Types and Add an Amazon Instance Type.</p>

Machine Resources Tab

Specify CPU, memory, storage, and EBS volume settings for your Amazon machine component.

You can also reconfigure all Amazon machine storage volumes in the deployment except for the root volume.

Table 3-22. Machine Resources Tab

Setting	Description
CPUs: Minimum and Maximum	Enter a minimum and maximum number of CPUs that can be provisioned by this machine component.
Memory (MB): Minimum and Maximum	Enter a minimum and maximum amount of memory that can be consumed by machines that are provisioned by this machine component.
Storage (GB): Minimum and Maximum	Enter a minimum and maximum amount of storage that can be consumed by machines that are provisioned by this machine component. For vSphere, KVM (RHEV), SCVMM, vCloud Air, and vCloud Director, minimum storage is set based on what you enter on the Storage tab.
EBS Storage (GB): Minimum and Maximum	<p>Enter a minimum and maximum amount of Amazon Elastic Block Store (EBS) storage volume that can be consumed by machine resources that are provisioned by this machine component.</p> <p>When destroying a deployment that contains an Amazon machine component, all EBS volumes that were added to the machine during its life cycle are detached, rather than destroyed. vRealize Automation does not provide an option for destroying the EBS volumes.</p>

Properties Tab

Optionally specify custom property and property group information for your Amazon machine component.

You can add individual and groups of custom properties to the machine component by using the **Properties** tab. You can add also custom properties and property groups to the overall blueprint by using the **Properties** tab when you create or edit a blueprint by using the **New Blueprint** or **Blueprint Properties** page, respectively.

You can use the **Custom Properties** tab to add and configure options for existing custom properties. Custom properties are supplied with vRealize Automation and you can also create property definitions.

Table 3-23. Properties > Custom Properties Tab Settings

Setting	Description
Name	Enter the name of a custom property or select an available custom property from the drop-down menu. For example, enter the custom property name <code>Machine.SSH</code> to specify whether machines provisioned by using this blueprint allow SSH connections. Properties only appear in the drop-down menu if your tenant administrator or fabric administrator created property definitions.
Value	Enter or edit a value to associate with the custom property name. For example, set the value as <code>true</code> to allow entitled users to connect by using SSH to machines provisioned by using your blueprint.
Encrypted	You can choose to encrypt the property value, for example, if the value is a password.

Table 3-23. Properties > Custom Properties Tab Settings (Continued)

Setting	Description
Overridable	You can specify that the property value can be overridden by the next or subsequent person who uses the property. Typically, this is another architect, but if you select Show in request, your business users are able to see and edit property values when they request catalog items.
Show in Request	If you want to display the property name and value to your end users, you can select to display the property on the request form when requesting machine provisioning. You must also select overridable if you want users to provide a value.

You can use the **Property Groups** tab to add and configure settings for existing custom property groups. You can create your own property groups or use property groups that have been created for you.

Table 3-24. Properties > Property Groups Tab Settings

Setting	Description
Name	Select an available property group from the drop-down menu.
Move Up and Move Down	Control the precedence level of listed property groups in descending order. The first-listed property group has precedence over the next-listed property group and so on.
View Properties	Display the custom properties in the selected property group.
View Merged Properties	Display all the custom properties in the listed property groups in the order in which they appear in the list of property groups. Where the same property appears in more than one property group, the property name appears only once in the list based on when it is first encountered in the list.

OpenStack Machine Component Settings

Understand the settings and options you can configure for an OpenStack machine component in the vRealize Automation blueprint design canvas.

General Tab

Configure general settings for an OpenStack machine component.

Table 3-25. General Tab Settings

Setting	Description
ID	Enter a name for your machine component, or accept the default.
Description	Summarize your machine component for the benefit of other architects.
Display location on request	In a cloud environment, such as vCloud Air, this allows users to select a region for their provisioned machines. For a virtual environment, such as vSphere, you can configure the locations feature to allow users to select a particular data center location at which to provision a requested machine. To fully configure this option, a system administrator adds data center location information to a locations file and a fabric administrator edits a compute resource to associate it with a location.

Table 3-25. General Tab Settings (Continued)

Setting	Description
Reservation policy	<p>Apply a reservation policy to a blueprint to restrict the machines provisioned from that blueprint to a subset of available reservations. Fabric administrators create reservation policies to provide an optional and helpful means of controlling how reservation requests are processed, for example to collect resources into groups for different service levels, or to make a specific type of resource easily available for a particular purpose. If your fabric administrator did not configure reservation policies, you do not see any available options in this drop-down menu.</p>
Machine prefix	<p>Machine prefixes are created by fabric administrators and are used to create the names of provisioned machines. If you select Use group default, machines provisioned from your blueprint are named according to the machine prefix configured as the default for the user's business group. If no machine prefix is configured, one is generated for you based on the name of the business group.</p> <p>If your fabric administrator configures other machine prefixes for you to select, you can apply one prefix to all machines provisioned from your blueprint, no matter who the requestor is.</p>
Instances: Minimum and Maximum	<p>Configure the maximum and minimum number of instances users can request for a deployment or for a scale in or scale out action. If you do not want to give users a choice, entering the same value in the Minimum and Maximum fields configures exactly how many instances to provision and disables scale actions against this machine component.</p> <p>XaaS components are not scalable and are not updated during a scale operation. If you are using XaaS components in your blueprint, you could create a resource action for users to run after a scale operation, which could either scale or update your XaaS components as required.</p> <p>Alternatively, you could disable scale by configuring exactly the number of instances you want to allow for each machine component.</p>

Build Information Tab

Configure build information settings for an OpenStack machine component.

Table 3-26. Build Information Tab

Setting	Description
Blueprint type	For record-keeping and licensing purposes, select whether machines provisioned from this blueprint are classified as Desktop or Server.
Provisioning workflow	<p>The following provisioning workflows are available for an OpenStack machine component:</p> <ul style="list-style-type: none"> CloudLinuxKickstartWorkflow <p>Provision a machine by booting from an ISO image, using a kickstart or autoYaSt configuration file and a Linux distribution image to install the operating system on the machine.</p> CloudProvisioningWorkflow <p>Create a machine by starting from either a virtual machine instance or cloud-based image.</p> CloudWIMImageWorkflow <p>Provision a machine by booting into a WinPE environment and installing an operating system using a Windows Imaging File Format (WIM) image of an existing Windows reference machine.</p> <p>When using a WIM provisioning workflow in a blueprint, specify a storage value that accounts for the size of each disk to be used on the machine. Use the total value of all disks as the minimum storage value for the machine component. Also specify a size for each disk that is large enough to accommodate the operating system.</p>
OpenStack image	Select an available OpenStack image. An OpenStack image is a template that contains a software configuration, including an operating system. The images are managed by OpenStack accounts. You can refine the list of OpenStack image names in the display by using the Filters option in the Names column drop-down menu.

Table 3-26. Build Information Tab (Continued)

Setting	Description
Key pair	<p>Key pairs are optional for provisioning with OpenStack. Key pairs are used to provision and connect to a cloud instance. They are also used to decrypt Windows passwords and to log in to a Linux machine.</p> <p>The following key pair options are available:</p> <ul style="list-style-type: none"> ■ Not specified <p>Controls key pair behavior at the blueprint level rather than at the reservation level.</p> ■ Auto-generated per business group <p>Specifies that each machine provisioned in the same business group has the same key pair, including machines provisioned on other reservations when the machine has the same compute resource and business group. Because the key pairs are associated with a business group, the key pairs are deleted when the business group is deleted.</p> ■ Auto-generated per machine <p>Specifies that each machine has a unique key pair. The auto-generated per machine option is the most secure method because no key pairs are shared among machines.</p>
Flavors	<p>Select one or more OpenStack flavors. An OpenStack flavor is a virtual hardware template that defines the machine resource specifications for instances provisioned in OpenStack. Flavors are managed within the OpenStack provider and are imported during data collection.</p>

Machine Resources Tab

Specify CPU, memory and storage settings for your OpenStack machine component.

Table 3-27. Machine Resources Tab

Setting	Description
CPUs: Minimum and Maximum	Enter a minimum and maximum number of CPUs that can be provisioned by this machine component.
Memory (MB): Minimum and Maximum	Enter a minimum and maximum amount of memory that can be consumed by machines that are provisioned by this machine component.
Storage (GB): Minimum and Maximum	<p>Enter a minimum and maximum amount of storage that can be consumed by machines that are provisioned by this machine component. For vSphere, KVM (RHEV), SCVMM, vCloud Air, and vCloud Director, minimum storage is set based on what you enter on the Storage tab.</p> <p>When using a WIM provisioning workflow in a blueprint, specify a storage value that accounts for the size of each disk to be used on the machine. Use the total value of all disks as the minimum storage value for the machine component. Also specify a size for each disk that is large enough to accommodate the operating system.</p>

Properties Tab

Optionally specify custom property and property group information for your OpenStack machine component.

You can add individual and groups of custom properties to the machine component by using the **Properties** tab. You can add also custom properties and property groups to the overall blueprint by using the **Properties** tab when you create or edit a blueprint by using the **New Blueprint** or **Blueprint Properties** page, respectively.

You can use the **Custom Properties** tab to add and configure options for existing custom properties. Custom properties are supplied with vRealize Automation and you can also create property definitions.

Table 3-28. Properties > Custom Properties Tab Settings

Setting	Description
Name	Enter the name of a custom property or select an available custom property from the drop-down menu. For example, enter the custom property name <code>Machine.SSH</code> to specify whether machines provisioned by using this blueprint allow SSH connections. Properties only appear in the drop-down menu if your tenant administrator or fabric administrator created property definitions.
Value	Enter or edit a value to associate with the custom property name. For example, set the value as <code>true</code> to allow entitled users to connect by using SSH to machines provisioned by using your blueprint.
Encrypted	You can choose to encrypt the property value, for example, if the value is a password.

Table 3-28. Properties > Custom Properties Tab Settings (Continued)

Setting	Description
Overridable	You can specify that the property value can be overridden by the next or subsequent person who uses the property. Typically, this is another architect, but if you select Show in request, your business users are able to see and edit property values when they request catalog items.
Show in Request	If you want to display the property name and value to your end users, you can select to display the property on the request form when requesting machine provisioning. You must also select overridable if you want users to provide a value.

You can use the **Property Groups** tab to add and configure settings for existing custom property groups. You can create your own property groups or use property groups that have been created for you.

Table 3-29. Properties > Property Groups Tab Settings

Setting	Description
Name	Select an available property group from the drop-down menu.
Move Up and Move Down	Control the precedence level of listed property groups in descending order. The first-listed property group has precedence over the next-listed property group and so on.
View Properties	Display the custom properties in the selected property group.
View Merged Properties	Display all the custom properties in the listed property groups in the order in which they appear in the list of property groups. Where the same property appears in more than one property group, the property name appears only once in the list based on when it is first encountered in the list.

Using Network Custom Properties

You can specify network and security information for machine components other than vSphere and blueprints that do not contain NSX by using network custom properties at either the blueprint or machine component level.

The **Network & Security** components are only available for use with vSphere machine components. Non-vSphere machine components do not contain a **Network** or **Security** tab.

For machine components that do not have a **Network** or **Security** tab, you can add network and security custom properties, such as `VirtualMachine.Network0.Name`, to their **Properties** tab in the design canvas. NSX network, security, and load balancer properties are only applicable to vSphere machines.

You can define custom properties individually or as part of an existing property group by using the **Properties** tab when configuring a machine component in the design canvas. The custom properties that you define for a machine component pertain to machines of that type that are provisioned from the blueprint.

For information about the available custom properties, see *Custom Properties Reference*.

Troubleshooting Blueprints for Clone and Linked Clone

When creating a linked clone or clone blueprint, machine or templates are missing. Using your shared clone blueprint to request machines fails to provision machines.

Problem

When working with clone or linked clone blueprints, you might encounter one of the following problems:

- When you create a linked clone blueprint, no machines appear in the list to clone, or the machine you want to clone does not appear.
- When you create a clone blueprint, no templates appear in the list of templates to clone, or the template you want does not appear.
- When machines are requested by using your shared clone blueprint, provisioning fails.
- Because of data collection timing, a template that has been removed is still visible to users as they create or edit linked clone blueprints.

Cause

There are multiple possible causes for common clone and linked clone blueprint problems.

For related information about the **Clone from** and **Clone from snapshot** with **Use current snapshot** options that are available when you create blueprints, see [vSphere Machine Component Settings](#).

Table 3-30. Causes for Common Clone and Linked Clone Blueprints Problems

Problem	Cause	Solution
Machines missing	You can only create linked clone blueprints by using machines you manage as a tenant administrator or business group manager.	<p>A user in your tenant or business group must request a vSphere machine. If you have the appropriate roles, you can do this yourself.</p> <p>You can also see unmanaged machines in this dialog.</p> <p>Managed machines may have been imported. There is no requirement that machines be provisioned from vRealize Automation to be visible in this dialog.</p>
Templates missing	Data collection has failed on a given endpoint or no endpoints are available for the component's platform.	<ul style="list-style-type: none"> ■ If your endpoints are clustered and contain multiple compute resources, verify that your IaaS administrator added the cluster containing the templates to your fabric group. ■ For new templates, verify that IT placed the templates on the same cluster included in your fabric group.

Table 3-30. Causes for Common Clone and Linked Clone Blueprints Problems (Continued)

Problem	Cause	Solution
Provisioning failure with a shared blueprint	For blueprints, no validation is available to ensure that the template you select exists in the reservation used to provision a machine from your shared clone blueprint.	Consider using entitlements to restrict the blueprint to users who have a reservation on the compute resource where the template exists.
Provisioning failure with a guest agent	The virtual machine might be rebooting immediately after the guest operating system customization is completed, but before the guest agent work items are completed, causing provisioning to fail. You can use the custom property <code>VirtualMachine.Admin.CustomizeGuestOSDelay</code> to increase the time delay.	Verify that you have added the custom property <code>VirtualMachine.Admin.CustomizeGuestOSDelay</code> . The value must be in HH:MM:SS format. If the value is not set, the default value is one minute (00:01:00).
Linked clone provisioning fails when using SDRS	When using linked clone provisioning and SDRS, the new machine must reside on the same cluster. A provisioning error occurs if the source machine's disks are on one cluster and you request to provision a machine on a different cluster.	When using SDRS and linked clone provisioning, provision machines to the same cluster as the linked clone source. Do not provision to a different cluster.
Clone or linked clone blueprint provisioning fails because the template on which the clone is based cannot be found	It is not possible to provision machines from a blueprint that is cloned from a template that no longer exists. vRealize Automation runs data collection periodically, default every 24 hours. If a template is removed, the change is not reflected until the next data collection and so it is possible to create a blueprint based on a non-existent template.	Redefine the blueprint using an existing template and then request provisioning. As a precaution and as applicable, you can run data collection before defining the clone or linked clone blueprint.

Designing Blueprints with NSX Settings

If you have an NSX instance integrated with vRealize Automation, you can configure your vSphere blueprints to leverage NSX for network and security virtualization.

If you have configured vRealize Automation integration with NSX, you can use network, security, and load balancer components in the design canvas to configure your blueprint for machine provisioning. You can also add the following NSX network and security settings to the overall blueprint when you create a new blueprint or edit an existing blueprint.

- Transport zone - contains the networks used for the provisioned machine deployment
- Edge and routed gateway reservation policy - manages network communication for the provisioned machine deployment
- App isolation - allows only internal traffic between machines used in the provisioned machine deployment

For additional information about vRealize Automation and NSX integration and the use of the NSX network and security components in the vRealize Automation blueprint, see this [vRA and NSX - Intro to Network and Security Automation](#) blog article.

NSX settings are only applicable to vSphere machine component types.

New Blueprint and Blueprint Properties Page Settings with NSX

You can specify settings that apply to the entire blueprint, including some NSX settings, by using the **New Blueprint** page when you create the blueprint. After you create the blueprint, you can edit these settings on the Blueprint Properties page.

General Tab

Apply settings across your entire blueprint, including all components you intend to add now or later.

Table 3-31. General Tab Settings

Setting	Description
Name	Enter a name for your blueprint.
Identifier	The identifier field automatically populates based on the name you entered. You can edit this field now, but after you save the blueprint you can never change it. Because identifiers are permanent and unique within your tenant, you can use them to programmatically interact with blueprints and to create property bindings.
Description	Summarize your blueprint for the benefit of other architects. This description also appears to users on the request form.
Archive days	You can specify an archival period to temporarily retain deployments instead of destroying deployments as soon as their lease expires. Specify 0 (default) to destroy the deployment when its lease expires. The archive period begins on the day the lease expires. When the archive period ends, the deployment is destroyed.
Deployment limit	Specify the maximum number of deployments that can be created when this blueprint is used to provision machines.
Lease days: Minimum and Maximum	Enter a minimum and maximum value to allow users to choose from within a range of lease lengths. When the lease ends, the deployment is either destroyed or archived. If you do not specify a minimum or maximum value, the lease is set to never expire.

NSX Settings Tab

If you have configured NSX you can specify NSX transport zone, Edge and routed gateway reservation policy, and app isolation settings when you create or edit a blueprint. These settings are available on the **NSX Settings** tab on the **Blueprint** and **Blueprint Properties** pages.

For information about configuring NSX, see *NSX Administration Guide*.

Table 3-32. NSX Settings Tab Settings

Setting	Description
Transport zone	<p>Select an existing NSX transport zone to contain the network or networks that the provisioned machine deployment can use.</p> <p>A transport zone defines which clusters the networks can span. When provisioning machines, if a transport zone is specified in a reservation and in a blueprint, the transport zone values must match.</p> <p>A transport zone is only required for blueprints that have an on-demand network. For security groups, security tags, and load balancers, the transport zone is optional. If you do not specify a transport zone, the endpoint is determined by the location of the security group, security tag, or network that the load balancer connects to.</p>
Edge and routed gateway reservation policy	<p>Select an NSX Edge or routed gateway reservation policy. This reservation policy applies to routed gateways and to all edges that are deployed as part of provisioning. There is only one edge provisioned per deployment.</p> <p>For routed networks, edges are not provisioned, but you can use a reservation policy to select a reservation with the routed gateways to be used for routed network provisioning.</p> <p>When vRealize Automation provisions a machine with NAT or routed networking, it provisions a routed gateway as the network router. The Edge or routed gateway is a management machine that consumes compute resources like other virtual machines but manages the network communications all machine in that deployment. The reservation used to provision the Edge or routed gateway determines the external network used for NAT and load balancer virtual IP addresses. As a best practice, use separate management clusters for management machines such as NSX Edges.</p>
App isolation	<p>Select the App isolation check box to use the app isolation security policy configured in NSX. The app isolation policy is applied to all vSphere machine components in the blueprint. You can optionally add NSX security groups and tags to allow vRealize Orchestrator to open the isolated network configuration to allow additional paths in and out of the app isolation.</p>

Properties Tab

Custom properties you add at the blueprint level apply to the entire blueprint, including all components. However, they can be overridden by custom properties assigned later in the precedence chain. For more information about order of precedence for custom properties, see *Custom Properties Reference*.

Table 3-33. Properties Tab Settings

Tab	Setting	Description
Property Groups		Property groups are reusable groups of properties that are designed to simplify the process of adding custom properties to blueprints. Your tenant administrators and fabric administrators can group properties that are often used together so you can add the property group to a blueprint instead of individually inserting custom properties.
	Add	Add one or more existing property groups and apply them to the overall blueprint. The following Containers-related property groups are supplied: <ul style="list-style-type: none"> ■ Container host properties with certificate authentication ■ Container host properties with user/password authentication
	Move up /Move down	Control the order of precedence given to each property group in relation to one another by prioritizing the groups. The first group in the list has the highest priority, and its custom properties have first precedence. You can also drag and drop to reorder.
	View properties	View the custom properties in the selected property group.
	View merged properties	If a custom property is included in more than one property group, the value included in the property group with the highest priority takes precedence. You can view these merged properties to assist you in prioritizing property groups.
Custom Properties		You can add individual custom properties instead of property groups.
	New	Add an individual custom property and apply it to the overall blueprint.
	Name	Enter the property name. For a list of custom properties and their definitions, see <i>Custom Properties Reference</i> .
	Value	Enter the value for the custom property.
	Encrypted	You can choose to encrypt the property value, for example, if the value is a password.

Table 3-33. Properties Tab Settings (Continued)

Tab	Setting	Description
	Overridable	You can specify that the property value can be overridden by the next or subsequent person who uses the property. Typically, this is another architect, but if you select Show in request, your business users are able to see and edit property values when they request catalog items.
	Show in request	If you want to display the property name and value to your end users, you can select to display the property on the request form when requesting machine provisioning. You must also select overridable if you want users to provide a value.

Applying an NSX Transport Zone to a Blueprint

An NSX administrator can create transport zones to control cluster use of networks.

If the blueprint contains an on-demand network, you must specify the NSX transport zone that contains the networks used by the provisioned machine deployment. The same transport zone must be specified in the reservation.

Applying an NSX Edge or Routed Gateway Reservation Policy to a Blueprint

You can specify a reservation policy to manage the network communications for machines provisioned by the blueprint. When requesting machine provisioning, the reservation policy is used to group the reservations that can be considered for the deployment. The routed gateway reservation policy is also referred to as an edge reservation policy.

Networking information is contained in each reservation. When the machines are provisioned, an edge or routed gateway is allocated as the network router to manage network communications for the provisioned machines in the deployment. You can add or edit blueprint-level properties by using the blueprint properties page.

A routed gateway reservation policy is optional. It controls which reservation or reservations can be used to provision the NSX edge associated to on-demand networking and on-demand load balancer components specified in the blueprint.

You use reservation policies to control the selection of reservations. You select a reservation policy in your virtual machine definition in the blueprint and then assign that policy to the reservations that you want your virtual machines to use.

You cannot share reservations among multiple business groups.

vRealize Automation provisions a routed gateway, for example an edge services gateway (ESG), for NAT networks and for load balancers. For routed networks, vRealize Automation uses existing distributed routers.

A NAT network profile and load balancer enable vRealize Automation to deploy an NSX edge services gateway. A routed network profile uses an NSX logical distributed router (DLR). The DLR must be created in NSX before it can be consumed by vRealize Automation. vRealize Automation cannot create DLRs. After data collection, vRealize Automation can use the DLR for virtual machine provisioning.

The reservation used to provision the edge or routed gateway determines the external network used for NAT and routed network profiles, as well as the load balancer virtual IP addresses.

When you use the blueprint to provision a machine deployment, vRealize Automation attempts to use only the reservations associated with the specified reservation policy to provision the edge or routed gateway.

Applying an NSX App Isolation Security Policy to a Blueprint

An NSX app isolation policy acts as a firewall to block all inbound and outbound traffic to and from the provisioned machines in the deployment. When you specify a defined NSX app isolation policy, the machines provisioned by the blueprint can communicate with each other but cannot connect outside the firewall.

You can apply app isolation at the blueprint level by using the **New Blueprint** or **Blueprint Properties** page.

When using an NSX app isolation policy, only internal traffic between the machines provisioned by the blueprint is allowed. When you request provisioning, a security group is created for the machines to be provisioned. An app isolation security policy is created in NSX and applied to the security group. Firewall rules are defined in the security policy to allow only internal traffic between the components in the deployment. For related information, see [Create an NSX Endpoint and Associate to a vSphere Endpoint](#).

Note When provisioning with a blueprint that uses both an NSX edge load balancer and an NSX app isolation security policy, the dynamically provisioned load balancer is not added to the security group. This prevents the load balancer from communicating with the machines for which it is meant to handle connections. Because edges are excluded from the NSX distributed firewall, they cannot be added to security groups. To allow load balancing to function properly, use another security group or security policy that allows the required traffic into the component VMs for load balancing.

The app isolation policy has a lower precedence compared to other security policies in NSX. For example, if the provisioned deployment contains a web component machine and an app component machine and the web component machine hosts a web service, then the service must allow inbound traffic on ports 80 and 443. In this case, users must create a web security policy in NSX with firewall rules defined to allow incoming traffic to these ports. In vRealize Automation, users must apply the web security policy on the web component of the provisioned machine deployment.

Note If a blueprint contains one or more load balancers and app isolation is enabled for the blueprint, the load balancer VIPs are added to the app isolation security group as an IPSet. If a blueprint contains an on-demand security group that is associated to a machine tier that is also associated to a load balancer, the on-demand security group includes the machine tier and the IPSet with the load balancer VIP.

If the web component machine needs access to the app component machine using a load balancer on ports 8080 and 8443, the web security policy should also include firewall rules to allow outbound traffic to these ports in addition to the existing firewall rules that allow inbound traffic to ports 80 and 443.

For information about security features that can be applied to a machine component in a blueprint, see [Using Security Components in the Design Canvas](#).

Configuring Network and Security Component Settings

vRealize Automation supports virtualized networks based on the NSX platform. Integrated Containers for vRealize Automation networks are also supported.

To integrate network and security with vRealize Automation, an IaaS administrator must configure vSphere and NSX endpoints.

For information about external preparation, see *Configuring vRealize Automation*.

You can create network profiles that specify network settings in reservations and in the design canvas. External network profiles define existing physical networks. NAT and routed profiles are templates that will build NSX logical switches and appropriate routing settings for a new network path and for configuring network interfaces to connect to network path when you provision virtual machines and configure NSX Edge devices.

The network and security component settings that you add to the design canvas are derived from your NSX configuration and require that you have run data collection for the NSX inventory for vSphere clusters. Network and security components are specific to NSX and are available for use with vSphere machine components only. For information about configuring NSX, see *NSX Administration Guide*.

For machine components that do not have a **Network** or **Security** tab, you can add network and security custom properties, such as `VirtualMachine.Network0.Name`, to their **Properties** tab in the design canvas. NSX network, security, and load balancer properties are only applicable to vSphere machines.

If you specify a network profile in a reservation and a blueprint, the blueprint value takes precedence. For example, if you specify a network profile in the blueprint by using the `VirtualMachine.NetworkN.ProfileName` custom property and in a reservation that is used by the blueprint, the network profile specified in the blueprint takes precedence. However, if the custom property is not used in the blueprint, and you select a network profile for a machine NIC, vRealize Automation uses the reservation network path for the machine NIC for which the network profile is specified.

Depending on the compute resource, you can select a transport zone that identifies a vSphere endpoint. A transport zone specifies the hosts and clusters that can be associated with logical switches created within the zone. A transport zone can span multiple vSphere clusters. The blueprint and the reservations used in the provisioning must have the same transport zone setting. Transport zones are defined in the NSX environments. See *NSX Administration Guide*.

You can configure security settings for the virtual machines to be provisioned by specifying information in a reservation, blueprint, or guest agent script. If the machines to be provisioned requires a guest agent, you must add a security rule that contains that requirement to the reservation or the blueprint. For example, if you use a default security policy that denies communication between all machines, and rely

on a separate security policy to allow communication between specific machines, the guest agent might be unable to communicate with vRealize Automation during the customization phase. To avoid this problem during machine provisioning, use a default security policy that allows communication during the customization phase.

You can also add a Containers network component to a blueprint.

Using Network Components in the Design Canvas

You can add one or more NSX network components to the design canvas and configure their settings for vSphere machine components in the blueprint.

You can add network components to the design canvas to make their configured settings available to one or more machine components in the blueprint.

The network and security component settings that you add to the design canvas are derived from your NSX configuration and require that you have run data collection for the NSX inventory for vSphere clusters. Network and security components are specific to NSX and are available for use with vSphere machine components only. For information about configuring NSX, see *NSX Administration Guide*.

Add an Existing Network Component

You can add an existing NSX network component to the design canvas in preparation for associating its settings to one or more vSphere machine components in the blueprint.

You can use an existing network component to add an NSX network to the design canvas and configure its settings for use with vSphere machine components and Software or XaaS components that pertain to vSphere.

When you associate an existing network component or an on-demand network component with a machine component, the NIC information is stored with the machine component. The network profile information that you specify is stored with the network component.

You can add multiple network and security components to the design canvas.

For machine components that do not have a **Network** or **Security** tab, you can add network and security custom properties, such as `VirtualMachine.Network0.Name`, to their **Properties** tab in the design canvas. NSX network, security, and load balancer properties are only applicable to vSphere machines.

Prerequisites

- Create and configure network settings for NSX. See *Configuring vRealize Automation* and *NSX Administration Guide*.
- Verify that the NSX inventory has executed successfully for your cluster.
To use NSX configurations in vRealize Automation, you must run data collection.
- Create a network profile.
- Log in to the vRealize Automation console as an **infrastructure architect**.
- Open a new or existing blueprint in the design canvas by using the **Design** tab.

Procedure

- 1 Click **Network & Security** in the Categories section to display the list of available network and security components.
- 2 Drag an **Existing Network** component onto the design canvas.
- 3 Click in the **Existing network** text box and select an existing network profile.
The description, subnet mask and gateway values are populated based on the selected network profile.
- 4 (Optional) Click the **DNS/WINS** tab.
- 5 (Optional) Specify or accept provided DNS and WINS settings for the network profile.
 - Primary DNS
 - Secondary DNS
 - DNS Suffix
 - Preferred WINS
 - Alternate WINS

You cannot change the DNS or WINS settings for an existing network.
- 6 (Optional) Click the **IP Ranges** tab.
The IP range or ranges specified in the network profile are displayed. You can change the sort order or column display. For NAT networks, you can also change IP range values.
- 7 Click **Finish** to save the blueprint as draft or continue configuring the blueprint.

What to do next

You can continue configuring network settings by adding additional network components and by selecting settings in the **Network** tab of a vSphere machine component in the design canvas.

Creating and Using NAT Rules

You can add NAT rules to a one-to-many NAT network component in a blueprint when the NAT network component is associated to a non-clustered vSphere machine component or an on-demand NSX load balancer component.

You can define NAT rules for any NSX-supported protocol. You can map a port or a port range from the external IP address of an Edge to a private IP address in the NAT network component.

■ vSphere Machine Component

You can create NAT rules for a NAT one-to-many network component that is associated to a non-clustered vSphere machine component.

For example, if two machines are associated to a NAT one-to-many network component on the blueprint, you can define a NAT rule that allows port 443 on the external IP to connect to the machines through port 80 on the NAT network using TCP protocol.

■ NSX Load Balancer Component

You can create NAT rules for a NAT one-to many network component that is associated to the VIP network of an NSX load balancer component.

For example, if the NAT network component is associated to a load balancer component that is load balancing three machines, you can define a NAT rule that allows port 90 on the external IP to connect to the load balancer VIP through port 80 on the NAT network using UDP protocol.

You can create any number of NAT rules and you can control the order in which the rules are processed.

The following elements are not supported for NAT rules:

- NICs that are not in the current network
- NICs that are configured to get IP addresses by using DHCP
- Machine clusters

To add NAT rules to a NAT network component in a blueprint, see [Add an On-Demand NAT or On-Demand Routed Network Component](#).

For related information about using NAT rules, see public articles such as this [vmwarelab blog post](#).

Add an On-Demand NAT or On-Demand Routed Network Component

You can add an NSX on-demand NAT network component or NSX on-demand routed network component to the design canvas in preparation for associating their settings to one or more vSphere machine components in the blueprint.

When you associate an existing network component or an on-demand network component with a machine component, the NIC information is stored with the machine component. The network profile information that you specify is stored with the network component.

You can add multiple network and security components to the design canvas.

You can have more than one on-demand network component in a single blueprint. However, all of the on-demand network profiles that are used in the blueprint must reference the same external network profile.

For machine components that do not have a **Network** or **Security** tab, you can add network and security custom properties, such as `VirtualMachine.Network0.Name`, to their **Properties** tab in the design canvas. NSX network, security, and load balancer properties are only applicable to vSphere machines.

Prerequisites

- Create and configure network settings for NSX. See *Configuring vRealize Automation* and *NSX Administration Guide*.
- Verify that the NSX inventory has executed successfully for your cluster.

To use NSX configurations in vRealize Automation, you must run data collection.

- Create an on-demand network profile. See [Creating a Network Profile](#).

For example, if you are adding an on-demand NAT network component see [Creating a NAT Network Profile For an On-Demand Network](#).

- Log in to the vRealize Automation console as an **infrastructure architect**.
- Open a new or existing blueprint in the design canvas by using the **Design** tab.
- If you want to specify NAT rules for a NAT network component, you must use a NAT one-to-many network profile. See [Create a NAT Network Profile By Using the Supplied IPAM Endpoint](#) or [Create a NAT Network Profile By Using a Third-Party IPAM Endpoint](#). For information about NAT rules, see [Creating and Using NAT Rules](#).

Procedure

- 1 Click **Network & Security** in the Categories section to display the list of available network and security components.
- 2 Drag an on-demand NAT or on-demand routed network component onto the design canvas.
- 3 Enter a component name in the **ID** text box to uniquely label the component in the design canvas.
- 4 Select an appropriate network profile from the **Parent network profile** drop-down menu. For example, if you want to add a NAT network component, select a NAT network profile that is configured to support your intended network settings.

If you want to specify NAT rules in a NAT network component, you must use a parent network profile that is configured for NAT one-to-many.

Depending on the profile type you select, the following network settings are populated based on your network profile selection. Changes to these values must be made in the network profile:

- External network profile name
 - NAT type (On-Demand NAT Network)
 - Subnet mask
 - Range subnet mask (On-Demand Routed Network)
 - Range subnet mask (On-Demand Routed Network)
 - Base IP address (On-Demand Routed Network)
- 5 (Optional) Enter a component description in the **Description** text box.
 - 6 (Optional) Click the **DNS/WINS** tab.
 - 7 (Optional) Specify or accept provided DNS and WINS settings for the network profile.
 - Primary DNS
 - Secondary DNS
 - DNS Suffix
 - Preferred WINS
 - Alternate WINS

You cannot change the DNS or WINS settings for an existing network.

8 Click the IP Ranges tab.

The IP range or ranges specified in the network profile are displayed. You can change the sort order or column display. For NAT networks, you can also change IP range values.

- a Enter a start IP address value in the **IP range start** text box.
- b Enter a start IP address value in the **IP range start** text box.

9 If you are using a NAT network that is based on a one-to-many NAT network profile that uses static IP ranges, you can use the NAT Rules tab to add rules that enable an external IP to access components in the internal NAT network.

For a NAT one-to-many network, you can define NAT rules that can be configured when you add a NAT network component to the blueprint and can be changed when you edit the NAT network in a deployment.

The options that are available for selection are based on the vSphere machine or NSX load balancer components that you have associated to the NAT network component.

- **Name** - Enter a unique rule name.
- **Component** - Select from a list of associated vSphere machine or load balancer components to which the NAT network is associated.
- **Source port** - Select the ANY option, enter a valid port or port range, or specify a valid property binding.
- **Destination port** - Select the ANY option, enter a valid port or port range, or specify a valid property binding.
- **Protocol** - Enter any valid NSX-supported protocol or select the TCP, UDP, or ANY option.
- **Description** - Enter a brief description of what the NAT rule is designed to do.

10 Click Finish to save the blueprint as draft or continue configuring the blueprint.**What to do next**

You can continue configuring network settings by adding additional network components and by selecting settings in the **Network** tab of a vSphere machine component in the design canvas.

Using Load Balancer Components in the Design Canvas

You can add one or more on-demand NSX load balancer components to the design canvas to configure vSphere machine component settings in the blueprint.

The network and security component settings that you add to the design canvas are derived from your NSX configuration and require that you have run data collection for the NSX inventory for vSphere clusters. Network and security components are specific to NSX and are available for use with vSphere machine components only. For information about configuring NSX, see *NSX Administration Guide*.

The following rules apply to load balancer pools and VIP network settings in the blueprint.

- If the pool network profile is NAT, the VIP network profile can be part of the NAT network profile.

- If the pool network profile is routed, the VIP network profile can only be on the same routed network.
- If the pool network profile is external, the VIP network profile can only be the same external network profile.

Each load balancer component can have multiple virtual servers, which are also referred to as load balancer services. Each virtual server in the load balancer component has one port and protocol. For example, you can load balance an HTTP service or HTTPS service. A load balancer can have multiple services that it is load balancing.

The NSX Edge is the network device that contains the load balancer virtual servers. While you can have more than one load balancer component in a blueprint, when you provision the deployment, the virtual servers defined in each load balancer component are contained in a single NSX Edge.

If a blueprint contains one or more load balancers and app isolation is enabled for the blueprint, the load balancer VIPs are added to the app isolation security group as an IPSet. If a blueprint contains an on-demand security group that is associated to a machine tier that is also associated to a load balancer, the on-demand security group includes the machine tier and the IPSet with the load balancer VIP.

You can reconfigure load balancer settings in an existing deployment to add, edit, or remove virtual servers. For information, see [Reconfigure a Load Balancer in a Deployment](#).

For information about working with load balancer components after upgrade or migration, see [Considerations When Working With Upgraded or Migrated Load Balancer Components](#).

Considerations When Working With Upgraded or Migrated Load Balancer Components

The following considerations are important to understand and act on relative to NSX load balancer components in the target vRealize Automation release.

This information applies to NSX load balancer components that were upgraded or migrated to this vRealize Automation release.

- You must run NSX Network and Security Inventory data collection before and after upgrading or migrating to this release to avoid issues when running the Reconfigure Load Balancer action. The Reconfigure Load Balancer action for new deployments is not affected.

For more information, see *Upgrading from vRealize Automation 7.1 or 7.2 to 7.3* and *Migrating vRealize Automation to 7.3*.

- As of vRealize Automation 7.3, you can reconfigure a load balancer. The required catalog entitlement is Reconfigure (Load Balancer). For related information, see [Reconfigure a Load Balancer in a Deployment](#).
- For deployments that were upgraded or migrated from vRealize Automation 7.x to this vRealize Automation release, load balancer reconfiguration is limited to deployments that contain a single load balancer.
- The Reconfigure Load Balancer operation is not supported for deployments that were upgraded or migrated from vRealize Automation 6.2.x to this vRealize Automation release.

Add an On-Demand Load Balancer Component

You can drag an NSX on-demand load balancer component onto the design canvas and configure its settings for use with vSphere machine components and container components in the blueprint.

For related information about creating NSX application profiles to define the behavior of a particular type of network traffic, see the *NSX Administration Guide* for your release at

https://www.vmware.com/support/pubs/nsx_pubs.html.

Procedure

1 Define Load Balancer Member Settings

You can define an on-demand NSX load balancer component to distribute task processing among provisioned vSphere member machines or container machines in a network.

2 Define Virtual Server General Settings

You can define a single virtual server protocol and port for your load balancer or you can add additional virtual servers to customize additional NSX load balancer options.

3 Define Virtual Server Distribution Settings

By selecting the **Customize** option on the **General** tab, you can specify information about the pool members such as the port on which the members receive traffic, the protocol type that the NSX load balancer can use for accessing that port, the algorithm used for load balancing, and persistence settings.

4 Define Virtual Server Health Check Settings

By selecting the **Customize** option on the **General** tab, you can specify how, or if, the NSX load balancer performs health checks on pool members within the virtual server.

5 Define Virtual Server Advanced Settings

By selecting the **Customize** option on the **General** tab, you can customize the NSX load balancer component to specify settings such as the number of concurrent connections that a single pool member can recognize and the maximum number of concurrent connections that the virtual server can process.

6 Define Load Balancer Logging Options

You can define the types of load balancer logging actions that are captured and recorded in the load balancer logs.

Define Load Balancer Member Settings

You can define an on-demand NSX load balancer component to distribute task processing among provisioned vSphere member machines or container machines in a network.

When you add a load balancer component to a blueprint in the design canvas, you can choose either a default or custom option when creating or editing your virtual server definitions in the load balancer component. The default option allows you to specify the virtual server protocol, port, and description and use defaults for all other settings. The custom option allows you to define additional levels of detail.

If the load balancer is provisioned with an external network, the VIP (specified with **VIP Network**) and member pool (specified with **Member Network**) must be on the same existing network. If the VIP and pool are not on the same external network, an error occurs during provisioning.

Prerequisites

- Create and configure load balancer settings for NSX. See *Configuring vRealize Automation and NSX Administration Guide*.
- Verify that the NSX inventory has executed successfully for your cluster.
To use NSX configurations in vRealize Automation, you must run data collection.
- Create a network profile.
- Log in to the vRealize Automation console as an **infrastructure architect**.
- Open a new or existing blueprint in the design canvas by using the **Design** tab.
- Verify that at least one vSphere machine component or container component exists in the blueprint.

Procedure

- 1 Click **Network & Security** in the Categories section to display the list of available network and security components.
- 2 Drag an **On-Demand Load Balancer** component onto the design canvas.
- 3 Enter a component name in the **ID** text box to uniquely label the component in the design canvas.
- 4 Select a vSphere machine component or container component name from the **Member** drop-down menu.

The list contains only the vSphere machine components and container components in the active blueprint.

- 5 Select the NIC to load balance from the **Member network** drop-down menu.
The list contains NICs that are defined for the selected vSphere machine member.
- 6 Select an available virtual IP address network from the **VIP Network** drop-down menu. For example, select an available external or NAT network.

While you can have multiple NSX load balancer and NSX on-demand network components in a blueprint, they must all be associated to the same VIP network.

- 7 (Optional) Enter a valid IP address for the NIC in the **IP Address** text box.

The default setting is the static IP address that is associated with the VIP network. You can specify another IP address or an IP address range. By default, the next available IP address is allocated from the associated VIP network.

Leave the IP address field empty to allow the IP address to be allocated from the associated VIP network during provisioning.

You can only specify an IP address when the VIP is created on a NAT network.

- 8 To create a virtual server definition, click **New** and see [Define Virtual Server General Settings](#).

Each load balancer component requires at least one virtual server.

To specify logging options, see [Define Load Balancer Logging Options](#).

Define Virtual Server General Settings

You can define a single virtual server protocol and port for your load balancer or you can add additional virtual servers to customize additional NSX load balancer options.

For example, you can customize the load balancer component to define settings such as health check protocol and port, algorithm, persistence, and transparency.

Prerequisites

[Define Load Balancer Member Settings](#).

Procedure

- 1 Click the **General** tab on the **New Virtual Server** page.
- 2 Select the network traffic protocol in the **Protocol** drop-down menu to use for load balancing the virtual server.

The protocol options are HTTP, HTTPS, TCP, and UDP.

- 3 Enter a port value in the **Port** text box.

The selected protocol determines the default port setting.

Protocol	Default port
HTTP	80
HTTPS	443
TCP	8080
UDP	no default

The HTTP, HTTPS, and TCP protocols can share a port with UDP. For example, if service 1 uses TCP, HTTP, or HTTPS on port 80, service 2 can use UDP on port 80. If service 1 uses UDP on port 80 though, service 2 cannot use UDP on port 80.

- 4 (Optional) Enter a description for the virtual server component.
- 5 Select one of the **Settings** options.

- **Use default value for all other settings**

Accept all other default settings. Click **OK** to finish the load balancer component definition and continue working in the blueprint.

You can display the defaults by clicking **Customize** and examining the additional tab options. If the default settings are acceptable, click **Use default value for all other settings** on the **General** tab.

- **Customize**

Configure the load balancer component with additional settings, for example to define a different protocol for health monitoring or a different port for monitoring member traffic.

Additional tabs appear that allow you to add customized settings.

If you selected **Use default value for all other settings** and clicked **OK** you are done and can continue to define or edit your blueprint in the design canvas. If you selected **Customize**, continue to the step.

- 6 Click the **Distribution** tab and proceed to the [Define Virtual Server Distribution Settings](#) topic to continue defining the virtual server in the NSX load balancer component.

Define Virtual Server Distribution Settings

By selecting the **Customize** option on the **General** tab, you can specify information about the pool members such as the port on which the members receive traffic, the protocol type that the NSX load balancer can use for accessing that port, the algorithm used for load balancing, and persistence settings.

A pool represents a cluster of machines that are being load balanced. A pool member represents one machine in that cluster.

The default member protocol and member port settings match the protocol and port settings on the **General** page.

The pool of member machines is shown in the **Member** option value in the blueprint load balancer component user interface. The **Member** entry is set to the pool or cluster of machines.

Prerequisites

[Define Virtual Server General Settings.](#)

Procedure

- 1 (Optional) The **Member protocol** setting matches the protocol that you specified on the **General** tab. This setting defines how the pool member is to receive network traffic.
- 2 (Optional) Enter a port number in the **Member port** text box to specify the port on which the pool member is to receive network traffic.

For example, if the incoming request on the load balancer virtual IP address (VIP) is on port 80, you might want to route the request to another port, for example port 8080, on the pool members.

3 (Optional) Select the algorithm balancing method for this pool.

The algorithm options and the algorithm parameters for the options that require them are described in the following table.

Option	Description and algorithm parameters
ROUND_ROBIN	<p>Each server is used in turn according to the weight assigned to it.</p> <p>If the load balancer was created in vRealize Automation, the weight is the same for all members.</p> <p>This is the smoothest and fairest algorithm when the server's processing time remains equally distributed.</p> <p>Algorithm parameters are disabled for this option.</p>
IP-HASH	<p>Selects a server based on a hash of the source IP address and the total weight of all the running servers.</p> <p>Algorithm parameters are disabled for this option.</p>
LEASTCONN	<p>Distributes client requests to multiple servers based on the number of connections already on the server.</p> <p>New connections are sent to the server that has the fewest connections.</p> <p>Algorithm parameters are disabled for this option.</p>
URI	<p>The left part of the URI (before the question mark) is hashed and divided by the total weight of the running servers.</p> <p>The result designates which server receives the request. This ensures that a URI is always directed to the same server as long as no server goes up or down.</p> <p>The URI algorithm parameter has two options -- <code>uriLength=<len></code> and <code>uriDepth=<dep></code>. Enter the length and depth parameters on separate lines in the Algorithm parameters text box.</p> <p>Length and depth parameters are followed by a positive integer number. These options can balance servers based on the beginning of the URI only.</p> <p>The length parameter indicates that the algorithm should only consider the defined characters at the beginning of the URI to compute the hash. The length parameter range should be <code>1<=len<256</code>.</p> <p>The depth parameter indicates the maximum directory depth to be used to compute the hash. One level is counted for each slash in the request. The depth parameter range should be <code>1<=dep<10</code>.</p> <p>If both parameters are specified, the evaluation stops when either parameter is reached.</p>

Option	Description and algorithm parameters
HTTPHEADER	<p>The HTTP header name is looked up in each HTTP request.</p> <p>The header name in parenthesis is not case sensitive which is similar to the ACL 'hdr()' function.</p> <p>The HTTPHEADER algorithm parameter has one option headerName=<name>. For example, you can use host as the HTTPHEADER algorithm parameter.</p> <p>If the header is absent or does not contain any value, the round robin algorithm is applied.</p>
URL	<p>The URL parameter specified in the argument is looked up in the query string of each HTTP GET request.</p> <p>The URL algorithm parameter has one option urlParam=<url>.</p> <p>If the parameter is followed by an equal sign = and a value, then the value is hashed and divided by the total weight of the running servers. The result designates which server receives the request. This process is used to track user identifiers in requests and ensure that a same user ID is always sent to the same server as long as no server goes up or down.</p> <p>If no value or parameter is found, then a round robin algorithm is applied.</p>

4 (Optional) Select the persistence method for this pool.

Persistence tracks and stores session data, such as the specific pool member that serviced a client request. With persistence, client requests are directed to the same pool member for the life of a session or during subsequent sessions.

Protocol	Persistence method supported
HTTP	None, Cookie, Source IP
HTTPS	None, Source IP and SSL Session ID
TCP	None, Source IP, MSRDp
UDP	None, Source IP

- Select **Cookie** to insert a unique cookie to identify the session the first time a client accesses the site. The cookie is referred in subsequent requests to persist the connection to the appropriate server.
- Select **Source IP** to track sessions based on the source IP address. When a client requests a connection to a virtual server that supports source address affinity persistence, the load balancer checks to see if that client previously connected, and if so, returns the client to the same pool member.
- Select **SSL Session ID** and select the SSL Passthrough HTTPS traffic pattern.
 - SSL Passthrough - Client -> HTTPS-> LB (SSL passthrough) -> HTTPS -> server
 - Client - HTTP-> LB -> HTTP -> servers

Note vRealize Automation currently supports SSL Passthrough only. The SSL Passthrough method is used regardless of which option you select.

- Select **MSRDP** to maintain persistent sessions between Windows clients and servers that are running the Microsoft Remote Desktop Protocol (RDP) service. The recommended scenario for enabling MSRDP persistence is to create a load balancing pool that consists of members running the supported Windows Server, where all members belong to a Windows cluster and participate in a Windows session directory.
 - Select **None** to specify that session actions are not stored for subsequent recall.
- 5 If you are using a cookie persistence setting, enter the cookie name.
 - 6 (Optional) Select the mode by which the cookie is inserted from the **Mode** drop-down menu.

Option	Description
Insert	<p>The NSX Edge sends a cookie.</p> <p>If the server sends one or more cookies, the client receives an extra cookie (the server cookie(s) + the NSX Edge cookie). If the server does not send a cookie, the client receives the NSX Edge cookie.</p>
Prefix	<p>The server sends a cookie. Use this option if your client does not support more than one cookie.</p> <p>If you have a proprietary application using a proprietary client that supports only one cookie, the Web server sends a cookie but the NSX Edge injects (as a prefix) its cookie information in the server cookie value</p>
App Session	<p>The server does not send a cookie. Instead, it sends the user session information as a URL.</p> <p>For example, http://mysite.com/admin/UpdateUserServlet;jsessionid=X000X0XXX0XXXX, where jsessionid is the user session information and is used for persistence.</p>

- 7 (Optional) Enter the persistence expiration time for the cookie in seconds.

As an example, for L7 load balancing with a TCP source IP, the persistence entry times out if no new TCP connections are made for the specified expiration time, even if the existing connections are still live.

- 8 (Optional) Click the **Health Check** tab and proceed to the [Define Virtual Server Health Check Settings](#) topic to continue defining the virtual server in the NSX load balancer component.

Define Virtual Server Health Check Settings

By selecting the **Customize** option on the **General** tab, you can specify how, or if, the NSX load balancer performs health checks on pool members within the virtual server.

The default health check protocol and health check port settings match the protocol and port settings on the **General** tab.

For related information see *Create a Service Monitor* in NSX Product Documentation at https://www.vmware.com/support/pubs/nsx_pubs.html. Note that the NSX documentation refers to the virtual server member as a pool member.

Prerequisites

[Define Virtual Server General Settings](#).

Procedure

- 1 (Optional) Select a health check protocol in the **Health check protocol** drop-down menu to specify how the pool member is accessed when the load balancer listens to determine the health of the pool member.

The protocol options are **HTTP**, **HTTPS**, **TCP**, **ICMP**, **UDP**, and **None**.

You can also accept the default protocol as specified on the General tab.

- 2 (Optional) Enter a value in the **Health check port** box to specify on which port the load balancer listens to monitor the health of the virtual server member or pool member.

Note that the NSX documentation refers to a virtual server member as a pool member.

The HTTP, HTTPS, and TCP protocols can share a port with UDP. For example, if service 1 uses TCP, HTTP, or HTTPS on port 80, service 2 can use UDP on port 80. If service 1 uses UDP on port 80 though, service 2 cannot use UDP on port 80.

- 3 Enter the **Interval** value in seconds at which a server is to be pinged.
- 4 Enter the maximum **Timeout** value in seconds within which a response from the server must be received.
- 5 Enter a **Max. retries** value as the number of times the server must be pinged before it is declared down.
- 6 Specify additional health check settings based on your selected **Health check protocol**.
 - a Enter the **Method** to be used for detecting server status. The options are GET, OPTIONS, and POST.
 - b Enter the **URL** to be used in the request for detecting server status. This is the URL that is used for by GET and POST ("/" by default) method options.
 - c In the **Send** text box, enter the string to be sent to the server after a connection is established.
In the **Send** text box, enter the string to be sent to the server after a connection is established.
 - d In the **Receive** text box, enter the string expected to receive from the server.
Only when the received string matches this definition is the server is considered as up.
The string can be a header or in the body of the response.
- 7 Click the **Advanced** tab and proceed to the [Define Virtual Server Advanced Settings](#) topic to continue defining the virtual server in the NSX load balancer component.

To specify logging options, see [Define Load Balancer Logging Options](#).

Define Virtual Server Advanced Settings

By selecting the **Customize** option on the **General** tab, you can customize the NSX load balancer component to specify settings such as the number of concurrent connections that a single pool member can recognize and the maximum number of concurrent connections that the virtual server can process.

Prerequisites

Define Virtual Server General Settings.

Procedure

- 1 Enter a value in the **Connection limit** text box to specify the maximum concurrent connections in NSX that the virtual server can process.

This setting considers the number of all member connections.

Enter a value of 0 to specify no limit.
- 2 Enter a value in the **Connection rate limit** text box to specify the maximum number of incoming connection requests in NSX that can be accepted per second.

This setting considers the number of all member connections.

Enter a value of 0 to specify no limit.
- 3 (Optional) Select the **Enable acceleration** check box to specify that each virtual IP (VIP) uses the faster L4 load balancer rather than the L7 load balancer.
- 4 (Optional) Select the **Transparent** check box to allow the load balancer pool members to view the IP address of the machines that are calling the load balancer.

If not selected, the members of the load balancer pool view the traffic source IP address as a load balancer internal IP address.
- 5 Enter a value in the **Max connections** text box to specify the maximum number of concurrent connections that a single pool member can recognize.

If the number of incoming requests is higher than this value, requests are queued and then processed in the order in which they are received as connections are released.

Enter a value of 0 to specify no maximum value.
- 6 Enter a value in the **Min connections** text box to specify the minimum number of concurrent connections that a single pool member must always accept.

Enter a value of 0 to specify no minimum value.
- 7 Click **OK** to complete the virtual server definition.
- 8 To specify logging options, see [Define Load Balancer Logging Options](#), otherwise click **Save** or **Finish**.

Define Load Balancer Logging Options

You can define the types of load balancer logging actions that are captured and recorded in the load balancer logs.

After you define a load balancer component, or while you are defining a load balancer component, you can specify a logging level for collecting load balancer traffic logs. The logging levels that you define for any load balancer component on the blueprint apply to all load balancers that are defined in the blueprint.

Logging levels include debug, info, warning, error, and critical. Debug and info options log user requests while warning, error, and critical options do not log users requests.

For additional information about NSX load balancer logging, see the *NSX Administration Guide*.

Prerequisites

Define Load Balancer Member Settings.

Procedure

- 1 Select the **Global** tab on the load balancer component in the design canvas.
- 2 Select one or more logging options from the **Logging level** drop-down menu.

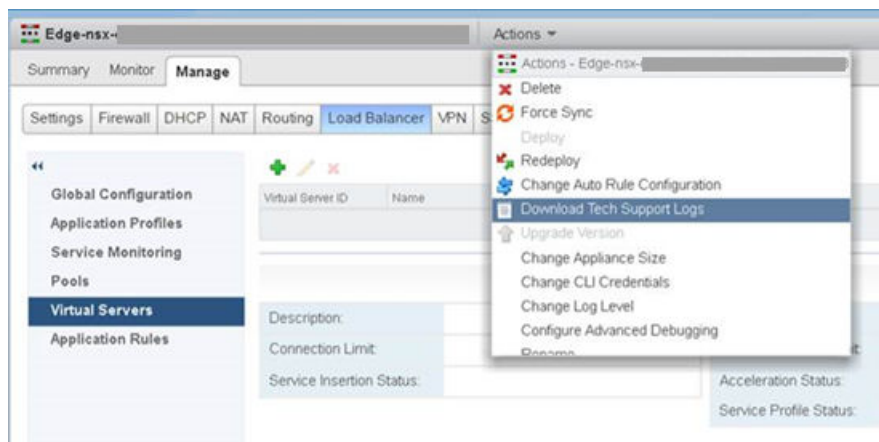

Select a logging level for collecting load balancer traffic logs. The setting applies to all NSX load balancer components in the blueprint.

The logging settings are defined in the vSphere web client.

- None
- Info
- Emergency
- Alert
- Critical
- Error
- Warning
- Notice
- Debug

- 3 Click **Save**.

You can view and download the logs in the vSphere web client by using the **Actions** menu for the NSX Edge as described in *Download Tech Support Logs for NSX Edge* in NSX Product Documentation at https://www.vmware.com/support/pubs/nsx_pubs.html.

Using Security Components in the Design Canvas

You can add NSX security components to the design canvas to make their configured settings available to one or more vSphere machine components in the blueprint.

Security groups, tags, and policies are configured outside of vRealize Automation in the NSX application.

The network and security component settings that you add to the design canvas are derived from your NSX configuration and require that you have run data collection for the NSX inventory for vSphere clusters. Network and security components are specific to NSX and are available for use with vSphere machine components only. For information about configuring NSX, see *NSX Administration Guide*.

You can add security controls to blueprints by configuring security groups, tags, and policies for the vSphere compute resource in NSX. After you run data collection, the security configurations are available for selection in vRealize Automation.

Security Group

A security group is a collection of assets or grouping objects from the vSphere inventory that is mapped to a set of security policies, for example distributed firewall rules and third party security service integrations such as anti-virus and intrusion detection. The grouping feature enables you to create custom containers to which you can assign resources, such as virtual machines and network adapters, for distributed firewall protection. After a group is defined, you can add the group as source or destination to a firewall rule for protection.

You can add NSX existing or on-demand security groups to a blueprint, in addition to the security groups specified in the reservation.

You can create one or more on-demand security groups. You can select one or more security policies to configure on a security group.

Security groups are managed in the source resource. For information about managing security groups for various resource types, see the NSX documentation.

If a blueprint contains one or more load balancers and app isolation is enabled for the blueprint, the load balancer VIPs are added to the app isolation security group as an IPSet. If a blueprint contains an on-demand security group that is associated to a machine tier that is also associated to a load balancer, the on-demand security group includes the machine tier and the IPSet with the load balancer VIP.

Security Tag

A security tag is a qualifier object or categorizing entry that you can use as a grouping mechanism. You define the criteria that an object must meet to be added to the security group you are creating. This gives you the ability to include machines by defining a filter criteria with a number of parameters supported to match the search criteria. For example, you can add all of the machines tagged with a specified security tag to a security group.

You can add a security tag to the design canvas.

Security Policy

A security policy is a set of endpoint, firewall, and network introspection services that can be applied to a security group. You can add security policies to a vSphere virtual machine by using an on-demand security group in a blueprint. You cannot add a security policy directly to a reservation. After data collection, the security policies that have been defined in NSX for a compute resource are available for selection in a blueprint.

App Isolation

When App isolation is enabled, a separate security policy is created. App isolation uses a logical firewall to block all inbound and outbound traffic to the applications in the blueprint. Component machines that are provisioned by a blueprint that contains an app isolation policy can communicate with each other but cannot connect outside the firewall unless other security groups are added to the blueprint with security policies that allow access.

Add an Existing Security Group Component

You can add an existing NSX security group component to the design canvas in preparation for associating its settings to one or more machine components or other available component types in the blueprint.

You can use an existing security group component to add an NSX security group to the design canvas and configure its settings for use with vSphere machine components and Software or XaaS components that pertain to vSphere.

You can add multiple network and security components to the design canvas.

Prerequisites

- Create and configure a security group in NSX. See *Configuring vRealize Automation* and *NSX Administration Guide*.
- Verify that the NSX inventory has executed successfully for your cluster.
To use NSX configurations in vRealize Automation, you must run data collection.
- Review security component concepts. See [Using Security Components in the Design Canvas](#).
- Log in to the vRealize Automation console as an **infrastructure architect**.
- Open a new or existing blueprint in the design canvas by using the **Design** tab.

Procedure

- 1 Click **Network & Security** in the Categories section to display the list of available network and security components.
- 2 Drag an **Existing Security Group** component onto the design canvas.
- 3 Select an existing security group from the **Security Group** drop-down menu.
- 4 Click **OK**.
- 5 Click **Finish** to save the blueprint as draft or continue configuring the blueprint.

You can continue configuring security settings by adding additional security components and by selecting settings in the **Security** tab of a vSphere machine component in the design canvas.

Add an On-Demand Security Group Component

You can add an on-demand NSX security group component to the design canvas in preparation for associating its settings to one or more vSphere machine components or other available component types in the blueprint.

Prerequisites

- Create and configure a security policy in NSX. See *NSX Administration Guide*.
- Verify that the NSX inventory has executed successfully for your cluster.
To use NSX configurations in vRealize Automation, you must run data collection.
- Review security component concepts. See [Using Security Components in the Design Canvas](#).
- Log in to the vRealize Automation console as an **infrastructure architect**.
- Open a new or existing blueprint in the design canvas by using the **Design** tab.

Procedure

- 1 Click **Network & Security** in the Categories section to display the list of available network and security components.
- 2 Drag an **On-Demand Security Group** component onto the design canvas.
- 3 Enter a name and, optionally, a description.
- 4 Add one or more security policies by clicking the Add icon in the **Security policies** area and selecting available security policies.
- 5 Click **OK**.
- 6 Click **Finish** to save the blueprint as draft or continue configuring the blueprint.

You can continue configuring security settings by adding additional security components and by selecting settings in the **Security** tab of a vSphere machine component in the design canvas.

Add an Existing Security Tag Component

You can add an NSX security tag component to the blueprint design canvas in preparation for associating its settings to one or more machine components in the blueprint.

You can use a security tag component to add an NSX security tag to the design canvas and configure its settings for use with vSphere machine components and Software components that pertain to vSphere.

You can add multiple network and security components to the design canvas.

Prerequisites

- Create and configure security tags in NSX. See *Configuring vRealize Automation* and *NSX Administration Guide*.

- Verify that the NSX inventory has executed successfully for your cluster.
To use NSX configurations in vRealize Automation, you must run data collection.
- Log in to the vRealize Automation console as an **infrastructure architect**.
- Open a new or existing blueprint in the design canvas by using the **Design** tab.

Procedure

- 1 Click **Network & Security** in the Categories section to display the list of available network and security components.
- 2 Drag a **Existing Security Tag** component onto the design canvas.
- 3 Click in the **Security tag** text box and select an existing security tag.
- 4 Click **OK**.
- 5 Click **Finish** to save the blueprint as draft or continue configuring the blueprint.

You can continue configuring security settings by adding additional security components and by selecting settings in the **Security** tab of a vSphere machine component in the design canvas.

Associating Network and Security Components

You can drag network and security components onto the design canvas to make their settings available for machine component configuration in the blueprint. After you have defined network and security settings for the machine, you can optionally associate settings from a load balancer component.

After you add an NSX network or security component to the design canvas and define its available settings, you can open the network and security tabs of a vSphere machine component in the canvas and configure its settings.

You can drag an on-demand NAT network component onto the design canvas and associate it with a vSphere machine component or NSX load balancer component in the blueprint.

The network and security component settings that you add to the design canvas are derived from your NSX configuration and require that you have run data collection for the NSX inventory for vSphere clusters. Network and security components are specific to NSX and are available for use with vSphere machine components only. For information about configuring NSX, see *NSX Administration Guide*.

Note If a blueprint contains one or more load balancers and app isolation is enabled for the blueprint, the load balancer VIPs are added to the app isolation security group as an IPSet. If a blueprints contains an on-demand security group that is associated to a machine tier that is also associated to a load balancer, the on-demand security group includes the machine tier and the IPSet with the load balancer VIP.

For information about using NAT rules to allow a TCP or UDP port to map from the external IP address of an Edge (source port) to a private IP address in the NAT network component (target port), see [Creating and Using NAT Rules](#).

Using Container Components in Blueprints

You can configure and use container components in the blueprint.

After a container administrator has created container definitions in Containers for vRealize Automation, a container architect can add and configure container components for vRealize Automation blueprints in the design canvas.

Container Component Settings

You can configure blueprint settings and options for a Containers for vRealize Automation container component in the vRealize Automation design canvas.

General Tab

Configure general settings for the blueprint container component in the design canvas.

Table 3-34. General Tab Settings

Setting	Description
Name	Enter a name for your container component in the blueprint.
Description	Summarize your container component for the benefit of other architects.
Image	Enter the full name of an image in a managed registry such as a private registry or Docker Hub registry, for example <code>registry.hub.docker.com/library/python</code> .
Commands	Enter a command that applies to the specified image, such as <code>python app.py</code> . The command is run when the container provisioning process is started.
Links	Links provide another way to connect containers on a single host or across hosts. Enter one or more services to which this container is to be linked, such as <code>redis</code> or <code>datadog</code> .

Network Tab

Configure network settings for the blueprint container component in the design canvas.

You can attach a container to a network. The network is represented as a container network component on the design canvas. Information about available networks is specified in Network page of the container component form.

Table 3-35. Network Tab Settings

Setting	Description
Networks	Specify the existing networks that are defined for the selected image. You can also create a new network. When you add a network container component to the design form, the networks that you specify here are listed as available options for selection.
Port bindings	Specify the port bindings for the selected network. Port bindings consist of protocol host, host port, and container port.

Table 3-35. Network Tab Settings (Continued)

Setting	Description
Publish All Ports	Select the check mark box to expose the ports that are used in the container image to all users.
Host name	Specify the container host name. If no name is specified, the value defaults to the name of the container component in the blueprint.
Network mode	Specify the networking stack of the container. If no value is specified, the container is configured in Bridge network mode.

Storage Tab

Configure storage settings for the blueprint container component in the design canvas.

Table 3-36. Storage Tab Settings

Settings	Description
Volumes	Specify the storage volumes that are mapped from the host to be used by the container.
Volumes from	Specify the storage volumes to be inherited from another container.
Working directory	Specify the directory from which to run commands.

Policy Tab

Configure policy settings such as deployment policy and affinity constraints for the blueprint container component in the design canvas.

Table 3-37. Policy Tab Settings

Settings	Description
Deployment policy	Specify a deployment policy to set preferences for which set of hosts to use for deploying this container. You can associate deployment policies to hosts, policies, and container definitions to set a preference for hosts, policies, and quotas when deploying a container. You can add a deployment policy by using the Containers tab in vRealize Automation.
Cluster size	Specify the number of instances to generate as a cluster from this container.
Restart policy	Specify a restart policy for how a container is restarted on exit.
Max restart	If you selected on-failure as a restart policy, you can specify the maximum number of restarts.
CPU shares	Specify the number of CPU shares allocated for the provisioned resource.
Memory limit	Specify a number between 0 and the memory available in the placement zone. This is the total memory available for resources in this placement. 0 means no limit.

Table 3-37. Policy Tab Settings (Continued)

Settings	Description
Memory swap	Total memory limit.
Affinity constraints	<p>Defines rules for provisioning of containers on the same or different hosts.</p> <ul style="list-style-type: none"> ■ Affinity type <p>For anti-affinity, the containers are placed on different hosts, otherwise they are placed on the same host .</p> ■ Service <p>The service name that is available from the drop-down menu matches the container component name specified in the Name field on the General tab.</p> ■ Constraint <p>A hard constraint specifies that if the constraint cannot be satisfied, provisioning should fail. A soft constraint specifies that if the constraint cannot be satisfied, provisioning should continue.</p>

Environment Tab

Configure environment settings such as property bindings for the blueprint container component in the design canvas.

Table 3-38. Environment Tab Settings

Setting	Description
Name	The variable name.
Binding	<p>Bind the variable to another property, that is a part of the template. When you select binding, you must input a value in the</p> <p><i>_resource~TemplateComponent~TemplateComponentProperty</i> syntax.</p>
Value	The value of the environment variable or if you selected binding, the value of the property you want to bind.

Properties Tab

Configure individual and groups of custom properties for the blueprint container component in the design canvas.

If you select the **Property Groups** tab and click **Add**, the following options are available:

- Container host properties with certificate authentication
- Container host properties with user/password authentication

If additional property groups have been defined, they are also listed.

If you select the **Custom Properties** tab and click **Add** you can add individual custom properties to the container component.

Table 3-39. Properties Tab Settings for Custom Properties

Setting	Description
Name	Enter the name of a custom property or select an available custom property from the drop-down menu.
Value	Enter or edit a value to associate with the custom property name.
Encrypted	You can choose to encrypt the property value, for example, if the value is a password.
Overridable	You can specify that the property value can be overridden by the next or subsequent person who uses the property. Typically, this is another architect, but if you select Show in request , your business users are able to see and edit property values when they request catalog items.
Show in Request	If you want to display the property name and value to your end users, you can select to display the property on the request form when requesting machine provisioning. You must also select Overridable if you want users to provide a value.

Health Config Tab

Specify a health configuration mode for the blueprint container component in the design canvas.

Table 3-40. Health Config Tab Settings

Mode setting	Description
None	Default. No health checks are configured.
HTTP	<p>If you select HTTP, you must provide an API to access and an HTTP method and version to use. The API is relative and you do not need to enter the address of the container. You can also specify a timeout period for the operation and set health thresholds.</p> <p>For example, a healthy threshold of 2 means that two consecutive successful calls must occur for the container to be considered healthy and in the RUNNING status. An unhealthy threshold of 2 means that two unsuccessful calls must occur for the container to be considered unhealthy and in the ERROR status. For all the states in between the healthy and unhealthy thresholds, the container status is DEGRADED.</p>
TCP connection	If you select TCP connection , you must only enter a port for the container. The health check attempts to establish a TCP connection with the container on the provided port. You can also specify a timeout value for the operation and set healthy or unhealthy thresholds as with HTTP.
Command	If you select Command , you must enter a command to be executed on the container. The success of the health check is determined by the exit status of the command.

Table 3-40. Health Config Tab Settings (Continued)

Mode setting	Description
Ignore health check on provision	Uncheck this option to force health check on provision. By forcing it, a container is not considered provisioned until one successful health check passes.
Autodeploy	Automatic redeployment of containers when they are in ERROR state.

Log Config Tab

Specify a logging mode, and optional logging options, for the blueprint container component in the design canvas.

Table 3-41. Log Config Tab Settings

Setting	Description
Driver	Select a logging format from the drop-down menu.
Options	Enter driver options using a name and value format that adheres to the logging format.

Using Container Properties and Property Groups in a Blueprint

You can add predefined property groups to a containers component in a vRealize Automation blueprint. When machines are provisioned by using a blueprint that contain these properties, the provisioned machine is registered as a Docker Container host machine.

Containers for vRealize Automation supplied the following two property groups of container-specific custom properties. When you add a container component to a blueprint you can add these property groups to the container to register provisioned machines as container hosts.

- Container host properties with certificate authentication
- Container host properties with user/password authentication

These property groups are visible in vRealize Automation when you select **Administration > Property Dictionary > Property Groups**.

Because property groups are shared by all tenants, if you are working in a multi-tenant environment, consider cloning and customizing your properties. By uniquely naming property groups and properties in the groups, you can edit them to define custom values for use in a specific tenant.

The most commonly used properties are `Container.Auth.PublicKey` and `Container.Auth.PrivateKey` in which the container administrator provides the client certificate for authenticating with the container host.

Table 3-42. Containers Custom Properties

Property	Description
<code>containers.ipam.driver</code>	For use with containers only. Specifies the IPAM driver to be used when adding a Containers network component to a blueprint. The supported values depend on the drivers installed in the container host environment in which they are used. For example, a supported value might be <code>infoblox</code> or <code>calico</code> depending on the IPAM plug-ins that are installed on the container host.
<code>containers.network.driver</code>	For use with containers only. Specifies the network driver to be used when adding a Containers network component to a blueprint. The supported values depend on the drivers installed in the container host environment in which they are used. By default, Docker-supplied network drivers include <code>bridge</code> , <code>overlay</code> , and <code>macvlan</code> , while Virtual Container Host (VCH)-supplied network drivers include the <code>bridge</code> driver. Third-party network drivers such as <code>weave</code> and <code>calico</code> might also be available, depending on what network plug-ins are installed on the container host.
<code>Container</code>	For use with containers only. The default value is <code>App.Docker</code> and is required. Do not modify this property.
<code>Container.Auth.User</code>	For use with containers only. Specifies the user name for connecting to the Containers host.
<code>Container.Auth.Password</code>	For use with containers only. Specifies either the password for the user name or the public or private key password to be used. Encrypted property value is supported.
<code>Container.Auth.PublicKey</code>	For use with containers only. Specifies the public key for connecting to the Containers host.
<code>Container.Auth.PrivateKey</code>	For use with containers only. Specifies private key for connecting to the Containers host. Encrypted property value is supported.
<code>Container.Connection.Protocol</code>	For use with containers only. Specifies the communication protocol. The default value is <code>API</code> and is required. Do not modify this property.
<code>Container.Connection.Scheme</code>	For use with containers only. Specifies the communication scheme. The default is <code>https</code> .
<code>Container.Connection.Port</code>	For use with containers only. Specifies the Containers connection port. The default is <code>2376</code> .
<code>Extensibility.Lifecycle.Properties.VMPSMasterWorkf low32.MachineActivated</code>	For use with containers only. Specifies the event broker property to expose all Containers properties and is used for registering a provisioned host. The default value is <code>Container*</code> and is required. Do not modify this property.
<code>Extensibility.Lifecycle.Properties.VMPSMasterWorkf low32.Disposing</code>	For use with containers only. Specifies the event broker property to expose all Containers properties above and is used for unregistering a provisioned host. The default value is <code>Container*</code> and is required. Do not modify this property.

Using Containers Network Components in the Design Canvas

You can add one or more Containers network components to the design canvas and configure their settings for vSphere machine components in the blueprint.

You can add the `containers.ipam.driver` and `containers.network.driver` to the component when you add it to the blueprint.

Add a Container Network Component

You can add container network information to a vRealize Automation blueprint that contains container components.

You can configure containers in Containers for vRealize Automation by using the vRealize Automation **Containers** tab. You can add those containers and their network settings as components in a blueprint by using options on the vRealize Automation **Design** tab.

Prerequisites

- Log in to the vRealize Automation console as a **container architect**.
- Open a new or existing blueprint in the design canvas by using the **Design** tab.

Procedure

- 1 Click **Network & Security** in the Categories section to display the list of available network and security components.
- 2 Drag a **Container Network** component onto the design canvas.
- 3 Enter a name in the **Name** text box to uniquely label the component in the design canvas.
- 4 (Optional) Enter a component description in the **Description** text box.
- 5 (Optional) Select the **External** check box if you do not want to specify external IPAM settings.

If you select the **External** check box, the **IPAM Configuration** tab is removed.

- 6 Click the **IPAM Configuration** tab to specify a new or edit an existing subnet, IP range, and gateway for the network specified in a container component in the blueprint.

IPAM configuration applies to new networks that are created by vRealize Automation as opposed to those that have been previously created in Docker or other supported container application. These settings are not validated and provisioning fails if the settings overlap with other networks. For example, the subnet and gateway must be unique within the container host.

- 7 Click the **Properties** tab to specify custom properties for the component.

If you select the **Property Groups** tab and click **Add**, the following options are available:

- Container host properties with certificate authentication
- Container host properties with user/password authentication

If additional property groups have been defined, they are also listed.

If you select the **Custom Properties** tab and click **Add** you can add individual custom properties to the container component.

Table 3-43. Properties Tab Settings for Custom Properties

Setting	Description
Name	Enter the name of a custom property or select an available custom property from the drop-down menu.
Value	Enter or edit a value to associate with the custom property name.
Encrypted	You can choose to encrypt the property value, for example, if the value is a password.
Overridable	You can specify that the property value can be overridden by the next or subsequent person who uses the property. Typically, this is another architect, but if you select Show in request , your business users are able to see and edit property values when they request catalog items.
Show in Request	If you want to display the property name and value to your end users, you can select to display the property on the request form when requesting machine provisioning. You must also select Overridable if you want users to provide a value.

8 Click **Finish** to save the blueprint as draft or continue configuring the blueprint.

What to do next

You can continue configuring container network settings in the **Network** tab of a container component in the design canvas.

Pushing Container Templates for Use in Blueprints

You can make a container template available for use in a vRealize Automation blueprint.

A container template can include multiple containers. When you push a multi-container template to vRealize Automation, the template is created as a multi-component blueprint in vRealize Automation.

The container-specific properties that you add to the container template are recognized in the vRealize Automation blueprint. See [Using Container Properties and Property Groups in a Blueprint](#).

When you request to provision a blueprint published in the vRealize Automation catalog, you provision the source container application for that blueprint.

You can add other components to the vRealize Automation blueprint, including the following component types:

- Machine types
- Software components
- Other blueprints
- NSX network and security components

- XaaS components
- Custom components

You can push a template from Containers to vRealize Automation. Changes that you make to the vRealize Automation blueprint have no effect on the Containers template.

You can make subsequent changes in the Containers template and push again to overwrite the blueprint in vRealize Automation. Pushing the template to vRealize Automation overwrites the blueprint, and any changes made to the blueprint in vRealize Automation between pushes are lost. To avoid losing blueprint changes, use vRealize CloudClient to clone a new blueprint or to export the blueprint.

Provisioning a Docker Container or Host from a Blueprint

You can create and use vRealize Automation blueprints to provision machines as registered Docker Container hosts.

For a provisioned machine to be registered as a container host, it must meet the following requirements:

- The machine is provisioned by a blueprint that contains Containers-specific custom properties.
The required container-specific custom properties are supplied in two property groups. See [Using Container Properties and Property Groups in a Blueprint](#).

For information about using custom properties and property groups in vRealize Automation, see *Custom Properties Reference*.

- The machine is accessible over the network.

For example, the machine must have a valid IP address and be powered on.

You can define a vRealize Automation blueprint to contain specific custom properties that designate a machine as a container host when provisioned using the blueprint.

When a machine with the required blueprint properties is successfully provisioned, it is registered in the Containers and receives events and actions from vRealize Automation.

Creating Microsoft Azure Blueprints and Incorporating Resource Actions

As a cloud or fabric administrator, you can create Microsoft Azure virtual machine blueprints that business group administrators employ as a building block to create customized provisioned machines for consumers. DevOps administrators can also create Azure machine blueprints, or they can use existing Azure machine blueprints when creating composite blueprints.

- [Create a Blueprint for Microsoft Azure](#)

You can create Microsoft Azure virtual machine blueprints that provide access to Azure virtual machine resources.

- [Create Azure Custom Resource Actions](#)

You can create and use custom resource actions to control Azure virtual machines.

Create a Blueprint for Microsoft Azure

You can create Microsoft Azure virtual machine blueprints that provide access to Azure virtual machine resources.

A default Azure Machine template appears in the **Machine Types** category on the vRealize Automation Edit Blueprint page. You can use this virtual machine template as the basis of an Azure blueprint as described in the following procedure. After you create an Azure blueprint, you can publish and deploy it as designed, or you can use it in conjunction with custom Azure resources or with other blueprints to create a composite blueprint.

After creating and publishing the blueprint, users with appropriate privileges can request and provision an Azure instance through the vRealize Automation Service Catalog.

Note that Azure blueprints define virtual machine requirements. vRealize Automation uses these requirements to select the most appropriate reservation for the deployment.

For information about the NSX Settings and Properties tab on the New Blueprint dialog box, see *Configuring vRealize Automation*.

If you want to create two virtual machines from a single deployment simultaneously, you must create two network interface names and two virtual machine names.

Prerequisites

- Obtain a valid Azure subscription ID and related information including resource group, storage account, and virtual network information that you may need to create a blueprint.
- Configure an Azure endpoint to create a connection to Azure for use with your vRealize Automation deployment.
- Configure Azure reservations as appropriate for your business groups.

Procedure

- 1 Select **Design > Blueprints**.
- 2 Click the **New** icon (+).
- 3 Enter a blueprint name in the **Name** text box.
The name you enter also populates the **ID** text box. For most cases, you can ignore the **NSX Settings** and **Properties** tabs.
- 4 Click **OK**.
- 5 Click **Machine Types** in the Categories menu.
- 6 Drag the **Azure Machine** virtual machine template to the Design canvas.

If you created a custom Azure resource for use as the basis of a blueprint, you can select that resource from the assigned category in the Categories list.

- 7 Enter the required information for the Azure virtual machine in the text boxes on the tabbed pages located on the bottom half of the Design Canvas that appear when you drag the Azure Machine template to the Design Canvas.

Available selections for text boxes and other parameters on all of these tabs are determined primarily by the Azure endpoint that was configured as a basis for blueprints.

For most parameters, when you can click the text box beside the parameter name, a new pane opens on the right side of the page. In this pane, you can enter parameter values in the **Value** text box and indicate whether or not it is **Required**. Note that in some cases you can also enter a **Minimum value** and a **Maximum value**. Click **Apply** within the right pane to populate the initial text box.

Figure 3-1. Azure blueprint right side menu

The screenshot shows the 'Azure_Machine_1' configuration window with tabs for General, Build Information, Machine Resources, Storage, and Network. The 'Storage' tab is active. On the left, under 'Resource Group', there are radio buttons for 'Create New' and 'Use Existing', with 'Use Existing' selected. Below this is a text box for 'Resource Group Name' containing 'RG1-vAficionado'. Under 'Availability Set', there are radio buttons for 'None', 'Create New', and 'Use Existing', with 'None' selected. On the right, a configuration pane shows a 'Required' dropdown set to 'No' and a 'Value' text box containing 'RG1-vAficionado'. A red arrow points from the 'Use Existing' radio button to the 'Value' text box.

Most parameters also have an **Advanced Options** button. These options enable you to specify parameter lengths and even hide parameters from end users.

Note You must populate required parameters on each tab in order to proceed with the blueprint configuration. If you want to leave a field empty, you can go back and delete the entry before saving.

Tab	Description	Important Parameters
General	Select basic connection information for the Azure virtual machine such as the endpoint to be used.	<p>ID - Identifies the Azure virtual machine you are creating. If you change this name, the Azure virtual machine image on the Design Canvas is also updated automatically.</p> <p>Description - Identifies the virtual machine you are creating and whether or not it is required.</p> <p>Instances - This selection enables you to create a scalable virtual machine. Use the Minimum and Maximum fields to identify the number of Azure instances that can be spawned from this machine.</p> <p>Use password authentication: Select Yes to use password authentication or No to use SSH.</p> <p>Admin username - Leave this blank and it can be assigned by the user provisioning the machine.</p> <p>Admin password - Leave this field blank, and the individual who provisions the machine can supply the appropriate password,</p>
Build Information	Enables you to configure information about the virtual machine being created.	<p>Location - Select the geographical location where this virtual machine will be deployed.</p> <p>Machine Prefix - Select the appropriate radio button to indicate whether you want to use the machine prefix from the associated business group or to create a custom prefix. If you want to use a custom prefix, enter it in the Custom Machine Prefix text box.</p> <p>Virtual machine image type - Choose the appropriate radio button for a Custom or Stock virtual machine image. A custom virtual machine is created from the Azure classic deployment and offers more configuration options regarding cloud services, storage accounts, and availability sets,</p> <p>Virtual Machine Image - Identify the Azure virtual machine image that the blueprint will be based upon.</p> <ul style="list-style-type: none"> For a stock virtual machine image, the machine image URN should match the following format: (publisher):(offer):(sku):(version). For a custom virtual machine image, the machine image URN should match the following format: <pre>https://storageaccount.blob.core.windows.net/container/image.vhd</pre> <p>Also you must complete OS Image Type (Windows or Linux) text box for Custom images.</p> <p>Admin User - Type the name of the designated admin user configured for virtual machines based on this blueprint. Alternatively, it can be left blank here entered on the request form.</p> <p>Authentication - Select the appropriate radio button to indicate whether virtual machines based on this blueprint will require password or SSH authentication.</p> <p>Admin Password - The administrator password for the virtual machine instance.</p> <p>Series - Defines the general size of a virtual machine instance. See the Azure documentation at https://azure.microsoft.com/en-us/documentation/articles/virtual-machines-windows-sizes/ for series information.</p>

Tab	Description	Important Parameters
Machine Resources	<p>Organize virtual machine resources into buckets. A resource group is an organizational construct that groups virtual machine resources such as Web sites, accounts, databases and networks.</p> <p>An Availability Set is a mechanism for managing two or more virtual machines to support redundancy. See https://azure.microsoft.com/en-us/documentation/articles/virtual-machines-windows-manage-availability/ for more information about Azure Availability Sets.</p> <hr/> <p>Note If you configure a blueprint with the maximum number of Azure instances set to a value greater than 1, then you should use the existing resource group and availability set rather than create new ones. Using new resource groups or new availability sets on more than one instance in the same deployment will cause errors and other problems if associated with load balancers.</p>	<p>Size - Defines the specific virtual machine instance size within a series. Size is related to the selected Series. If you have a valid connection to an Azure instance, the available sizes are populated dynamically based on the subscription and selected location and series. See the Azure documentation for size information.</p> <p>Instance Size Details - Optional information about the virtual machine instance series and size.</p> <hr/> <p>Create or reuse Resource group: - Select the appropriate radio button to indicate whether you want to use the existing Azure resource group or create a new one. You can find this name of the existing resource group on the Resource Groups page in the Azure portal. If you choose to create a new resource group, an appropriate name for the new group appears automatically in the Resource Group text box.</p> <p>Create or reuse Availability set: Select the appropriate radio button depending on what you want to do. If you select Create New, the appropriate information for the new Availability set info appears in the text box.</p>

Tab	Description	Important Parameters
Storage	<p>Enables you to organize Azure storage accounts. A storage account provides access to the different types of Azure storage, such as Azure Blob, Queue Table, and File storage. For most blueprints, you can accept the defaults.</p>	<p>Storage account - Enter the storage account name for the virtual machine if appropriate. The Azure virtual machine operating system disk is deployed to this storage account. You can find storage group information in the Azure portal. You may have one or more storage accounts.</p> <hr/> <p>Note Storage account names with underscores or other special characters may cause errors.</p> <hr/> <p>Add Diagnostic Storage - Select this check box if you use diagnostic data with your Azure instance.</p> <p>Number of Storage Disks - Select the appropriate number of data storage disks as used with your virtual machine. You can specify up to four disks. These disks are in addition to the operating system disk as specified in the Storage account text box.</p> <p>Storage Disk #</p> <ul style="list-style-type: none"> ■ Disk Name - Identifying name assigned to the disk. ■ Disk Type - Storage device type. ■ Disk Size - Storage size. ■ Replication - Redundancy method used for disk back up. ■ Host Caching - Indicates whether read/writes are cached to increase performance.
Network	<p>Enables you to select networking for the virtual machine blueprint. For most blueprints, you can accept the defaults and the consumer will enter the appropriate network information during deployment.</p> <hr/> <p>Note You can create only one virtual machine per interface, but each virtual machine can have up to four interfaces.</p>	<p>Click the table to open a dialog to the right that contains another editable table with the following fields.</p> <ul style="list-style-type: none"> ■ Load Balancer Name - The load balancer used with the Azure instance. ■ Number of Network Interfaces - Select the number of network interfaces used with the Azure instance. The number of network interfaces must be supported by the virtual machine size as selected on the Storage tab. ■ Network interface - Select the appropriate network interface for the virtual machine blueprint. If you enter an existing network, you can ignore all other network tabs. If you enter a network interface name that does not exist, a new interface with that name is created, and you can use the other Network tabs to configure the interface. ■ NIC Name Prefix - The prefix for the network interface card. ■ IP Address Type - Indicate whether the virtual machine uses a static or dynamic IP address. ■ Networking Configuration - Enter the appropriate networking configuration. Network profiles are supported. There are two options, Specify Azure Networks and Use Network Profile, and the subsequent fields change depending on which option you select. <ul style="list-style-type: none"> ■ The following options are available if you select Specify Azure Networks. If you leave these text boxes empty, then default network constructs are used based on information specified in the applicable reservation. <ul style="list-style-type: none"> ■ vNet Name - Name of the virtual network

Tab	Description	Important Parameters
		<ul style="list-style-type: none"> ■ subNet Name - The domain name of the Azure subnet. <hr/> <p>Note You can set the public IP address for Azure during day 2 operations.</p> <hr/> <ul style="list-style-type: none"> ■ If you select Use Network Profile, the network configuration is detached from underlying Azure constructs and is instead coupled with the vRealize Automation networking profile. <ul style="list-style-type: none"> ■ If you leave the Network Profile text box empty, the default Azure vNet and subnet pair are resolved based on applicable reservations which have a network profile specified. ■ If you enter a network profile, then the Azure vNet and subnet are resolved based on the matching reservation.

8 Click **Finish** to save the blueprint configuration and return to the main Blueprints page.

What to do next

If you have configured custom properties in your Azure reservation to support a VPN tunnel, you can add software components to Azure blueprints.

- 1 Select **Software Components** on the Categories menu. Software components that you have configured Azure blueprints appear in the pane below.
- 2 Select Azure Virtual Machine in the container drop-down values.
- 3 Select the desired software component and drag it to the Azure virtual machine on the Design Canvas.
- 4 If there are properties required for the software component, enter them in the appropriate parameter text boxes below the Design Canvas.
- 5 Click **Save**.

If you want to publish the blueprint, select it on the main Blueprints page and click **Publish**. A published blueprint is available on Catalog Items page. Also, a business group manager or equivalent can use this published blueprint as the basis of a composite blueprint.

Create Azure Custom Resource Actions

You can create and use custom resource actions to control Azure virtual machines.

The vRealize Automation Azure implementation is supplied with two custom resource actions out of the box:

- Start virtual machine
- Stop virtual machine

In addition, you can create custom resource actions using workflows that are accessible through vRealize Orchestrator library available from the vRealize Automation interface.

You can work with Azure resource actions just as with any other XaaS resource actions in vRealize Automation. See *Creating XaaS Blueprints and Resource Actions* and *vRealize Orchestrator Integration in vRealize Automation* in *Configuring vRealize Automation* for more information about XaaS resource actions.

Prerequisites

Configure a valid Azure Endpoint for your vRealize Automation deployment.

Procedure

- 1 Select **Design > XaaS > Resource Actions**
- 2 Click **New**.
- 3 Navigate to **Orchestrator > Library > Azure** in the vRealize Orchestrator workflow library.
- 4 Select the desired folder and workflow.
- 5 Configure the action for your needs as you would any other XaaS resource action.

Creating Puppet Enabled vSphere Blueprints

You can create Puppet enabled vSphere blueprints that support Puppet-based configuration management of vSphere virtual machines.

Puppet-based configuration management typically uses roles and environments to define and manage software configuration. Be aware that the meaning of role and environment in Puppet differs for the more IT generic meaning.

An endpoint establishes a connection with an existing Puppet enterprise deployment. When the endpoint is created, vRealize Automation retrieves the list of environments and roles associated with the specified deployments. You can use these environments and roles in either early binding or late binding scenarios when configuring a Puppet enabled virtual machine blueprint.

Note Puppet components are currently supported only on vSphere blueprints and virtual machines.

Add a Puppet Component to a vSphere Blueprint

You can add a Puppet configuration management component to a vSphere blueprint to facilitate enforced management of vSphere virtual machines using a Puppet Master.

Adding a Puppet component to a vSphere blueprint adds a Puppet agent to virtual machines created from that blueprint.

When creating Puppet-enabled vSphere blueprints, you must choose whether to create an early binding or late binding configuration.

With early binding, users define the Puppet role and environment settings for all virtual machines based on a particular blueprint when the Puppet component is added to the blueprint. These settings remain static during the life of the blueprint. For late binding, you have several options.

- Leave the **Puppet environment** and **Puppet role** text boxes empty in the blueprint, and users provide these settings at request time.

- Specify a **Puppet environment** and leave the **Puppet role** box empty. Users must specify the role at request time.

Prerequisites

Create an appropriate vSphere blueprint. See [vSphere Machine Component Settings](#) for more information.

Procedure

- 1 Select **Design > Blueprints**.
- 2 Select **Configuration Management** from the Categories menu on the Design page for blueprints.
- 3 Select the Puppet component and drag it to the vSphere component on the Design Canvas.
- 4 Enter an **ID** and **Description** for the Puppet component on the General tab at the bottom of the page.
The ID and description are arbitrary.
- 5 Click the Server tab.
- 6 Click the drop-down and select the appropriate Puppet Master for the blueprint.
- 7 Select the appropriate **Puppet environment** and **Puppet role** if you want to use early binding for this component.

To configure early binding, select a Puppet environment and role. If you want to create a component with late binding, select a **Puppet environment**, or leave the **Puppet environment** and **Puppet role** text boxes empty and select the **Set in Request form** check boxes.

Note The **Set in Request form** check boxes are tied together. If you select one, the other is selected automatically.

- 8 Click **Finish** to save the Puppet component configuration and return to the main blueprint Design page.

Add RDP Connection Support to Your Windows Machine Blueprints

To allow catalog administrators to entitle users to the Connect using RDP action for Windows blueprints, add RDP custom properties to the blueprint and reference the RDP file that the system administrator prepared.

Note If your fabric administrator creates a property group that contains the required custom properties and you include it in your blueprint, you do not need to individually add the custom properties to the blueprint.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **business group manager**.
- Obtain the name of the custom RDP file that your system administrator created for you. See [Create a Custom RDP File to Support RDP Connections for Provisioned Machines](#).

- Create at least one Windows machine blueprint.

Procedure

- 1 Select **Design > Blueprints**.
- 2 Point to the blueprint to update and click **Edit**.
- 3 Select the machine component on your canvas to edit the details.
- 4 Click the **Properties** tab.
- 5 Click the **Custom Properties** tab.
- 6 Configure RDP settings.
 - a Click **New Property**.
 - b Enter the RDP custom property names in the **Name** text box and the corresponding values in the **Value** text box.

Option	Description and Value
(Required) RDP.File.Name	Specifies an RDP file from which to obtain settings, for example <code>My_RDP_Settings.rdp</code> . The file must reside in the <code>Website\Rdp</code> subdirectory of the vRealize Automation installation directory.
(Required) VirtualMachine.Rdp.SettingN	Specifies the RDP settings to be used when opening an RDP link to the machine. <i>N</i> is a unique number used to distinguish one RDP setting from another. For example, to specify the RDP authentication level so that no authentication requirement is specified, define the custom property <code>VirtualMachine.Rdp.Setting1</code> and set the value to <code>authentication level:i:3</code> . For information about available RDP settings, and their correct syntax, see Microsoft Windows RDP documentation such as RDP Settings for Remote Desktop Services in Windows Server .
VirtualMachine.Admin.NameCompletion	Specifies the domain name to include in the fully qualified domain name of the machine that the RDP or SSH files generate for the user interface options Connect Using RDP or Connect Using SSH option. For example, set the value to <code>myCompany.com</code> to generate the fully qualified domain name <code>my-machine-name.myCompany.com</code> in the RDP or SSH file.

- c Click **Save**.

- 7 Select the blueprint row and click **Publish**.

Your catalog administrators can entitle users to the **Connect Using RDP** action for machines provisioned from your blueprint. If users are not entitled to the action, they are not able to connect by using RDP.

Scenario: Add Active Directory Cleanup to Your CentOS Blueprint

As an IaaS architect, you want to configure vRealize Automation to clean up your Active Directory environment whenever provisioned machines are removed from your hypervisors. So you edit your existing vSphere CentOS blueprint to configure the Active Directory cleanup plugin.

Using the Active Directory Cleanup Plugin, you can specify the following Active Directory account actions to occur when a machine is deleted from a hypervisor:

- Delete the AD account
- Disable the AD account
- Rename AD account
- Move the AD account to another AD organizational unit (OU)

Prerequisites

Note This information does not apply to Amazon Web Services.

- Log in to the vRealize Automation console as an **infrastructure architect**.
- Gather the following information about your Active Directory environment:
 - An Active Directory account user name and password with sufficient rights to delete, disable, rename, or move AD accounts. The user name must be in domain\username format.
 - (Optional) The name of the OU to which to move destroyed machines.
 - (Optional) The prefix to attach to destroyed machines.
- Create a machine blueprint. See *Installing and Configuring vRealize Automation for the Rainpole Scenario*.

Procedure

- 1 Select **Design > Blueprints**.
- 2 Point to your **Centos on vSphere** blueprint and click **Edit**.
- 3 Select the machine component on your canvas to bring up the details tab.
- 4 Click the **Properties** tab.
- 5 Click the **Custom properties** tab to configure the Active Directory Cleanup Plugin.
 - a Click **New Property**.
 - b Type `Plugin.AdMachineCleanup.Execute` in the **Name** text box.
 - c Type **true** in the **Value** text box.
 - d Click the **Save** icon (✓).
- 6 Configure the Active Directory Cleanup Plugin by adding custom properties.

Option	Description and Value
<code>Plugin.AdMachineCleanup.UserName</code>	Enter the Active Directory account user name in the Value text box. This user must have sufficient privileges to delete, disable, move, and rename Active Directory accounts. The user name must be in the format domain\username.
<code>Plugin.AdMachineCleanup.Password</code>	Enter the password for the Active Directory account user name in the Value text box.

Option	Description and Value
<code>Plugin.AdMachineCleanup.Delete</code>	Set to True to delete the accounts of destroyed machines, instead of disabling them.
<code>Plugin.AdMachineCleanup.MoveToOu</code>	Moves the account of destroyed machines to a new Active Directory organizational unit. The value is the organization unit to which you are moving the account. This value must be in <i>ou=OU, dc=dc</i> format, for example <i>ou=trash,cn=computers,dc=lab,dc=local</i> .
<code>Plugin.AdMachineCleanup.RenamePrefix</code>	Renames the accounts of destroyed machines by adding a prefix. The value is the prefix string to prepend, for example <i>destroyed_</i> .

7 Click **OK**.

Whenever machines provisioned from your blueprint are deleted from your hypervisor, your Active Directory environment is updated.

Scenario: Allow Requesters to Specify Machine Host Name

As a blueprint architect, you want to allow your users to choose their own machine names when they request your blueprints. So you edit your existing CentOS vSphere blueprint to add the Hostname custom property and configure it to prompt users for a value during their requests.

Note If your fabric administrator creates a property group that contains the required custom properties and you include it in your blueprint, you do not need to individually add the custom properties to the blueprint.

Prerequisites

- Log in to the vRealize Automation console as an **infrastructure architect**.
- Create a machine blueprint. See *Installing and Configuring vRealize Automation for the Rainpole Scenario*.

Procedure

- 1 Select **Design > Blueprints**.
- 2 Point to your **Centos on vSphere** blueprint and click **Edit**.
- 3 Select the machine component on your canvas to bring up the details tab.
- 4 Click the **Properties** tab.
- 5 Click **New Property**.
- 6 Enter **Hostname** in the **Name** text box.
- 7 Leave the **Value** text box blank.

8 Configure vRealize Automation to prompt users for a hostname value during request.

- a Select **Overridable**.
- b Select **Show in Request**.

Because host names must be unique, users can only request one machine at a time from this blueprint.

9 Click the **Save** icon (✔).

10 Click **OK**.

Users who request a machine from your blueprint are required to specify a host name for their machine. vRealize Automation validates that the specified host name is unique.

Scenario: Enable Users to Select Datacenter Locations for Cross Region Deployments

As a blueprint architect, you want to allow your users to choose whether to provision machines on your Boston or London infrastructure, so you edit your existing vSphere CentOS blueprint to enable the locations feature.

You have a datacenter in London, and a datacenter in Boston, and you don't want users in Boston provisioning machines on your London infrastructure or vice versa. To ensure that Boston users provision on your Boston infrastructure, and London users provision on your London infrastructure, you want to allow users to select an appropriate location for provisioning when they request machines.

Prerequisites

- Log in to the vRealize Automation console as an **infrastructure architect**.
- As a system administrator, define the datacenter locations. See [Scenario: Add Datacenter Locations for Cross Region Deployments](#).
- As a fabric administrator, apply the appropriate locations to your compute resources. See [Scenario: Apply a Location to a Compute Resource for Cross Region Deployments](#).
- Create a machine blueprint. See *Installing and Configuring vRealize Automation for the Rainpole Scenario*.

Procedure

1 Select **Design > Blueprints**.

- 2 Point to your **Centos on vSphere** blueprint and click **Edit**.
- 3 Select the machine component on your canvas to bring up the **General** details tab.
- 4 Select the **Display location on request** check box.
- 5 Click **Finish**.
- 6 Point to your **Centos on vSphere** blueprint and click **Publish**.

Business group users are now prompted to select a datacenter location when they request a machine to be provisioned from your blueprint.

Designing Software Components

As the software architect, you create reusable software components, standardizing configuration properties and using action scripts to specify exactly how components are installed, configured, uninstalled, or updated during deployment scale operations. You can rewrite these action scripts at any time and publish live to push changes to provisioned software components.

You can design your action scripts to be generic and reusable by defining and consuming name and value pairs called software properties and passing them as parameters to your action scripts. If your software properties have values that are unknown or need to be defined in the future, you can either require or allow other blueprint architects or end users to provide the values. If you need a value from another component in a blueprint, for example the IP address of a machine, you can bind your software property to that machine's IP address property. Using software properties to parameterize your action scripts makes them generic and reusable so you can deploy software components on different environments without modifying your scripts.

Table 3-44. Life Cycle Actions

Life Cycle Actions	Description
Install	Install your software. For example, you might download Tomcat server installation bits and install a Tomcat service. Scripts you write for the Install life cycle action run when software is first provisioned, either during an initial deployment request or as part of a scale out.
Configure	Configure your software. For the Tomcat example, you might set the JAVA_OPTS and CATALINA_OPTS. Configuration scripts run after the install action completes.
Start	Start your software. For example, you might start the Tomcat service using the start command in the Tomcat server. Start scripts run after the configure action completes.
Update	If you are designing your software component to support scalable blueprints, handle any updates that are required after a scale in or scale out operation. For example, you might change the cluster size for a scaled deployment and manage the clustered nodes using a load balancer. Design your update scripts to run multiple times (idempotent) and to handle both the scale in and the scale out cases. When a scale operation is performed, update scripts run on all dependent software components.
Uninstall	Uninstall your software. For example, you might perform specific actions in the application before a deployment is destroyed. Uninstall scripts run whenever software components are destroyed.

You can download predefined Software components for a variety of middleware services and applications from the VMware Solution Exchange. Using either the vRealize CloudClient or vRealize Automation REST API, you can programmatically import predefined Software components into your vRealize Automation instance.

- To visit the VMware Solution Exchange, see https://solutionexchange.vmware.com/store/category_groups/cloud-management.
- For information about vRealize Automation REST API, see *Programming Guide* and *vRealize Automation API Reference*.
- For information about vRealize CloudClient, see <https://developercenter.vmware.com/tool/cloudclient>.

Property Types and Setting Options

You can design your action scripts to be generic and reusable by defining and consuming name and value pairs called software properties and passing them as parameters to your action scripts. You can create software properties that expect string, array, content, boolean, or integer values. You can supply the value yourself, require someone else to supply the value, or retrieve the value from another blueprint component by creating a binding.

Property Options

You can compute the value of any string property by selecting the computed check box, and you can make any property encrypted, overridable, or required by selecting the appropriate check boxes when you configure Software properties. Combine these options with your values to achieve different purposes. For example, you want to require blueprint architects to supply a value for a password and encrypt that value when they use your software component in a blueprint. Create the password property, but leave the value text box blank. Select Overridable, Required, and Encrypted. If the password you are expecting belongs to your end user, the blueprint architect can select **Show in Request** to require your users to enter the password when they fill out the request form.

Option	Description
Encrypted	Mark properties as encrypted to mask the value and display as asterisks in vRealize Automation. If you change a property from encrypted to unencrypted, vRealize Automation resets the property value. For security, you must set a new value for the property.
Overridable	Allow architects to edit the value of this property when they are assembling an application blueprint. If you enter a value, it displays as a default.
Required	Require architects to provide a value for this property, or to accept the default value you supply.
Computed	Values for computed properties are assigned by the INSTALL, CONFIGURE, START, or UPDATE life cycle scripts. The assigned value is propagated to the subsequent available life cycle stages and to components that bind to these properties in a blueprint. If you select Computed for a property that is not a string property, the property type is changed to string.

If you select the computed property option, leave the value for your custom property blank. Design your scripts for the computed values.

Table 3-45. Scripting Examples for the Computed Property Option

Sample String Property	Script Syntax	Sample Usage
my_unique_id = ""	Bash - \$my_unique_id	export my_unique_id="0123456789"
	Windows CMD - %my_unique_id%	set my_unique_id=0123456789
	Windows PowerShell - \$my_unique_id	\$my_unique_id = "0123456789"

String Property

String properties expect string values. You can supply the string yourself, require someone else to supply the value, or retrieve the value from another blueprint component by creating a binding to another string property. String values can contain any ASCII characters. To create a property binding, use the **Properties** tab on the design canvas to select the appropriate property for binding. The property value is then passed to the action scripts as raw string data. When you bind to a blueprint string property, make sure the blueprint component you bind to is not clusterable. If the component is clustered, the string value becomes an array and you do not retrieve the value you expect.

Sample String Property	Script Syntax	Sample Usage
admin_email = "admin@email987.com"	Bash - \$admin_email	echo \$admin_email
	Windows CMD - %admin_email%	echo %admin_email%
	Windows PowerShell - \$admin_email	write-output \$admin_email

Array Property

Array properties expect an array of string, integer, decimal, or boolean values defined as [*“value1”, “value2”, “value3”...]*. You can supply the values yourself, require someone else to supply the values, or retrieve the values from another blueprint component by creating a property binding.

When you create a software property of type Array, where the data type is integer or decimal, you must use a semicolon as an array element separator, regardless of the locale. Do not use a comma (,) or a dot (.). For some locales, you can use a comma (,) as the decimal separator. For example:

- A valid array for French resembles: [1,11;2,22;3,33]
- A valid array for English resembles: [1.11,2.22,3.33]

When you pass large numbers into an array, do not use the grouping format. For example: do not use **4444 444.000** (French), **4.444.444,000** (Italian), or **4,444,444.000** (English), because data files that contain locale-specific formats might be misinterpreted when they are transferred to a machine that has a different locale. The grouping format is not allowed, because a number such as **4,444,444.000** would be considered as three separate numbers. Instead, just enter **4444444.000**.

When you define values for an array property you must enclose the array in square brackets. For an array of strings, the value in the array elements can contain any ASCII characters. To properly encode a backslash character in an Array property value, add an extra backslash, for example, `["c:\\test1\\test2"]`. For a bound property, use the **Properties** tab in the design canvas to select the appropriate property for binding. If you bind to an array, you must design your software components so they don't expect a value array in any specific order.

For example, consider a load balancer virtual machine that is balancing the load for a cluster of application server virtual machines. In such a case, an array property is defined for the load balancer service and set to the array of IP addresses of the application server virtual machines.

These load balancer service configure scripts use the array property to configure the appropriate load balancing scheme on the Red Hat, Windows, and Ubuntu operating systems.

Sample Array Property	Script Syntax	Sample Usage
operating_systems = ["Red Hat","Windows","Ubuntu"]	Bash - <code>\${operating_systems[@]}</code> for the entire array of strings <code>\${operating_systems[N]}</code> for the individual array element	<pre>for ((i = 0 ; i < \$ {#operating_systems[@]}; i++)); do echo \${operating_systems[i]} done</pre>
	Windows CMD - <code>%operating_systems_N%</code> where <i>N</i> represents the position of the element in the array	<pre>for /F "delims== tokens=2" %A in ('set operating_systems_') do (echo %A)</pre>
	Windows PowerShell - <code>\$operating_systems</code> for the entire array of strings <code>\$operating_systems[N]</code> for the individual array element	<pre>foreach (\$os in \$operating_systems){ write-output \$os }</pre>

Content Property

The content property value is a URL to a file to download content. Software agent downloads the content from the URL to the virtual machine and passes the location of the local file in the virtual machine to the script.

Content properties must be defined as a valid URL with the HTTP or HTTPS protocol. For example, the JBOSS Application Server Software component in the Dukes Bank sample application specifies a content property `cheetah_tgz_url`. The artifacts are hosted in the Software appliance and the URL points to that location in the appliance. The Software agent downloads the artifacts from the specified location into the deployed virtual machine.

For information about `software.http.proxy` settings that you can use with content properties, see *Custom Properties Reference*.

Sample String Property	Script Syntax	Sample Usage
cheetah_tgz_url = "http://app_content_server_ip:port/artifacts/software/jboss/cheetah-2.4.4.tar.gz"	Bash - \$cheetah_tgz_url	tar -zxvf \$cheetah_tgz_url
	Windows CMD - %cheetah_tgz_url %	start /wait c:\unzip.exe %cheetah_tgz_url %
	Windows PowerShell - \$cheetah_tgz_url	& c:\unzip.exe \$cheetah_tgz_url

Boolean Property

Use the boolean property type to provide True and False choices in the Value drop-down menu.

Integer Property

Use the integer property type for zeros, and positive or negative integers.

Decimal Property

Use the decimal property type for values representing non-repeating decimal fractions.

When Your Software Component Needs Information from Another Component

In several deployment scenarios, a component needs the property value of another component to customize itself. You can do this with vRealize Automation by creating property bindings. You can design your Software action scripts for property bindings, but the actual bindings are configured by the architect that assembles the blueprint.

In addition to setting a property to a hard-coded value, a software architect, IaaS architect, or application architect can bind Software component properties to other properties in the blueprint, such as an IP address or an installation location. When you bind a Software property to another property, you can customize a script based on the value of another component property or virtual machine property. For example, a WAR component might need the installation location of the Apache Tomcat server. In your scripts, you can configure the WAR component to set the server_home property value to the Apache Tomcat server install_path property value in your script. As long as the architect who assembles the blueprint binds the server_home property to the Apache Tomcat server install_path property, then the server_home property value is set correctly.

Your action scripts can only use properties that you define in those scripts, and you can only create property bindings with string and array values. Blueprint property arrays are not returned in any specific order, so binding to clusterable or scalable components might not produce the values you expect. For example, your software component requires each of the machine IDs of a cluster of machines, and you allow your users to request a cluster from 1-10, and to scale the deployment from 1-10 machines. If you configure your software property as a string type, you get a single randomly selected machine ID from the cluster. If you configure your software property as an array type, you get an array of all the machine IDs in

the cluster, but in no particular order. If your users scale the deployment, the order of values could be different for each operation. To make sure you never lose values for clustered components, you can use the array type for any software properties. However, you must design your software components so they don't expect a value array in any specific order.

See the Examples of String Property Bindings table for examples of a string property value when binding to different types of properties.

Table 3-46. Examples of String Property Bindings

Sample Property Type	Property Type to Bind	Binding Outcome (A binds to B)
String (property A)	String (property B="Hi")	A="Hi"
String (property A)	Content (property B="http://my.com/content")	A="http://my.com/content"
String (property A)	Array (property B=["1", "2"])	A=["1", "2"]
String (property A)	Computed (property B="Hello")	A="Hello"

See the Examples of Array Property Bindings table for examples of an array property value when binding to different types of properties.

Table 3-47. Examples of Array Property Bindings

Sample Property Type	Property Type to Bind	Binding Outcome (A binds to B)
Array (property A)	String (property B="Hi")	A="Hi"
Array (property A)	Content (property B="http://my.com/content")	A="http://my.com/content"
Array (property A)	Computed (property B="Hello")	A="Hello"

For a detailed explanation of supported property types, see [Property Types and Setting Options](#).

Passing Property Values Between Life Cycle Stages

You can modify and pass property values between life cycle stages by using the action scripts.

For a computed property, you can modify the value of a property and pass the value to the next life cycle stage of the action script. For example, if component A has the `progress_status` value defined as `staged`, in the `INSTALL` and `CONFIGURE` life cycle stage you change the value to `progress_status=installed` in the respective action scripts. If component B is bound to component A, the property values of `progress_status` in the life cycle stages of the action script are the same as component A.

Define in the software component that component B depends on A. This dependency defines the passing of correct property values between components whether they are in the same node or across different nodes.

For example, you can update a property value in an action script by using the supported scripts.

- Bash `progress_status="completed"`
- Windows CMD `set progress_status=completed`

- Windows PowerShell `$progress_status="completed"`

Note Array and content property do not support passing modified property values between action scripts of life cycle stages.

Best Practices for Developing Components

To familiarize yourself with best practices for defining properties and action scripts, you can download and import Software components and application blueprints from the VMware Solution Exchange.

Follow these best practices when developing Software components.

- For a script to run without any interruptions, the return value must be set to zero (0). This setting allows the agent to capture all of the properties and send them to the Software server.
- Some installers might need access to the tty console. Redirect the input from `/dev/console`. For example, a RabbitMQ Software component might use the `./rabbitmq_rhel.py --setup-rabbitmq < /dev/console` command in its install script.
- When a component uses multiple life cycle stages, the property value can be changed in the INSTALL life cycle stage. The new value is sent to the next life cycle stage. Action scripts can compute the value of a property during deployment to supply the value to other dependent scripts. For example, in the Clustered Dukes Bank sample application, JBossAppServer service computes the JVM_ROUTE property during the install life cycle stage. This property is used by the JBossAppServer service to configure the life cycle. Apache load balancer service then binds its JVM_ROUTE property to the all (appserver:JBossAppServer:JVM_ROUTE) property to get the final computed value of node0 and node1. If a component requires a property value from another component to complete an application deployment successfully, you must state explicit dependencies in the application blueprint.

Note You cannot change the content property value for a component that uses multiple life cycle stages.

Create a Software Component

Configure and publish a Software component that other software architects, IaaS architects, and application architects can use to assemble application blueprints.

Prerequisites

Log in to the vRealize Automation console as a **software architect**.

Procedure

- 1 Select **Design > Software Components**.
- 2 Click the **Add** icon ()

3 Enter a name and, optionally, a description.

Using the name you specified for your Software component, vRealize Automation creates an ID for the Software component that is unique within your tenant. You can edit this field now, but after you save the blueprint you can never change it. Because IDs are permanent and unique within your tenant, you can use them to programmatically interact with blueprints and to create property bindings.

4 (Optional) If you want to control how your Software component is included in blueprints, select a container type from the **Container** drop-down menu.

Option	Description
Machines	Your Software component must be placed directly on a machine.
One of your published Software components	If you are designing a Software component specifically to install on top of another Software component that you created, select that Software component from the list. For example, if you are designing an EAR component to install on top of your previously created JBOSS component, select your JBOSS component from the list.
Software components	If you are designing a Software component that should not be installed directly on a machine, but can be installed on several different Software components, then select the software components option. For example, if you are designing a WAR component and you want it to be installed on your Tomcat Server Software component, and your Tcserver Software component, select the software components container type.

5 Click **Next**.

6 Define any properties you intend to use in your action scripts.

- a Click the **Add** icon (.
- b Enter a name for the property.
- c Enter a description for the property.

This description displays to architects who use your Software component in blueprints.

- d Select the expected type for the value of your property.
- e Define the value for your property.

Option	Description
Use the value you supply now	<ul style="list-style-type: none"> ■ Enter a value. ■ Deselect Overridable. ■ Select Required.
Require architects to supply a value	<ul style="list-style-type: none"> ■ To provide a default, enter a value. ■ Select Overridable. ■ Select Required.
Allow architects to supply a value if they choose	<ul style="list-style-type: none"> ■ To provide a default, enter a value. ■ Select Overridable. ■ Deselect Required.

Architects can configure your Software properties to show to users in the request form. Architects can use the Show in Request option to require or request that users fill in values for properties that you mark as overridable.

- 7 Follow the prompts to provide a script for at least one of the software life cycle actions.

Table 3-48. Life Cycle Actions

Life Cycle Actions	Description
Install	Install your software. For example, you might download Tomcat server installation bits and install a Tomcat service. Scripts you write for the Install life cycle action run when software is first provisioned, either during an initial deployment request or as part of a scale out.
Configure	Configure your software. For the Tomcat example, you might set the JAVA_OPTS and CATALINA_OPTS. Configuration scripts run after the install action completes.
Start	Start your software. For example, you might start the Tomcat service using the start command in the Tomcat server. Start scripts run after the configure action completes.
Update	If you are designing your software component to support scalable blueprints, handle any updates that are required after a scale in or scale out operation. For example, you might change the cluster size for a scaled deployment and manage the clustered nodes using a load balancer. Design your update scripts to run multiple times (idempotent) and to handle both the scale in and the scale out cases. When a scale operation is performed, update scripts run on all dependent software components.
Uninstall	Uninstall your software. For example, you might perform specific actions in the application before a deployment is destroyed. Uninstall scripts run whenever software components are destroyed.

Include exit and status codes in your action scripts. Each supported script type has unique exit and status code requirements.

Script Type	Success Status	Error Status	Unsupported Commands
Bash	<ul style="list-style-type: none"> ■ return 0 ■ exit 0 	<ul style="list-style-type: none"> ■ return non-zero ■ exit non-zero 	None
Windows CMD	exit /b 0	exit /b non-zero	Do not use exit 0 or exit non-zero codes.
PowerShell	exit 0	exit non-zero;	Do not use warning, verbose, debug, or host calls.

- 8 Select the **Reboot** checkbox for any script that requires you to reboot the machine.

After the script runs, the machine reboots before starting the next life cycle script.

- 9 Click **Finish**.

- 10 Select your Software component and click **Publish**.

You configured and published a Software component. Other software architects, IaaS architects, and application architects can use this Software component to add software to application blueprints.

What to do next

Add your published Software component to an application blueprint. See [Assembling Composite Blueprints](#).

Software Component Settings

Configure general settings, create properties, and write custom action scripts to install, configure, update, or uninstall your Software component on provisioned machines.

As a software architect, click **Design > Software components** and click the **Add** icon to create a new Software component.

New Software General Settings

Apply general settings to your Software component.

Table 3-49. New Software General Settings

Setting	Description
Name	Enter a name for your Software component.
ID	Using the name you specified for your Software component, vRealize Automation creates an ID for the Software component that is unique within your tenant. You can edit this field now, but after you save the blueprint you can never change it. Because IDs are permanent and unique within your tenant, you can use them to programmatically interact with blueprints and to create property bindings.

Table 3-49. New Software General Settings (Continued)

Setting	Description
Description	Summarize your Software component for the benefit of other architects.
Container	<p>On the design canvas, blueprint architects can only place your Software component inside the container type you select.</p> <ul style="list-style-type: none"> ■ Select Machines to require architects to place your Software component directly on a machine component in the design canvas. ■ Select Software components if you are designing a Software component that should never be placed directly on a machine component, but can be nested inside one of several different Software components. ■ Select a specific published Software component if you are designing a Software component specifically to nest inside another Software component that you created. ■ Select Azure Virtual Machine if you are designing a Software component specifically for an Azure blueprint.

New Software Properties

Software component properties are used to parameterize scripts to pass defined properties as environment variables to scripts running in a machine. Before running your scripts, the Software agent in the provisioned machine communicates with vRealize Automation to resolve the properties. The agent then creates script-specific variables from these properties and passes them to the scripts.

Table 3-50. New Software Properties

Setting	Description
Name	Enter a name for your Software property. Property names are case-sensitive and can contain only alphabetic, numeric, hyphen (-), or underscore (_) characters.
Description	For the benefit of other users, summarize your property and any requirements for the value.
Type	Software supports string, array, content, boolean, and integer types. For a detailed explanation of supported property types, see Property Types and Setting Options . For information about property bindings, see When Your Software Component Needs Information from Another Component and Creating Property Bindings Between Blueprint Components .

Table 3-50. New Software Properties (Continued)

Setting	Description
Value	<ul style="list-style-type: none"> ■ To use the value you supply: <ul style="list-style-type: none"> ■ Enter a Value. ■ Select Required. ■ Deselect Overridable. ■ To require architects to supply a value: <ul style="list-style-type: none"> ■ (Optional) Enter a Value to provide a default. ■ Select Overridable. ■ Select Required. ■ Allow architects to supply a value or leave the value blank: <ul style="list-style-type: none"> ■ (Optional) Enter a Value to provide a default. ■ Select Overridable. ■ Deselect Required.
Encrypted	<p>Mark properties as encrypted to mask the value and display as asterisks in vRealize Automation. If you change a property from encrypted to unencrypted, vRealize Automation resets the property value. For security, you must set a new value for the property.</p> <p>Important If secured properties are printed in the script using the echo command or other similar commands, these values appear in plain text in the log files. The values in the log files are not masked.</p>
Overridable	Allow architects to edit the value of this property when they are assembling an application blueprint. If you enter a value, it displays as a default.
Required	Require architects to provide a value for this property, or to accept the default value you supply.
Computed	Values for computed properties are assigned by the INSTALL, CONFIGURE, START, or UPDATE life cycle scripts. The assigned value is propagated to the subsequent available life cycle stages and to components that bind to these properties in a blueprint. If you select Computed for a property that is not a string property, the property type is changed to string.

New Software Actions

You create Bash, Windows CMD, or PowerShell action scripts to specify exactly how components are installed, configured, uninstalled, or updated during deployment scale operations.

Table 3-51. Life Cycle Actions

Life Cycle Actions	Description
Install	Install your software. For example, you might download Tomcat server installation bits and install a Tomcat service. Scripts you write for the Install life cycle action run when software is first provisioned, either during an initial deployment request or as part of a scale out.
Configure	Configure your software. For the Tomcat example, you might set the JAVA_OPTS and CATALINA_OPTS. Configuration scripts run after the install action completes.

Table 3-51. Life Cycle Actions (Continued)

Life Cycle Actions	Description
Start	Start your software. For example, you might start the Tomcat service using the start command in the Tomcat server. Start scripts run after the configure action completes.
Update	If you are designing your software component to support scalable blueprints, handle any updates that are required after a scale in or scale out operation. For example, you might change the cluster size for a scaled deployment and manage the clustered nodes using a load balancer. Design your update scripts to run multiple times (idempotent) and to handle both the scale in and the scale out cases. When a scale operation is performed, update scripts run on all dependent software components.
Uninstall	Uninstall your software. For example, you might perform specific actions in the application before a deployment is destroyed. Uninstall scripts run whenever software components are destroyed.

Select the **Reboot** checkbox for any script that requires you to reboot the machine. After the script runs, the machine reboots before starting the next life cycle script. Verify that no processes are prompting for user interaction when the action script is running. Interruptions pause the script, causing it to remain in an idle state indefinitely, eventually failing. Additionally, your scripts must include proper exit codes that are applicable to the application deployment. If the script lacks exit and return codes, the last command that ran in the script becomes the exit status. Exit and return codes vary between the supported script types, Bash, Windows CMD, PowerShell.

Script Type	Success Status	Error Status	Unsupported Commands
Bash	<ul style="list-style-type: none"> ■ return 0 ■ exit 0 	<ul style="list-style-type: none"> ■ return non-zero ■ exit non-zero 	None
Windows CMD	exit /b 0	exit /b non-zero	Do not use exit 0 or exit non-zero codes.
PowerShell	exit 0	exit non-zero;	Do not use warning, verbose, debug, or host calls.

Designing XaaS Blueprints and Resource Actions

The XaaS blueprints can be published as catalog items or used in the blueprint design canvas. The resource actions are actions that you run on deployed items.

XaaS uses vRealize Orchestrator to run workflows that provision items or run actions. For example, you can configure the workflows to create vSphere virtual machines, Active Directory users in groups, or run PowerShell scripts. If you create a custom vRealize Orchestrator workflow, you can provide that workflow as an item in the service catalog so that the entitled users can run the workflow.

You can use an XaaS blueprint as a component in a blueprint that you create in the design canvas, or you can publish it directly to the service catalog.

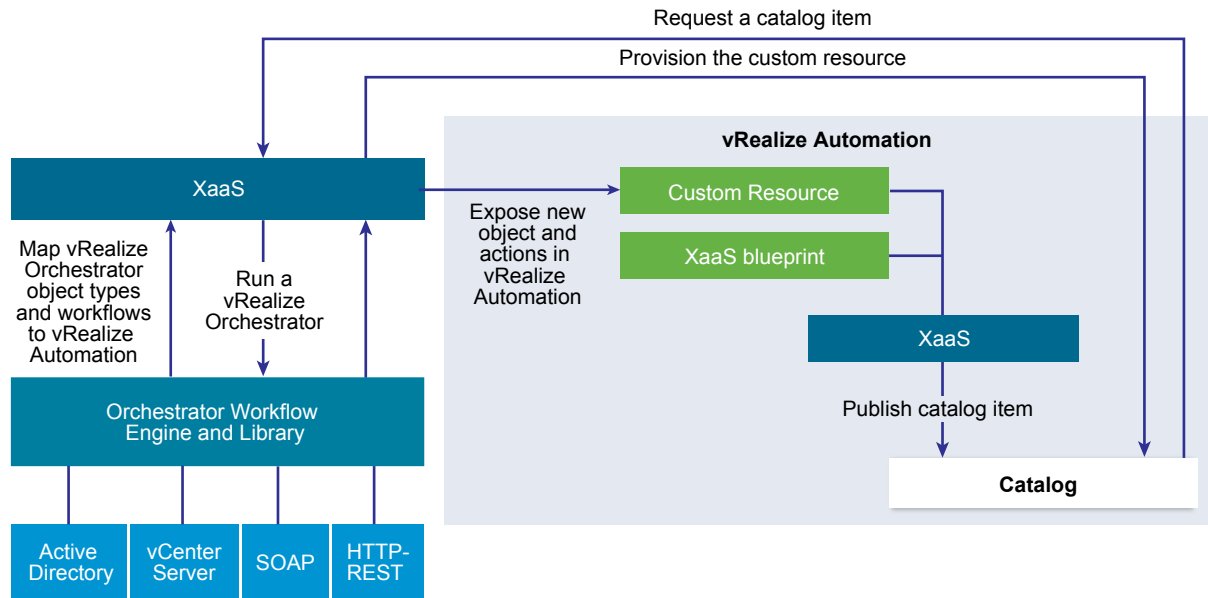

If you use a blueprint as a component in another blueprint, you can configure it to scale when the deployed blueprint is scaled in or out.

vRealize Orchestrator Integration in vRealize Automation

vRealize Orchestrator is the workflow engine integrated in vRealize Automation.

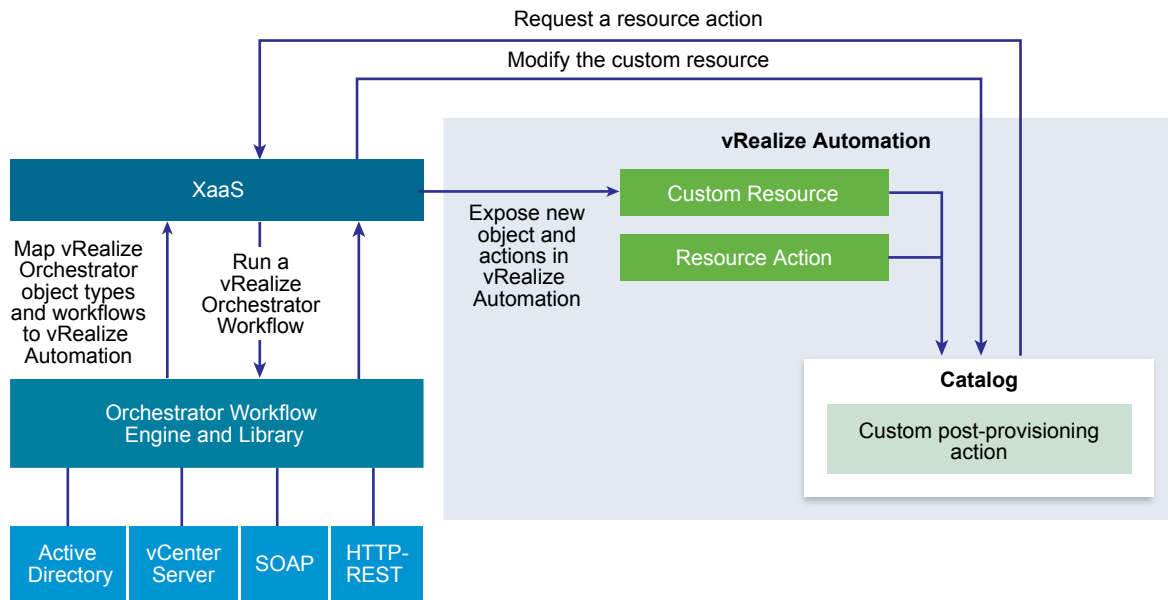

The vRealize Orchestrator server distributed with vRealize Automation is preconfigured, and therefore when your system administrator deploys the vRealize Automation Appliance, the vRealize Orchestrator server is up and running.

Figure 3-2. Create and Request Catalog Items Included in an XaaS to Provision a Custom Resource

XaaS architects add custom resources related to the supported endpoints and provided workflows, and then create XaaS blueprints and actions based on those resources. Tenant administrators and business group managers can add the XaaS blueprints and actions to the service catalog. The XaaS blueprint can also be used in the blueprint designer.

When the service catalog user requests an item, vRealize Automation runs a vRealize Orchestrator workflow to provision the custom resource.

Figure 3-3. Create and Request Custom Resource Actions to Modify a Custom Resource

XaaS architects can also add vRealize Orchestrator workflows as resource actions to extend vRealize Automation capabilities. After the service catalog users provision a custom resource, they can run post-provisioning action. This way, the consumers run a vRealize Orchestrator workflow and modify the provisioned custom resource.

When a service catalog user requests an XaaS blueprint or resource action as a catalog item, the XaaS service runs the corresponding vRealize Orchestrator workflow passing the following data as global parameters to the workflow:

Table 3-52. XaaS Global Parameters

Parameter	Description
__asd_tenantRef	The tenant of the user requesting the workflow.
__asd_subtenantRef	The business group of the user requesting the workflow.
__asd_catalogRequestId	The request id from the catalog for this workflow run.
__asd_requestedFor	The target user of the request. If the request is on behalf of a user, then this is the user on behalf of whom the workflow is requested, otherwise it is the user requesting the workflow.
__asd_requestedBy	The user requesting the workflow.

If an XaaS blueprint or resource action uses a vRealize Orchestrator workflow that contains a User Interaction schema element, when a consumer requests the service, the workflow suspends its run and waits for the user to provide the required data. To answer to a waiting user interaction, the user must navigate to **Inbox > Manual User Action**.

The default vRealize Orchestrator server inventory is shared across all tenants and cannot be used per tenant. For example, if a service architect creates a service blueprint for creating a cluster compute resource, the consumers from different tenants have to browse through the inventory items of all vCenter Server instances although they might belong to a different tenant.

System administrators can install vRealize Orchestrator or deploy the vRealize Orchestrator Appliances separately to set up an external vRealize Orchestrator instance and configure vRealize Automation to work with that external vRealize Orchestrator instance.

System administrators can also configure vRealize Orchestrator workflow categories per tenant and define which workflows are available to each tenant.

In addition, tenant administrators can also configure an external vRealize Orchestrator instance but only for their own tenants.

For information about configuring an external vRealize Orchestrator instance and vRealize Orchestrator workflow categories, see *Configuring vCenter Orchestrator and Plug-Ins*.

List of vRealize Orchestrator Plug-Ins

With plug-ins you can use vRealize Orchestrator to access and control external technologies and applications. By exposing an external technology in a vRealize Orchestrator plug-in, you can incorporate objects and functions in workflows that access the objects and functions of the external technology.

The external technologies that you can access by using plug-ins can include virtualization management tools, email systems, databases, directory services, remote control interfaces, and so on.

You can use the standard set of vRealize Orchestrator plug-ins to incorporate external technologies such as the vCenter Server API and email capabilities into workflows. In addition, you can use the vRealize Orchestrator open plug-in architecture to develop plug-ins to access other applications.

Table 3-53. Plug-Ins Included by Default in vRealize Orchestrator

Plug-In	Purpose
vCenter Server	Provides access to the vCenter Server API so that you can incorporate all of the vCenter Server objects and functions into the management processes that you automate by using vRealize Orchestrator.
Configuration	Provides workflows for configuring the vRealize Orchestrator authentication, database connection, SSL certificates, and so on.
vCO Library	Provides workflows that act as basic building blocks for customization and automation of client processes. The workflow library includes templates for life cycle management, provisioning, disaster recovery, hot backup, and other standard processes. You can copy and edit the templates to modify them according to your needs.
SQL	Provides the Java Database Connectivity (JDBC) API, which is the industry standard for database-independent connectivity between the Java programming language and a wide range of databases. The databases include SQL databases and other tabular data sources, such as spreadsheets or flat files. The JDBC API provides a call-level API for SQL-based database access from workflows.
SSH	Provides an implementation of the Secure Shell v2 (SSH-2) protocol. Allows remote command and file transfer sessions with password and public key-based authentication in workflows. Supports keyboard-interactive authentication. Optionally, the SSH plug-in can provide remote file system browsing directly in the vRealize Orchestrator client inventory.

Table 3-53. Plug-Ins Included by Default in vRealize Orchestrator (Continued)

Plug-In	Purpose
XML	A complete Document Object Model (DOM) XML parser that you can implement in workflows. Alternatively, you can use the ECMAScript for XML (E4X) implementation in the vRealize Orchestrator JavaScript API.
Mail	Uses Simple Mail Transfer Protocol (SMTP) to send email from workflows.
Net	Wraps the Jakarta Apache Commons Net Library. Provides implementations of Telnet, FTP, POP3, and IMAP. The POP3 and IMAP part is used for reading email. In combination with the Mail plug-in, the Net plug-in provides complete email send and receive capabilities in workflows.
Enumeration	Provides common enumerated types that can be used in workflows by other plug-ins.
Workflow documentation	Provides workflows that let you generate information in PDF format about a workflow or a workflow category.
HTTP-REST	Lets you manage REST Web services by providing interaction between vCenter Orchestrator and REST hosts.
SOAP	Lets you manage SOAP Web services by providing interaction between vCenter Orchestrator and SOAP hosts.
AMQP	Lets you interact with Advanced Message Queuing Protocol (AMQP) servers also known as brokers.
SNMP	Enables vCenter Orchestrator to connect and receive information from SNMP-enabled systems and devices.
Active Directory	Provides interaction between vCenter Orchestrator and Microsoft Active Directory.
vCO WebOperator	A Web view that lets you to access the workflows in the vRealize Orchestrator library and interact with them across a network by using a Web browser.
Dynamic Types	Lets you define dynamic types and create and use objects of these dynamic types.
PowerShell	Lets you manage PowerShell hosts and run custom PowerShell operations.
Multi-Node	Contains workflows for hierarchical orchestration, management of Orchestrator instances, and scale-out of Orchestrator activities.
vRealize Automation	Lets you create and run workflows for interaction between vRealize Orchestrator and vRealize Automation.

For more information about the vRealize Orchestrator plug-ins that VMware develops and distributes, see the VMware vRealize™ Orchestrator™ Documentation landing page.

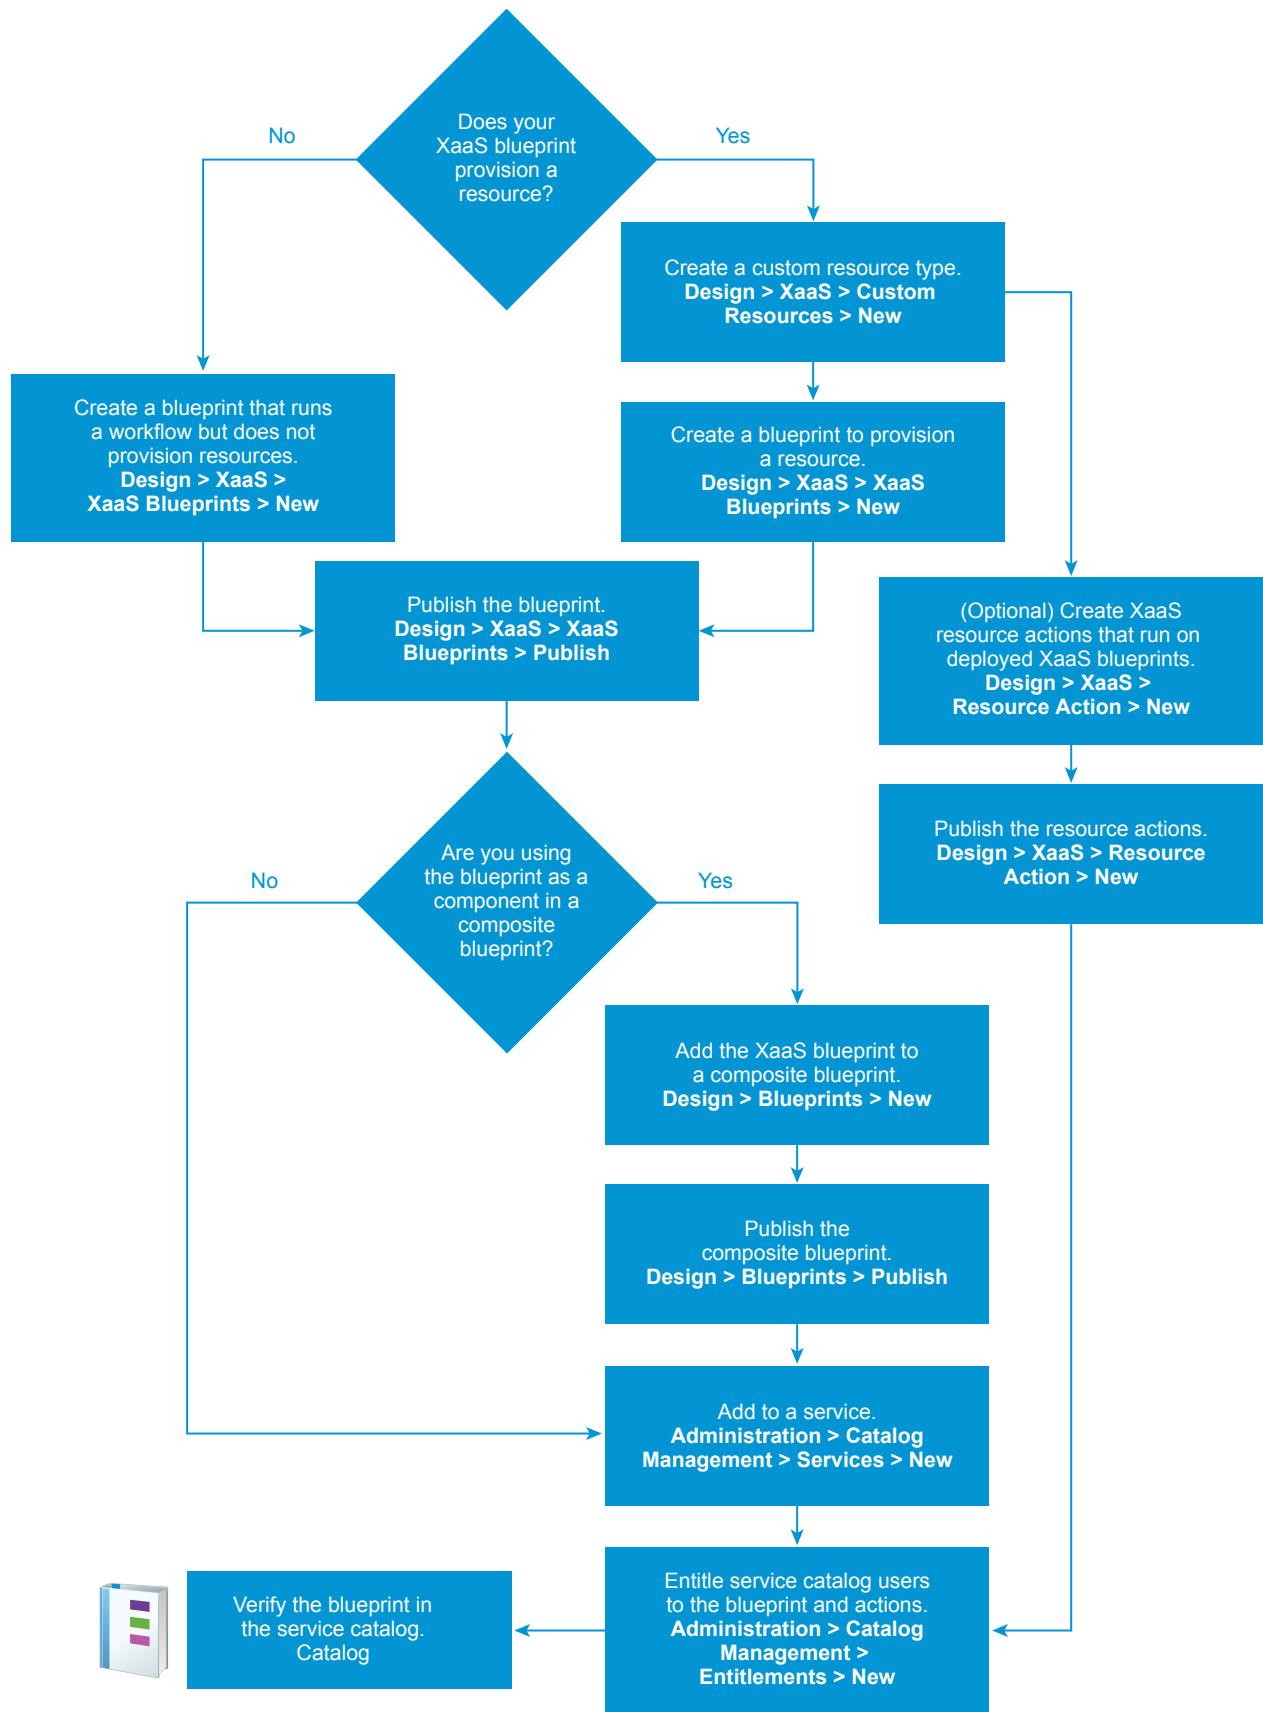

Creating XaaS Blueprints and Resource Actions

The XaaS blueprints can be entitled to users as catalog items, or they can be assembled into a composite blueprints using the design canvas. The resource actions run on the provisioned items to manage the items after they are provisioned.

For example, you can use an XaaS blueprint to create Active Directory users in a group . You can then use a resource action to require that the user change the password.

XaaS Blueprint Workflow

The workflow that you follow to create an XaaS blueprint and any optional resource actions varies depending on how you intend to use the blueprint. The following workflow provides the basic process.

XaaS Blueprint Terminology

XaaS blueprints are vRealize Orchestrator workflows that can provision resources, make changes to provisioned resources, or behave as a service that performs a task in your environment. The blueprints and the resource actions have several nuances that you must understand when you design blueprints for your service catalog users.

The following definitions help you understand the terms used when working with XaaS blueprints.

Custom resource	A vRealize Orchestrator object type that is exposed as a resource through the API of a vRealize Orchestrator plug-in. You create a custom resource to define the output parameter of an XaaS provisioning blueprint and to define an input parameter of a resource action.
XaaS blueprint component	A provisioning or non-provisioning blueprint that you can use in the blueprint design canvas. This blueprint might also be a standalone XaaS blueprint.
Standalone XaaS blueprint	A provisioning or non-provisioning blueprint that is published and entitled directly to the service catalog.
Provisioning blueprint	<p>A provisioning blueprint that runs a vRealize Orchestrator workflow to provision resources on the target endpoint using the vRealize Orchestrator plug-in API for the endpoint. For example, add virtual NICs to a network device in vSphere. To create a provisioning blueprint, you must have a custom resource that defines the vRealize Orchestrator resource type.</p> <p>When a service catalog user requests this type of catalog items, the workflow provisions the item and the deployed item is stored on the Items tab. You can define post-provisioning operations for this type of provisioned resources. You can also make the blueprints scalable by adding or removing instance when needed.</p>
Non-provisioning blueprint	<p>A non-provisioning blueprint runs a vRealize Orchestrator workflow to perform a task that does not require the API to make changes to an endpoint. For example, the workflow that runs builds a report and then emails it or posts it to a target communication system.</p> <p>When a service catalog user requests this type of catalog item, the workflow runs to perform the scripted task, but the item is not added on the Items tab. You cannot perform post-provisioning operations on this type of blueprint. You can use non-provisioning blueprints as supporting workflows in scalable blueprints. For example, you can create a blueprint to update a high availability load balancer.</p>
Composite blueprint	A blueprint that was created using the design canvas. The composite blueprint uses one or more components. For example, a machine component, a software component, or an XaaS component. When you add it to a service, it is listed as a Deployment. When you add it to an

entitlement to make it available to the service catalog users, it is listed as a Composite Blueprint. A composite blueprint can have one blueprint component, or it can include an entire application with multiple machines, software, and networking.

Resource action

A workflow that you can run on a deployed provisioning blueprint. The deployed blueprint can be an XaaS blueprint or blueprint component, or it can be a machine type that you mapped to a vRealize Orchestrator resource type.

XaaS Blueprint Design Considerations

Before you create an XaaS blueprint, you must understand the intent of your blueprint so that you can create one that correctly provisions your resources.

You can create and use XaaS blueprints as a blueprint component in the design canvas or as a standalone blueprint. The blueprint can be a provisioning blueprint or a non-provisioning blueprint.

Table 3-54. XaaS Blueprint Types and Outcomes

XaaS Blueprint Type	Is a custom resource required?	Is the blueprint scalable in a deployment?	Can I run a resource action on the deployed blueprint?
Blueprint component that provisions resources	Yes	Yes. If it is configured to scale, it will scale when the deployment is scaled.	Yes. It scales when the deployment is scaled, and you can run other resource actions on the deployed component. The blueprint component appears on your Items tab.
Blueprint component that runs a workflow but does not provision resources	No. The blueprint uses the vRealize Orchestrator server configuration, but it does not require an XaaS custom resource.	No. It does not provision resources, but it can run as part of a scale operation. For example, update a load balancer with the new configuration based on the scale operation.	No. You cannot run a resource action on a non-provisioning component.

Table 3-54. XaaS Blueprint Types and Outcomes (Continued)

XaaS Blueprint Type	Is a custom resource required?	Is the blueprint scalable in a deployment?	Can I run a resource action on the deployed blueprint?
Standalone blueprint that provisions resources	Yes	No. You must create resource actions to add or destroy instances.	Yes. You can run resource actions on the deployed resource, including any actions that you created to support scaling. The blueprint appears on your Items tab.
Standalone blueprint that runs a workflow but does not provision resources	No. The blueprint uses the vRealize Orchestrator server configuration, but it does not require an XaaS custom resource.	No. It does not provision resources, but it can run as part of a resource action.	No. You cannot run a resource action on a non-provisioning component.

Add an XaaS Custom Resource

You create a custom resource to define the XaaS item for provisioning. Before you can create an XaaS blueprint or action, you must have a custom resource that is compatible with the object type of the blueprint or action workflow.

By creating a custom resource, you map an object type exposed through the API of a vRealize Orchestrator plug-in as a resource. The custom resource defines the output parameter of an XaaS blueprint for provisioning and to define an input parameter of a resource action.

If a blueprint or resource action workflow does not provision a resource or run on a deployed blueprint, you do not need to create a custom resource. For example, you do not need a custom resource if your workflow updates a database value or sends an email message after a provisioning operation.

As you create a custom resource, you can specify the fields of the read-only form on the details of a provisioned item. See [Designing a Custom Resource Form](#).

Prerequisites

- Log in to the vRealize Automation console as an **XaaS architect**.
- Use the detailed options information to configure the custom resource. See [XaaS Custom Resource Wizard Options](#).

Procedure

- 1 Select **Design > XaaS > Custom Resources**.
- 2 Click the **New** icon (+).

3 Configure the values on the **Resource type** tab.

- a Enter or select the vRealize Orchestrator object type in the **Orchestrator Type** text box.
For example, enter **v** to see the types that contain the letter v. To see all types, enter a space.
- b Enter a name and, optionally, a description.
- c Enter a version.
The supported format extends to major.minor.micro-revision.
- d Click **Next**.

4 Edit the **Details Form** tab as needed.

You can edit the custom resource form by deleting, editing, and rearranging elements. You can also add a form and form pages and drag elements to the new form and form page.

5 Click **Finish**.

You created a custom resource and you can see it on the Custom Resources page. You can create XaaS blueprints or actions based on this custom resource.

What to do next

- Create an XaaS blueprint. See [Add an XaaS Blueprint](#).
- Create an XaaS resource action. See [Create an XaaS Resource Action](#).

XaaS Custom Resource Wizard Options

You use these custom resource options to create or modify a custom resource so that you can run XaaS blueprint and resource action workflows that provision resources or modify provisioned resources.

You can create only one custom resource for an object type. You can use the custom resource for multiple blueprints and resource actions.

To create a custom resource action, select **Design > XaaS > Custom Resources**

Resource Type

The list of possible object types that appears on the **Resource type** tab based on the installed plug-ins in the configured vRealize Orchestrator instance. vRealize Automation collects the values from the configured vRealize Orchestrator instance.

Table 3-55. Resource Type Options

Option	Description
Orchestrator type	<p>Enter or select the type that supports the workflow that you are using to provision.</p> <p>The type is composed of the plug-in name as it appears in the scripting API, for example, VC for vCenter, and the object type, for example, VirtualMachine. In this example, the API uses the value VC:VirtualMachine.</p> <p>This type can be the blueprint workflow output parameter or the resource action workflow input parameter.</p>
Name	Enter an informative name for the custom resource so that you can identify it when you create XaaS blueprints or resource actions.
Description	Enter a verbose description.
Version	The supported form extends to major.minor.micro-revision.

Details Form

These form fields appear as read-only values when your service catalog users provision an item that uses this custom resource. You can modify the existing fields and add new externally defined fields.

For more information about configuring the forms, see [Designing a Custom Resource Form](#).

Where Used

Because you can create only one custom resource per object type, you can use this page of the wizard to understand how the custom resource is used.

This tab is available for saved custom resources, not when you create the resource.

Table 3-56. Where Used Options

Option	Description
XaaS Blueprints	<p>A list of the blueprints that are configured to use this custom resource.</p> <p>From this page you can perform the following actions:</p> <ul style="list-style-type: none"> ■ Edit. Opens the blueprint so that you can see how it is configured or to modify it. ■ Publish/Unpublish. Change the state of the blueprint by making it available to use in a composite blueprint or to add to a service. If you unpublish a blueprint, you can potentially make it unavailable for use in composite blueprints, to add to a service, or make it unavailable in the service catalog. ■ Delete. Remove this blueprint from the system.
Resource Actions	<p>A list of the resource actions that are configured to use this custom resource.</p> <p>From this page you can perform the following actions:</p> <ul style="list-style-type: none"> ■ Edit. Opens the resource action so that you can see how it is configured or modify it. ■ Publish/Unpublish. Change the state of the resource action by making it available in an entitlement. If you unpublish a resource action, you can potentially make it unavailable to add to a service, or make it unavailable to run on deployed blueprints. ■ Delete. Remove this resource action from the system.

Create an XaaS Blueprint

An XaaS blueprint is a provisioning or non-provisioning blueprint. Some of the provided vRealize Orchestrator provisioning workflows include creating virtual machines, adding users to Active Directory, or taking virtual machine snapshots. Some of the non-provisioning workflows that you might create include updating your load balancer or to building a report and sending it to recipients.

You can create XaaS blueprints based on workflows provided in vRealize Orchestrator or you can use workflows that you create to accomplish goals specific to your environment.

Procedure

1 Add an XaaS Blueprint

An XaaS blueprint is a specification to run a vRealize Orchestrator workflow that makes a change to a target system in your environment. The blueprint includes the workflow, and it can include the input parameters, submission and read-only forms, sequence of actions, and the provisioning or non-provisioning operation.

2 Add an XaaS Blueprint to a Composite Blueprint

You add an XaaS blueprint as a component of a composite blueprint similar to how you add other blueprint components in the design canvas.

Add an XaaS Blueprint

An XaaS blueprint is a specification to run a vRealize Orchestrator workflow that makes a change to a target system in your environment. The blueprint includes the workflow, and it can include the input parameters, submission and read-only forms, sequence of actions, and the provisioning or non-provisioning operation.

You can create XaaS blueprints that you use in one or more of the following ways:

- Create an XaaS blueprint component. A component blueprint is a provisioning or non-provisioning blueprint that you can use in the blueprint design canvas as part of a composite blueprint. If you are using it as a component, you must configure the component life cycle options that support scale-in and scale-out operations on the deployed composite blueprint.

This blueprint type might also be published as a standalone blueprint.

- Create a standalone XaaS blueprint. A standalone blueprint is a provisioning or non-provisioning blueprint that is published and entitled directly to the service catalog.

For an example of how to create Active Directory users using an XaaS blueprint, see [Create an XaaS Blueprint and Action for Creating and Modifying a User](#).

Prerequisites

- Log in to the vRealize Automation console as an **XaaS architect**.
- If the blueprint must provision resources, create a custom resource corresponding to the output parameter of the service blueprint. See [Add an XaaS Custom Resource](#). If it does not use a vRealize Orchestrator plug-in API, you do not need to configure a custom resource.
- By creating an XaaS blueprint, you publish a vRealize Orchestrator workflow as a potential component blueprint or catalog item. The blueprint includes a form that you might edit. See [Designing an XaaS Blueprint Form](#).
- Use the detailed options information to configure the blueprint. See [XaaS Blueprint New or Edit Wizard Options](#).

Procedure

- 1 Select **Design > XaaS > XaaS Blueprints**.
- 2 Click the **New** icon ()
- 3 On the **Workflow** tab, select the workflow that runs when the blueprint provisions the resource.

This tab is not available if you are editing a blueprint.

- a Navigate through the vRealize Orchestrator workflow library and select a workflow relevant to your custom resource.
- b Review the input and output parameters to ensure that you can later provide the correct values.
- c Click **Next**.

- 4 On the **General** tab, configure the options and click **Next**.
 - a In the **Name** text box, enter a name that differentiates this blueprint from similar blueprints.
 - b If you do not want to use this blueprint as a component in a composite blueprint, deselect the **Make available as a component in the design canvas** check box.
- 5 On the **Blueprint Form** tab, edit the form as needed and click **Next**.
- 6 On the **Provisioned Resource** page, select a value and click **Next**.

Option	Description
No provisioning	If the workflow does not provision resources, you can select this option or leave the field empty.
<A custom resource that you previously created>	Select the custom resource that supports this provisioning workflow.

- 7 On the **Component Lifecycle** tab, define how this blueprint behaves during scale-in, scale-out, and destroy operations.

These workflows run on a deployed composite blueprint where this blueprint is a component. The availability of the different options depends on blueprint. Not all blueprint workflows support or require all the options.
- 8 Click **Finish**.
- 9 Select the row for you blueprint and click **Publish**.

You created and published an XaaS blueprint.

What to do next

- To add this blueprint directly to the service catalog as a standalone blueprint, add a service and add the blueprint to a service. See [Add a Service](#).
- To use this blueprint as a component in a composite blueprint, see [Add an XaaS Blueprint to a Composite Blueprint](#).

XaaS Blueprint New or Edit Wizard Options

You use these options to create an XaaS blueprint that runs a vRealize Orchestrator workflow when the blueprint is deployed. The workflow changes a target system in your environment.

For the steps that you follow to create the blueprint, see [Add an XaaS Blueprint](#).

To use this wizard, select **Design > XaaS > XaaS Blueprints**.

Workflow Tab

Select the workflow that runs when the blueprint provisions the resource.

This tab is not available if you are editing a blueprint.

In the following figure, the workflow tree is on the left and the parameters are on the right.

Figure 3-4. Workflow Tab in the XaaS Blueprint Wizard

New Blueprint

Workflow | General | Blueprint Form | Provisioned Resource | Component

Select a workflow:

- Microsoft
 - Active Directory
 - Computer
 - Configuration
 - Organizational Unit
 - Samples
 - User
 - Add a user to a user group
 - Change a user password
 - Create a user in a group**
 - Create a user in an organizational unit
 - Create a user with a password in a group
 - Create a user with a password in an organizational unit
 - Destroy a user
 - Disable a user
 - Enable a user
 - Remove a user from a user group
- NSX
- Orchestrator
- PowerShell

Selected workflow:

Name: Create a user in a group

Description: Creates a user without specifying a password. The password must be changed at the next login. Domain policies must allow users to have empty passwords.

Input parameters:

Name	Type
accountName	string
domainName	string
displayName	string
groupContainer	AD:Group

Displaying 1 - 4 of 4

Output parameters:

Name	Type
newUser	AD:User

Displaying 1 - 1 of 1

< Back | Next > | Finish | Cancel

Review the input and output parameters to ensure that you or your service catalog users can provide the correct values under the following circumstances:

- If you customize the blueprint form in this wizard or in the blueprint design canvas.
- If you leave all the input parameters blank, the service catalog users can set the values.

General Tab

Configure the metadata about and the behavior of the blueprint.

Table 3-57. General Tab Options

Option	Description
Name	<p>The name of the blueprint as you want it to appear in the following locations:</p> <ul style="list-style-type: none"> ■ Design canvas. If you select Make available as a component in the design canvas, this value is the name that appears in the categories list. ■ Services. If you use this blueprint as a standalone blueprint, this value is the name that you see when you add catalog items to service. ■ Entitlements. If you entitle the blueprint as an individual item, this value is the name that you see in the Add Items list.
Description	<p>Provide a verbose description that helps you differentiate between similar items.</p>
Hide catalog request information page	<p>Select the check box when you do not want to require the service catalog consumers to provide a description and reason when they request the item. The check box is selected by default.</p>

Table 3-57. General Tab Options (Continued)

Option	Description
Version	The supported format extends to major.minor.micro-revision.
Make available as a component in the design canvas	<p>If you plan to use the blueprint as a component in a design canvas blueprint, select this option.</p> <p>When it is published, the blueprint is available in the category you selected when you configured the custom resource.</p> <p>If you do not select this option, the blueprint does not appear in the design canvas. However, you can still add it to a service and entitle users to deploy it as a standalone blueprint.</p>

Blueprint Form Tab

The fields that appear on this page of the wizard are the workflow input parameters. You can make one or more of the following changes:

- Add fields to the form.
- Modify existing fields by deleting or rearranging the fields.
- Provide default values as the input parameters.

Any changes affect the form that is presented to:

- The application architect working in the design canvas when this XaaS blueprint is used as a blueprint component.
- The service catalog user if this blueprint is published as a standalone blueprint.

For more information about configuring the forms, see [Designing an XaaS Blueprint Form](#).

Provisioned Resource

The provisioned resource links the blueprint to a relevant XaaS custom resource that you configured on the Custom Resource page at **Design > XaaS > Custom Resource**.

Table 3-58. Provisioned Resource Options

Option	Description
A custom resource that you previously created	<p>Select the custom resource that defines the vRealize Orchestrator resource type required to run the provisioning blueprint.</p> <p>A provisioning blueprint runs a vRealize Orchestrator workflow to provision resources on the target endpoint using the vRealize Orchestrator plug-in API for the endpoint. For example, add virtual NICs to a network device in vSphere. You can define post-provisioning operations for this type of provisioned resources. You can also make the blueprint scalable, by adding or removing instances when needed.</p> <p>Results</p> <ul style="list-style-type: none"> ■ The blueprint is eligible to for scaling. ■ The blueprint appears in the design canvas in the category specified for the selected custom resource. ■ The blueprint is displayed on the Items tab when you deploy a blueprint that includes it, and you can run any actions on the item after deployment.
No provisioning	<p>A non-provisioning blueprint runs a vRealize Orchestrator workflow to perform a task that does not require the API to make changes to an endpoint. For example, build a report and email or post it to a target communication system.</p> <p>Results</p> <ul style="list-style-type: none"> ■ The blueprint is not eligible for scaling. You can use non-provisioning blueprints as supporting workflows in scalable blueprints. For example, you can create a blueprint to update a high availability load balancer. ■ The blueprint appears in the XaaS category in the design canvas. ■ The blueprint is not displayed on the Items tab when you deploy a blueprint that includes it, nor can you run any actions on the item after deployment.

Component Lifecycle Tab

The Component Lifecycle tab is available if you selected **Make available as a component in the design canvas** on the **General** tab.

You use these options to define how this blueprint behaves post-deployment during scale-in and scale-out operations when it is used as a component in a composite blueprint.

The availability of the different options depends on the blueprint. Not all blueprint workflows support or require all the options. Because your XaaS might be used in a composite blueprint, you should configure the update and destroy options, as well as allocate and deallocate, if they are available for the blueprint so that the blueprint scales correctly.

Table 3-59. Component Lifecycle Options

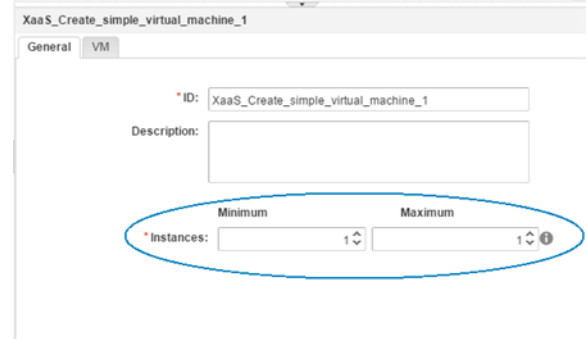

Option	Description
Scalable	<p>Select the option to allow the service catalog user to change the number of instances of this blueprint component after it is deployed as part of a scale-in or scale-out operation.</p> <p>This option is available if you selected a custom resource on the Provisioned Resource tab. It is not available if you selected the No provisioning option.</p> <p>If you make this blueprint scalable, the Instances option is added to the General tab in the design canvas. See the example below. If you do not select Scalable, the Instances option is not available in the design canvas.</p> 
Provisioning workflow	<p>The workflow that runs during a provisioning or scale-out operation. This workflow was selected when you created this blueprint, and you cannot edit the value.</p>
Allocation workflow	<p>Select the workflow that runs before any initial provisioning or scale-out operation.</p> <p>This life cycle workflow type is available for Azure allocations. If you create an allocation workflow for a scale operation, it must include the following values:</p> <ul style="list-style-type: none"> ■ Input parameters <ul style="list-style-type: none"> ■ Parameter name is requestData and the parameter type is Properties. ■ Parameter name is subtenant and the parameter type is Properties. ■ reservations and the parameter type is Arrays/Properties. ■ Output parameter <ul style="list-style-type: none"> ■ Must include a parameter where the parameter type is Properties.

Table 3-59. Component Lifecycle Options (Continued)

Option	Description
Update workflow	<p>Select the workflow that runs during update operations, including scale-in or scale out where a component is not scalable, but it can be updated.</p> <p>For example, a load balancer is updated with the new configuration created with the scale-in or scale-out operation for any of the components in the composite blueprint.</p> <p>The update workflow might apply to a component that is bound to the scaled component, but which is not itself scalable. This update workflow can change the non-scalable component based on an update operation.</p> <p>If you create an update workflow for a scale operation, it must include the following values:</p> <ul style="list-style-type: none"> ■ Input parameters. <ul style="list-style-type: none"> ■ Must include a parameter, regardless of the parameter name, that matches the output parameter type of the provisioning workflow. ■ Parameter name is <code>data</code> and the parameter type is <code>Properties</code>.
Destroy workflow	<p>Select the workflow that runs during a scale-in or destroy operation.</p> <p>If you create a destroy workflow for a scale operation, it must include the following value:</p> <ul style="list-style-type: none"> ■ Input parameter. <ul style="list-style-type: none"> ■ Must include a parameter, regardless of the parameter name, that matches the output parameter type of the provisioning workflow. <p>For example, if the Create simple virtual machine provisioning workflow includes the output parameter <code>VC:VirtualMachine</code>, the destroy workflow must include an input parameter where the type is <code>VC:VirtualMachine</code>.</p>

Table 3-59. Component Lifecycle Options (Continued)

Option	Description
Deallocation workflow	<p>Select the workflow that runs after any destroy or scale-in operation. If the deallocation fails during the operation, the destroy workflow still runs as expected.</p> <p>Deallocation is the final process when you scale-in or destroy a composite blueprint. It runs after to the destroy operation, releasing resources.</p> <p>This life cycle workflow type is available for Azure allocations. If you create an deallocation workflow for a scale operation, it must include the following value:</p> <ul style="list-style-type: none"> ■ Input parameter. <ul style="list-style-type: none"> ■ Parameter name is <code>data</code> and the parameter type is <code>Properties</code>.
Category	<p>To specify where the XaaS blueprint appears in the design canvas, select a value in the Design canvas category drop-down menu.</p> <p>If you do not select a category, the blueprint is added to the XaaS category when it is published.</p>

Add an XaaS Blueprint to a Composite Blueprint

You add an XaaS blueprint as a component of a composite blueprint similar to how you add other blueprint components in the design canvas.

Use this method to add an XaaS to a composite blueprint. This blueprint can be the only blueprint component or it can be one of several components that make up an application blueprint.

If the XaaS blueprint is all that you want to provide to your users, you can add it to a service and entitle users to it without adding it to a composite blueprint.

If you run a scale-in or scale-out operation on a deployed application blueprint, the XaaS blueprint scales based on how you configured the blueprint life cycle options.

Prerequisites

- Log in to the vRealize Automation console as an **infrastructure architect**.
- Create and publish an XaaS blueprint. See [Create an XaaS Blueprint](#). When you created the blueprint, you specified the category where the blueprint is located in the design canvas.
- Review how to customize the XaaS blueprint forms in the composite blueprint. See [Designing Forms for XaaS Blueprints and Actions](#).

Procedure

- 1 Select **Design > Blueprints**.
- 2 Select the name of the blueprint to which you are adding the XaaS.

The design canvas appears. It contains the current application component blueprints and other components.

3 In the Categories list, locate the blueprint.

4 Drag your blueprint to the canvas.

5 Configure the default values on the General and Create tabs.

These are the default values that appear in the service catalog form when a user requests the item.

6 Click **Finish**.

7 Select the blueprint and click **Publish**.

The XaaS blueprint is now part of the composite blueprint.

What to do next

Add the composite blueprint to a service. See [Managing the Service Catalog](#).

Create an XaaS Resource Action

You create a resource action so that you can manage provisioned items using vRealize Orchestrator workflows.

Prerequisites

- Log in to the vRealize Automation console as an **XaaS architect**.
- Verify that you have a custom resource that support the action. See [Add an XaaS Custom Resource](#).
- If you are creating actions to run on items not provisioned as XaaS catalog items, verify that you mapped the target resources. See [Mapping Other Resources to Work with XaaS Resource Actions](#).

Procedure

1 [Create a Resource Action](#)

A resource action is an XaaS workflow that service catalog users can run on provisioned catalog items. As an XaaS architect, you can create resource actions to define the operations that consumers can perform on the provisioned items.

2 [Publish a Resource Action](#)

The newly created resource action is in draft state, and you must publish the resource action.

3 [Assign an Icon to an XaaS Resource Action](#)

After you create and publish a resource action, you can edit it and assign an icon to the action.

Create a Resource Action

A resource action is an XaaS workflow that service catalog users can run on provisioned catalog items. As an XaaS architect, you can create resource actions to define the operations that consumers can perform on the provisioned items.

By creating a resource action, you associate a vRealize Orchestrator workflow as a post-provisioning operation. During this process, you can edit the default submission and read-only forms. See [Designing a Resource Action Form](#).

Prerequisites

- Log in to the vRealize Automation console as an **XaaS architect**.
- Create a custom resource corresponding to the input parameter of the resource action.

Procedure

- 1 Select **Design > XaaS > Resource Actions**.

- 2 Click the **New** icon (+).

- 3 Navigate through the vRealize Orchestrator workflow library and select a workflow relevant to your custom resource.

You can see the name and description of the selected workflow, and the input and output parameters as they are defined in vRealize Orchestrator.

- 4 Click **Next**.

- 5 Select the custom resource that you previously created from the **Resource type** drop-down menu.

- 6 Select the input parameter for the resource action from the **Input parameter** drop-down menu.

- 7 Click **Next**.

- 8 Enter a name and, optionally, a description.

The **Name** and **Description** text boxes are prepopulated with the name and description of the workflow as they are defined in vRealize Orchestrator.

- 9 (Optional) If you do not want to prompt consumers to enter a description and reason for requesting this resource action, select the **Hide catalog request information page** check box.

- 10 Enter a version.

The supported format extends to major.minor.micro-revision.

- 11 (Optional) Select the type of the action.

Option	Description
Disposal	The input parameter of the resource action workflow is disposed and the item is removed from the Items tab. For example, the resource action is for deleting a provisioned machine.
Provisioning	<p>The resource action is for provisioning. For example, the resource action is for copying a catalog item.</p> <p>From the drop-down menu, select an output parameter. You can select a custom resource that you previously created so that when the consumers request this resource action, the provisioned items are added on the Items tab. If you have only the No provisioning option, either the resource action is not for provisioning, or you did not create a proper custom resource for the output parameter, and you cannot proceed.</p>

Depending on the action workflow, you can select one, both, or none of the options.

- 12 Select the conditions under which the resource action is available to users, and click **Next**.

13 (Optional) Edit the form of the resource action on the **Form** tab.

The form of the resource action maps the vRealize Orchestrator workflow presentation. You can change the form by deleting, editing, and rearranging the elements. You can also add a new form and form pages and drag the necessary elements to the new form and form page.

Option	Action
Add a form	Click the New Form icon () next to the form name, provide the required information, and click Submit .
Edit a form	Click the Edit icon () next to the form name, make the necessary changes, and click Submit .
Regenerate the workflow presentation	Click the Rebuild icon () next to the form name and click OK .
Delete a form	Click the Delete icon () next to the form name, and in the confirmation dialog box click OK .
Add a form page	Click the New Page icon () next to the form page name, provide the required information, and click Submit .
Edit a form page	Click the Edit icon () next to the form page name, make the necessary changes, and click Submit .
Delete a form page	Click the Delete icon () next to the form name, and in the confirmation dialog box click OK .
Add an element to the form page	Drag an element from the New Fields pane on the left to the pane on the right. You can then provide the required information and click Submit .
Edit an element	Click the Edit icon () next to the element to edit, make the necessary changes, and click Submit .
Delete an element	Click the Delete icon () next to the element to delete, and in the confirmation dialog box click OK .

14 Click **Finish**.

You created a resource action and you can see it listed on the Resource Actions page.

What to do next

Publish the resource action. See [Publish a Resource Action](#).

Publish a Resource Action

The newly created resource action is in draft state, and you must publish the resource action.

Prerequisites

Log in to the vRealize Automation console as an **XaaS architect**.

Procedure

- 1 Select **Design > XaaS > Resource Actions**.
- 2 Select the row of the resource action to publish, and click **Publish**.

The status of the resource action changes to Published.

What to do next

Assign an icon to the resource action. See [Assign an Icon to an XaaS Resource Action](#). Business group managers and tenant administrators can then use the action when they create an entitlement.

Assign an Icon to an XaaS Resource Action

After you create and publish a resource action, you can edit it and assign an icon to the action.

Prerequisites

Log in to the vRealize Automation console as an **XaaS architect**.

Procedure

- 1 Select **Administration > Catalog Management > Actions**.
- 2 Select the resource action that you created.
- 3 Click **Configure**.
- 4 Click **Browse** and select the icon to add.
- 5 Click **Open**.
- 6 Click **Update**.

You assigned an icon to the resource action. Business group managers and tenant administrators can use the resource action in an entitlement.

Mapping Other Resources to Work with XaaS Resource Actions

You map items that were not provisioned using XaaS so that you can run resource actions to run on those items.

Resource Mapping Script Actions and Workflows

You can use the provided resource mappings for vSphere, vCloud Director, or vCloud Air virtual machines or you can create custom vRealize Orchestrator script actions or workflows to map other vRealize Automation catalog resource types to vRealize Orchestrator inventory types.

Resource Mappings Provided With vRealize Automation

vRealize Automation includes resource mappings for IaaS vSphere virtual machines, IaaS vCloud Director, and deployments.

vRealize Automation includes vRealize Orchestrator resource mapping script actions for each of the provided XaaS resource mappings. Script actions for the provided resource mappings are located in the `com.vmware.vcac.asd.mappings` package of the embedded vRealize Orchestrator server.

When you create a resource action that runs on a deployed composite blueprint that uses a vRealize Orchestrator workflow with `vCACAFE:CatalogResource` as an input parameter, the Deployment mapping is applied as the input resource type. The Deployment mapping is applied only if the selected workflow includes `vCACAFE:CatalogResource` as an input parameter. For example, if you create an action to request a resource action on behalf of a user, the resource type on the Input Resource tab is Deployment because this workflow uses `vCACAFE:CatalogResource`.

The IaaS vCD VM and IaaS VC VirtualMachine resource mappings are used by an action to map the virtual machines that match the IaaS resource to the vRealize Orchestrator vSphere or vCloud Director virtual machine.

Developing Resource Mappings

Depending on your version of vRealize Orchestrator, you can create either a vRealize Orchestrator workflow or a script action to map resources between vRealize Orchestrator and vRealize Automation.

To develop the resource mapping, you use an input parameter of type `Properties`, which contains a key-value pair defining the provisioned resource, and an output parameter of a vRealize Orchestrator inventory type expected by the corresponding vRealize Orchestrator plug-in. The properties available for the mapping depend on the type of resource. For example, the `EXTERNAL_REFERENCE_ID` property is a common key parameter that defines individual virtual machines, and you can use this property to query a catalog resource. If you are creating a mapping for a resource that does not use an `EXTERNAL_REFERENCE_ID`, you can use one of the other properties that are passed for the individual virtual machines. For example, name, description, and so on.

For more information about developing workflows and script actions, see *Developing with VMware vCenter Orchestrator*.

Create a Resource Mapping

vRealize Automation provides resource mappings for vSphere, vCloud Director, and vCloud Air machines. You can create additional resource mappings for other types of catalog resources.

Prerequisites

- Log in to the vRealize Automation console as an **XaaS architect**.
- Verify that the mapping script or workflow is available in vRealize Orchestrator. See [Resource Mapping Script Actions and Workflows](#)

Procedure

- 1 Select **Design > XaaS > Resource Mappings**.
- 2 Click the **New** icon ()
- 3 Enter a name and, optionally, a description.
- 4 Enter a version.

The supported format extends to major.minor.micro-revision.

- 5 Enter the type of the catalog resource in the **Catalog Resource Type** text box and press enter.

The type of catalog resource appears on the details view of the provisioned item.

- 6 Enter the vRealize Orchestrator object type in the **Orchestrator Type** text box and press enter.

This is the output parameter of the resource mapping workflow.

- 7 (Optional) Add target criteria to restrict the availability of resource actions created by using this resource mapping.

Resource actions are also subject to restrictions based on approvals and entitlements.

- a Select **Available based on conditions**.

- b Select the type of condition.

Option	Description
All of the following	If all of the clauses you define are satisfied, resource actions created by using this resource mapping are available to the user.
Any of the following	If any one of the clauses you define are satisfied, resource actions created by using this resource mapping are available to the user.
Not the following	If the clause you define exists, resource actions created by using this resource mapping are not available.

- c Follow the prompts to build your clauses and complete the condition.

- 8 Select your resource mapping script action or workflow from the vRealize Orchestrator library.

- 9 Click **OK**.

Designing Forms for XaaS Blueprints and Actions

The XaaS includes a form designer that you can use to design submission and details forms for blueprints and resources actions. Based on the presentation of the workflows, the form designer dynamically generates default forms and fields you can use to modify the default forms.

You can create interactive forms that the users can complete for submission of catalog items and resource actions. You can also create read-only forms that define what information the users can see on the details view for a catalog item or a provisioned resource.

As you create XaaS custom resources, XaaS blueprints, and resource actions, forms are generated for common use cases.

Table 3-60. XaaS Object Types and Associated Forms

Object Type	Default Form	Additional Forms
Custom resource	Resource details form based on the attributes of the vRealize Orchestrator plug-in inventory type (read-only).	<ul style="list-style-type: none"> ■ None
XaaS blueprint	Request submission form based on the presentation of the selected workflow.	<ul style="list-style-type: none"> ■ Catalog item details (read-only) ■ Submitted request details (read-only)
Resource action	Action submission form based on the presentation of the selected workflow.	<ul style="list-style-type: none"> ■ Submitted action details (read-only)

You can modify the default forms and design new forms. You can drag fields to add and reorder them on the form. You can place constraints on the values of certain fields, specify default values, or provide instructional text for the end user who is completing the form.

Because of their different purposes, the operations you can perform to design read-only forms are limited compared to the operations for designing submission forms.

Fields in the Form Designer

You can extend the workflow presentation and functionality by adding new predefined fields to the default generated forms of resource actions and XaaS blueprints.

If an input parameter is defined in the vRealize Orchestrator workflow, in vRealize Automation it appears on the default generated form. If you do not want to use the default generated fields in the form, you can delete them and drag and drop new fields from the palette. You can replace default generated fields without breaking the workflow mappings if you use the same ID as the field you are replacing.

You can also add new fields, other than the ones that were generated based on the vRealize Orchestrator workflow inputs, so that you can extend the workflow presentation and functionality in the following cases:

- Add constraints to the existing fields

For example, you can create a new drop-down menu and name it **dd**. You can also create predefined options of Gold, Silver, Bronze, and Custom. If there is a predefined field, such as CPU, you can add the following constraints to this field:

- If dd equals Gold, then CPU is 2000 MHz
- If dd equals Silver, then CPU is 1000 MHz
- If dd equals Bronze then CPU is 500 MHz
- If dd equals Custom, the CPU field is editable, and the consumer can specify a custom value

- Add external value definitions to fields

You can add an external value definition to a field so that you can run vRealize Orchestrator script actions and supply additional information to consumers on the forms you design. For instance, you might want to create a workflow to change the firewall settings of a virtual machine. On the resource action request page, you want to provide the user with the ability to change the open port settings, but

you also want to restrict the options to ports that are open. You can add an external value definition to a dual list field and select a custom vRealize Orchestrator script action that queries for open ports. When the request form loads, the script actions runs, and the open ports are presented as options to the user.

- Add new fields that are handled in the vRealize Orchestrator workflow as global parameters

For instance, the workflow provides an integration with a third-party system and the workflow developer defined input parameters to be handled in the general case, but has also provided a way for passing custom fields. For example, in a scripting box, all global parameters that start with **my3rdparty** are handled. Then, if the XaaS architect wants to pass specific values for consumers to provide, the XaaS architect can add a new field named **my3rdparty_CPU**.

Table 3-61. New Fields in the Resource Action or XaaS Blueprint Form

Field	Description
Text field	Single-line text box
Text area	Multi-line text box
Link	Field in which consumers enter a URL
Email	Field in which consumers enter an email address
Password field	Field in which consumers enter a password
Integer field	Text box in which consumers entre an integer You can make this field a slider with a minimum and maximum value, as well as an increment.
Decimal field	Text box in which consumers enter a decimal You can make this field a slider with a minimum and maximum value, as well as an increment.
Date & time	Text boxes in which consumers specify a date (by selecting a date from a calendar menu) and can also select the time (by using up and down arrows)
Dual List	A list builder in which consumers move a predefined set of values between two lists, the first list contains all unselected options and the second list contains the user's choices.
Check box	Check box
Yes/No	Drop-down menu for selecting Yes or No
Drop-down	Drop-down menu
List	List
Check box list	Check box list
Radio button group	Group of radio buttons
Search	Search text box that auto completes the query and where consumers select an object

Table 3-61. New Fields in the Resource Action or XaaS Blueprint Form (Continued)

Field	Description
Tree	Tree that consumers use to browse and select available objects
Map	Map table that consumers use to define key-value pairs for properties

You can also use the **Section header** form field to split form pages in sections with separate headings and the **Text** form field to add read-only informational texts.

Constraints and Values in the Form Designer

When you edit an element of the blueprint or resource action form, you can apply various constraints and values to the element.

Constraints

The constraints that you can apply to an element vary depending on the type of element you are editing or adding to the form. Some constraint values might be configured in the vRealize Orchestrator workflow. Those values do not appear on the Constraints tab because they are often dependent on conditions that are evaluated when the workflow runs. Any constraint values that you configure for the blueprint form overrides any constraints included in the vRealize Orchestrator workflow.

For each constraint you apply to an element, you can select one of the following options to define the constraint:

Not set	Gets the property from the vRealize Orchestrator workflow presentation.
Constant	Sets the element you are editing to required or optional.
Field	Binds the element to another element from the form. For example, you can set the element to be required only when another element, such as a check box, is selected.
Conditional	Applies a condition. Use the conditions to create various clauses and expressions and apply them to the state or constraints of the element.
External	Select a vRealize Orchestrator script action that defines the value.

Table 3-62. Constraints in the Forms Designer

Constraint	Description
Required	Indicates whether the element is required.
Read only	Indicates whether the field is read-only.
Value	Sets a value for the element.

Table 3-62. Constraints in the Forms Designer (Continued)

Constraint	Description
Visible	<p>Indicates whether the consumer can see the element.</p> <p>If you apply a visibility constraint on a display group in the vRealize Orchestrator workflow, the constraint is ignored in the XaaS Submitted Request Details form and the fields that you want hidden appear in the form.</p> <p>To hide fields that you do not want to appear in the Submitted Request Details form, and they are not required for the requesting user, remove the fields from the Submitted Request Details form on the Blueprints Form tab in the XaaS blueprint designer. To locate this tab, see Add a New XaaS Blueprint Form.</p>
Minimum length	Sets a minimum number of characters of the string input element.
Maximum length	Sets a maximum allowed number of characters of the string input element.
Minimum value	Sets a minimum value of the number input element.
Maximum value	Sets a maximum value of the number input element.
Increment	Sets an increment for an element such as a Decimal or Integer field. For example, when you want an Integer field to be rendered as a Slider , you can use the value of the step.
Minimum count	<p>Sets a minimum count of items of the element that can be selected.</p> <p>For example, when you add or edit a Check box list you can set the minimum number of check boxes that the consumer must select to proceed.</p>
Maximum count	<p>Sets a maximum count of items of the element that can be selected.</p> <p>For example, when you add or edit a Check box list you can set the maximum number of check boxes that the consumer must select to proceed.</p>

Values

You can apply values to some of the elements and define what the consumers see for some of the fields. The options available depend on the type of element you are editing or adding to the form.

Table 3-63. Values in the Form Designer

Value	Description
Not set	Get the value of the element you are editing from the vRealize Orchestrator workflow presentation.
Predefined values	Select values from a list of related objects from the vRealize Orchestrator inventory.
Value	Define a static custom value with labels.
External Values	Select a vRealize Orchestrator script action that defines your value with information not directly exposed by the workflow.

External Value Definitions in the Form Designer

When you edit some elements in the forms designer, you can assign external value definitions that use custom vRealize Orchestrator script actions to supply information not directly exposed by the workflow.

For instance, you might want to publish a resource action to install software on a provisioned machine. Instead of providing the consumer with a static list of all software available for download, you can dynamically populate that list with software that is relevant for the machine's operating system, software that the user has not previously installed on the machine, or software that is out of date on the machine and requires an update.

To provide custom dynamic content for your consumer, you create a vRealize Orchestrator script action that retrieves the information you want to display to your consumers. You assign your script action to a field in the form designer as an external value definition. When the resource or service blueprint form is presented to your consumers, the script action retrieves your custom information and displays it to your consumer.

You can use external value definitions to supply default or read-only values, to build boolean expressions, to define constraints, or to provide options for consumers to select from lists, check boxes, and so on.

Working With the Form Designer

When you create XaaS blueprints, custom resource actions, and custom resources, you can edit the forms of the blueprints, actions, and resources by using the form designer. You can edit the representation and define what the consumers of the item or action see when they request the catalog item or run the post-provisioning operation.

By default, any XaaS blueprint, resource action, or custom resource form is generated based on the workflow presentation in vRealize Orchestrator.

Start Workflow : Create cluster

1 Common parameters

2 vCloud Distributed Storage

* Parent host folder
Not set

* Name of the new cluster

* Enable VMware HA
☐ Yes ☒ No

* Enable VMware DRS
☐ Yes ☒ No

Cancel Back Next Submit

The steps in the vRealize Orchestrator presentation are represented as form pages and the vRealize Orchestrator presentation groups are represented as separate sections. The input types of the selected workflow are displayed as various fields in the form. For example, the vRealize Orchestrator type string is represented by a text box. A complex type such as VC:VirtualMachine is represented by a search box or a tree, so that the consumers can type an alphanumeric value to search for a virtual machine or browse to select a virtual machine.

Add Blueprint

You can edit how an object is represented in the form designer. For example, you can edit the default VC:VirtualMachine representation and make it a tree instead of a search box. You can also add new fields such as check boxes, drop-down menus, and so on, and apply various constraints. If the new fields you add are not valid or are not correctly mapped to the vRealize Orchestrator workflow inputs, when the consumer runs the workflow, vRealize Orchestrator skips the invalid or unmapped fields.

Designing a Custom Resource Form

All fields on the resource details form are displayed as read-only to the consumer on the item details page when they provision your custom resource. You can perform basic edit operations to the form, such as deleting, modifying, or rearranging fields, or you can add new externally defined fields that use vRealize Orchestrator script actions to supply additional read-only information to consumers.

- [Edit a Custom Resource Element](#)

You can edit some of the characteristics of an element on the custom resource Details Form page. Each default field on the page represents a property of the custom resource. You cannot change the type of a property or the default values, but you can edit the name, size, description.

- [Add a New Custom Resource Form Page](#)

You can add a new page to rearrange the form into multiple tabs.

- [Insert a Section Header in a Custom Resource Form](#)

You can insert a section header to split the form into sections.

- [Insert a Text Element in a Custom Resource Form](#)

You can insert a text box to add some descriptive text to the form.

- [Insert an Externally Defined Field in a Custom Resource Form](#)

You can insert a new field and assign it an external value definition to dynamically provide read-only information that consumers can see on the item details page when they provision a custom resource.

Edit a Custom Resource Element

You can edit some of the characteristics of an element on the custom resource Details Form page. Each default field on the page represents a property of the custom resource. You cannot change the type of a property or the default values, but you can edit the name, size, description.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **XaaS architect**.
- [Add an XaaS Custom Resource](#).

Procedure

- 1 Select **Design > XaaS > Custom Resources**.
- 2 Click the custom resource to edit.
- 3 Click the **Details Form** tab.
- 4 Point to the element you want to edit and click the **Edit** icon.
- 5 Enter a new name for the field in the **Label** text box to change the label.
- 6 Edit the description in the **Description** text box.
- 7 Select an option from the **Size** drop-down menu to change the size of the element.
- 8 Select an option from the **Label size** drop-down menu to change the size of the label.
- 9 Click **Submit**.
- 10 Click **Finish**.

Add a New Custom Resource Form Page

You can add a new page to rearrange the form into multiple tabs.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **XaaS architect**.
- [Add an XaaS Custom Resource](#).

Procedure

- 1 Select **Design > XaaS > Custom Resources**.
- 2 Click the custom resource to edit.

- 3 Click the **Details Form** tab.
- 4 Click the **New Page** icon () next to the **Form page** name.
- 5 Select the unused screen type and click **Submit**.
If you already have a resource details or resource list view, you cannot create two of the same type.
- 6 Click **Submit**.
- 7 Configure the form.
- 8 Click **Finish**.

You can delete some of the elements from the original form page and insert them in the new form page, or you can add new fields that use external value definitions to provide information to consumers that is not directly exposed by the vRealize Orchestrator workflow.

Insert a Section Header in a Custom Resource Form

You can insert a section header to split the form into sections.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **XaaS architect**.
- [Add an XaaS Custom Resource](#).

Procedure

- 1 Select **Design > XaaS > Custom Resources**.
- 2 Click the custom resource to edit.
- 3 Click the **Details Form** tab.
- 4 Drag the **Section header** element from the Form pane to the Form page pane.
- 5 Type a name for the section.
- 6 Click outside of the element to save the changes.
- 7 Click **Finish**.

Insert a Text Element in a Custom Resource Form

You can insert a text box to add some descriptive text to the form.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **XaaS architect**.
- [Add an XaaS Custom Resource](#).

Procedure

- 1 Select **Design > XaaS > Custom Resources**.
- 2 Click the custom resource to edit.

- 3 Click the **Details Form** tab.
- 4 Drag the **Text** element from the Form pane to the Form page pane.
- 5 Enter the text you want to add.
- 6 Click outside of the element to save the changes.
- 7 Click **Finish**.

Insert an Externally Defined Field in a Custom Resource Form

You can insert a new field and assign it an external value definition to dynamically provide read-only information that consumers can see on the item details page when they provision a custom resource.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **XaaS architect**.
- [Add an XaaS Custom Resource](#).
- Develop or import a vRealize Orchestrator script action to retrieve the information you want to provide to consumers.

Procedure

- 1 Select **Design > XaaS > Custom Resources**.
- 2 Click the custom resource to edit.
- 3 Click the **Details Form** tab.
- 4 Drag an element from the New Fields pane and drop it to the Form page pane.
- 5 Enter an ID for the element in the **ID** text box.
- 6 Enter a label in the **Label** text box.
Labels appear to consumers on the forms.
- 7 (Optional) Select a type for the field from the **Type** drop-down menu.
- 8 Enter the result type of your vRealize Orchestrator script action in the **Entity Type** search box and press Enter.

For example, if you want to use a script action to display the current user, and the script returns a vRealize Orchestrator result type of `LdapUser`, enter **LdapUser** in the **Entity Type** search box and press Enter.
- 9 Click **Add External Value**.
- 10 Select your custom vRealize Orchestrator script action.
- 11 Click **Submit**.
- 12 Click **Submit** again.
- 13 Click **Finish**.

When the form is presented to your consumers, the script action retrieves your custom information and displays it to your consumer.

Designing an XaaS Blueprint Form

When you create an XaaS blueprint, you can edit the form of the blueprint by adding new fields to the form, modifying the existing fields, deleting, or rearranging fields. You can also create new forms and form pages, and drag and drop new fields to them.

- [Add a New XaaS Blueprint Form](#)

When you edit the default generated form of a workflow that you want to publish as a XaaS blueprint, you can add a new XaaS blueprint form.

- [Edit an XaaS Blueprint Element](#)

You can edit some of the characteristics of an element on the Blueprint Form page of a XaaS blueprint. You can change the type of an element, its default values, and apply various constraints and values.

- [Add a New Element](#)

When you edit the default generated form of a XaaS blueprint, you can add a predefined new element to the form. For example, if you do not want to use a default generated field, you can delete it and replace it with a new one.

- [Insert a Section Header in a XaaS Blueprint Form](#)

You can insert a section header to split the form into sections.

- [Add a Text Element to an XaaS Blueprint Form](#)

You can insert a text box to add some descriptive text to the form.

Add a New XaaS Blueprint Form

When you edit the default generated form of a workflow that you want to publish as a XaaS blueprint, you can add a new XaaS blueprint form.

By adding a new XaaS blueprint form, you define the look and feel of the catalog item details and submitted request details pages. If you do not add a catalog item details and submitted request details forms, the consumer sees what is defined in the request form.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **XaaS architect**.
- [Add an XaaS Blueprint](#).

Procedure

- 1 Select **Design > XaaS > XaaS Blueprints**.
- 2 Click the XaaS blueprint you want to edit.
- 3 Click the **Blueprint Form** tab.
- 4 Click the **New Form** icon ().

- 5 Enter a name and, optionally, a description.
- 6 Select the screen type from the **Screen type** menu.

Option	Description
Catalog item details	A catalog item details page that consumers see when they click a catalog item.
Request form	The default XaaS blueprint form. The consumers see the request form when they request the catalog item.
Submitted request details	A request details page that consumers see after they request the item and want to view the request details on the Request tab.

- 7 Click **Submit**.

What to do next

Add the fields you want by dragging them from the New fields pane to the Form page pane.

Edit an XaaS Blueprint Element

You can edit some of the characteristics of an element on the Blueprint Form page of a XaaS blueprint. You can change the type of an element, its default values, and apply various constraints and values.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **XaaS architect**.
- [Add an XaaS Blueprint](#).

Procedure

- 1 Select **Design > XaaS > XaaS Blueprints**.
- 2 Click the XaaS blueprint you want to edit.
- 3 Click the **Blueprint Form** tab.
- 4 Locate the element you want to edit.
- 5 Click the **Edit** icon ().
- 6 Enter a new name for the field in the **Label** text box to change the label that consumers see.
- 7 Edit the description in the **Description** text box.
- 8 Select an option from the **Type** drop-down menu to change the display type of the element.
The options vary depending on the type of element you edit.
- 9 Select an option from the **Size** drop-down menu to change the size of the element.
- 10 Select an option from the **Label size** drop-down menu to change the size of the label.

11 Edit the default value of the element.

Option	Description
Not set	Gets the value of the element you are editing from the vRealize Orchestrator workflow presentation.
Constant	Sets the default value of the element you are editing to a constant value that you specify.
Field	Binds the default value of the element to a parameter of another element from the representation.
Conditional	Applies a condition. By using conditions you can create various clauses and expressions and apply them to an element.
External	Select a vRealize Orchestrator script action to define the value.

12 Apply constraints to the element on the **Constraints** tab.

Option	Description
Not set	Gets the value of the element you are editing from the vRealize Orchestrator workflow presentation.
Constant	Sets the default value of the element you are editing to a constant value that you specify.
Field	Binds the default value of the element to a parameter of another element from the representation.
Conditional	Applies a condition. By using conditions you can create various clauses and expressions and apply them to an element.
External	Select a vRealize Orchestrator script action to define the value.

13 Add one or more values for the element on the **Values** tab.

The options available depend on the type of element you are editing.

Option	Description
Not set	Gets the value of the element you are editing from the vRealize Orchestrator workflow presentation.
Predefined values	<p>Select values from a list of related objects from the vRealize Orchestrator inventory.</p> <ol style="list-style-type: none"> Enter a value in the Predefined values search box to search the vRealize Orchestrator inventory. Select a value from the search results and press Enter.
Value	<p>Define custom values with labels.</p> <ol style="list-style-type: none"> Enter a value in the Value text box. Enter a label for the value in the Label text box. Click the Add icon ().
External Values	<p>Select a vRealize Orchestrator script action to define your value with information not directly exposed by the workflow.</p> <ul style="list-style-type: none"> ■ Select Add External Value. ■ Select your vRealize Orchestrator script action. ■ Click Submit.

14 Click **Submit**.

15 Click **Finish**.

Add a New Element

When you edit the default generated form of a XaaS blueprint, you can add a predefined new element to the form. For example, if you do not want to use a default generated field, you can delete it and replace it with a new one.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **XaaS architect**.
- [Add an XaaS Blueprint](#).

Procedure

- 1 Select **Design > XaaS > XaaS Blueprints**.
- 2 Click the XaaS blueprint you want to edit.
- 3 Click the **Blueprint Form** tab.
- 4 Drag an element from the New Fields pane and drop it to the Form page pane.
- 5 Enter the ID of a workflow input parameter in the **ID** text box.
- 6 Enter a label in the **Label** text box.
- 7 (Optional) Select a type for the field from the **Type** drop-down menu.
- 8 Enter a vRealize Orchestrator object in the **Entity type** text box and press Enter.

This step is not required for all field types.

Option	Description
Result Type	If you are using a script action to define an external value for the field, enter the result type of your vRealize Orchestrator script action.
Input Parameter	If you are using the field to accept consumer input and pass parameters back to vRealize Orchestrator, enter the type for the input parameter accepted by the vRealize Orchestrator workflow.
Output Parameter	If you are using the field to display information to consumers, enter the type for the output parameter of the vRealize Orchestrator workflow.

- 9 (Optional) Select the **Multiple values** check box to allow consumers to select more than one object.
This option is not available for all field types.
- 10 Click **Submit**.
- 11 Click **Update**.

What to do next

You can edit the element to change the default settings and apply various constraints or values.

Insert a Section Header in a XaaS Blueprint Form

You can insert a section header to split the form into sections.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **XaaS architect**.
- [Add an XaaS Blueprint](#).

Procedure

- 1 Select **Design > XaaS > XaaS Blueprints**.
- 2 Click the XaaS blueprint you want to edit.
- 3 Click the **Blueprint Form** tab.
- 4 Drag the **Section header** element from the Form pane to the Form page pane.
- 5 Type a name for the section.
- 6 Click outside of the element to save the changes.
- 7 Click **Update**.

Add a Text Element to an XaaS Blueprint Form

You can insert a text box to add some descriptive text to the form.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **XaaS architect**.
- [Add an XaaS Blueprint](#).

Procedure

- 1 Select **Design > XaaS > XaaS Blueprints**.
- 2 Click the XaaS blueprint you want to edit.
- 3 Click the **Blueprint Form** tab.
- 4 Drag the **Text** element from the New Fields pane to the Form page pane.
- 5 Enter the text you want to add.
- 6 Click outside of the element to save the changes.
- 7 Click **Update**.

Designing a Resource Action Form

When you create a resource action, you can edit the form of the action by adding new fields to the form, modifying the existing fields, deleting, or rearranging fields. You can also create new forms and form pages, and drag and drop new fields to them.

Add a New Resource Action Form

When you edit the default generated form of a workflow you want to publish as a resource action, you can add a new resource action form.

By adding a new resource action form, you define how the submitted action details page looks. If you do not add a submitted action details form, the consumer sees what is defined in the action form.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **XaaS architect**.
- [Create a Resource Action](#).

Procedure

- 1 Select **Design > XaaS > Resource Actions**.
- 2 Click the resource action you want to edit.
- 3 Click the **Form** tab.
- 4 Click the **New Form** icon ()
- 5 Enter a name and, optionally, a description.
- 6 Select the screen type from the **Screen type** menu.

Option	Description
Action form	The default resource action form that consumers see when they decide to run the post-provisioning action.
Submitted action details	A request details page that consumers see when they request the action and decide to view the request details on the Request tab.

- 7 Click **Submit**.

What to do next

Add the fields you want by dragging them from the New fields pane to the Form page pane.

Add a New Element to a Resource Action Form

When you edit the default generated form of a resource action, you can add a predefined new element to the form. For example, if you do not want to use a default generated field, you can delete it and replace it with a new one.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **XaaS architect**.

- [Create a Resource Action.](#)

Procedure

- 1 Select **Design > XaaS > Resource Actions**.
- 2 Click the resource action you want to edit.
- 3 Click the **Form** tab.
- 4 Drag an element from the New Fields pane and drop it to the Form page pane.
- 5 Enter the ID of a workflow input parameter in the **ID** text box.
- 6 Enter a label in the **Label** text box.

Labels appear to consumers on the forms.

- 7 (Optional) Select a type for the field from the **Type** drop-down menu.
- 8 Enter a vRealize Orchestrator object in the **Entity type** text box and press Enter.

This step is not required for all field types.

Option	Description
Result Type	If you are using a script action to define an external value for the field, enter the result type of your vRealize Orchestrator script action.
Input Parameter	If you are using the field to accept consumer input and pass parameters back to vRealize Orchestrator, enter the type for the input parameter accepted by the vRealize Orchestrator workflow.
Output Parameter	If you are using the field to display information to consumers, enter the type for the output parameter of the vRealize Orchestrator workflow.

- 9 (Optional) Select the **Multiple values** check box to allow consumers to select more than one object.
This option is not available for all field types.
- 10 Click **Submit**.
- 11 Click **Finish**.

What to do next

You can edit the element to change the default settings and apply various constraints or values.

Edit a Resource Action Element

You can edit some of the characteristics of an element on the resource action Form page. You can change the type of an element, its default values, and apply various constraints and values.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **XaaS architect**.
- [Create a Resource Action.](#)

Procedure

- 1 Select **Design > XaaS > Resource Actions**.
- 2 Click the resource action you want to edit.
- 3 Click the **Form** tab.
- 4 Locate the element you want to edit.
- 5 Click the **Edit** icon ()
- 6 Enter a new name for the field in the **Label** text box to change the label that consumers see.
- 7 Edit the description in the **Description** text box.
- 8 Select an option from the **Type** drop-down menu to change the display type of the element.
The options vary depending on the type of element you edit.
- 9 Select an option from the **Size** drop-down menu to change the size of the element.
- 10 Select an option from the **Label size** drop-down menu to change the size of the label.
- 11 Edit the default value of the element.

Option	Description
Not set	Gets the value of the element you are editing from the vRealize Orchestrator workflow presentation.
Constant	Sets the default value of the element you are editing to a constant value that you specify.
Field	Binds the default value of the element to a parameter of another element from the representation.
Conditional	Applies a condition. By using conditions you can create various clauses and expressions and apply them to an element.
External	Select a vRealize Orchestrator script action to define the value.

- 12 Apply constraints to the element on the **Constraints** tab.

Option	Description
Not set	Gets the value of the element you are editing from the vRealize Orchestrator workflow presentation.
Constant	Sets the default value of the element you are editing to a constant value that you specify.
Field	Binds the default value of the element to a parameter of another element from the representation.
Conditional	Applies a condition. By using conditions you can create various clauses and expressions and apply them to an element.
External	Select a vRealize Orchestrator script action to define the value.

13 Add one or more values for the element on the **Values** tab.

The options available depend on the type of element you are editing.

Option	Description
Not set	Gets the value of the element you are editing from the vRealize Orchestrator workflow presentation.
Predefined values	<p>Select values from a list of related objects from the vRealize Orchestrator inventory.</p> <ol style="list-style-type: none"> Enter a value in the Predefined values search box to search the vRealize Orchestrator inventory. Select a value from the search results and press Enter.
Value	<p>Define custom values with labels.</p> <ol style="list-style-type: none"> Enter a value in the Value text box. Enter a label for the value in the Label text box. Click the Add icon ().
External Values	<p>Select a vRealize Orchestrator script action to define your value with information not directly exposed by the workflow.</p> <ul style="list-style-type: none"> ■ Select Add External Value. ■ Select your vRealize Orchestrator script action. ■ Click Submit.

14 Click **Submit**.

15 Click **Update**.

Insert a Section Header in a Resource Action Form

You can insert a section header to split the form into sections.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **XaaS architect**.
- [Create a Resource Action](#).

Procedure

- 1 Select **Design > XaaS > Resource Actions**.
- 2 Click the resource action you want to edit.
- 3 Click the **Form** tab.
- 4 Drag the **Section header** element from the Form pane to the Form page pane.
- 5 Type a name for the section.
- 6 Click outside of the element to save the changes.
- 7 Click **Finish**.

Add a Text Element to a Resource Action Form

You can insert a text box to add some descriptive text to the form.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **XaaS architect**.
- [Create a Resource Action](#).

Procedure

- 1 Select **Design > XaaS > Resource Actions**.
- 2 Click the resource action you want to edit.
- 3 Click the **Form** tab.
- 4 Drag the **Text** element from the New Fields pane to the Form page pane.
- 5 Enter the text you want to add.
- 6 Click outside of the element to save the changes.
- 7 Click **Finish**.

XaaS Examples and Scenarios

The examples and scenarios suggest ways that you can use vRealize Automation to accomplish common tasks using XaaS blueprints and resource actions.

Create an XaaS Blueprint and Action for Creating and Modifying a User

By using XaaS, you can create and publish a catalog item for provisioning a user in a group. You can also associate a new post-provisioning operation to the provisioned user. For example, an operation so that the service catalog users can change the user password.

As an XaaS architect, you create a custom resource, an XaaS blueprint, and publish a catalog item for creating a user. You also create a resource action for changing the password of the user.

As a catalog administrator, you create a service and include the blueprint catalog item in the service. In addition, you edit the workflow presentation of the catalog item by using the form designer and change the way the consumers see the request form.

As a business group manager or a tenant administrator, you entitle the newly created service, catalog item, and resource action to a consumer.

Prerequisites

Verify that the Active Directory plug-in is properly configured and you have the rights to create users in Active Directory.

Procedure

- 1 [Create a Test User as a Custom Resource](#)

You can create a custom resource and map it to the vRealize Orchestrator object type `AD:User`.

2 Create an XaaS Blueprint for Creating a User

You create the Create a user in a group XaaS blueprint so that you can run the workflow that adds an Active Directory user and assigns the user to an Active Directory group. You can create the blueprint as a standalone XaaS blueprint or as a blueprint component. In this scenario, you are creating a standalone blueprint.

3 Create a Resource Action to Change a User Password

You can create a resource action to allow the consumers of the XaaS create a user blueprint to change the password of the user after they provision the user.

4 Create a Service and Add Creating a Test User Blueprint to the Service

You can create a service to display the Create a user catalog item in the service catalog.

5 Entitle the Service and the Resource Action to a Consumer

Business group managers and tenant administrators can entitle the service and the resource action to a user or a group of users. After they are entitled, they can see the service in their catalog and request the Create a test user catalog item that is included in the service. After the consumers provision the item, they can request to change the user password.

Create a Test User as a Custom Resource

You can create a custom resource and map it to the vRealize Orchestrator object type AD:User.

Prerequisites

Log in to the vRealize Automation console as an **XaaS architect**.

Procedure

- 1 Select **Design > XaaS > Custom Resources**.
- 2 Click the **New** icon ()
- 3 In the **Orchestrator type** text box, enter **AD:User** and press Enter.
- 4 Select **AD:User** in the list.
- 5 Type a name for the resource.
For example, **Test User**.
- 6 Enter a description for the resource.
For example,
This is a test custom resource that I will use for my catalog item to create a user in a group.
- 7 Click **Next**.
- 8 Leave the default values in the form.
- 9 Click **Finish**.

You created a Test User custom resource and you can see it on the Custom Resources page.

What to do next

Create an XaaS blueprint.

Create an XaaS Blueprint for Creating a User

You create the Create a user in a group XaaS blueprint so that you can run the workflow that adds an Active Directory user and assigns the user to an Active Directory group. You can create the blueprint as a standalone XaaS blueprint or as a blueprint component. In this scenario, you are creating a standalone blueprint.

Prerequisites

- Verify that you create a custom resource action that supports provisioning Active Directory users. See [Create a Test User as a Custom Resource](#).
- Log in to the vRealize Automation console as an **XaaS architect**.

Procedure

- 1 Select **Design > XaaS > XaaS Blueprints**.
- 2 Click the **New** icon ()
- 3 In the Select a workflow pane, navigate to **Orchestrator > Library > Microsoft > Active Directory > User** and select the **Create a user in a group** workflow.
- 4 Click **Next**.
- 5 Configure the **General** tab options.
 - a Change the name of the blueprint to **Create a test user**, and leave the description as is.
 - b Deselect the **Make available as a component in the design canvas** check box.

You are publishing this blueprint directly to the service catalog rather than using it as a blueprint component in the design canvas. You do not need to configure any scale-in or scale-out workflows.

The **Component Lifecycle** tab is removed from the user interface.
- 6 Click **Next**.
- 7 Edit the blueprint form.
 - a Click **The domain name in Win2000 form**.
 - b Click the **Constraints** tab.
 - c Click the **Value** drop-down arrow, select **Constant** in the drop-down menu, and enter **test.domain**.

- d Click the **Visible** drop-down arrow, select **Constant** in the drop-down menu, and select **No** in the drop-down menu.

You made the domain name invisible to the consumer of the catalog item.

- e Click **Apply** to save the changes.

8 Click **Next**.

9 Select **newUser [Test User]** as an output parameter to be provisioned.

10 Click **Next**.

11 Click **Finish**.

12 On the **XaaS Blueprints** page, select the **Create a test user** row and click **Publish**.

You created a blueprint for creating a test user and you made the blueprint available to add to a service.

What to do next

Create an action to run on the provisioned user account. See [Create a Resource Action to Change a User Password](#).

Create a Resource Action to Change a User Password

You can create a resource action to allow the consumers of the XaaS create a user blueprint to change the password of the user after they provision the user.

Prerequisites

- Log in to the vRealize Automation console as an **XaaS architect**.
- Verify that you create a custom resource action that supports provisioning Active Directory users. See [Create a Test User as a Custom Resource](#).

Procedure

- 1 Select **Design > XaaS > Resource Actions**.
- 2 Click the **New** icon (.
- 3 Navigate to **Orchestrator > Library > Microsoft > Active Directory > User** in the vRealize Orchestrator workflow library, and select the **Change a user password** workflow.
- 4 Click **Next**.
- 5 Select **Test User** from the **Resource type** drop-down menu.
This selection is the custom resource you created previously.
- 6 Select **user** from the **Input parameter** drop-down menu.
- 7 Click **Next**.
- 8 Change the name of the resource action to **Change the password of the Test User**, and leave the description as it appears on the **Details** tab.

- 9 Click **Next**.
- 10 (Optional) Leave the form as is.
- 11 Click **Finish**.
- 12 On the Resource Actions page, select the **Change the password of the Test User** row and click **Publish**.

You created a resource action for changing the password of a user, and you made it available to add to an entitlement.

What to do next

Add the Create a test user blueprint to a service. See [Create a Service and Add Creating a Test User Blueprint to the Service](#).

Create a Service and Add Creating a Test User Blueprint to the Service

You can create a service to display the Create a user catalog item in the service catalog.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **catalog administrator**.
- Verify that you created an XaaS blueprint. See [Create an XaaS Blueprint for Creating a User](#).

Log in to the vRealize Automation console as a **tenant administrator** or **catalog administrator**.

Procedure

- 1 Select **Administration > Catalog Management > Services**.
- 2 Click the **New** icon (.
- 3 Enter **Active Directory Test User** as the name of the service.
- 4 Select **Active** from the **Status** drop-down menu.
- 5 Leave the other text boxes blank.
- 6 Click **OK**.
- 7 In the Services list, select the **Active Directory Test User** row and click **Manage Catalog Items**.
- 8 Click the **New** icon (.
- 9 Select **Create a test user**, and click **OK**.

The Create a test user XaaS blueprint is added to the list of catalog items.

- 10 Click **Close**.

The Active Directory Test User service now includes the Create a test user blueprint. You do not need to add actions to services.

What to do next

You can entitle users to request the blueprint and then run the action. See [Entitle the Service and the Resource Action to a Consumer](#).

Entitle the Service and the Resource Action to a Consumer

Business group managers and tenant administrators can entitle the service and the resource action to a user or a group of users. After they are entitled, they can see the service in their catalog and request the Create a test user catalog item that is included in the service. After the consumers provision the item, they can request to change the user password.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **business group manager**.
- Verify that the Create a user blueprint is added to a service. See [Create a Service and Add Creating a Test User Blueprint to the Service](#).
- Verify that the Change a User Password resource action exists. See [Create a Resource Action to Change a User Password](#).

Procedure

- 1 Select **Administration > Catalog Management > Entitlements**.
- 2 Click the **New** icon ().
- 3 Enter **Create an Active Directory user** in the **Name** text box.
- 4 Leave the **Description** and **Expiration Date** text boxes empty.
- 5 Select **Active** from the **Status** drop-down menu.
- 6 Select the target business group from the **Business Group** drop-down menu.
For example, IT account managers.
- 7 Select **All Users and Groups** to entitle all the members of the business group, for example, IT account managers, to create a user account.

The users that you select can see the service and the catalog items included in the service in the catalog. They can run the change password action on the user account after it is created.
- 8 Click **Next**.
- 9 In the **Entitled Services** text box, enter **Active Directory Test User** and press Enter.
- 10 In the **Entitled Actions** text box, enter **Change the password of the Test User** and press Enter.
- 11 Click **Finish**.

You created an active entitlement so that users who are members of the IT account managers business group can create users. After the user is provisioned, they can run the change password resource action on the provisioned user account.

What to do next

Log in as user who is entitled to create an Active Directory user. On the **Catalog** tab, verify that the XaaS blueprint creates the user as expected. After the user is created, run the change password action from the **Items** tab.

Create and Publish an XaaS Action to Migrate a Virtual Machine

You can create and publish an XaaS resource action to extend the operations that consumers can perform on IaaS-provisioned vSphere virtual machines.

In this scenario, you create a resource action for quick migration of a vSphere virtual machine.

Prerequisites

Log in to the vRealize Automation console as an **XaaS architect**.

Procedure

1 [Create a Resource Action to Migrate a vSphere Virtual Machine](#)

You create a custom resource action to allow the consumers to migrate vSphere virtual machines after they provision the vSphere virtual machines with IaaS.

2 [Publish the Action for Migrating a vSphere Virtual Machine](#)

To use the Quick migration of virtual machine resource action as a post-provisioning operation, you must publish it.

Create a Resource Action to Migrate a vSphere Virtual Machine

You create a custom resource action to allow the consumers to migrate vSphere virtual machines after they provision the vSphere virtual machines with IaaS.

Procedure

- 1 Select **Design > XaaS > Resource Actions**.
- 2 Click **Add** (+).
- 3 Navigate to **Orchestrator > Library > vCenter > Virtual Machine management > Move and migrate** in the vRealize Orchestrator workflow library and select the **Quick migration of virtual machine** workflow.
- 4 Click **Next**.
- 5 Select **IaaS VC VirtualMachine** from the **Resource type** drop-down menu.
- 6 Select **vm** from the **Input parameter** drop-down menu.
- 7 Click **Next**.
- 8 Leave the name of the resource action and the description as they appear on the **Details** tab.
- 9 Click **Next**.
- 10 Leave the form as is.

11 Click **Finish**.

You created a resource action for migrating a virtual machine and you can see it listed on the Resource Actions page.

What to do next

[Publish the Action for Migrating a vSphere Virtual Machine](#)

Publish the Action for Migrating a vSphere Virtual Machine

To use the Quick migration of virtual machine resource action as a post-provisioning operation, you must publish it.

Procedure

- 1 Select **Design > XaaS > Resource Actions**.
- 2 Select the row of the Quick migration of virtual machine resource action, and click the **Publish** button.

You created and published a vRealize Orchestrator workflow as a resource action. You can navigate to **Administration > Catalog Management > Actions** and see the Quick migration of virtual machine resource action in the list of actions. You can assign an icon to the resource action. See [Assign an Icon to an XaaS Resource Action](#).

What to do next

Add the action to the entitlements that contain the IaaS-provisioned vSphere virtual machines. See [Entitle Users to Services, Catalog Items, and Actions](#).

Create an XaaS Action to Migrate a Virtual Machine With vMotion

By using XaaS, you can create and publish a resource action to migrate an IaaS-provisioned virtual machine with vMotion.

In this scenario, you create a resource action to migrate a vSphere virtual machine with vMotion. In addition, you edit the workflow presentation by using the form designer and change the way the consumers see the action when they request it.

Prerequisites

Log in to the vRealize Automation console as an **XaaS architect**.

Procedure

1 [Create an Action to Migrate a vSphere Virtual Machine With vMotion](#)

You can create a custom resource action to allow the service catalog users to migrate a vSphere virtual machine with vMotion after they provision the machine with IaaS.

2 [Edit the Resource Action Form](#)

The resource action form maps the vRealize Orchestrator workflow presentation. You can edit the form and define what the consumers of the resource action see when they decide to run the post-provisioning operation.

3 Add a Submitted Action Details Form and Save the Action

You can add a new form to the Migrate a virtual machine with vMotion resource action to define what the consumers see after they request to run the post-provisioning operation.

4 Publish the Action for Migrating a Virtual Machine with vMotion

To use the Migrate a virtual machine with vMotion resource action as a post-provisioning operation, you must publish it.

Create an Action to Migrate a vSphere Virtual Machine With vMotion

You can create a custom resource action to allow the service catalog users to migrate a vSphere virtual machine with vMotion after they provision the machine with IaaS.

Procedure

- 1 Select **Design > XaaS > Resource Actions**.
- 2 Click **Add** ()
- 3 Navigate to **Orchestrator > Library > vCenter > Virtual Machine management > Move and migrate** in the vRealize Orchestrator workflow library and select the **Migrate virtual machine with vMotion** workflow.
- 4 Click **Next**.
- 5 Select **IaaS VC VirtualMachine** from the **Resource type** drop-down menu.
- 6 Select **vm** from the **Input parameter** drop-down menu.
- 7 Click **Next**.
- 8 Leave the name of the resource action and the description as they appear on the **Details** tab.
- 9 Click **Next**.

What to do next

[Edit the Resource Action Form.](#)

Edit the Resource Action Form

The resource action form maps the vRealize Orchestrator workflow presentation. You can edit the form and define what the consumers of the resource action see when they decide to run the post-provisioning operation.

Procedure

- 1 Click the **Delete** icon () to delete the **pool** element.
- 2 Edit the **host** element.
 - a Click the **Edit** icon () next to the **host** field.
 - b Type **Target host** in the **Label** text box.
 - c Select **Search** from the **Type** drop-down menu.

- d Click the **Constraints** tab.
- e Select **Constant** from the **Required** drop-down menu and select **Yes**.
You made the host field always required.
- f Click **Submit**.

3 Edit the **priority** element.

- a Click the **Edit** icon () next to the **priority** field.
- b Type **Priority of the task** in the **Label** text box.
- c Select **Radio button group** from the **Type** drop-down menu.
- d Click the **Values** tab, and deselect the **Not set** check box.
- e Enter **lowPriority** in the **Predefined values** search text box, and press Enter.
- f Enter **defaultPriority** in the **Predefined values** search text box, and press Enter.
- g Enter **highPriority** in the **Predefined values** search text box, and press Enter.
- h Click **Submit**.

When the consumers request the resource action, they see a radio button group with three radio buttons: **lowPriority**, **defaultPriority**, and **highPriority**.

4 Edit the **state** element.

- a Click the **Edit** icon () next to the **state** field.
- b Type **Virtual machine state** in the **Label** text box.
- c Select **Drop-down** from the **Type** drop-down menu.
- d Click the **Values** tab, and deselect the **Not set** check box.
- e Enter **poweredOff** in the **Predefined values** search text box, and press Enter.
- f Enter **poweredOn** in the **Predefined values** search text box, and press Enter.
- g Enter **suspended** in the **Predefined values** search text box, and press Enter.
- h Click **Submit**.

When the consumers request the resource action, they see a drop-down menu with three options: **poweredOff**, **poweredOn**, and **suspended**.

You edited workflow presentation of the Migrate a virtual machine with vMotion workflow.

What to do next

[Add a Submitted Action Details Form and Save the Action.](#)

Add a Submitted Action Details Form and Save the Action

You can add a new form to the Migrate a virtual machine with vMotion resource action to define what the consumers see after they request to run the post-provisioning operation.

Procedure

- 1 Click the **New Form** icon () next to the **Form** drop-down menu.
- 2 Type **Submitted action** in the **Name** text box.
- 3 Leave the **Description** field blank.
- 4 Select **Submitted action details** from the **Screen type** menu.
- 5 Click **Submit**.
- 6 Click the **Edit** icon () next to the **Form page** drop-down menu.
- 7 Type **Details** in the **Heading** text box.
- 8 Click **Submit**.
- 9 Drag the **Text** element from the Form pane and drop it to the **Form** page.
- 10 Type
You submitted a request to migrate your machine with vMotion. Wait until the process completes successfully.
- 11 Click outside of the text box to save the changes.
- 12 Click **Submit**.
- 13 Click **Add**.

You created a resource action to migrate a virtual machine with vMotion and you can see it listed on the Resource Actions page.

What to do next

[Publish the Action for Migrating a Virtual Machine with vMotion.](#)

Publish the Action for Migrating a Virtual Machine with vMotion

To use the Migrate a virtual machine with vMotion resource action as a post-provisioning operation, you must publish it.

Procedure

- 1 Select **Design > XaaS > Resource Actions**.
- 2 Select the row of the Migrate a virtual machine with vMotion action, and click the **Publish** button.

You created and published a vRealize Orchestrator workflow as a resource action. You can navigate to **Administration > Catalog Management > Actions** and see the Migrate virtual machine with vMotion resource action in the list of actions. You can assign an icon to the resource action. See [Assign an Icon to an XaaS Resource Action](#).

You also edited the presentation of the workflow and defined the look and feel of the action.

What to do next

Business group managers and tenant administrators can include the Migrate a virtual machine with vMotion resource action in an entitlement. For more information about how to create and publish IaaS blueprints for virtual platforms, see [Designing Machine Blueprints](#).

Create and Publish an XaaS Action to Take a Snapshot

By using XaaS, you can create and publish a resource action to take a snapshot of a vSphere virtual machine that was provisioned with IaaS.

In this scenario, you create a resource action to take a snapshot of a vSphere virtual machine provisioned with IaaS. In addition, you edit the workflow presentation by using the form designer and change the way the consumers see the action when they request it.

Prerequisites

Log in to the vRealize Automation console as an **XaaS architect**.

Procedure

1 [Create the Action to Take a Snapshot of a vSphere Virtual Machine](#)

You can create a custom resource action to allow the consumers to take a snapshot of a vSphere virtual machine after they provision the machine with IaaS.

2 [Publish the Action for Taking a Snapshot](#)

To use the Create a snapshot resource action as a post-provisioning operation, you must publish it.

Create the Action to Take a Snapshot of a vSphere Virtual Machine

You can create a custom resource action to allow the consumers to take a snapshot of a vSphere virtual machine after they provision the machine with IaaS.

Procedure

- 1 Select **Design > XaaS > Resource Actions**.
- 2 Click **Add** (+).
- 3 Navigate to **Orchestrator > Library > vCenter > Virtual Machine management > Snapshot** in the vRealize Orchestrator workflow library and select the **Create a snapshot** workflow.
- 4 Click **Next**.
- 5 Select **IaaS VC VirtualMachine** from the **Resource type** drop-down menu.
- 6 Select **vm** from the **Input parameter** drop-down menu.

- 7 Click **Next**.
- 8 Leave the name of the resource action and the description as they appear on the **Details** tab.
- 9 Click **Next**.
- 10 Leave the form as is.
- 11 Click **Add**.

You created a resource action for taking a snapshot of a virtual machine and you can see it listed on the Resource Actions page.

What to do next

[Publish the Action for Taking a Snapshot](#).

Publish the Action for Taking a Snapshot

To use the Create a snapshot resource action as a post-provisioning operation, you must publish it.

Procedure

- 1 Select **Design > XaaS > Resource Actions**.
- 2 Select the row of the Create a snapshot action, and click the **Publish** button.

You created and published a vRealize Orchestrator workflow as a resource action. You can navigate to **Administration > Catalog Management > Actions** and see the Create a snapshot resource action in the list of actions. You can assign an icon to the resource action. See [Assign an Icon to an XaaS Resource Action](#).

What to do next

Business group managers and tenant administrators can include the Create a snapshot resource action in an entitlement. For more information about how to create and publish IaaS blueprints for virtual platforms, see [Designing Machine Blueprints](#).

Create and Publish an XaaS Action to Start an Amazon Virtual Machine

By using XaaS, you can create and publish actions to extend the operations that the consumers can perform on third-party provisioned resources.

In this scenario, you create and publish a resource action for quick starting of Amazon virtual machines.

Prerequisites

- Install the vRealize Orchestrator plug-in for Amazon Web Services on your default vRealize Orchestrator server.
- Create or import a vRealize Orchestrator workflow for resource mapping of Amazon instances.

Procedure

1 [Create a Resource Mapping for Amazon Instances](#)

You can create a resource mapping to associate Amazon instances provisioned by using IaaS with the vRealize Orchestrator type `AWS:EC2Instance` exposed by the Amazon Web Services plug-in.

2 [Create a Resource Action to Start an Amazon Virtual Machine](#)

You can create a resource action so that the consumers can start provisioned Amazon virtual machines.

3 [Publish the Action for Starting Amazon Instances](#)

To use the newly created Start Instances resource action for post-provisioning operations on Amazon virtual machines, you must publish it.

Create a Resource Mapping for Amazon Instances

You can create a resource mapping to associate Amazon instances provisioned by using IaaS with the vRealize Orchestrator type `AWS:EC2Instance` exposed by the Amazon Web Services plug-in.

Prerequisites

- Log in to the vRealize Automation console as an **XaaS architect**.
- Create or import a vRealize Orchestrator resource mapping workflow or script action.

Procedure

- 1 Select **Design > XaaS > Resource Mappings**.
- 2 Click **Add** (+).
- 3 Enter **EC2 Instance** in the **Name** text box.
- 4 Enter **Cloud Machine** in the **Catalog Resource Type** text box.
- 5 Enter **AWS:EC2Instance** in the **Orchestrator Type** text box.
- 6 Select **Always available**.
- 7 Select the type of resource mapping to use.
- 8 Select your custom resource mapping script action or workflow from the vRealize Orchestrator library.
- 9 Click **Add**.

You can use your Amazon resource mapping to create resource actions for Amazon machines provisioned by using IaaS.

What to do next

[Create a Resource Action to Start an Amazon Virtual Machine](#).

Create a Resource Action to Start an Amazon Virtual Machine

You can create a resource action so that the consumers can start provisioned Amazon virtual machines.

Prerequisites

Log in to the vRealize Automation console as an **XaaS architect**.

Procedure

- 1 Select **Design > XaaS > Resource Actions**.
- 2 Click **Add** (+).
- 3 Select **Orchestrator > Library > Amazon Web Services > Elastic Cloud > Instances** and select the **Start Instances** workflow in the workflows folder.
- 4 Click **Next**.
- 5 Select **EC2 Instance** from the **Resource type** drop-down menu.
This is the name of the resource mapping you previously created.
- 6 Select **instance** from the **Input parameter** drop-down menu.
This is the input parameter of the resource action workflow to match the resource mapping.
- 7 Click **Next**.
- 8 Leave the name and the description as they are.
The default name of the resource action is Start Instances.
- 9 Click **Next**.
- 10 Leave the fields as they are on the **Form** tab.
- 11 Click **Add**.

You created a resource action for starting Amazon virtual machines and you can see it on the Resource Actions page.

What to do next

[Publish the Action for Starting Amazon Instances.](#)

Publish the Action for Starting Amazon Instances

To use the newly created Start Instances resource action for post-provisioning operations on Amazon virtual machines, you must publish it.

Prerequisites

Log in to the vRealize Automation console as an **XaaS architect**.

Procedure

- 1 Select **Design > XaaS > Resource Actions**.
- 2 Select the row of the Start Instances resource action, and click **Publish**.

The status of the Start Instances resource action changes to Published.

What to do next

Add the start instances action to the entitlement that includes the Amazon catalog item. See [Entitle Users to Services, Catalog Items, and Actions](#).

Troubleshooting Incorrect Accents and Special Characters in XaaS Blueprints

When you create XaaS blueprints for languages that use non-ASCII strings, the accents and special characters are displayed as unusable strings.

Cause

A vRealize Orchestrator configuration property that is not set by default, might be enabled.

Solution

- 1 On the Orchestrator server system, navigate to `/etc/vco/app-server/`.
- 2 Open the `vmo.properties` configuration file in a text editor.
- 3 Verify that the following property is disabled.

```
com.vmware.o11n.webview.htmlescaping.disabled
```

- 4 Save the `vmo.properties` file.
- 5 Restart the vRealize Orchestrator server.

Publishing a Blueprint

Blueprints are saved in the draft state and must be manually published before you can configure them as catalog items or use them as blueprint components in the design canvas.

After you publish the blueprint, you can entitle it to make it available for provisioning requests in the service catalog.

You need to publish a blueprint only once. Any changes you make to a published blueprint are automatically reflected in the catalog and in nested blueprint components.

Publish a Blueprint

You can publish a blueprint for use in machine provisioning and optionally for reuse in another blueprint. To use the blueprint for requesting machine provisioning, you must entitle the blueprint after publishing it. Blueprints that are consumed as components in other blueprints do not required entitlement.

Prerequisites

- Log in to the vRealize Automation console as an **infrastructure architect**.
- Create a blueprint. See *Checklist for Creating vRealize Automation Blueprints*.

Procedure

- 1 Click the **Design** tab.

- 2 Click **Blueprints**.
- 3 Point to the blueprint to publish and click **Publish**.
- 4 Click **OK**.

The blueprint is published as a catalog item but you must first entitle it to make it available to users in the service catalog.

What to do next

Add the blueprint to the catalog service and entitle users to request the catalog item for machine provisioning as defined in the blueprint.

Assembling Composite Blueprints

You can reuse published blueprints and blueprint components, combining them in new ways to create IT service packages that deliver elaborate functionality to your users.

Figure 3-5. Workflow for Assembling Composite Blueprints

- **Understanding Nested Blueprint Behavior**

You can reuse blueprints by nesting them in another blueprint as a component. You nest blueprints for reuse and modularity control in machine provisioning, but there are specific rules and considerations when you work with nested blueprints.

- **Using Machine Components and Software Components When Assembling a Blueprint**

You deliver Software components by placing them on top of supported machine components when you assemble blueprints.

- **Creating Property Bindings Between Blueprint Components**

In several deployment scenarios, a component needs the property value of another component to customize itself. You can bind properties of XaaS, machines, Software, and custom properties to other properties in a blueprint.

- **Creating Dependencies and Controlling the Order of Provisioning**

If you need information from one of your blueprint components to complete the provisioning of another component, you can draw an explicit dependency on the design canvas to stagger provisioning so the dependent component is not provisioned prematurely. Explicit dependencies control the build order of a deployment and trigger dependent updates during a scale in or scale out operation. Software components are required to be ordered in a blueprint.

Understanding Nested Blueprint Behavior

You can reuse blueprints by nesting them in another blueprint as a component. You nest blueprints for reuse and modularity control in machine provisioning, but there are specific rules and considerations when you work with nested blueprints.

A blueprint that contains one or more nested blueprints is called an outer blueprint. When you add a blueprint component to the design canvas while creating or editing another blueprint, the blueprint component is called a nested blueprint and the container blueprint to which it is added is called the outer blueprint.

Using nested blueprints presents considerations that are not always obvious. It is important to understand the rules and considerations to make the best use of your machine provisioning capabilities.

General Rules and Considerations for Nesting Blueprints

- As a best practice to minimize blueprint complexity, limit blueprints to three levels deep, with the top-level blueprint serving as one of the three levels.
- If a user is entitled to the outer blueprint, that user is entitled to its nested blueprints.
- You can apply an approval policy to a blueprint. When approved, the blueprint catalog item and all its components, including nested blueprints, are provisioned. You can also apply different approval policies to different components. All the approval policies must be approved before the requested blueprint is provisioned.

- When you edit a published blueprint, you are not changing deployments that are already provisioned by using that blueprint. At the time of provisioning, the resulting deployment reads current values from the blueprint, including from its nested blueprints. The only changes you can pass on to provisioned deployments are edits to software components, for example edits to update or uninstall scripts.
- Settings you define in the outer blueprint override settings configured in nested blueprints with the following exceptions:
 - You can change the name of a nested blueprint, but you cannot change the name of a machine component, or any other component, inside a nested blueprint.
 - You cannot add or delete custom properties for a machine component in a nested blueprint. However, you can edit those custom properties. You cannot add, edit, or delete property groups for a machine component in a nested blueprint.
- Changes you or another architect make to nested blueprint settings appear in the outer blueprints, unless you have overridden those settings in the outer blueprint.
- Limit the maximum lease time on the outer blueprint to the lowest maximum lease value of a component blueprint.

While the lease time specified on a nested blueprint and on the outer blueprint can be set to any value, the maximum lease time on the outer blueprint should be limited to the lowest maximum lease value of a nested blueprint. This allows the application architect to design a composite blueprint that has uniform and variable lease values, but is within the constraints identified by the infrastructure architect. If the maximum lease value defined on a nested blueprint is less than that defined on the outer blueprint, the provisioning request fails.

- When working in an outer blueprint, you can override the Machine Resources settings that are configured for a machine component in a nested blueprint.
- When working in an outer blueprint, you can drag a software component onto a machine component within a nested blueprint.
- If you open a blueprint in which a machine component in a nested blueprint was removed or its ID was changed, and the machine component was associated to components in the current blueprint, the associated components are removed and the following or similar message appears:

A machine component in a nested blueprint that is referenced by components in the current blueprint was removed or its machine component ID was changed. All components in the current blueprint that were associated to the missing or changed machine component ID have been removed. Click Cancel to keep the association history between the missing or changed machine component ID in the nested blueprint and components in the current blueprint and correct the problem in the nested blueprint. Open the nested blueprint and re-add the missing machine component with the original ID or change the machine component ID back to its original ID. Click Save to remove all association history between the missing or changed machine component ID in the nested blueprint and components in the current blueprint.

Networking and Security Rules and Considerations for Nesting Blueprints

- Networking and security components in outer blueprints can be associated with machines that are defined in nested blueprints.
- NSX network, security, and load balancer components and their settings are not supported in nested blueprints.
- When app isolation is applied in the outer blueprint, it overrides app isolation settings specified in nested blueprints.
- Transport zone settings that are defined in the outer blueprint override transport zone settings that are specified in nested blueprints.
- When working in an outer blueprint, you can configure load balancer settings relative to network component settings and machine component settings that are configured in an inner or nested blueprint.
- For a nested blueprint that contains an on-demand NAT network component, the IP ranges specified in that on-demand NAT network component are not editable in the outer blueprint.
- The outer blueprint cannot contain an inner blueprint that contains on-demand network settings or on-demand load balancer settings. Using an inner blueprint that contains an NSX on-demand network component or NSX load balancer component is not supported.
- For a nested blueprint that contains NSX network or security components, you cannot change the network profile or security policy information specified in the nested blueprint. You can, however, reuse those settings for other vSphere machine components that you add to the outer blueprint.
- To ensure that NSX network and security components in nested blueprints are uniquely named in a composite blueprint, vRealize Automation prefixes the nested blueprint ID to network and security component names that are not already unique. For example, if you add a blueprint with the ID name xbp_1 to an outer blueprint and both blueprints contain an on-demand security group component named OD_Security_Group_1, the component in the nested blueprint is renamed xbp_1_OD_Security_Group_1 in the blueprint design canvas. Network and security component names in the outer blueprint are not prefixed.
- Component settings can change depending on which blueprint the component resides on. For example, if you include security groups, security tags, or on-demand networks at both the inner and outer blueprint levels, the settings in the outer blueprint override those in the inner blueprint. Network and security components are supported only at the outer blueprint level except for existing networks that work at the inner blueprint level. To avoid issues, add all your security groups, security tags, and on-demand networks only to the outer blueprint.

Software Component Considerations for Nesting Blueprints

For scalable blueprints, it is a best practice to create single layer blueprints that do not reuse other blueprints. Normally, update processes during scale operations are triggered by implicit dependencies such as dependencies you create when you bind a software property to a machine property. However, implicit dependencies in a nested blueprint do not always trigger update processes. If you need to use nested blueprints in a scalable blueprint, you can manually draw dependencies between components in your nested blueprint to create explicit dependencies that always trigger an update.

Using Machine Components and Software Components When Assembling a Blueprint

You deliver Software components by placing them on top of supported machine components when you assemble blueprints.

To support Software components, the machine blueprint you select must contain a machine component based on a template, snapshot, or Amazon machine image that contains the guest agent and the Software bootstrap agent, and it must use a supported provisioning method.

Because the Software agents do not support Internet Protocol version 6 (IPv6), use IPv4 settings.

Note Software components must have an ordered dependency in the blueprint. Unordered software components can cause blueprint provisioning to fail. If there is no actual order dependency for the software components, you can satisfy the blueprint ordering requirement by adding a faux dependency between the software components.

If you are designing blueprints to be scalable, it is a best practice to create single layer blueprints that do not reuse other blueprints. Normally, the update processes that are used during scale operations are triggered by implicit dependencies such as property bindings. However, implicit dependencies in a nested blueprint do not always trigger update processes.

While IaaS architects, application architects, and software architects can all assemble blueprints, only IaaS architects can configure machine components. If you are not an IaaS architect, you cannot configure your own machine components, but you can reuse machine blueprints that your IaaS architect created and published.

To successfully add software components to the design canvas, you must also have business group member, business group administrator, or tenant administrator role access to the target catalog.

If you need to use nested blueprints in a scalable blueprint, you can manually draw dependencies between components in your nested blueprint to create explicit dependencies that always trigger an update.

Note When you publish a blueprint, software component data is treated like a snapshot. If you later make changes to the software component's properties, only new properties are recognized by the blueprint in which the software component exists. Updates to properties that existed in the software component at the time you published the blueprint are not updated in the blueprint. Only properties that are added after you have published the blueprint are inherited by the blueprint. However, you can make changes to instances of the software component in blueprints in which the software component resides to change that particular blueprint.

Table 3-64. Provisioning Methods that Support Software

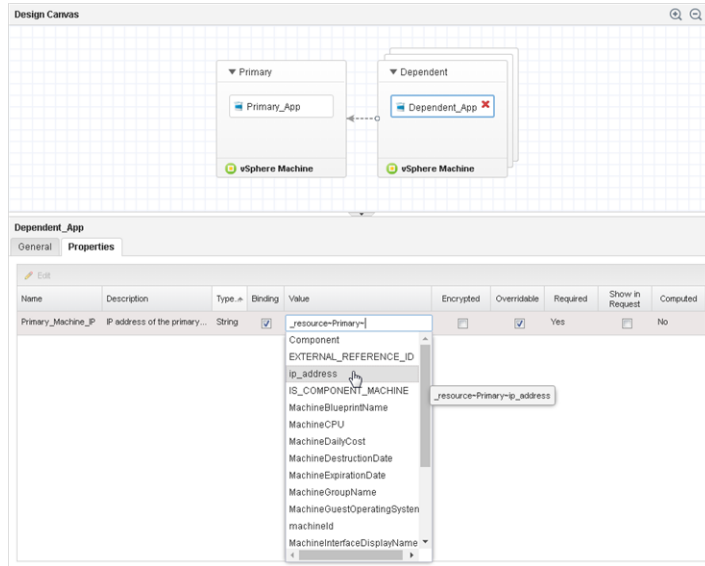

Machine Type	Provisioning Method
vSphere	Clone
vSphere	Linked Clone
vCloud Director	Clone
vCloud Air	Clone
Amazon AWS	Amazon Machine Image

Creating Property Bindings Between Blueprint Components

In several deployment scenarios, a component needs the property value of another component to customize itself. You can bind properties of XaaS, machines, Software, and custom properties to other properties in a blueprint.

For example, your software architect might modify property definitions in the life cycle scripts of a WAR component. A WAR component might need the installation location of the Apache Tomcat server component, so your software architect configures the WAR component to set the `server_home` property value to the Apache Tomcat server `install_path` property value. As the architect assembling the blueprint, you have to bind the `server_home` property to the Apache Tomcat server `install_path` property for the Software component to provision successfully.

You set property bindings when you configure components in a blueprint. On the Blueprint page, you drag your component onto the canvas and click the **Properties** tab. To bind a property to another property in a blueprint, select the **Bind** checkbox. You can enter *ComponentName~PropertyName* in the value text box, or you can use the down arrow to generate a list of available binding options. You use a tilde character ~ as a delimiter between components and properties. For example, to bind to the property `dp_port`, on your MySQL software component, you could type `mysql-db_port`. To bind to properties that are configured during provisioning, such as the IP address of a machine or the host name of a Software component, you enter *_resource~ComponentName~PropertyName*. For example, to bind to the reservation name of a machine, you might enter `_resource~vSphere_Machine_1~MachineReservationName`.

Figure 3-6. Bind a Software Property to the IP address of a machine

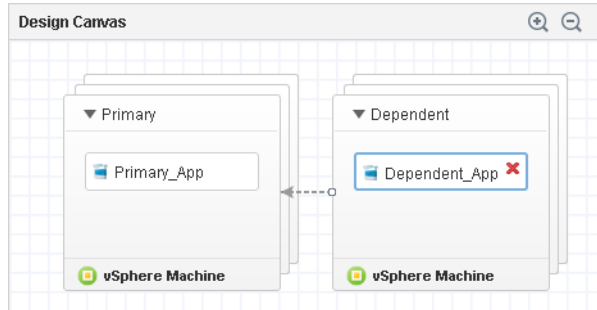

Creating Dependencies and Controlling the Order of Provisioning

If you need information from one of your blueprint components to complete the provisioning of another component, you can draw an explicit dependency on the design canvas to stagger provisioning so the dependent component is not provisioned prematurely. Explicit dependencies control the build order of a deployment and trigger dependent updates during a scale in or scale out operation. Software components are required to be ordered in a blueprint.

When you design blueprints with multiple machines and applications, you might have properties you need from one machine to finish an application installation on another. For example, if you are building a Web server you might need the host name of the database server before you can install the application and instantiate database tables. If you map an explicit dependency, your database server starts provisioning when your Web server finishes provisioning.

Note Software components must have an ordered dependency in the blueprint. Unordered software components can cause blueprint provisioning to fail. If there is no actual order dependency for the software components, you can satisfy the blueprint ordering requirement by adding a faux dependency between the software components.

To map a dependency on your design canvas, you draw a line from the dependent component to the component you are depending on. When you are finished, the component you want to build second has an arrow pointing to the component you want to build first. For example, in the Controlling the Build Order by Mapping Dependencies figure, the dependent machine is not provisioned until the primary machine is built. Alternatively, you can configure both machines to provision simultaneously but draw a dependency between the software components.

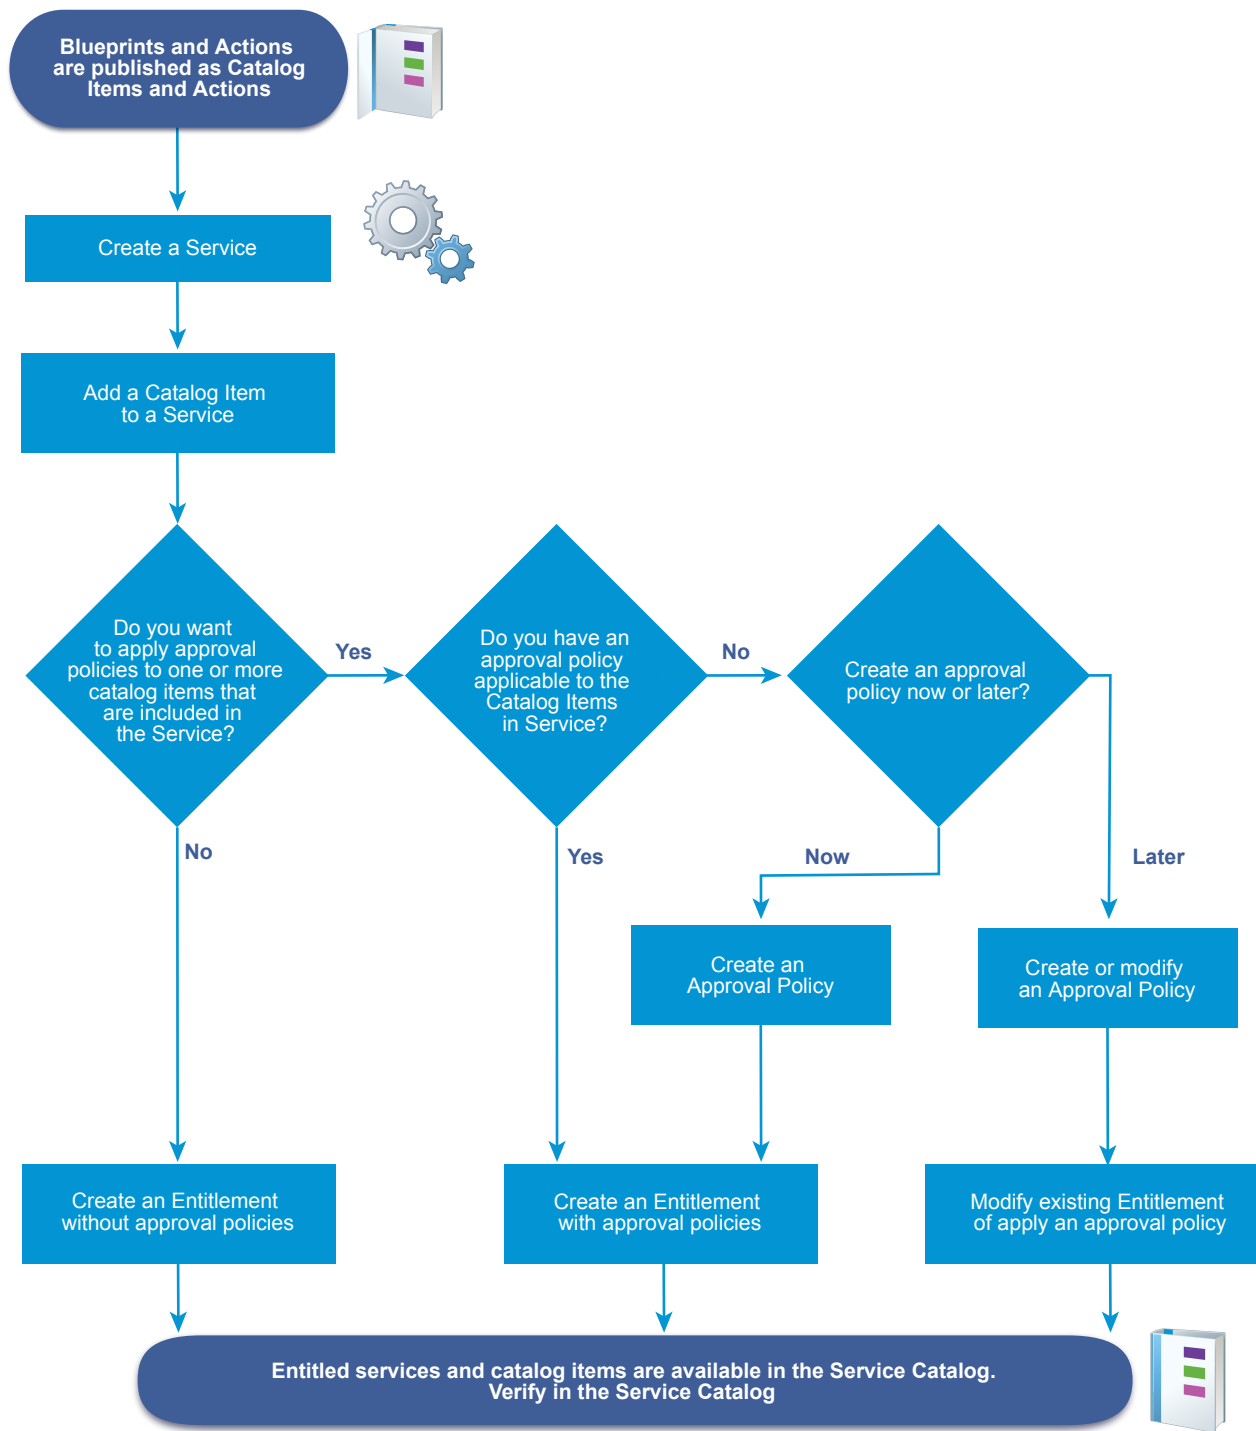

Figure 3-7. Controlling the Build Order by Mapping Dependencies

If you are designing blueprints to be scalable, it is a best practice to create single layer blueprints that do not reuse other blueprints. Normally, update processes during scale operations are triggered by implicit dependencies such as dependencies you create when you bind a software property to a machine property. However, implicit dependencies in a nested blueprint do not always trigger update processes. If you need to use nested blueprints in a scalable blueprint, you can manually draw dependencies between components in your nested blueprint to create explicit dependencies that always trigger an update.

Managing the Service Catalog

The service catalog is where your customers request machines and other items to provision for their use. You manage user access to the service catalog items based on how you build services, entitle users to one or more items, and apply governance.

The workflow that you follow to add items to the service catalog varies based on whether you create and apply approval policies.

Checklist for Configuring the Service Catalog

After you create and publish blueprints and actions, you can create a vRealize Automation service, configure catalog items, and assign entitlements and approvals.

The Configuring the Service Catalog Checklist provides a high-level overview of the steps required to configure catalog and provides links to decision points or detailed instructions for each step.

Table 3-65. Configuring the Service Catalog Checklist

Task	Required Role	Details
<input type="checkbox"/> Add a service.	tenant administrator or catalog administrator	See Add a Service .
<input type="checkbox"/> Add a catalog item to a service.	tenant administrator or catalog administrator	See Add Catalog Items to a Service .
<input type="checkbox"/> Configure the catalog item in the service.	tenant administrator or catalog administrator	See Configure a Catalog Item .
<input type="checkbox"/> Create and apply entitlements to the catalog item.	tenant administrator or business group manager	See Entitle Users to Services, Catalog Items, and Actions .
<input type="checkbox"/> Create and apply approval policies to the catalog item.	tenant administrator or approval administrator can create approval policies tenant administrator or business group manager can apply approval policies	See Create an Approval Policy .

Creating a Service

A service is a group of catalog items that you want included in the service catalog. You can entitle the service, which entitles business group users to all the associated catalog items, and you can apply an approval policy to the service.

A service operates as a dynamic group of catalog items. If you entitle a service, all the catalog items associated with the service are available in the service catalog to the specified users, and any catalog items that you add or remove from a service affect the service catalog.

As you create the service, you can use it as a service category so that you can assemble service offerings for your service catalog users. For example, a Windows desktop service that includes Windows 7, 8, and 10 operating system catalog items, or a Linux service that includes CentOS and RHEL operating system items.

Add a Service

Add a service to make catalog items available to your service catalog users. All catalog items must be associated with a service so that you can entitle the items to users.

When the service is entitled to users, the catalog items appear together in the service catalog. You can also entitle users to the individual catalog items.

Prerequisites

Log in to the vRealize Automation console as a **tenant administrator** or **catalog administrator**.

Procedure

- 1 Select **Administration > Catalog Management > Services**.

- 2 Click the **New** icon ().

- 3 Enter a name and description.

These values appear in the service catalog for the catalog users.

- 4 To add a specific icon for the service in the service catalog, click **Browse** and select an image.

The supported image file types are GIF, JPG, and PNG. The displayed image is 40 x 40 pixels. If you do not select a custom image, the default icon appears in the service catalog.

- 5 Select a status from the **Status** drop-down menu.

Option	Description
Inactive	The service is not available in the service catalog. When a service is in this state, you can associate catalog items with the service, but you cannot entitle the service or users. If you select Inactive for a service that is active and entitled, it is removed from the service catalog until you reactivate it.
Active	(Default) The service and the associated catalog items are available to entitle to users and, if entitled, are available for in the service catalog for those users.
Deleted	Removes the service from vRealize Automation. All associated catalog items are still present, but any items associated with the service in the service catalog are not available to the catalog users.

- 6 Configuring the service settings.

The following settings provide information to the service catalog users. The settings do not affect service availability.

Option	Description
Hours	Configure the time to coincide with the availability of the support team. The time is based on your local time. The hours of service cannot cross from one day to another. For example, you cannot set the hours of service as 4:00 PM to 4:00 AM. To cross midnight, create two entitlements. One entitlement for 4:00 PM to 12:00 AM, and another for 12:00 AM to 4:00 AM.
Owner	Specify the user or user group who is the primary owner of the service and the associated catalog items.
Support Team	Specify the custom user group or user who is available to support any problems that the service catalog users encounter when they provision items using the service.
Change Window	Select a date and time when you plan to make a change to the service. The date and time specified is informational and does not affect the availability of the service.

7 Click **Add**.

What to do next

Associate catalog items with a service so that you can entitle users to the items. See [Add Catalog Items to a Service](#).

Add Catalog Items to a Service

Add catalog items to services so that you can entitle users to request the items in the service catalog. A catalog item can be associated with only one service.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **catalog administrator**.
- Verify that a service exists. See [Add a Service](#).
- Verify that one or more catalog items are published. See [Configure a Catalog Item](#).

Procedure

- 1 Select **Administration > Catalog Management > Services**.
- 2 Select the service to which you are adding catalog items and click **Manage Catalog Items**.
- 3 Click the **Catalog Items** icon ()
 - a Select the catalog items to include in this service.

The Select Catalog Items dialog box displays only the items that are not already associated with a service.
 - b Click **Add**.
- 4 Click **Close**.

What to do next

- You can add a custom icon to the catalog item that will appear with the item in the service catalog. See [Configure a Catalog Item](#).
- Entitle users to the services or catalog items so that they can request them in the service catalog. See [Creating Entitlements](#).

Working with Catalog Items and Actions

Catalog items are published blueprints for machines, software components, and other objects. Actions in the catalog management area are published actions that you can run on the provisioned catalog items. You can use the lists to determine what blueprints and actions are published so that you can make them available to service catalog users.

Published Catalog Items

A catalog item is a published blueprint. Published blueprints can also be used in other blueprints. The reuse of blueprints in other blueprints is not displayed in the catalog items list.

The published catalog items can also include items that are only components of blueprints. For example, published software components are listed as catalog items, but they are available only as part of a deployment.

Deployment catalog items must be associated with a service so that you can make them available in the service catalog to entitled users. Only active items appear in the service catalog. You can configure catalog items to a different service, disable it if you want to temporarily remove it from the service catalog, and add a custom icon that appears in the catalog.

Published Actions

Actions are changes that you can make to provisioned catalog items. For example, you can reboot a virtual machine.

Actions can include built-in actions or actions created using XaaS. Built-in actions are added when you add a machine or other provided blueprint. XaaS actions must be created and published.

Actions are not associated with services. You must include an action in the entitlement that contains the catalog item on which the action runs. Actions that are entitled to users do not appear in the service catalog. The actions are available for the provisioned item on the service catalog user's **Items** tab based whether they are applicable to the item and to the current state of the item.

You can add a custom icon to the action that appears on the **Items** tab.

Configure a Catalog Item

A catalog item is a published blueprint that you can entitle to users. You use the catalog items options to change the status or associated service. You can also view the entitlements that include the selected catalog item.

Only catalog items that are associated with a service and entitled to users appear in the service catalog. Catalog items can be associated with only one service.

If you do not want a catalog item to appear in the service catalog without removing it from an entitlement or from the published catalog items list, you can deactivate it. The status of a deactivated catalog item is retired in the grid and inactive in the configuration details. You can activate it later.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **catalog administrator**.
- Verify that you have at least one blueprint published as a catalog item. See [Publish a Blueprint](#).

Procedure

- 1 Select **Administration > Catalog Management > Catalog Items**.

- 2 Select the catalog item and click **Configure**.
- 3 Configure the catalog item settings.

Option	Description
Icon	Browse for an image. The supported image file types are GIF, JPG, and PNG. The displayed image is 40 x 40 pixels. If you do not select a custom image, the default catalog icon appears in the service catalog.
Status	<p>Possible values include Active, Inactive, and Staging.</p> <ul style="list-style-type: none"> ■ Active. The catalog item appears in the service catalog and entitled users can use it to provision resources. The item appears in the catalog item list as published. ■ Inactive. The catalog item is not available in the service catalog. The item appears in the catalog item list as retired. ■ Staging. The catalog item is not available in the service catalog. Select this menu item if the item was once inactive and you are using staging to indicate that you are considering reactivating it. Appears in the catalog item list as staging.
Service	Select a service. All catalog items must be associated with a service if you want it to appear in the service catalog for entitled users. The list includes active and inactive services.
New and noteworthy	The catalog item appears in the New & Noteworthy area on the home page.

- 4 To view the entitlements where the catalog item is made available to users, click the **Entitlements** tab.
- 5 Click **Update**.

What to do next

- To make the catalog item available in the service catalog, you must entitle users to the service associated with the item or to the individual item. See [Creating Entitlements](#).
- To specify the entitlements processing order so that the approval policies for individual users are applied correctly, set the priority order for multiple entitlements for the same business group. See [Prioritize Entitlements](#).

Configure an Action for the Service Catalog

An action is a change or workflow that can run on provisioned items. You can add an icon or view the entitlements that include the selected action.

An action is either a built-in action for a provisioned machine, network, and other blueprint components, or it is a published XaaS action.

For the icon, the supported image file types are GIF, JPG, and PNG. The displayed image is 40 x 40 pixels. If you do not select a custom image, the default action icon appears on the **Items** tab.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **catalog administrator**.

- Verify that you have at least one published action. See [Publish a Blueprint](#) and [Publish a Resource Action](#).

Procedure

- 1 Select **Administration > Catalog Management > Actions**.
- 2 Select the shared action and click **View Details**.
- 3 Browse for an image.
- 4 To view the entitlements where the action is made available to users, click the **Entitlements** tab.
- 5 Click **Update**.

What to do next

[Entitle Users to Services, Catalog Items, and Actions](#).

Creating Entitlements

Entitlements control what items and actions are available in the service catalog for the members of the selected business group. An entitlement must be active for the items to appear in the service catalog. If you have items that require governance, you can use entitlements to apply approval policies to different items.

To configure the entitlement, the catalog items must be included in a service. Entitlements can include multiple services, catalog items from services that are included in other entitlements, and actions that you can run on the deployed catalog items.

Understanding Entitlement Option Interactions

How you configure an entitlement determines what appears in the service catalog. The interaction of services, catalog items and components, action, and approval policies affects what the service catalog user can request and how approval policies are applied.

You must consider the interactions of services, catalog items, actions, and approvals when you create an entitlement.

■ [Services in Entitlements](#)

An entitled service operates as a dynamic group of catalog items. If a catalog item is added to a service after it is entitled, the new catalog item is available to the specified users without any additional configuration.

■ [Catalog Items and Components in Entitlements](#)

Entitled catalog items are blueprints that you can request in the service catalog. Entitled components are part of the blueprints, but you cannot specifically request them in the service catalog.

- **Actions in Entitlements**

Actions run on deployed catalog items. Provisioned catalog items, and the actions you are entitled to run on them, appear in your Items tab. To run actions on a deployed item, the action must be included in the same entitlement as the catalog item that provisioned the item from the service catalog.

- **Approval Policies in Entitlements**

Approval policies are applied in entitlements so that you can manage resources in your environment.

Services in Entitlements

An entitled service operates as a dynamic group of catalog items. If a catalog item is added to a service after it is entitled, the new catalog item is available to the specified users without any additional configuration.

If you apply an approval policy to a service, all the items, when requested, are subject to the same approval policy.

Catalog Items and Components in Entitlements

Entitled catalog items are blueprints that you can request in the service catalog. Entitled components are part of the blueprints, but you cannot specifically request them in the service catalog.

Entitled catalog items and components can include any of the following items:

Catalog Items

- Items from any service that you want to provide to entitled users, even services not included in the current entitlement.

For example, as a catalog administrator you associated several different versions of the Red Hat Enterprise Linux with a Red Hat service and entitle the service to the quality engineers for product A. Then you receive a request to create service catalog items that includes only the latest version of Linux-based operating systems for the training team. You create an entitlement for the training team that includes the latest versions of the other operating systems in a service. You already have the latest version of RHEL associated with another service, so you add RHEL as a catalog item rather than add the entire Red Hat service.

- Items that are included in a service that is included in the current entitlement, but you want to apply an approval policy to the individual catalog item that differs from the policy you applied to the service.

For example, as a business group manager, you entitle your development team to a service that includes three virtual machine catalog items. You apply an approval policy that requires the approval of the virtual infrastructure administrator for machines with more than four CPUs. One of the virtual machines is used for performance testing, so you add it as a catalog item and apply less restrictive approval policy for the same group of users.

Components

- Components are not available by name in the service catalog because they are a part of a catalog item. You entitle them individually so that you can apply a specific approval policy that differs from the catalog item in which it is included.

For example, an item includes a machine and software. The machine is available as a provisionable item and has an approval policy that requires site manager approval. The software is not available as a standalone, provisionable item, only as part of a machine request, but the approval policy for the software requires approval from your organization's software licensing administrator. When the machine is requested in the services catalog, it must be approved by the site administrator and the software licensing administrator before it is provisioned. After it is provisioned, the machine, with the software entry, appears in the requestor's Items tab as part of the machine.

Actions in Entitlements

Actions run on deployed catalog items. Provisioned catalog items, and the actions you are entitled to run on them, appear in your Items tab. To run actions on a deployed item, the action must be included in the same entitlement as the catalog item that provisioned the item from the service catalog.

For example, entitlement 1 includes a vSphere virtual machine and a create snapshot action, and entitlement 2 includes only a vSphere virtual machine. When you deploy a vSphere machine from entitlement 1, the create snapshot action is available. When you deploy a vSphere machine from entitlement 2, there is no action. To make the action available to entitlement 2 users, add the create snapshot action to entitlement 2.

If you select an action that is not applicable to any of the catalog items in the entitlement, it will not appear as an action on the Items tab. For example, your entitlement includes a vSphere machine and you entitle a destroy action for a cloud machine. The destroy action is not available to run on the provisioned machine.

You can apply an approval policy to an action that is different from the policy applied to the catalog item in the entitlement.

If the service catalog user is the member of multiple business groups, and one group is only entitled to power on and power off and the other is only entitled to destroy, that user will have all three actions available to them for the applicable provisioned machine.

Best Practices When Entitling Users to Actions

Blueprints are complex and entitling actions to run on provisioned blueprints can result in unexpected behavior. Use the following best practices when entitling service catalog users to run actions on their provisioned items.

- When you entitle users to the Destroy Machine action, entitle them to Destroy Deployment. A provisioned blueprint is a deployment.

A deployment can contain a machine. If the service catalog user is entitled to run the Destroy Machine action and is not entitled to run the Destroy Deployment, when the user runs the Destroy Machine action on the last or only machine in a deployment, a message appears indicating that they do not have permission to run the action. Entitling both actions ensures that the deployment is removed from your environment. To manage governance on the Destroy Deployment action, you can create a pre approval policy and apply it to the action. This policy will allow the designated approver to validate the Destroy Deployment request before it runs.

- When you entitle service catalog users to the Change Lease, Change Owner, Expire, Reconfigure and other actions that can apply to machines and to deployments, entitle them to both actions.

Approval Policies in Entitlements

Approval policies are applied in entitlements so that you can manage resources in your environment.

To apply an approval policy when you create the entitlement, the policy must already exist. If it does not, you can still create the entitlement and leave it in a draft or inactive state until you create the approval policies needed for the catalog items and actions in this entitlement, and then apply the policies later.

You are not required to apply an approval policy to any of the items or actions. If no approval policy is applied, the items and actions are deployed when requested without triggering an approval request.

Entitle Users to Services, Catalog Items, and Actions

When you add a service, catalog item, or action to an entitlement, you allow the users identified in the entitlement to request the provisionable items in the service catalog. Actions are associated with items and appear on the **Items** tab for the requesting user.

There are several user roles with permission to create entitlements for business groups.

- Tenant administrators can create entitlements for any business group in their tenant.
- Business group managers can create entitlements for the groups that they manage.
- Catalog administrators can create entitlements for any business group in their tenant.

When you create an entitlement, you must select a business group and the members in the business group for the entitlement.

To understand how to create an entitlement so that you can use the interactions of services, catalog items, and actions with approvals, see [Creating Entitlements](#).

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **catalog administrator**.
- Verify that the catalog items to which you are entitling users are associated with a service. See [Add Catalog Items to a Service](#).
- Verify that the business group for which you are defining the entitlement exists and that the member users and user groups are defined. See [Create a Business Group](#).
- Verify that the approval policies exist if you plan to add approvals when you create this entitlement. See [Create an Approval Policy](#). If you want to entitle users to the items in the service catalog without approvals, you can modify the entitlement later to add approvals.

Procedure

- 1 Select **Administration > Catalog Management > Entitlements**.
- 2 Click the **New** icon ().

3 Configure the **Details** options.

Details determine how the entitlement appears in the entitlement list and which users have access to the items in the service catalog.

Option	Description
Name and Description	Information about the entitlement that appears in the entitlements list.
Expiration Date	Set the date and time if you want the entitlement to become inactive on a particular date.
Status	<p>Possible values include Active, Inactive, and Deleted.</p> <ul style="list-style-type: none"> ■ Active. Items are available in the service catalog. This option is available when you add or edit entitlements. ■ Inactive. Items are not available in the service catalog. The entitlement was deactivated by the expiration date or by a user. ■ Deleted. Deletes the entitlement.
Business Group	<p>Select a business group. You can create entitlements for only one business group and entitled users must be members of the business group.</p> <p>If you want to make an entitlement available to all users, you must have an All Users business group, or you must create entitlements for each business group.</p> <p>If you are logged in as a business group manager, you can create entitlements only for your business group.</p>
Users and Groups	<p>Select All Users and Groups to entitle all the members of the business group to the catalog items and actions, or you can entitle individual users or groups. To activate an entitlement, you must select at least one business group user or group.</p>

4 Click **Next**.

- 5 Click an **New** icon (+) to entitle users to services, catalog items, or actions with this entitlement.

You can create an entitlement with various combinations of the services, items, and actions.

Option	Description
Entitled Services	<p>Add a service when you want to allow entitled users access to all the published catalog items associated with the service.</p> <p>An entitled service is a dynamic entitlement. If an item is added to the service later, it is added to the service catalog for the entitled users. Entitlements can include both services and individual catalog items.</p>
Entitled Catalog Items and Components	<p>Add individual items that are available to the entitled users.</p> <p>Entitlements can include both services and individual catalog items. To apply a different approval policy to an item that is included in the service, add it as a catalog item. The approval policy on an item takes precedence over the approval policy on the service to which it belongs when they are in the same entitlement. If they are in different entitlements, the order is based on the set priority.</p> <p>Catalog items must be associated with a service to be available in the service catalog. The catalog item can be associated with any service, not only a service in the current entitlement.</p> <p>Components are a part of a catalog item but are not available by name in the service catalog. For example, MySQL software is a component of a CentOS virtual machine catalog item. Components are entitled with the catalog item. If you want to apply an approval policy that is specific to software, you entitle the item individually. Otherwise, you do not need to entitle a component for it to be deployed with the parent item.</p>
Entitled Actions	<p>Add actions when you want to allow users to run the actions for a provisioned item.</p> <p>Actions that you want to run on the items provisioned from this entitlement must be included in the same entitlement.</p> <p>Entitled actions do not appear in the service catalog. They appear on the Items tab for a provisioned item.</p>
Actions only apply to items defined in this entitlement	<p>Determines if the entitled actions are entitled for all applicable service catalog items or only the items in this entitlement.</p> <p>If selected, the actions are entitled to the business group members for the applicable items in this entitlement. This method of entitling the actions allows you to specify the actions for the specific items.</p> <p>If this option is not selected, the actions are entitled to the users specified in the entitlement for all applicable catalog items, whether or not the items are included in this entitlement. Any applied approval policies on these actions are also active.</p>

- 6 Use the drop-down menus in each section to filter the available items.
- 7 Select the check boxes to include items to the entitlement.
- 8 To add an approval policy to the selected service, item, or action, select an approval policy from the **Apply this Policy to selected Items** drop-down menu.

If you apply an approval policy to a service, all the items in the service have the same approval policy. To apply a different policy to an item, add it as a catalog item and apply the appropriate policy.

9 Click **OK**.

The service, item, or action is added to the entitlement.

10 Click **Finish** to save the entitlement.

If entitlement status is active, the service and items are added to the service catalog.

What to do next

Verify that the entitled services and catalog items appear in the service catalog for the entitled users and that the requested items provision the target objects as expected. You can request the item on behalf of the selected users.

Prioritize Entitlements

If multiple entitlements exist for the same business group, you can prioritize the entitlements so that when a service catalog user makes a request, the entitlement and associated approval policy are processed in the specified order.

If you configure an approval policy for a user group, and you want a group member to have a unique policy for one or more of the services, catalog items, or actions, prioritize the member entitlement before the group entitlement. When the member requests an item in the service catalog, the approval policy that is applied is based on the priority order of the entitlements for the business group. The first time that the member's name is found, either as part of a custom user group or as an individual user, that is the applied approval policy.

For example, you create two entitlements for the same catalog item so that you can apply one approval policy for the accounting user group and a different approval policy for Chris, a member of that group.

Table 3-66. Example Entitlements

Entitlement 1	Entitlement 2
Business Group: Finance	Business Group: Finance
Users and Groups: Accounting group	Users and Groups: Chris
Catalog Item 1: Policy A	Catalog Item 1: Policy C

Chris requests Catalog Item 1 in the service catalog. Depending on the priority order of the entitlements for the Finance business group, a different policy is applied to Chris's request.

Table 3-67. Example Results

Configuration and Result	Priority Order	Priority Order
Priority Order	1: Entitlement 1 2: Entitlement 2	1: Entitlement 2 2: Entitlement 1
Applied Policy	Policy A is applied. Chris is a member of the Accounting user group. The search for Chris as an entitled user stops at Entitlement 1 and the approval policy is applied.	Policy C is applied. The search for Chris as an entitled user stops at Entitlement 2 and the approval policy is applied.

Prerequisites

Log in to the vRealize Automation console as a **tenant administrator** or **catalog administrator**.

Procedure

- 1 Select **Administration > Catalog Management > Entitlements**.
- 2 Click the **Prioritize** icon ().
- 3 Select a business group from the **Business Group** drop-down list.
- 4 Drag an entitlement to a new location in the list to change its priority.
- 5 Select an update method.

Option	Description
Update	Saves your changes.
Update & Close	Saves your changes and closes the Prioritize Elements window.

Working with Approval Policies

Approval policies are governance that you add to service catalog requests so that you can manage resources in your environment. Each policy is a defined set of conditions that can be applied to services, catalog items, and actions when you entitle users to those items.

Approval Policy Process

First, a tenant administrator or approval administrator creates the approval policies where provisioning governance is needed.

Approval policies are created for approval policy types or specific items. If the policy is based on a policy type, you can apply it to matching catalog item types. For example, if a policy is based on a software policy type, then you can define it for and apply it to any software items in the entitlements. If the policy is for a specific item, you should apply it only to that item. For example, if the item is a specific software item, then you should apply it only to that specific database software item in the entitlement.

Policies can include pre-approval and post-approval requirements. For pre approval, the request must be approved before the requested item is provisioned. Post approval policies require that the approver accept the request before the provisioned item is made available to the requesting user.

The pre and post approval configurations are composed of one or more levels that determine when the approval policy is triggered and who or how the request is approved. You can include multiple levels. For example, an approval policy can have one level for manager approval, followed by a level for finance approval.

Next, a tenant administrator or business group manager applies the approval policies to the services, catalog items, and actions as appropriate.

Finally, when a service catalog user requests an item to which an approval policy is applied, the approvers approve or reject the request on their **Inbox** tab, on **Approvals** page . The requesting user can track the approval status for a specific request on their **Requests** tab.

Examples of Approval Policies Based on the Virtual Machine Policy Type

You can create an approval policy that you can apply to the same catalog item type, but it produces different results when an item is requested in the service catalog. Depending on how the approval policy is defined and applied, the effect on the service catalog user and the approver varies.

The following table includes examples of different approval policies that are all based on the same approval policy type. These examples illustrate some of the ways that you can configure approval policies to accomplish different types of governance.

Table 3-68. Examples of Approval Policies and Results

Governance Goals	Selected Policy Type	Pre or Post Approval	When is Approval Required	Who are the Approvers	How is the Policy Applied in the Entitlement	Results When the Item is Requested in the Service Catalog
The business group manager must approve any virtual machine requests. The approval policy must be applicable to multiple business groups in multiple entitlements.	Service Catalog - Catalog Item Request - Virtual Machine	Add to Pre Approval tab	Select Always required	Select Determine approvers from the request. Select condition Business Group > Managers > Users > manager. Select Anyone can approve.	Entitlements are based on business groups. This approval can be used in any entitlement where manager approval is required for the virtual machine.	When the service catalog user requests a virtual machine to which this approval was applied, the business group manager must approve the request before the machine is provisioned.
The virtual infrastructure administrator must verify the correct provisioning of the virtual machine and approve the request before the virtual machine is released to the requesting user.	Service Catalog - Catalog Item Request - Virtual Machine	Add to Post Approval tab	Select Always required	Select Specific Users and Groups. Select your virtual infrastructure administrators custom users group. Select Anyone can approve.	This approval can be used in any entitlement where you want the virtual infrastructure administrator to check the virtual machine on the vCenter Server after it is provisioned.	When the service catalog user requests a virtual machine to which this approval was applied, the virtual machine is provisioned. If each member of the VI admin group approves the request, the machine is released to the user.

Table 3-68. Examples of Approval Policies and Results (Continued)

Governance Goals	Selected Policy Type	Pre or Post Approval	When is Approval Required	Who are the Approvers	How is the Policy Applied in the Entitlement	Results When the Item is Requested in the Service Catalog
To manage virtual infrastructure resources and to control prices, you add two pre-approval levels because one approval is for machine resources and the other is for price of machine per day.	Service Catalog - Catalog Item Request - Virtual Machine	Add To Pre Approval tab	Level 1 Select Required based on conditions . Configure the conditions where CPUs > 6 or Memory > 8 or Storage > 100 GB.	Select Determine approvers from the request . Select condition Requested by > manager. Select . Click System Properties and select CPUs , Memory , and Storage so that the approver can change the value to an acceptable level.	This approval policy can be used in an entitlement where you want the requesting user's manager and a member of the finance department to approve the request.	When the service catalog user requests a virtual machine, the request is evaluated to determine whether the requested CPU, memory, or storage amounts are over the amounts specified in level 1. If they are not, then the level 2 condition is evaluated. If the requests exceeds at least one of the level 1 conditions, then the manager must approve the request. The manager has the option to decrease the requested configuration amounts and approve or the manager can reject the request.

Table 3-68. Examples of Approval Policies and Results (Continued)

Governance Goals	Selected Policy Type	Pre or Post Approval	When is Approval Required	Who are the Approvers	How is the Policy Applied in the Entitlement	Results When the Item is Requested in the Service Catalog
			Level 2 Select Required based on conditions . Configure the condition Price > 15.00 per day.	Select Specific Users and Groups . Select the finance custom users group. Select Anyone can approve .		
For parameterized blueprint catalog items, a cloud administrator must approve deployment requests in which a vSphere machine component profile of size is set to large.	Service Catalog - Catalog Item Request - Virtual Machine	Add To Pre Approval tab	Level 1 Select Required based on conditions . Level 2 Select Single Condition . Select Component profile > vSphere Machine Size . Configure the condition size = large.	Select Specific Users and Groups . Select users and groups who are allowed to approve the request. Select Anyone can approve .	This approval policy can be used in an entitlement where you want a cloud administrator to approve the provisioning request.	When the service catalog user requests a virtual machine to which this approval was applied, a cloud administrator must approve the request before the machine is provisioned.

Example of Actions with Approval Policies Applied in a Composite Deployment

When you apply approval policies to actions that can run on various components in a composite blueprint, the approval process varies depending on how the entitlement is configured and how the approval policies are applied.

This example uses specific details to build the blueprint and then apply approval policies to actions that you can run from the service catalog on the provisioned blueprint in different entitlements. The blueprint is a composite blueprint that includes another blueprint. The actions used are to destroy the provisioned items, destroy a deployment for the blueprints and destroy a virtual machine for the machine. The resulting behavior includes what is destroyed and when the applied approval policies trigger approval requests.

Example Blueprint

In this example, you configure a blueprint that includes a nested blueprint with a virtual machine.

- Blueprint 1 - Continuous Integration Blueprint
 - Blueprint 2 - Pre-Production Blueprint
 - Virtual Machine 1 - TestAsAService vSphere VM

Approval Policies for Destroy Actions

You configure the two approval policies to destroy provisioned items. A Destroy - Deployment action can run on Blueprint 1 or Blueprint 2 in this example. A Destroy - Virtual machine action can run on Virtual Machine 1. You create the approval policies so that you can apply them to the actions in the entitlement.

Approval Policy Name	Approval Policy Type
Approval Policy A	Service Catalog - Resource Action Request - Destroy - Deployment
Approval Policy B	Service Catalog - Resource Action Request - Destroy - Virtual Machine

Entitlements and Approval Policies Applied to Actions

You configure three entitlements. Each entitlement includes the composite blueprint. In each entitlement, you add the destroy actions and apply the approval policies.

Entitlement Name	Entitled Action on Provisioned Machine	Applied Approval Policy
Entitlement 1	Destroy - Deployment	Approval Policy A
Entitlement 2	Destroy - Virtual Machine	Approval Policy B
Entitlement 3	Destroy - Deployment	Approval Policy A
	Destroy - Virtual Machine	Approval Policy B

User Actions in the Service Catalog

When the service catalog user runs the action, blueprints or machines are destroyed depending on which item your user ran the action.

User Action in the Service Catalog	Selected Action	Destroyed Blueprints or Machines
Action 1	Destroy - Deployment action runs on Blueprint 1 - Continuous Integration Blueprint	Blueprint 1, Blueprint 2, and Virtual Machine 1
Action 2	Destroy - Deployment action runs on the nested Blueprint 2 - Pre-production Blueprint	Blueprint 2 and Virtual Machine 1
Action 3	Destroy - Virtual Machine action runs on the machine that is inside a deployment, Virtual Machine 1 - TestAsAService vSphere VM	Virtual Machine 1

Approval Policies Applied to Actions in the Entitlements

You apply the approval policies, the approvers receive an approval request depending on the blueprint or machine on which your service catalog user ran the action.

Entitlement Name	Approval Policy on Actions	User Action	Approval Request Triggered	If Approved, Destroyed Blueprints or Machines
Entitlement 1 - Destroy Deployment Approval Policy	Policy A (Destroy Deployment Approval Policy) on Destroy - Deployment action only	Action 1 (Run Destroy - Deployment action on Blueprint 1)	Approval requests are triggered for Blueprint 1 only	Blueprint 1, Blueprint 2, and Virtual Machine 1
		Action 2 (Run Destroy - Deployment action on the Blueprint 2)	Approval requests are triggered for Blueprint 2 only	Blueprint 2 and Virtual Machine 1
		Action 3 (Destroy - Virtual Machine action runs on Virtual Machine 1)	No Approval requests are triggered	Virtual Machine 1
Entitlement 2	Policy B (Destroy - Virtual Machine Policy) on Destroy - Virtual Machine action only	Action 1 (Run Destroy - Deployment action on Blueprint 1)	No Approval requests are triggered	Blueprint 1, Blueprint 2, and Virtual Machine 1
		Action 2 (Run Destroy - Deployment action on the Blueprint 2)	No Approval requests are triggered	Blueprint 2 and Virtual Machine 1
		Action 3 (Destroy - Virtual Machine action runs on Virtual Machine 1)	Approval requests are triggered for Virtual Machine 1 only	Virtual Machine 1
Entitlement 3	Policy A (Destroy Deployment Approval Policy) on Destroy - Deployment action and Policy B (Destroy - Virtual Machine Policy) on Destroy - Virtual Machine action	Action 1 (Run Destroy - Deployment action on Blueprint 1)	Approval requests are triggered for Blueprint 1 only	Blueprint 1, Blueprint 2, and Virtual Machine 1
		Action 2 (Run Destroy - Deployment action on the Blueprint 2)	Approval requests are triggered for Blueprint 2 only	Blueprint 2 and Virtual Machine 1
		Action 3 (Destroy - Virtual Machine action runs on Virtual Machine 1)	Approval requests are triggered for Virtual Machine 1 only	Virtual Machine 1

Example of an Approval Policy in Multiple Entitlements

If you apply an approval policy to an item that is used in multiple entitlements that are entitled to same users in a business group, the approval policy is triggered on the item even in the service where the approval policy is not explicitly applied in the entitlement.

For example, you create the following blueprints, services, approval policies, and entitlements.

Blueprints

- RHEL vSphere virtual machine

- QE Testing includes RHEL vSphere virtual machine
- QE Training includes RHEL vSphere virtual machine

Services

- The QE Testing blueprint is associated with the Testing service
- The QE Training blueprint is associated with the Training service

Entitlements

- Entitlement 1
- Entitlement 2

Table 3-69. Entitlement Configurations

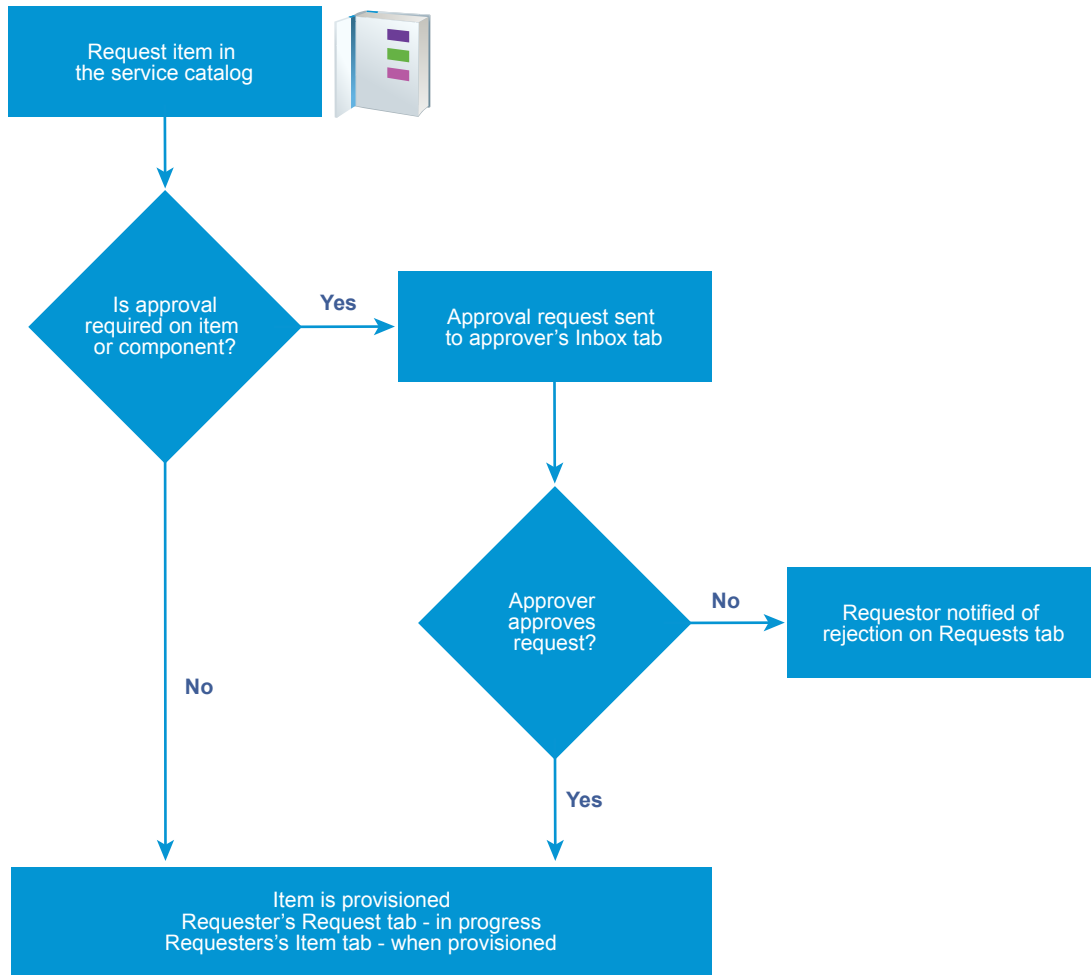

Entitlement Name	Business Group	Entitled Service	Entitled Item
Entitlement 1	QE	Testing	Catalog Item Request - Virtual Machine applied to Virtual Machine Component
Entitlement 2	QE	Training	

Results

When the user selects QE Training in the service catalog, the approval policy is triggered for RHEL vSphere virtual machine because it is a blueprint based on virtual machine component that is used in the QE Training blueprint.

Processing Approval Policies in the Service Catalog

When a user requests an item in the service catalog that has an approval policy applied, the request is processed by the approver and the requesting user similar to the following workflow

Create an Approval Policy

Tenant administrators and approval administrators can define approval policies and use them in entitlements. You can configure the approval policies with multiple levels for pre-approval and post-approval events.

If you modify a setting in a software component blueprint and an approval policy uses that setting to trigger an approval request, the approval policy might not work as expected. If you must modify a setting in a component, verify that your changes do not affect one or more approval policies.

Prerequisites

Log in to the vRealize Automation console as a **tenant administrator** or **approval administrator**.

Procedure

1 Specify Approval Policy Information

When you create an approval policy, define the approval policy type, name, description, and status.

2 Create an Approval Level

When you create an approval policy, you can add pre-approval and post-approval levels.

3 Configure the Approval Form to Include System and Custom Properties

You can add system and custom properties that appear on an approval form. You add these properties so that the approvers can change the values of system properties for machine resource settings such as CPU, lease, or memory, and custom properties before they complete an approval request.

4 Approval Policy Settings

When you create an approval policy, you configure various options that determine when an item requested by a service catalog users must be approved. The approval can be required before the request begins provisioning or after the item is provisioned but before it is released to the requesting user.

Specify Approval Policy Information

When you create an approval policy, define the approval policy type, name, description, and status.

Prerequisites

Log in to the vRealize Automation console as a **tenant administrator** or **approval administrator**.

Procedure

- 1 Select **Administration > Approval Policies**.
- 2 Click the **New** icon (+).
- 3 Select a policy type or software component.

Option	Description
Select an approval policy type	<p>Create an approval policy based on the policy request type.</p> <p>Select this option to define an approval policy that is applicable to all catalog items of that type. The request type can be a generic request, a catalog item request, or a resource action request.</p> <p>The available condition configuration options vary depending on the type. The more specific the type the more specific the configuration fields. For example, Service Catalog - Catalog Item Request provides only the fields that are common to all catalog item requests, but a Service Catalog - Catalog Item Request - Virtual Machine also includes the common options and options specific to virtual machines.</p> <p>The request type limits the catalog items or actions to which you can apply the approval policy.</p>
Select an item	<p>Create an approval policy based on a specific item.</p> <p>Select this option to define an approval policy that is applicable to specific items that are not available as individual items in the service catalog, only as part of a machine or other deployment. For example, software components.</p> <p>The available condition configuration fields are specific to the item and can be more detailed than the criteria offered for a policy type item.</p>
List	<p>Lists the available policy type or catalog items.</p> <p>Search or sort the columns to locate a specific item or type.</p>

- 4 Click **OK**.

- 5 Enter a name and, optionally, a description.
- 6 Select the state of the policy from the **Status** drop-down menu.

Option	Description
Draft	Saves the approval policy in an editable state.
Active	Saves the approval policy in a read-only state that you can use in an entitlement.
Inactive	Saves the approval policy in a read-only state that you cannot use in an entitlement until you activate the policy.

What to do next

Create the pre-approval and post-approval levels.

Create an Approval Level

When you create an approval policy, you can add pre-approval and post-approval levels.

You can create multiple approval levels for an approval policy. When a service catalog user requests an item to which an approval policy with multiple levels is applied, each the first level must be accepted before the approval request is sent to the next approver. See [Working with Approval Policies](#).

Prerequisites

[Specify Approval Policy Information](#).

Procedure

- 1 On the **Pre Approval** or **Post Approval** tab, click the **New** icon (+).
- 2 Enter a name and, optionally, a description.
- 3 Select an approval requirement.

Option	Description
Always Required	The approval policy is triggered for every request.
Required based on conditions	<p>The approval policy is based on one or more condition clauses.</p> <p>If you select this option, you must create the conditions. When this approval policy is applied to eligible services, catalog items, or actions in an entitlement, then the conditions are evaluated. If the conditions are true, then the request must be approved by the specified approver method before it is provisioned. If the conditions are false, then the request is provisioned without requiring an approval. For example, any requests for a virtual machine with 4 or more CPUs must be approved by the virtual infrastructure administrator.</p> <p>The availability of the fields on which to base the conditions is determined by the selected approval policy type or catalog item.</p> <p>When you enter a value for a condition, the values are case-sensitive.</p> <p>To configure more than one condition clause, select the Boolean operation for the clauses.</p>

4 Select the approvers.

Option	Action
Specific Users and Groups	Sends the approval request to the selected users.
Determine approvers from the request	Sends the approval request to the users based on the defined condition.
Use event subscription	Processes the approval request based on defined event subscriptions. The workflow subscription must be defined in Administration > Events > Subscriptions . The applicable workflow subscriptions are pre-approval and post-approval.

5 Indicate who must approve the request or action.

Option	Description
Anyone can approve	Only one of the approvers must approve before the request is processed. When the item is requested in the service catalog, requests for approval are sent to all approvers. If one approver approves the request, the request is approved and the request for approval is removed from the other approvers' inboxes.
All must approve	All of the specified approvers must approve before the request is processed.

6 Add properties to an approval form or save the level.

- To add properties to the approval form, click **System Properties** or **Custom Properties**.
- To save the level, click **OK**.

What to do next

To add properties to the approval form, see [Configure the Approval Form to Include System and Custom Properties](#).

Configure the Approval Form to Include System and Custom Properties

You can add system and custom properties that appear on an approval form. You add these properties so that the approvers can change the values of system properties for machine resource settings such as CPU, lease, or memory, and custom properties before they complete an approval request.

The available system properties depend on the approval policy type and how the blueprint is configured. For some properties, the configured field in the blueprint must include a minimum and maximum value before the property appears in the system properties list.

Custom properties can be added when you add the approval level. If a custom property is configured and included in a blueprint, the custom properties you add to the approval form overwrite any other instances of that custom property for example, in blueprints, property groups, or endpoints.

The approver can modify selected or configured properties in the approval form.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **approval administrator**.
- [Create an Approval Level](#).

Procedure

- 1 On the **Pre Approval** or **Post Approval** tab, click the **New** icon (+).
- 2 Click the **System Properties** tab.
- 3 Select the check box for each system property that you want the approver to configure during the approval process.
- 4 Configure the custom properties.

Add one or more custom properties that you want the approver to configure during the approval process.

- a Click the **Custom Properties** tab.
- b Click the **New** icon (+).
- c Enter the custom property values.

Option	Description
Name	Enter the property name.
Label	Enter the label that is presented to the approver in the approval form.
Description	Enter the extended information for the approver. This information appears as the field tooltip in the form.

- d Click **Save**.
- e To delete multiple custom properties, select the rows and click **Delete**.

- 5 Click **OK**.

What to do next

- Add additional pre-approval or post-approval levels.
- Save the approval policy. The policy must be active to apply to services, items, or actions in the **Entitlements**.

Approval Policy Settings

When you create an approval policy, you configure various options that determine when an item requested by a service catalog users must be approved. The approval can be required before the request begins provisioning or after the item is provisioned but before it is released to the requesting user.

Select **Administration > Approval Policies**. Click **New**.

■ [Approval Policy Type Settings](#)

The approval policy type determines how the approval policy is configured and to what items or actions you can apply it in the entitlement. When you add approval levels, the policy type or item affects which fields are available to create conditions for the approval levels.

- [Add Approval Policy Settings](#)

You configure the basic information about the approval policy, including the state to the policy, so that you can manage the policy.

- [Add Level Information to Approval Policy Settings](#)

An approval level includes the conditions that trigger an approval process when the service catalog user requests the item, and any system properties and customer properties that you want to include. When triggered, the approval requests are sent to the designated approvers.

- [Add System Properties to Approval Policy Settings](#)

You selected system properties that you want to add to the approval form and allow the approver to modify the value.

- [Add Custom Properties to Approval Policy Settings](#)

You configure custom properties that you want to add to the approval form to allow the approver to modify the value.

Approval Policy Type Settings

The approval policy type determines how the approval policy is configured and to what items or actions you can apply it in the entitlement. When you add approval levels, the policy type or item affects which fields are available to create conditions for the approval levels.

Select **Administration > Approval Policies**. Click **New**.

Table 3-70. Approval Policy Type Options

Option	Description
Select an approval policy type	<p>Create an approval policy based on the policy request type.</p> <p>Select this option to define an approval policy that is applicable to all catalog items of that type. The request type can be a generic request, a catalog item request, or a resource action request.</p> <p>The available condition configuration options vary depending on the type. The more specific the type the more specific the configuration fields. For example, Service Catalog - Catalog Item Request provides only the fields that are common to all catalog item requests, but a Service Catalog - Catalog Item Request - Virtual Machine also includes the common options and options specific to virtual machines.</p> <p>The request type limits the catalog items or actions to which you can apply the approval policy.</p>
Select an item	<p>Create an approval policy based on a specific item.</p> <p>Select this option to define an approval policy that is applicable to specific items that are not available as individual items in the service catalog, only as part of a machine or other deployment. For example, software components.</p> <p>The available condition configuration fields are specific to the item and can be more detailed than the criteria offered for a policy type item.</p>
List	<p>Lists the available policy type or catalog items.</p> <p>Search or sort the columns to locate a specific item or type.</p>

Add Approval Policy Settings

You configure the basic information about the approval policy, including the state to the policy, so that you can manage the policy.

To define the basic approval policy information, select **Administration > Approval Policies**. Click **New**. Select the policy type and click **OK**.

Table 3-71. Approval Policy Options

Option	Description
Name	Name that appears when applying the approval policy in an entitlement.
Description	Provide a verbose description of how the approval policy is constructed. This information will help you manage your approval policies.

Table 3-71. Approval Policy Options (Continued)

Option	Description
Status	<p>Possible values include:</p> <ul style="list-style-type: none"> ■ Draft. The approval policy is not available to apply in entitlements. After you make a policy active, you can never return it to draft. ■ Active. The approval policy is available to apply in entitlements. ■ Inactive. The approval policy is not available to apply in entitlements. If the policy has not been applied to entitlements and you make inactive, you can delete the policy but you cannot reactivate it. If the policy has been applied and you make inactive, the items to which it applies must be linked to a different policy or the items are unlinked. Unlinked items and actions are still entitled to users, but they do not have an applied approval policy.
Policy Type	<p>Displays the approval policy request type.</p> <p>If you selected a catalog item on which to base the approval policy, the associated request type is displayed.</p>
Item	<p>Displays the selected catalog item.</p> <p>If you selected a request type on which to base the approval policy, this field is blank.</p>
Last Updated By	Name of the user who made changes to the approval policy.
Last Updated On	Date of the last change to the approval policy.
Pre Approval Level	To require approval before the requested items is provisioned or the actions run, configure one or more conditions that trigger an approval process when the service catalog user requests the item.
Post Approval Level	<p>To require approval after the item is provisioned but before the provisioned or modified item is released to the requesting service catalog user, configure one or more conditions that trigger an approval process.</p> <p>For example, the virtual infrastructure administrator verifies that the virtual machine is in a workable state before releasing it to the service catalog user.</p>
View Linked Entitlements	<p>Displays all the entitlements where the approval policy is applied to services, catalog items, or actions. You can link the items in one entitlement to a different policy.</p> <p>This option is only available when you view an active approval policy.</p>

Add Level Information to Approval Policy Settings

An approval level includes the conditions that trigger an approval process when the service catalog user requests the item, and any system properties and customer properties that you want to include. When triggered, the approval requests are sent to the designated approvers.

To define the basic approval policy information, select **Administration > Approval Policies**. Click **New**. Select the policy type and click **OK**. On the Pre Approval or Post Approval tab, click the **New** icon (+). You prioritize levels based on the order that you want them processed. When the approval policy is triggered, if the first level of approval is rejected, the request is rejected.

Table 3-72. Level Information Options

Option	Description
Name	Enter a name. The level name appears when you are reviewing requests with approval policies.
Description	Enter a level description. For example, CPU>4 to VI Admin.
When is approval required?	Select when the approval policy is triggered.
Always required	The approval policy is triggered for every request. If you select this option and apply this approval policy to eligible services, catalog items, or actions in an entitlement, then the request must be approved by the specified approver method before it is provisioned. For example, all requests must be approved by the requesting user's manager.
Required based on conditions	The approval policy is based on one or more condition clauses. If you select this option, you must create the conditions. When this approval policy is applied to eligible services, catalog items, or actions in an entitlement, then the conditions are evaluated. If the conditions are true, then the request must be approved by the specified approver method before it is provisioned. If the conditions are false, then the request is provisioned without requiring an approval. For example, any requests for a virtual machine with 4 or more CPUs must be approved by the virtual infrastructure administrator. The availability of the fields on which to base the conditions is determined by the selected approval policy type or catalog item. When you enter a value for a condition, the values are case-sensitive. To configure more than one condition clause, select the Boolean operation for the clauses. <ul style="list-style-type: none"> ■ All of the following. The approval is triggered when all of the clauses are true. This is a Boolean AND operator between each clause. ■ Any of the following. The approval level is triggered when at least one of clauses is true. This is a Boolean OR operator between each clause. ■ Not the following. The approval level is triggered is none of the clauses are true. This is a Boolean NOT operator between each clause.
Approvers	Select the approver method.

Table 3-72. Level Information Options (Continued)

Option	Description
Specific Users and Groups	<p>Sends the approval request to the selected users.</p> <p>Select the users or user groups that must approve the service catalog request before it is provisioned or an action runs. For example, the request goes to the virtual infrastructure administrator group with Anyone can approve selected.</p>
Determine users from the request	<p>Sends the approval request to the users based on the defined condition.</p> <p>For example, if you are applying this approval policy across business groups and you want the business group manager to approve the request, select Business group > Consumer > Users > Manager.</p>
Use event subscription	<p>Processes the approval request based on defined event subscriptions.</p> <p>The workflow subscription must be defined in Administration > Events > Subscriptions. The applicable workflow subscriptions are pre-approval and post-approval.</p>
Anyone can approve	<p>Only one of the approvers must approve before the request is processed.</p> <p>When the item is requested in the service catalog, requests for approval are sent to all approvers. If one approver approves the request, the request is approved and the request for approval is removed from the other approvers' inboxes.</p> <p>If the first approver rejects the request, the requesting user is notified about the rejection and the approval request is removed from the approvers' inboxes.</p> <p>If the first approver approves and the approval request is open in the second approver's console, the approver is not allowed to submit the approval request. It was considered completed by the first approvers response.</p> <p>If you select Specific Users and Groups or Determine approvers from the request, and there is more than one approver, this is one of the additional options. If there is only one approver, this option to not apply.</p>
All must approve	<p>All of the specified approvers must approve before the request is processed.</p> <p>If you select Specific Users and Groups or Determine approvers from the request, and there is more than one approver, this is one of the additional options. If there is only one approver, this option to not apply.</p>

Add System Properties to Approval Policy Settings

You selected system properties that you want to add to the approval form and allow the approver to modify the value.

For example, for a virtual machine approval, select CPU if you want to allow the approver to modify a request for 6 CPUs to 4 CPUs.

To select system properties, select **Administration > Approval Policies**. Click **New**. Select the policy type and click **OK**. On the Pre Approval or Post Approval tab, click the **New** icon () and click the **System Properties** tab.

Table 3-73. System Properties Options

Option	Description
Properties	<p>The list of available system properties depends on the selected request type or catalog item, and whether system properties exist for the item.</p> <p>Some properties are available only when the blueprint is configured in a particular way. For example, CPUs. The blueprint to which you are applying the approval policy with the CPU system property must be configured as a range. For example, CPU minimum is 2 and the maximum is 8.</p>

Add Custom Properties to Approval Policy Settings

You configure custom properties that you want to add to the approval form to allow the approver to modify the value.

For example, for a virtual machine approval, add **VMware.VirtualCenter.Folder** if you want to allow the approver to specify the folder to which the machine is added in vCenter Server.

You can also add a custom property that is specific to this approval policy form.

To select system properties, select **Administration > Approval Policies**. Click **New**. Select the policy type and click **OK**. On the Pre Approval or Post Approval tab, click the **New** icon () and click the **Custom Properties** tab.

Table 3-74. Custom Properties

Option	Description
Name	Enter the property name.
Label	Enter the label that is presented to the approver in the approval form.
Description	<p>Enter the extended information for the approver.</p> <p>This information appears as the field tooltip in the form.</p>

Modify an Approval Policy

You cannot modify an active or inactive approval policy. You must create a copy of the original policy and replace the policy that is not producing the required results. Active and inactive approval policies are read-only. You can modify approval policies that are in a draft state.

When you make the copy of the approval policy, the new policy is based on the original policy type. You can edit all of the attributes except the policy type. You do this when you want to modify the approval levels to modify, add, or remove levels, or to add system or custom properties to the forms.

You can create pre-approval and post-approval levels. For instructions about creating an approval level, see [Create an Approval Level](#).

Prerequisites

Log in to the vRealize Automation console as a **tenant administrator** or **approval administrator**.

Procedure

- 1 Select **Administration > Approval Policies**.
- 2 Select the row of the approval policy to copy.
- 3 Click the **Copy** icon ().
A copy of the approval policy is created.
- 4 Select the new approval policy to edit.
- 5 Enter a name in the **Name** text box.
- 6 (Optional) Enter a description in the **Description** text box.
- 7 Select the state of the policy from the **Status** drop-down menu.

Option	Description
Draft	Saves the approval policy in an editable state.
Active	Saves the approval policy in a read-only state that you can use in an entitlement.
Inactive	Saves the approval policy in a read-only state that you cannot use in an entitlement until you activate the policy.

- 8 Edit the pre-approval and post-approval levels.
- 9 Click **OK**.

You created a new approval policy based on an existing approval policy.

What to do next

Apply the new approval policy in an entitlement. See [Entitle Users to Services, Catalog Items, and Actions](#).

Deactivate an Approval Policy

When you determine that an approval policy is outdated, you can deactivate the policy so that it is not available during provisioning.

To deactivate an approval policy, you must assign a new policy for each entitlement to which the approval policy is currently applied.

You can later reactivate a deactivated approval policy, or you can delete a deactivated policy.

Prerequisites

Log in to the vRealize Automation console as a **tenant administrator** or **approval administrator**.

Procedure

- 1 Select **Administration > Approval Policies**.

- 2 Click the approval policy name.
- 3 Click **View Linked Entitlements**.
 - a In the **Replace All With** drop-down menu, select the new approval policy.

If the list includes more than one entitlement, the new approval policy is applied to all the listed entitlements.
 - b Click **OK**.
- 4 After you verify that no entitlements that are linked to the approval policy, select **Inactive** from the Status drop-menu.
- 5 Click **OK**.
- 6 To delete an approval policy, select the row containing the inactive policy.
 - a Click **Delete**.
 - b Click **OK**.

The approval policy is unlinked from any entitlements where it is used and deactivated. You can later reactivate and reapply it to items in an entitlement.

What to do next

If you no longer need the approval policy, you can delete it. See [Delete an Approval Policy](#).

Delete an Approval Policy

If you have approval policies that you deactivated and do not need, you can delete them from vRealize Automation.

Prerequisites

- Unlink and deactivate approval policies. See [Deactivate an Approval Policy](#).
- Log in to the vRealize Automation console as a **tenant administrator** or **approval administrator**.

Procedure

- 1 Select **Administration > Approval Policies**.
- 2 Select the row containing the inactive policy.
- 3 Click **Delete**.
- 4 Click **OK**.

The approval policy is deleted.

Scenario: Create and Apply CentOS with MySQL Approval Policies

As the tenant administrator for the development and quality engineering business group, you want to apply strict governance to catalog item requests. Before your users can provision the CentOS with MySQL catalog item, you want your vSphere virtual infrastructure administrator to approve the machine request and you want your software manager to approve the software request.

You create and apply one approval policy for the vSphere CentOS with MySQL service catalog request to require approval for the machine by a vSphere virtual infrastructure administrator based on specific conditions, and another approval policy for the MySQL Software component to require approval by your software manager for every request.

Approval administrators can only create the approvals, and a business group managers can apply them to entitlements. As a tenant administrator, you can both create the approvals and apply them to entitlements.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator**. Only a tenant administrator can both create and apply approval policies.
- Ensure that the CentOS with MySQL catalog item is included in a service. See [Scenario: Make the CentOS with MySQL Application Blueprint Available in the Service Catalog](#).

Scenario: Create a CentOS with MySQL Virtual Machine Approval Policy

As the tenant administrator you want to ensure that the development and quality engineering group receives virtual machines that are properly provisioned in your environment, so you create an approval policy that requires pre approval for certain types of requests.

Because the CentOS with MySQL virtual machine consumes vCenter Server resources, you want the vSphere virtual infrastructure administrator to approve requests when the requested memory is more than 2048 MB or more than 2 CPUs to ensure that the resources are consumed wisely. You also you give the approver the ability to modify the requested CPU and memory values before approving a request.

Procedure

- 1 Select **Administration > Approval Policies**.
- 2 Create an approval policy for virtual machine provisioning.
 - a Click the **New** icon (.
 - b Select **Select an approval policy type**.
 - c In the list, select **Service Catalog - Catalog Item Request - Virtual Machine**.

- d Click **OK**.
- e Configure the following options:

Option	Configuration
Name	Enter CentOS on vSphere CPU or Memory VM .
Description	Enter Requires VI Admin approval for CPU>2 or Memory>2048 .
Status	Select Active .

- 3 On the **Pre Approval** tab, click the **Add** icon (+).
- 4 Configure the **Level Information** tab with the triggering criteria and the approval actions.
 - a In the **Name** text box, enter **CPU>2 or Memory>2048 – VI Admin**.
 - b In the **Description** text box, enter **VI Admin approval for CPU and Memory**.
 - c Select **Required based on conditions**.
 - d In the Clause drop-down list, select **Any of the following**.
 - e In the new Clause drop-down list, select **CPUs** and configure the clause with the values **CPU > 2**.
 - f Click **Add expression** and configure the clause with the values **Memory (MB) > 2048**.
 - g Select **Specific Users and Groups**.
 - h Enter the name of the vSphere virtual infrastructure administrator or administrator group in the search text box and click the search icon (🔍).
 - i Select the user or group.
 - j Select **Anyone can approve**.

The request only needs one virtual infrastructure administrator to verify the resources and approve the request.
- 5 Click the **System Properties** tab and select the properties that allow the approver to modify the requested CPU and Memory values before approving a request.
 - a Select the **CPUs** and **Memory (MB)** check boxes.
 - b Click **OK**.

- 6 Click **OK**.

You created an approval policy for virtual machine requests, but you still want to create an approval for the MySQL component. Until you apply the policies to an entitlement, no approvals are triggered.

Scenario: Create a MySQL Software Component Approval Policy

As the tenant administrator, your software managers asked you to create and apply approval policies for MySQL installations to track licensing usage. You create a policy to notify the software license manager whenever the MySQL for Linux Virtual Machines Software component is requested.

In some environments you might need this type of approval because license keys must be provided by the software manager. In this scenario, you only need the software manager to track and approve the request. After you create the approval policy, you apply the policy to the MySQL for Linux Virtual Machines catalog item. This approval policy is very specific and can only be applied to the MySQL for Linux Virtual Machines Software component in the entitlements.

Procedure

- 1 Select **Administration > Approval Policies**.
- 2 Create an approval policy for the MySQL Software component.
 - a Click the **New** icon (+).
 - b Select **Select an item**.
 - c Select **MySQL for Linux Virtual Machines**.
 - d Click **OK**.
 - e Configure the following options:

Option	Configuration
Name	Enter MySQL tracking approval.
Description	Enter Approval request sent to software manager.
Status	Select Active.

- 3 On the **Pre Approval** tab, click the **Add** icon (+).
- 4 Configure the **Level Information** tab with the triggering criteria and the approval actions.
 - a In the **Name** text box, enter **MySQL software deployment notice**.
 - b In the **Description** text box, enter **Software mgr approval of software installation**.
 - c Select **Always required**.
 - d Select **Specific Users and Groups**.
 - e Enter the name of the software manager in the search text box and click the search icon (🔍) and select the user.
 - f Select **Anyone can approve**.

The request only needs one software manager to approve the request.

Click **OK**.

- 5 Click **OK**.

You created the approval policies for virtual machines and for MySQL for Linux Virtual Machines Software components. Until you apply the approval policies to an entitlement, no approvals are triggered.

Scenario: Apply Approval Policies to CentOS with MySQL Components

As the tenant administrator, you can create approval policies and entitlements. You modify the Dev and QE entitlement to apply the approval policies that you created so that approvals are triggered when a service catalog user requests the item.

While it might be easier to entitle the entire catalog service to your business group, it does not allow you to have the same control and governance as when you create individual entitlements for catalog items. For example, if you entitle users to a service, they can request any catalog items that are in the service and all items that are added to the service in the future. It also means that you can only use very high-level approval policies that apply to every catalog item in the service, such as always requiring approval from a manager. If you choose to entitle catalog items individually, you can create and apply very specific approval policies for each item and tightly control who can request which items in the service. If you choose to entitle the individual components of catalog items individually, you can have even greater control.

If you do not know what approval policies you want to apply to items in an entitlement, you can return later and apply them. In this scenario, you apply different approval policies to two components of the same published application blueprint.

Procedure

- 1 Select **Administration > Catalog Management > Entitlements**.
- 2 Click the **Dev and QE Entitlement**.
- 3 Click the **Items and Approvals** tab.
- 4 Add the CentOS with MySQL machine and apply the approval policy.
 - a Click the **Add Items** icon () beside the Entitled Items heading.
 - b Select the **CentOS with MySQL** check box.
 - c Click the **Apply this policy to selected items** drop-down arrow.
The CentOS on vSphere CPU and Memory policy is not in the list.
 - d Click **Show all** and click the down-arrow to view all approval policies.
 - e Select **CentOS on vSphere CPU and Memory [Service Catalog - Catalog Item Request - Virtual Machine]**.

The vSphere CentOS machine is a machine blueprint in an application blueprint. Review the policy names so that you select the one that is appropriate to your catalog item type. If you apply the wrong policy, the approval policy fails or triggers approval requests based on incorrect conditions.

 - f Click **OK**.

- 5 Add the MySQL for Linux Virtual Machine software component as an item and apply an approval policy to the MySQL item.

- a Click the **Add Catalog Items and Components** icon () beside the Entitled Catalog Items and Components heading.
- b In the **Catalog Items and Components** drop-down menu, select **No**.
Software components are always associated with a machine. They are not available to individually request in the service catalog.
- c Select the **MySQL for Linux Virtual Machines** check box.
- d Click the **Apply this policy to selected items** drop-down arrow.
- e Select **MySQL tracking approval [Service Catalog - Catalog Item Request - Software Component]**.
You do not need the advanced option because the approval policy was created for this specific software component, which is added to a virtual machine.
- f Click **OK**.

- 6 Add actions that the users can run on the provisioned machine.

Approval policies are not applied to actions in this scenario.

- a Click the **Add Actions** icon () beside the Entitled Actions heading.
- b Select the following actions.

Name / Type	Description
Create Snapshot / Virtual Machine	Creates a snapshot of the virtual machine, including the installed software. Allows the developers to create snapshots to which they can revert during development.
Destroy / Deployment	Destroys the entire provisioned blueprint, not just the machine. Use this action to avoid orphaned components.
Power Off / Machine	Turns the virtual machine off.
Power On / Machine	Turns the virtual machine on.
Revert to Snapshot / Virtual Machine	Reverts to a previously created snapshot.

- c Click **OK**.

- 7 Click **Finish**.

This entitlement allows you to require different approvals on different blueprint components.

What to do next

Request the CentOS with MySQL item in the service catalog as a member of the business group to verify that the entitlement and the approvals are behaving as expected.

Request Machine Provisioning By Using a Parameterized Blueprint

When you request machine provisioning for a vSphere machine blueprint that has been designed to include the size or image component profiles, you specify provisioning setting by selecting an available value set.

When you request provisioning from the catalog, you can select from available value set choices for the Size and Image component profiles. When you choose one of the value sets, its corresponding property values are then bound to the request.

The component profile value set is applied to all vSphere machines in a cluster.

For information about component profile configuration, see [Understanding and Using Blueprint Parameterization](#).

Prerequisites

- Define value sets for Size or Image component profiles. See and in *Custom Properties Reference*.
- Create a blueprint that contains a vSphere machine component that contains an Image or Size component profile. See [Configure a Machine Blueprint](#) and [vSphere Machine Component Settings](#).
- Publish the blueprint to the catalog. See [Publish a Blueprint](#).
- Configure the blueprint in the catalog. See [Checklist for Configuring the Service Catalog](#) and [Examples of Approval Policies Based on the Virtual Machine Policy Type](#).

Procedure

- 1 Click **Catalog**.
- 2 Select the catalog service to request and click **Request**.

- 3 Select the vSphere machine component to provision and specify the number of instances to provision.

- 4 Select an image value set option from the **Image** drop-down menu.

New Request

Windows
Generic Windows Blueprint

vSphere (vCenter) Machine: windows-machine

General Storage

*Instances: 1 (Select 1-10)

Description:

*Image: Windows 10

*Size: Windows 10

Windows 2008 R2

Windows 2012 R2

- 5 Select a size value set option from the **Size** drop-down menu.

New Request

Windows
Generic Windows Blueprint

vSphere (vCenter) Machine: windows-machine

General Storage

*Instances: 1 (Select 1-10)

Description:

*Image: Windows 10

*Size: Small

Large

Medium

Small

- 6 Click **Submit**.

What to do next

The value sets that you defined for the Size and Image component profiles are now available on the **Image** and **Size** drop-down menus on the **Catalog** tab in the catalog provisioning request form.

Scenario: Make the CentOS with MySQL Application Blueprint Available in the Service Catalog

As the tenant administrator, you requested that your blueprint architects create a catalog item to deliver MySQL on CentOS virtual machines for your development and quality engineering group to run test cases. Your software architect has informed you that the catalog item is ready for users. To make the item available to your business users, you need to associate the blueprints and Software component with a catalog service and then entitle the business group members to request the catalog item.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator** or **catalog administrator**.
- Publish a blueprint to deliver MySQL on vSphere CentOS virtual machines. See *Installing and Configuring vRealize Automation for the Rainpole Scenario*.
- If you create blueprints in a development environment, import your blueprint into your production environment. See [Exporting and Importing Blueprints and Content](#).
- Create a reservation to allocate vSphere resources to your Dev and QE business group. See [Create a Reservation for Hyper-V, KVM, SCVMM, vSphere, or XenServer](#).

Procedure

1 Scenario: Create a Development and Quality Engineering Catalog Service

As the tenant administrator, you want to create a separate catalog service for your development and quality engineering group so your other groups, such as finance and human resources, don't see the specialized catalog items. You create a catalog service called Dev and QE Service to publish all the catalog items development and engineering need to run their test cases.

2 Scenario: Add CentOS with MySQL to Your Dev and QE Service

As the tenant administrator, you want to add the CentOS with MySQL catalog item to the Dev and QE service.

3 Scenario: Entitle Users to Request Dev and QE Service Items as a Catalog Item

As the tenant administrator, you create a Dev and QE entitlement and add the catalog items and some relevant actions so your development and quality engineering users can request the CentOS with MySQL catalog item, and run actions against the machine and the deployment.

Scenario: Create a Development and Quality Engineering Catalog Service

As the tenant administrator, you want to create a separate catalog service for your development and quality engineering group so your other groups, such as finance and human resources, don't see the specialized catalog items. You create a catalog service called Dev and QE Service to publish all the catalog items development and engineering need to run their test cases.

Procedure

- 1 Select **Administration > Catalog Management > Services**.
- 2 Click the **New** icon ().
- 3 Enter the name **Dev and QE Service** in the **Name** text box.
- 4 Enter the description **Dev and QE application catalog items for test cases** in the **Description** text box.
- 5 Select **Active** from the **Status** drop-down menu.
- 6 As the catalog administrator who is creating the service, use the search option to add your name as the Owner.
- 7 Add the Support Team custom user group.

For example, add a custom user group that includes the IaaS architects and software architects so that you and the service catalog users have someone to contact if you encounter problems provisioning the catalog items.
- 8 Click **OK**.

You created and activated a Dev and QE catalog service, but it doesn't contain any catalog items yet.

Scenario: Add CentOS with MySQL to Your Dev and QE Service

As the tenant administrator, you want to add the CentOS with MySQL catalog item to the Dev and QE service.

Procedure

- 1 Select **Administration > Catalog Management > Services**.
- 2 Select the Dev and QE Service row in the **Services** list and click **Manage Catalog Items**.
- 3 Click the **New** icon ()
- 4 Select **CentOS with MySQL**.

Only published blueprints and components that are not yet associated with a service appear in the list. If you do not see the blueprint, verify that it was published or that it is not included in another service.

- 5 Click **OK**.
- 6 Click **Close**.

You published the CentOS with MySQL catalog item to the Dev and QE service, but until you entitle users to the item or the service, no one can see or request the item.

Scenario: Entitle Users to Request Dev and QE Service Items as a Catalog Item

As the tenant administrator, you create a Dev and QE entitlement and add the catalog items and some relevant actions so your development and quality engineering users can request the CentOS with MySQL catalog item, and run actions against the machine and the deployment.

In this scenario, you entitle the service because you want users to be entitled to any future catalog items that are added to this service. You also want to allow your users to manage their provisioned deployment, so you add actions like power on and off, snapshot, and destroy deployment to the entitlement.

Procedure

- 1 Select **Administration > Catalog Management > Entitlements**.
- 2 Click the **New** icon ()
- 3 Configure the details.
 - a Enter the name **Dev and QE Entitlement** in the **Name** text box.
 - b In the **Status** drop-down menu, select **Active**.
 - c In the **Business Group** drop-down menu, select the **Dev and QE** group.

- d In the Users and Groups area, add one or more users.

Add yourself only, unless you are certain that the blueprint is working as intended. If it is, you can add individual users and you can add custom user groups.

- e Click **Next**.

4 Add the service.

Although you are adding the CentOS and MySQL catalog items separately, adding the service ensures that any addition items that you add to the service at a later date are available to the business group members in the service catalog.

- a Click the **Add Services** icon () beside the Entitled Services heading.
- b Select **Dev and QE Service**.
- c Click **OK**.

Dev and QE service is added to the Entitled Services list.

5 Add actions.

- a Click the **Add Actions** icon () beside the Entitled Actions heading.
- b Click the Type column header to sort the list.

Select the following actions based on type. These actions are useful to the development and quality engineering users working with their test case machines, and are the only actions that you want these business group members to use.

Type	Action Name
Machine	Power On
Machine	Power Off
Virtual Machine	Create Snapshot
Virtual Machine	Revert To Snapshot
Deployment	Destroy
	The deployment destroy action destroys the entire deployment and not just the virtual machine.

- c Click **OK**.

The five actions are added to the Entitled Actions list.

6 Click **Finish**.

You added the CentOS with MySQL catalog item to your new Dev and QE catalog service and entitled your business group members to request and manage the item.

What to do next

After you verify your work by provisioning the CentOS with MySQL catalog item, you can add additional users to the entitlement to make the catalog item publicly available to your development and quality engineering users. If you want to further govern the provisioning of resources in your environment, you can create approval policies for the MySQL Software component and the CentOS for Software Testing machine. See [Scenario: Create and Apply CentOS with MySQL Approval Policies](#).

Managing Deployed Catalog Items

You can view and act on provisioned deployments, including machines, load balancers, networks, and other deployment resources.

Running Actions for Provisioned Resources

The actions that are available for a provisioned resource depend on the type of resource, how the action was configured and made available for provisioned items, and the operational state of the item.

The configured actions that are available for a provisioned machine or deployment appear in the **Actions** menu for the selected resource on the **Items** tab.

If the item was provisioned by IaaS using an IaaS machine blueprint, the list of available actions is determined by what was selected on the **Actions** tab for the machine type component when the blueprint was created, and then by what is applicable based on machine type or state.

If the item was provisioned using an XaaS blueprint, the resource actions must be created, published, and entitled in the same service that is used to provision the item. The list of available actions is determined by the item type and the current state of the item.

The available actions for an item that was provisioned as an IaaS machine might also include XaaS resource actions if the actions are mapped to the item.

Action Menu Commands for Provisioned Resources

Actions are changes that you can make to provisioned resources. The vRealize Automation actions are used to manage the life cycle of the resources.

The commands on the **Action** menu for a provisioned resource include the actions specified on the blueprint and might include custom menu operations created by your service architects. The available actions depend on how your business group manager or tenant administrator configured the entitlement that contains the resource on which the actions run.

You should not manage vRealize Automation-administered NSX objects outside of vRealize Automation. For example, if you modify the member port of a deployed NSX load balancer in NSX, rather than in vRealize Automation, then NSX data collection breaks association between the deployed machine and its otherwise associated load balancer member pool. Scale in and scale out operations also produce unexpected results if a deployed load balancer member port is changed outside of vRealize Automation.

Table 3-75. Action Menu Commands

Action	Resource Type	Description
Associate Floating IP	Machine (OpenStack)	Associate a floating IP address with an OpenStack machine.
Cancel Reconfigure	Machine	Cancel a running reconfiguration action.
Change Lease	Deployment and Machine	Change the number of days remaining in the lease for either a specific machine or for all resources included in a deployment. If you do not provide a value, the lease does not expire.
Change Owner	Deployment	<p>Change the owner of the deployment and all the included resources. Only Business group managers and support users can change the ownership of a deployment.</p> <p>The machine must be in the On, Off, or Active state when you initiate the change owner action or the action fails with the following message:</p> <p>The action is invalid for the machine.</p>
Connect using VMRC	Machine	<p>Connect to the virtual machine using a VMRC 8.x application.</p> <p>To use this action, the VMRC application must be installed on the local system of the service catalog user who is running the action.</p> <p>For installation and user instructions, see VMware Remote Console Documentation. To download, see Download VMware Remote Console.</p> <p>The VMRC 8.x replaces the previous VMware Remote Console.</p>
Connect to remote console	Machine	<p>Connect to the selected machine using VMware Remote Console.</p> <p>The virtual machine console appears in the browser. The VMRC 8.x replaces the VMware Remote Console.</p>

Table 3-75. Action Menu Commands (Continued)

Action	Resource Type	Description
Connect using Console Ticket	Machine (OpenStack and KVM)	Connect to the OpenStack or KVM virtual machine using a console ticket for a VMware Remote Console connection.
Connect using ICA	Machine (Citrix)	Connect to the Citrix machine using the Independent Computing Architecture.
Connect using RDP	Machine	Connect to the machine by using Microsoft Remote Desktop Protocol.
Connect using SSH	Machine	<p>Connect to the selected machine by using SSH.</p> <p>The Connect Using SSH option requires that your browser has a plug-in that supports SSH, for example the FireSSH SSH terminal client for Mozilla Firefox and Google Chrome. When the plug-in is present, selecting Connect Using SSH displays an SSH console and prompts for your administrator credentials.</p> <p>To use this action, the <code>Machine.SSH</code> custom property must be included and set to true in the blueprint's machine component in either a property group or individual custom property.</p>
Connect using Virtual Desktop	Machine	Connect to the selected machine using Microsoft virtual desktop.
Create Snapshot	Virtual Machine	Create a snapshot of the virtual machine. If you are allowed only two snapshots and you already have them, this command is not available until you delete a snapshot.
Delete Snapshot	Virtual Machine	Delete a snapshot of the virtual machine.

Table 3-75. Action Menu Commands (Continued)

Action	Resource Type	Description
Destroy	Cloud Machine, Deployment, Virtual Machine, and NSX Edge	<p>Immediately destroy a provisioned resource. You must run this action to destroy XaaS resources, even if they are part of a deployment you are destroying. Other resources are destroyed when their lease or their archival period ends.</p> <p>Except for XaaS, destroying components of a deployment is not a best practice. Use the scale in action to reduce the number of machines in your deployment, or destroy the entire deployment.</p> <p>The Destroy action is not available for the following deployment situations:</p> <ul style="list-style-type: none"> ■ physical machine deployments ■ deployments with an NSX existing network or NSX existing security resource ■ deployments with an NSX on-demand load balancer resource <p>Because an NSX load balancer is property of an on-demand NSX edge, when an NSX edge is destroyed, the load balancer resource is also destroyed and resources are released. When a machine tier that is load balanced is destroyed, it is removed from the load balancer pool on the respective NSX edge.</p> <p>Business group administrators can choose to force destroy a deployment after a failed destroy request. Force destroy instructs vRealize Automation to ignore failures to destroy individual resources while destroying the</p>

Table 3-75. Action Menu Commands (Continued)

Action	Resource Type	Description
		<p>deployment. For more information on using force destroy, see Force Destroy a Deployment After a Failed Destroy Request.</p> <hr/> <p>Note Storage and memory that are assigned to a provisioned machine by a reservation are released when the machine to which they are assigned is deleted in vRealize Automation by the Destroy action. The storage and memory are not released if the machine is deleted in the vCenter Server.</p> <hr/> <p>When destroying a deployment that contains an Amazon machine component, all EBS volumes that were added to the machine during its life cycle are detached, rather than destroyed. vRealize Automation does not provide an option for destroying the EBS volumes.</p>
Destroy Existing Network	Existing Network	Destroy the network.
Destroy VMWare NSX Load Balancer	VMWare NSX Load Balancer	Destroy the NSX load balancer.
Destroy VMWare NSX Network	VMWare NSX Network	Destroy the NSX network.
Destroy VMWare NSX Security Group	VMWare NSX Security Group	Destroy the NSX security group.
Destroy VMWare NSX Security Tag	VMWare NSX Security Tag	Destroy the NSX security tag.
Disassociate Floating IP	Machine (Openstack)	Remove the floating IP from the Openstack machine.
Execute Reconfigure	Machine	Override a scheduled reconfiguration, or rerun or reschedule a failed reconfiguration.
Expire	Deployment and Machine	Terminate the deployment or machine lease for all resources included in the deployment.
Export Certificate	Machine	Export the certificate from a Cloud machine.
Get Expiration Reminder	Machine	Downloads a calendar event file for the current lease expiration date.

Table 3-75. Action Menu Commands (Continued)

Action	Resource Type	Description
Install Tools	Machine	Install VMware Tools on a vSphere virtual machine.
Power Cycle	Machine	Power off the machine, then power it back on.
Power Off	Machine	Power off the machine without shutting down the guest operating system.
Power On	Machine	Power on the machine. If the machine was suspended, normal operation resumes from the point at which the machine was suspended.
Reboot	Machine	Reboot the guest operating system on a vSphere virtual machine. VMware Tools must be installed on the machine to use this action.
Reconfigure	Machine	<p>A business group manager, support user, or machine owner can perform the following reconfigure actions for the selected vSphere machine:</p> <ul style="list-style-type: none"> ■ Change description ■ Change CPU, memory, network, and disk settings ■ Add, edit, and delete custom properties and property groups ■ Add, edit, or delete security tags and security groups ■ Add, edit, reorder, or delete NAT port forwarding rules ■ Reconfigure shutdown ■ Change machine owner (available for business group managers and support users only) <p>You cannot change a storage reservation policy if doing so would change the storage profile on a disk.</p>

Table 3-75. Action Menu Commands (Continued)

Action	Resource Type	Description
Reconfigure	Load Balancer	<p>An entitled machine owner, support user, tenant administrator, or business group manager can change any of the settings in a virtual server and can add or remove virtual servers in the NSX load balancer:</p> <p>For information about virtual server settings in the load balancer, see Add an On-Demand Load Balancer Component.</p>
Register VDI	Virtual Machine (XenServer)	Register the virtual disk image on XenServer items.
Reprovision	Machine	<p>Destroys the machine, then initiates the provisioning workflow to create a machine with the same name.</p> <p>When you request that a machine be reprovisioned, a known issue might cause vRealize Automation to display the reprovisioning status as Complete in the catalog, when the actual state is In Progress. After you submit a request to reprovision a machine, you can use any of the following sequences to check the status of the reprovisioned machine:</p> <ul style="list-style-type: none"> ■ Infrastructure > Managed Machines ■ Items > Item Details ■ Administration > Events > Event Logs <p>Note You cannot reprovision an Amazon machine.</p> <p>For related information, see the VMware Knowledge Base article Reprovisioned machine tasks ... (2065873) at http://kb.vmware.com/kb/2065873.</p>
Revert Snapshot	Virtual Machine	Revert to a previous snapshot of the machine. You must have an existing snapshot to use this action.

Table 3-75. Action Menu Commands (Continued)

Action	Resource Type	Description
Scale In	Deployment	<p>Destroy unneeded instances of machines in your deployment to adjust to reduced capacity requirements. Machine components and any software components installed on them are destroyed. Dependent software components and networking and security components are updated for the new deployment configuration. XaaS components are not scalable and are not updated during scale operations.</p> <p>You can try to repair partially successful scale operations by attempting to scale the deployment again. However, you cannot scale a deployment to its current size, and fixing a partially successful scale this way does not deallocate the dangling resources. You can view the request execution details screen and find out which tasks failed on which nodes to help you decide whether to fix the partially successful scale with another scale operation. Failed and partially successful scale operations do not impact the functionality of your original deployment, and you can continue to use your catalog items while you troubleshoot any failures.</p>

Table 3-75. Action Menu Commands (Continued)

Action	Resource Type	Description
Scale Out	Deployment	<p>Provision additional instances of machines in your deployment to adjust to expanding capacity requirements. Machine components and any software components installed on them are provisioned. Dependent software components and networking and security components are updated for the new deployment configuration. XaaS components are not scalable and are not updated during scale operations.</p> <p>You can try to repair partially successful scale operations by attempting to scale the deployment again. However, you cannot scale a deployment to its current size, and fixing a partially successful scale this way does not deallocate the dangling resources. You can view the request execution details screen and find out which tasks failed on which nodes to help you decide whether to fix the partially successful scale with another scale operation. Failed and partially successful scale operations do not impact the functionality of your original deployment, and you can continue to use your catalog items while you troubleshoot any failures.</p>
Shutdown	Machine	Shut down the guest operating system and power off the machine. VMware Tools must be installed on the machine to use this action.
Suspend	Machine	Pause the machine so that it cannot be used and does not consume any system resources other than the storage it is using.
Unregister	Machine	Remove the machine from the inventory without destroying it. Unregistered machines are not usable.
Unregister VDI	Virtual Machine (XenServer)	Unregister the virtual disk image on XenServer items.

Configure a Metrics Provider

You can configure vRealize Automation to use vRealize Operations Manager health and resource metrics for vSphere virtual machines.

For more information about vRealize Operations Manager health badges and metrics, see the vRealize Operations Manager documentation.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator**, **business group manager**, or **machine owner**.
- Create a vRealize Operations Manager user account with view and resource metrics query privileges for all vSphere servers that you integrate with vRealize Automation.
- Create vRealize Operations Manager adapter instances for all vSphere servers you add as endpoints in vRealize Automation. For information about creating adapter instances, see the vRealize Operations Manager documentation.

Procedure

- 1 Select **Administration > Reclamation > Metrics Provider**.
- 2 Select a metrics provider.

Option	Description
(Default) vRealize Automation metrics provider	If you do not have a vRealize Operations Manager instance, vRealize Automation provides basic machine metrics.
vRealize Operations Manager endpoint	Provide connection information for the vRealize Operations Manager instance you want to use as your metrics provider for vSphere virtual machines.

- 3 Click **Test Connection**.
- 4 Click **Save**.

Tenant administrators, machine owners, and business group managers of the group in which the machine resides can view health badges and health alerts on the item details pages for vSphere virtual machines. They can also view vRealize Operations Manager metrics and health badges when they filter by the platform type vSphere on the reclamations page.

What to do next

[Send Reclamation Requests](#).

Send Reclamation Requests

You can view and manage deployments and send reclamation requests to deployment owners. A reclamation request specifies a new lease length in days, the amount of time given for a deployment owner's response, and which machines to target for reclamation.

Prerequisites

- Log in to the vRealize Automation console as a **tenant administrator**.
- (Optional) To see health badges or view metrics provided by vRealize Operations Manager, see [Configure a Metrics Provider](#).

Procedure

- 1 Select **Administration > Reclamation > Deployments**.

2 Find virtual machine deployments that match your search criteria.

You must select platform type vSphere to view metrics provided by vRealize Operations Manager.

- a Click the **Advanced Search** down arrow to open the search box.
- b Enter or select one or more search values.

Option	Action
Virtual Machine name contains	Enter one or more characters in the text box to find virtual machine names that match.
Owner name contains	Enter a name in the text box to find owner names that match.
Business group names contains	Enter a name in the text box to find business group names that match.
Platform Type	Select a platform type from the drop-down menu. Select vSphere to view metrics provided by vRealize Operations Manager. Required for vRealize Operations Manager.
Power State	Select a power state value from the drop-down menu to find virtual machines with a matching power state.
Expiration date between	Click the calendar icons and select start and end dates to find expiration dates inside the range.
CPU usage	Select a value from the drop-down menu to find virtual machines with High CPU use, above 80%, Low CPU use below 5%, or None, no value. If you are querying vRealize Operations Manager metrics, you cannot use this filter to query, and you cannot sort results by CPU usage.
Memory usage	Select a value from the drop-down menu to find virtual machines with High Memory use, above 80%, Low Memory use, below 10%, or None, no value. If you are querying vRealize Operations Manager metrics, you cannot use this filter to query, and you cannot sort results by memory usage.
Disk usage	Select a value from the drop-down menu to find virtual machines with Low Hard Disk use, less than 2 KBs per second or None, no value. If you are querying vRealize Operations Manager metrics, you cannot use this filter to query, and you cannot sort results by disk usage.
Network usage	Select a value from the drop-down menu to find virtual machines with Low Network use, less than 1 KB per second, or None, no value. If you are querying vRealize Operations Manager metrics, you cannot use this filter to query, and you cannot sort results by network usage.
Complex metric	Select a value from the drop-down menu to find virtual machines based on complex metrics. For example, select idle to find machines that have CPU, network, memory, and disk usage values all under 20%. You cannot use this filter if you are querying vRealize Operations Manager metrics.

- c Click the search icon ().

3 From the Deployments page, select one or more machines whose parent deployment is to be reclaimed.

Only selected machines that are visible on the current results page are reclaimed.

4 Click **Reclaim**.

The deployments that contain virtual machines that are selected on the current page are included in the request.

Note The Reclaim Deployment page can list machines that are not available for reclamation, such as machines for which the lease has expired. If you specify a machine that is not available for reclamation, you receive the following error:

```
Selection Error: Virtual machine name is not in valid state for reclamation.
```

5 Enter the duration of the new lease in the **New lease length (days)** text box.

The minimum is 1 day, the maximum is 365 days, and the default is 7 days.

6 Enter how many days the deployment owner has to respond to the reclamation request in the **Wait before forcing lease (days)** text box

At the end of that time, the deployment gets a new lease with the new lease length. The minimum waiting period is 1 day, the maximum is 365 days, and the default is 3 days.

7 Enter a reason for the request in the **Reason for request** text box.

8 Click **Submit**.

9 Click **OK**.

When you send a reclamation request, it appears in the Inbox of the deployment owner. If the owner does not respond to the request in the required number of days, the deployment gets a new lease of the specified length, unless its current lease is shorter. If the owner clicks **Item in Use** on the reclamation request, the deployment's lease remains unchanged. If the owner clicks **Release for Reclamation**, the deployment lease expires immediately.

What to do next

[Track Reclamation Requests.](#)

Track Reclamation Requests

You can track the current state of reclamation requests and other details.

The following alternative methods are available for checking a recent reclamation request:

- Click the **Inbox** tab and select **Reclamation Requests** to view reclamation request information.
- Click the **Reclamation Requests** tab and view the list of recent requests
- Click the **Items** tab and select **Deployments** to view recent deployment changes.

Prerequisites

Log in to the vRealize Automation console as a **tenant administrator**.

Procedure

- 1 Select **Administration > Reclamation > Reclamation Requests**.
- 2 Find the virtual machines that match your search criteria.
 - a Click the **Advanced Search** down arrow to open the search box.
 - b Type or select one or more search values.

Option	Action
Virtual Machine name contains	Type one or more characters in the text box to find virtual machine names that match.
Owner name contains	Type one or more characters in the text box to find owner names that match.
Request Reason contains	Type one or more characters in the text box to find a request reason that matches.
Request State	Select a request state value from the drop-down menu to find virtual machines with a matching request state.

- c Click the **Search** icon () or press Enter to start the search.
 - d Click the **Advanced Search** up arrow to close the search box.
- 3 (Optional) Click **Refresh Data** to update the display of reclamation requests.

Change the Reservation of a Managed Machine

You can change the reservation or storage setting for a managed machine. This ability is useful when a machine moves to a new storage path that is not available in its current reservation. For a single machine deployment, you can also change the business group for the machine.

You can move a machine in a single machine deployment to a different business group if the machine owner is a member of the target business group. You must be a business group manager of the original and the target business group to change the business group setting.

Note If there is a reservation policy assigned to the machine, you cannot change its business group.

You can create additional reservations for the associated compute resource by using the **Administration > Compute Resource** menu options.

Storage and memory that are assigned to a provisioned machine by a reservation are released when the machine to which they are assigned is deleted in vRealize Automation by the Destroy action. The storage and memory are not released if the machine is deleted in the vCenter Server.

For example, you cannot delete a reservation that is associated with machines in an existing deployment. If you move or delete deployed machines manually in the vCenter Server, vRealize Automation continues to recognize the deployed machines as live and prevents you from deleting associated reservations.

If changing the reservation will move a machine in vCenter Server to a new storage path that is not part of that machine's reservation in vRealize Automation, verify that the target or new storage path is selected in the machine's target reservation before you change the machine's reservation.

Prerequisites

Log in to the vRealize Automation console as a **fabric administrator**.

Procedure

1 Select **Infrastructure > Managed Machines**.

2 Locate the machine with the reservation to change.

3 Click **Change Reservation** in the drop-down menu.

You can view information about the managed machine, such as its associated blueprint and compute resource, by clicking **View** in the drop-down menu.

4 (Optional) Select a business group from the **Business group** drop-down menu.

5 (Optional) Select a reservation from the **Reservation** drop-down menu.

6 (Optional) Select a storage policy from **Storage** drop-down menu.

7 Click **OK**.

Create a Snapshot of Your Machine

Depending on how your administrators have configured your environment, you might be able to create a snapshot of your virtual machine. A snapshot is an image of a virtual machine at a specific time. It is a space-efficient copy of the original VM image. Snapshots are an easy way to recover a system from damage, data loss, or security threats. After you create a snapshot of your virtual machine, you can apply it and reset your system back to the point where the snapshot was taken.

When you create a memory snapshot, the snapshot captures the state of the virtual machine power settings and, optionally, the virtual machine's memory. When you capture the virtual machine's memory state, the snapshot operation takes longer to complete. You might also see a momentary lapse in response over the network.

Prerequisites

- An existing virtual machine that is powered on, off, or suspended.
- If your virtual machine is configured for one or more independent disks, power off the machine before creating a snapshot. You cannot create a snapshot when it is powered on. For disk configuration information, see *Custom Properties V Table*.
- Your tenant administrator or business group manager entitled you to the snapshot action.

Procedure

1 Select **Items > Machines**.

Alternatively you can select **Items > Deployment** and navigate to the machine in the deployment.

2 Locate the machine to snapshot.

3 In the Actions column, click the down arrow and click **View Details**.

4 Click **Create Snapshot** in the Actions menu.

- 5 Enter a name and, optionally, a description.
- 6 If you want to capture the memory and power settings of the machine, select **Include memory**.
- 7 Click **Submit**.

Connect Remotely to a Machine

You can connect remotely to a machine from the vRealize Automation console.

Prerequisites

- Log in to the vRealize Automation console as a **machine owner**, **tenant administrator**, or **business group manager**.
- Verify that VMware Tools is installed.

VMware Tools must be installed on your vRealize Automation client to support fully functioning access when connecting with VMware Remote Console. If VMware Tools is not installed, problems occur, such as the mouse pointer and mouse keys not working after connecting to the target machine. For information about supported VMware Tools versions, see *vRealize Automation Support Matrix*.
- Verify that the provisioned machine is powered on.

Procedure

- 1 Select **Items > Deployment**.
- 2 Click **Actions** in the machine name row or select the machine and click **Actions** on its machine page.
- 3 Select the remote connection method.
 - Select **Connect Using RDP** to connect by using RDP.
 - Select **Connect to remote console** to connect by using VMware Remote Console.
 Respond to any prompts.
- 4 Click **Connect** and log in to the machine as directed.
- 5 When finished, log out and close the browser window.

Configuring Remote Consoles for vSphere with Untrusted SSL Certificates

If your vRealize Automation deployment uses untrusted certificates, before you can use remote consoles with VMware Remote Console, you must configure your client browser to trust the certificate. The steps to do this vary by browser.

If vRealize Automation is configured with a trusted SSL certificate for your environment, then VMware Remote Console does not require additional configuration on client browsers. When a vRealize Automation appliance certificate is replaced and is a trusted certificate, there is no need to update certificate information for the Web browser client.

If you want to replace the certificate, see the topic on replacing a vRealize Automation appliance certificate in the *System Administration* guide for vRealize Automation.

Remote connections using VMware Remote Console for machines provisioned on vSphere are secured by vRealize Automation appliance certificates through a proxy console. VMware Remote Console requires WebSockets support in the browser and browsers must trust the vRealize Automation appliance certificate. The certificate can be obtained by going to the root-level virtual appliance at an address of the form `https://vra-va.eng.mycompany.com/`.

For information about support requirements for browsers and vSphere, see the *vRealize Automation Support Matrix*.

Configure Firefox to Trust a Certificate for vRealize Automation

Untrusted vRealize Automation appliance certificates must be manually imported to client browsers to support VMware Remote Console on clients provisioned on vSphere.

For information about supported versions of Firefox, see the *VMware vRealize Support Matrix* in the vRealize Automation [Information Center](#).

Note If vRealize Automation is configured with a trusted SSL certificate for your environment, then VMware Remote Console does not require additional configuration on client browsers.

Procedure

- 1 In a Firefox browser, log in to the vRealize Automation appliance.
A message appears saying that the certificate is not trusted.
- 2 Choose the option to display the current connection information. Click **View Certificate** to display the current SSL certificate and click **Detail** in the Certificate Viewer.
- 3 Click **More Information** and click the **Security** tab on the Page Info page.
- 4 Select a certificate from the Certificate Hierarchy pane.

Option	Action
Certificate Authority issued certificates	Select the top-level vRealize Automation certificate.
Self-signed certificates	Select the vRealize Automation certificate.

- 5 Click **Export**.
- 6 Configure the certificate information in the Save Certificate To File text box.
 - a Enter a certificate name in the **Save As** text box. The certificate name must end in `.crt`, `.cert`, or `.cer`.
 - b Select a location in which to save the file.
 - c Select **X.509 Certificate (PEM)** as the format.
- 7 Click **Save**.

- 8 Click the **Authorities** tab in the Certificate Management text box.

Option	Action
Windows	Select Preference > Advanced > Certificates from the Firefox menu.
iOS	Select Preference > Advanced > Certificates from the Firefox menu and click View Certificates .

- 9 Click the **Authorities** tab and click **Import**.
- 10 Select the certificate file you saved earlier and click **Open** in the text box.
- 11 Edit the trust settings.

Option	Action
Self-signed certificates	Select This certificate can identify websites .
Certificates issued by a Certificate Authority	Select Trust this CA to identify websites .

- 12 Click **OK** and restart the browser.

You can connect to the remote console without certificate errors.

Configure Internet Explorer to Trust a Certificate for vRealize Automation Appliance

Untrusted vRealize Automation appliance certificates must be manually imported to client browsers to support VMware Remote Console on clients provisioned on vSphere.

Note If vRealize Automation is configured with a trusted SSL certificate for your environment, then VMware Remote Console does not require additional configuration on client browsers.

The steps in this procedure apply for self-signed certificates and certificates issued by a Certificate Authority.

For information about supported versions of Internet Explorer, see the *VMware vRealize Support Matrix* on the VMware Web site.

Procedure

- 1 In an Internet Explorer browser, log in to the vRealize Automation appliance.
- 2 Click **View Certificate** on the certificate error message that appears in the browser address bar.
- 3 Click the **General** tab of the Certificate Information window..
- 4 Verify that the information about the certificate is correct and click **Install Certificate**.
- 5 Select **Place all certificates in the following store** in the Certificate Store dialog box.
- 6 Click **Browse** to locate the certificate store.
- 7 Select **Trusted Root Certification Authority** and click **OK**.
- 8 Click **Next** on the Certificate Store dialog box.

- 9 Click **Yes** in the Security Warning dialog box to install the certificate.
- 10 Restart the browser.

You can connect to the remote console without certificate errors.

Configure Chrome to Trust a Certificate for vRealize Automation Appliance

Untrusted vRealize Automation appliance certificates must be manually imported to client browsers to support VMware Remote Console on clients provisioned on vSphere.

For information about supported versions of Chrome, see the *VMware vRealize Support Matrix* on the VMware Web site.

Note If vRealize Automation is configured with a trusted SSL certificate for your environment, then VMware Remote Console does not require additional configuration on client browsers.

On Windows, Chrome and Internet Explorer use the same certificate store. This means that certificates that are trusted by Internet Explorer are also trusted by Chrome. To establish trusted certificates for Chrome, import them through Internet Explorer. For information about this procedure, see [Configure Internet Explorer to Trust a Certificate for vRealize Automation Appliance](#).

When you complete the procedure, restart Chrome.

To permanently trust a certificate on the Macintosh operating system, download the certificate file and install the certificate as trusted in your certificate management tool.

Procedure

- 1 In a Chrome browser, log in to the vRealize Automation appliance.
- 2 Click the icon in the address bar.
- 3 Click the certificate information link.
- 4 Save the certificate by dragging the certificate icon to the desktop.
- 5 Start the Keychain Access application.
- 6 Select **File > Import Items**.
- 7 On the Keychain Access screen, select the certificate file you saved earlier.
Set the value of **Destination Key** to **System**.
- 8 Click **Open** to import the certificate.
- 9 Restart the browser.

Force Destroy a Deployment After a Failed Destroy Request

You can force destroy a deployment that is in an inconsistent state as the result of a failed destroy request.

When vRealize Automation fails to destroy a deployment resource during a destroy deployment operation, the destroy operation stops immediately without destroying the remaining deployment resources. This failure leaves the deployment in an inconsistent state, using up resources with no obvious way of destroying the deployment. Business group administrators can force destroy deployments that are left in this inconsistent state.

Prerequisites

Verify that you are logged in to vRealize Automation as a **business group administrator**.

Procedure

- 1 On the **Items** tab, click **Deployments** and select the deployment to destroy.
- 2 Click **Actions** and click **Destroy**.
- 3 Enter a description for and reason for the request.
- 4 Select **Force destroy** and click **Submit**.

vRealize Automation attempts to fully destroy the deployment, including all resources in the deployment. If vRealize Automation is unable to destroy a deployment resource, it skips that resource and continues to destroy the remaining resources in the deployment.

What to do next

Click the **Requests** tab and verify that all resources in the deployment have been successfully destroyed. Any resources not destroyed during a force destroy operation must be manually destroyed. Also ensure that any provisioned virtual machine objects are destroyed, as vRealize Automation may attempt to reuse their hostnames, IP addresses, and other configuration details during subsequent provisioning operations.

Troubleshooting Missing Actions in the Resource Actions Menu

As a machine or resource owner, you do not see all entitled actions for a provisioned item.

Problem

In an environment where you know that an action was entitled for your user or business group, you expect to see all actions when you select an item in your **Items** list.

Cause

The availability of actions depends on the type of provisioned resource, operational state of the resource, and how it was configured and made available. The following list provides some reasons why you do not see all configured actions.

- The action is not applicable based on the current state of the provisioned resource. For example, Power Off is available only when the machine is powered on.

- The action is not applicable to the selected item type. If the item does not support the action, it does not appear in the list. For example, the Create Snapshot action is not available for a physical machine, and the Connect by Using RDP action is not available if the selected item is a Linux machine.
- The action is applicable for the provisioned resource type, but the action is disabled in the Infrastructure blueprint. If the action is disabled, it never appears as an available action for any of the items that were provisioned using the blueprint.
- The action is not included in the entitlement used to provision the item on which you need to run the action. Only entitled actions, either as part of an IaaS blueprint or as an XaaS resource action, can appear in the Actions menu.
- The action is created as an XaaS resource action but was not included in the entitlement used to provision the item on which you need to run the action. Only entitled actions appear in the Actions menu.
- The action might be limited based on the configured target criteria for XaaS resource actions or resource mappings to provisioned IaaS machines.

Solution

- Verify that the action is applicable to the provisioned item or the state of the provisioned item.
- Verify that the action is configured and included in the entitlement used to provision the item.

Troubleshooting a Failed Deployment That Includes a vRealize Orchestrator Workflow

If a failed blueprint deployment includes a vRealize Orchestrator workflow, you can use the token ID to troubleshoot problems with the workflow. You use the token ID to locate the logs in vRealize Orchestrator.

Solution

- 1 Locate the token ID for the failed workflow.
 - a In vRealize Automation, click the **Request** tab.
 - b Click the number in the Request column.
The request can be a deployment or an action.
 - c Click the **General** tab.
If the blueprint is based on a vRealize Orchestrator workflow, the page title is vRealize Orchestrator Workflow Execution Details.
 - d Locate the Token ID and copy it to your clipboard or a text file.
For example, ff8080815a685352015a6c8d450801ee.

2 Locate the workflow logs in vRealize Orchestrator using the Control Center

- a Enter the base URL for vRealize Automation in a browser search box.

The VMware vRealize Automation Appliance page appears.

- b Click **vRealize Orchestrator Control Center**.

- c Log in as a user with root privileges.

- d Click **Inspect Workflows**.

- e Click **Finished Workflows**.

- f Paste the workflow token in the Token ID text box.

The list displays on the workflow that matches the token ID.

- g Click the row and inspect the logs for the cause of the failure.

Specify Machine Reconfiguration Settings and Considerations for Reconfiguration

vSphere, vCloud Air, and vCloud Director platforms support reconfiguration of existing machines in a deployment to modify specifications such as CPU, memory, and storage.

Reconfiguration requests are subject to approval based on entitlements, policies, and the actions enabled for the machine component in the blueprint.

Reconfiguring a virtual machine that is assigned to an on-demand network is not supported. You cannot reconfigure a NIC that is attached to an on-demand network. If you attempt to reconfigure an on-demand NAT or routed network, the error 'Original network [<network>] is not selected in the machine's reservation. is displayed, the networks on the machine remains intact, and IP addresses on the machine are unchanged.

If you are entitled to the Cancel Reconfigure (Machine) and Execute Reconfigure (Machine) actions, you can cancel a reconfiguration or retry a failed reconfiguration.

Expanding a disk on a VM that was provisioned from a linked clone blueprint is not supported.

You cannot reconfigure machines by using the Size or Image component profiles but the range of CPU, memory, and storage that is calculated based on the profile remains available for reconfigure actions. For example if you used a small (1 CPU, 1024MB memory, and 10 GB storage), medium (3 CPUs, 2048 MB memory, 12 GB storage) and large (5 CPUs, 3072 MB memory, 15 GB storage) Size value set, the available ranges during machine reconfiguration are 1-5 CPUs, 1024-3072 memory, and 1-15 GB storage.

vRealize Automation takes a blueprint snapshot at deployment. If you encounter reconfigure problems when updating machine properties such as CPU and RAM in a deployment, see Knowledge Base article [2150829 vRA 7.x Blueprint Snapshotting](#).

Prerequisites

- Log in to the vRealize Automation console as a **machine owner**, **support user**, **business group user with a shared access role**, or **business group manager**.
- The machine you want to reconfigure must have the status On or Off with no active reconfigure status.
- The machine type must be vSphere, vCloud Air, or vCloud Director although the NSX settings apply only to vSphere.
- Verify that you are entitled to reconfigure a machine.

Procedure

- 1 Select **Items > Machines**.

Alternatively you can select **Items > Deployment** and navigate to the machine in the deployment.

- 2 Select the machine to reconfigure.

- 3 Select **Reconfigure** from the **Actions** menu.
- 4 Select the tab appropriate to the settings that you want to reconfigure.

Table 3-76. Request Reconfiguration Changes

Tab	Topic
General	Reconfigure CPUs and Memory
Storage	Edit Storage Settings
Network	Change Network Settings To change NAT rules, see Change NAT Rules in a Deployment .
Security	To reconfigure security settings, see Add or Remove Security Items in a Deployment .
Properties	Change Custom Property and Property Group Settings

What to do next

[Execute the Requested Machine Reconfiguration.](#)

Reconfigure CPUs and Memory

You can change the number of CPUs or the amount of memory and storage used by the provisioned machine, within the limits set by the provisioning blueprint.

For provisioned Amazon deployments, you can reconfigure all storage volumes in the deployment except for the root volume.

Expanding a disk on a VM that was provisioned from a linked clone blueprint is not supported.

Prerequisites

[Specify Machine Reconfiguration Settings and Considerations for Reconfiguration.](#)

Procedure

- 1 Click the **General** tab.
- 2 Enter the number of CPUs in the **# CPUs** text box.
- 3 Enter the amount of memory in the **Memory (MB)** text box.
- 4 Enter the amount of storage in the **Storage (GB)** text box.

What to do next

Specify additional machine reconfiguration settings. If you have finished changing machine settings, start the machine reconfiguration request. See [Execute the Requested Machine Reconfiguration](#).

Edit Storage Settings

You can add, delete, or change the size of a storage volume on a provisioned virtual machine.

You cannot reconfigure storage for the IDE disk type.

Storage and memory that are assigned to a provisioned machine by a reservation are released when the machine to which they are assigned is deleted in vRealize Automation by the Destroy action. The storage and memory are not released if the machine is deleted in the vCenter Server.

For example, you cannot delete a reservation that is associated with machines in an existing deployment. If you move or delete deployed machines manually in the vCenter Server, vRealize Automation continues to recognize the deployed machines as live and prevents you from deleting associated reservations.

Prerequisites

[Specify Machine Reconfiguration Settings and Considerations for Reconfiguration.](#)

For provisioned Amazon deployments, you can reconfigure all storage volumes in the deployment except for the root volume.

Procedure

- 1 Click the **Storage** tab.
The allowable range for storage appears below the Storage volumes table.
- 2 Add or edit available storage volume settings.
 - a Click **New Volume**.
 - b Type the capacity in the **Capacity (GB)** text box.
 - c Select a storage reservation policy from the **Storage reservation policy** drop-down menu.
 - d Click the **Save** icon (✔).

3 Delete a volume.

- a Locate the volume.
- b Click the **Delete** icon ()

An unselectable icon indicates an undeletable volume such as one from a linked clone.

4 Increase the size of a volume.

You cannot reduce the size of existing volumes. Volume size is limited by the total amount of storage specified in the blueprint, less the amount allocated to other volumes.

- a Locate the volume.
- b Click the **Edit** icon ()
- c Type the new size in the **Capacity (GB)** text box.
- d Click the **Save** icon ()

What to do next

Specify additional machine reconfiguration settings. If you have finished changing machine settings, start the machine reconfiguration request. See [Execute the Requested Machine Reconfiguration](#).

Change Network Settings

You can add, remove, or edit a network adapter.

You can change the following network settings during the machine reconfiguration process:

- Add or remove NICs.
- Allocate or release IP addresses for existing NICs.
- Assign new IP addresses to NICs, provided that the network is not an on-demand NAT or on-demand routed network.

You cannot reconfigure an on-demand routed or on-demand NAT network.

Network reconfiguration requires that the source and target networks be selected in the reservation.

When you add NICs, IP addresses are allocated. When you remove NICs, IP addresses are released.

When you change network settings based on reservation and network profile information, the new network IP is assigned in vRealize Automation but the deployed machine is not updated at the endpoint with the new IP information. You must manually assign the IP to the machine after the reconfiguration process is finished.

Reconfiguring a virtual machine that is assigned to an on-demand network is not supported. You cannot reconfigure a NIC that is attached to an on-demand network. If you attempt to reconfigure an on-demand NAT or routed network, the error 'Original network [<network>] is not selected in the machine's reservation. is displayed, the networks on the machine remains intact, and IP addresses on the machine are unchanged.

Changing NSX network settings is not supported for deployments that were upgraded or migrated from vRealize Automation 6.2.x to this vRealize Automation release.

Prerequisites

[Specify Machine Reconfiguration Settings and Considerations for Reconfiguration.](#)

Procedure

- 1 Click the **Network** tab.
- 2 (Optional) Add a network adapter.
 - a Click **New Network Adapter**.
 - b Select a network from the **Network Path** drop-down menu.
All networks selected on the machine's reservation are available.
 - c Type a static IP address for the network in the **Address** text box.
The IP address must be unallocated in the network profile assigned in the reservation.
 - d Click the **Save** icon (✓).
- 3 (Optional) Remove a network adapter.
 - a Locate the network adapter.
 - b Click the **Delete** icon (🗑).

You cannot remove network adapter 0.
- 4 (Optional) Edit a network adapter.
 - a Locate the network adapter.
 - b Click the **Edit** icon (✎).
 - c Select a network from the **Network Path** drop-down menu.
 - d Click the **Save** icon (✓).

What to do next

Specify additional machine reconfiguration settings. If you have finished changing machine settings, start the machine reconfiguration request. See [Execute the Requested Machine Reconfiguration](#).

Change Custom Property and Property Group Settings

You can edit, add, or delete custom properties in the deployed machine.

You cannot use custom properties to enter values for volume disk number, capacity, label, or storage reservation policy. You must enter these values by adding or editing a volume in the Storage volumes table. See [Edit Storage Settings](#).

Prerequisites

[Specify Machine Reconfiguration Settings and Considerations for Reconfiguration.](#)

Procedure

- 1 Click the **Properties** tab.
- 2 To add a property, click **New Property**.
- 3 Enter the property name in the **Name** text box.
- 4 Enter the property value in the **Value** text box.
- 5 Select the **Encrypted** check box to encrypt the value.
- 6 Select the **Prompt user** check box to prompt users for the value when they request the machine.
- 7 Add another property, edit an existing property, or delete a property.

What to do next

Specify additional machine reconfiguration settings. If you have finished changing machine settings, start the machine reconfiguration request. See [Execute the Requested Machine Reconfiguration](#).

Execute the Requested Machine Reconfiguration

You can start the requested machine reconfiguration immediately or schedule it to start at a particular day and time. You can also specify the power option for the machine before reconfiguring it.

Prerequisites

[Specify Machine Reconfiguration Settings and Considerations for Reconfiguration.](#)

Procedure

- 1 If the **Execution** tab is visible, you can select it to specify additional reconfiguration settings. If it is not visible, click **Submit** to start machine reconfiguration.
- 2 If the **Execution** tab is visible, click **Execution** to schedule the reconfiguration action.
- 3 (Optional) Select an option from the **Execute request** drop-down menu.

Option	Description
Immediate	Start reconfiguration as soon as possible after approval.
Scheduled	Start reconfiguration at the specified date and time. Type or select the date and time in the text boxes that appear.

The scheduled time is the local time where the vRealize Automation Web server is located. If **Execute request** is not available, reconfiguration starts immediately.

- 4 (Optional) Select a power action from the **Power action** drop-down menu.

Option	Description
Reboot if required	(Default) If required, reboot the machine before reconfiguring it.
Reboot	Reboot the machine before reconfiguring it, regardless of whether reboot is required.
Do not reboot	Do not reboot the machine before reconfiguring it, even if reboot is required.

The following conditions require that the machine be rebooted before reconfiguration:

- CPU change where hot add is not supported or is disabled
- Memory change where hot memory is not supported or is disabled
- Storage change where hot storage is disabled

If the machine is in the shutdown state, it is not rebooted.

Note You can disable the vSphere hot add option by using the `VirtualMachine.Reconfigure.DisableHotCpu` custom property.

- 5 Click **OK**.

What to do next

You can monitor the progress of the reconfiguration by observing the workflow states displayed in the user interface. See [Workflow States of Reconfigure Operations](#).

Workflow States of Reconfigure Operations

When reconfiguration starts and as it progresses through the workflow, you can monitor the progress from the Edit page.

Table 3-77. Workflow States of Reconfigure Operations

State	Description
Reconfigure pending	The State Operation was created.
Scheduled	A scheduled workflow has been created for the Distributed Execution Manager (DEM).
Reconfiguring	The interface-specific workflow is being executed.
Reconfigure failed, waiting to retry	The reconfigure failed, waiting for the owner to request a retry. If the machine owner is entitled to the actions execute reconfigure or cancel reconfigure, the owner can retry or cancel a reconfiguration.
ReconfigureFailed	The reconfigure failed, waiting for the RVG workflow to perform the next action.
ReconfigureSuccessful	The reconfigure was successful, waiting for the RVG workflow to perform the next action.
Canceled	The user has canceled the reconfiguration. Machine owners who are entitled to the cancel reconfigure action can cancel a reconfiguration.
Complete	The completion workflow sets this state after completing the cleanup, so that the RVG workflow can proceed to clean up the state operations and approvals. A status of complete indicates that the request from vRealize Automation is finished, but it does not indicate that the machine reconfiguration completed successfully.

Reconfigure a Load Balancer in a Deployment

You can add, edit, or delete a virtual server in a deployed NSX load balancer.

The following considerations apply to deployments that originated in vRealize Automation 7.2 or earlier:

- Load balancer reconfiguration is limited to deployments that contain a single load balancer.
- The Items detail page for any load balancer in a deployment displays the virtual servers that are used by all the load balancers in the deployment. For more information, see [Knowledge Base Article 2150276](#).

For upgraded load balancers and load balancers deployed in the current vRealize Automation release, do not edit a virtual server and add a virtual server in the same request. For more information, see [Knowledge Base Article 2150240](#).

If you submit a request to reconfigure a load balancer while another action is being performed on the deployment, for example when a scale out operation on the deployment is in progress, reconfiguration fails with a supporting message. In this situation, you can wait until the action is finished and then submit the reconfiguration request.

The Reconfigure Load Balancer operation is not supported for deployments that were upgraded or migrated from vRealize Automation 6.2.x to this vRealize Automation release.

You should not manage vRealize Automation-administered NSX objects outside of vRealize Automation. For example, if you modify the member port of a deployed NSX load balancer in NSX, rather than in vRealize Automation, then NSX data collection breaks association between the deployed machine and its otherwise associated load balancer member pool. Scale in and scale out operations also produce unexpected results if a deployed load balancer member port is changed outside of vRealize Automation.

See the vRealize Automation [release notes](#) for any known issues.

For information about the settings that are available when you add or edit a virtual server, see [Add an On-Demand Load Balancer Component](#).

When you reconfigure a load balancer in vRealize Automation, some of the settings that were configured in NSX and that are not available as settings in vRealize Automation, are reverted back to their default value. After you run the load balancer reconfigure action in vRealize Automation, verify and update as needed the following settings in NSX:

- Insert-X-Forwarded for HTTP Header
- HTTP Redirect URL
- Service Monitor Extension

Prerequisites

- Log in to the vRealize Automation console as a **machine owner**, **support user**, **business group user with a shared access role**, or **business group manager**.
- Verify that you are entitled to reconfigure load balancers in a deployment. The required catalog entitlement is Reconfigure (Load Balancer).

Procedure

- 1 Select **Items > Deployment**.
- 2 Locate the deployment and display its children components.

- 3 Select the NSX load balancer to edit.

- 4 Select **Reconfigure** from the **Actions** menu.
- 5 Add, edit, or remove virtual servers.

Virtual servers:

Protocol	Port	Description	Member Protocol	Member Port	Health Check Protocol	Health Check Port
HTTP	80		HTTP	80	HTTP	80
HTTP	81		HTTP	81	HTTP	81

- 6 When you have finished adding, editing, or deleting virtual servers click **Submit** to submit the reconfiguration request.

Change NAT Rules in a Deployment

You can add, edit, and delete existing NSX NAT rules in a deployed one-to-many NAT network. You can also change the order in which the NAT rules are processed.

For information about the NAT rules, see [Creating and Using NAT Rules](#) and [Add an On-Demand NAT or On-Demand Routed Network Component](#).

The Change NAT Rules operation is not supported for deployments that were upgraded or migrated from vRealize Automation 6.2.x to this vRealize Automation release.

You cannot add a NAT rule to a deployment that is mapped to a third-party IPAM endpoint such as Infoblox.

See the vRealize Automation [release notes](#) for any known issues.

Prerequisites

- Log in to the vRealize Automation console as a **machine owner**, **support user**, **business group user with a shared access role**, or **business group manager**.
- Verify that you are entitled to change NAT rules in a network.
- The NAT network must be configured as a NAT one-to-many network. The action is not available for NAT one-to-one networks. See

Procedure

- 1 Select **Items > Deployment**.

- 2 Locate the deployment and display its children components.

- 3 Select the NAT network component to edit.

- 4 Click **Change NAT Rules** from the **Actions** menu.

- 5 Add new NAT port forwarding rules, reorder rules, edit existing rules, or delete rules.
- 6 When you have finished making changes, click **Save** or **Submit** to submit the reconfiguration request.

Add or Remove Security Items in a Deployment

You can add or remove existing NSX security groups and security tags in a machine deployment. You cannot add on-demand security groups but you can remove them.

The change security action is based on a machine component or cluster. For example, if security is associated to a cluster named AppTier2 which consists of 2 machines, you perform the change security operation on the AppTier2 cluster, not the individual machines within the cluster.

The Change Security operation is not supported for deployments that were upgraded or migrated from vRealize Automation 6.2.x to this vRealize Automation release.

Prerequisites

- Log in to the vRealize Automation console as a **machine owner**, **support user**, **business group user with a shared access role**, or **business group manager**.
- Verify that you are entitled to change security in a deployment. The required catalog entitlement is Change Security (Deployment).

Procedure

- 1 Select **Items > Deployment**.
- 2 Locate the deployment and display its children components.

- 3 Click **Change Security** from the **Actions** menu.

- 4 Select the deployed machine component or cluster in which to add or remove security items.

- 5 Add or remove existing security groups and security tags for each machine component or cluster in the deployment as required.
- 6 Remove on-demand security groups for each machine component or cluster in the deployment as required.
- 7 (Optional) Click the **Reason** tab and enter a reason for the request.
- 8 When you have finished making changes, click **Save** or click **Submit** to submit the change request.

Display All NAT Rules for an Existing NSX Edge

You can display NAT rule information about the NSX Edges that are used in active deployments.

The NAT rules are displayed in the Edge view as an aggregate of all the NAT rules that are used in the deployment. In the Edge view, the rules are not necessarily displayed in the order in which they are processed.

To see and optionally change the order in which the NAT rules are processed in a NAT one-to-many network, see [Change NAT Rules in a Deployment](#).

Prerequisites

- Log in to the vRealize Automation console as a **machine owner**, **support user**, **business group user with a shared access role**, or **business group manager**.

Procedure

- 1 Select **Items > Deployment**.
- 2 Locate the deployment and display its children components.

- 3 Select the NSX Edge that you want to view.

- 4 Click **Close** when you are finished.
